56.6.2.2 Asynchronous list queue head pointer

The Asynchronous Transfer List (based at the USB_ASYNCLISTADDR register) is where all of the control and bulk transfers are managed. Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

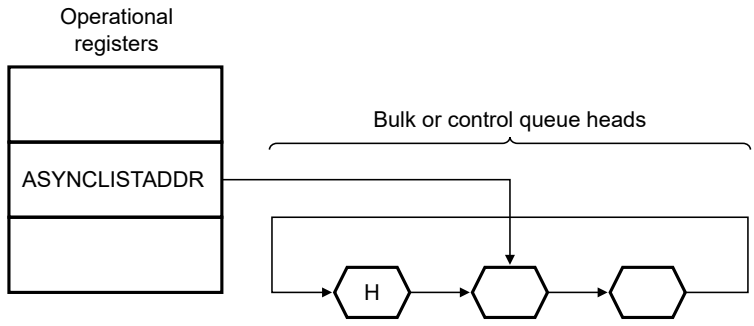

Figure 427. Asynchronous Schedule Organization

The Asynchronous list is a simple circular list of queue heads. The USB_ASYNCLISTADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

56.6.2.3 Isochronous (high-speed) transfer descriptor (iTD)

The format of an isochronous transfer descriptor is shown in the table below. This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 872. Isochronous Transaction Descriptor (iTD)

These fields may be modified by the host controller if the I/O field indicates an OUT.

56.6.2.3.1 Next link pointer

The first DWord of an iTD is a pointer to the next schedule data structure. The following table describes the Next Schedule Element pointer field.

Table 873. Next Schedule Element Pointer

Bit	Description
31-5 Link Pointer (LP)	These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iTD/siTD) or Queue Head (QH).
4-3 Reserved	These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2-1 QH/(s)iTD Select (Typ)	This field indicates to the Host Controller whether the item referenced is an iTD, siTD, or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0 Terminate (T)	1= Link Pointer field is not valid. 0= Link Pointer field is valid.

56.6.2.3.2 iTD transaction status and control list

DWords 1 through 8 are eight slots of transaction control and status. Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

The following table describes iTD Transaction Status and Control fields.

Table 874. iTD Transaction Status and Control

Bit	Description	
31-28 Status	This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.
	30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
	29	Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.
	28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16 Transaction X Length	For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0‡zero length data, 1‡one byte, 2‡two bytes, and so on). The maximum value this field may contain is 0xC00 (3072).	
15 Interrupt On Complete (IOC)	If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.	
14-12 Page Select (PG)	These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.	
11-0 Transaction X Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent *PG* field to produce the starting buffer address for this transaction.	

56.6.2.3.3 iTD buffer page pointer list (plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous. Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

Table 875. iTD Buffer Pointer Page 0 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 0)	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8 Endpoint Number (Endpt)	This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7 Reserved	Bit reserved for future use and should be initialized by software to zero.
6-0 Device Address	This field selects the specific device serving as the data source or sink.

Table 876. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 1)	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11 Direction (I/O)	0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0 Maximum Packet Size	This directly corresponds to the maximum packet size of the associated endpoint *(wMaxPacketSize)*. This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the *Multi* field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 877. iTD Buffer Pointer Page 2 (Plus)

Bit	Description
31-12 Buffer Pointer	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2 Reserved	This bit reserved for future use and should be set to zero.
1-0 Multi	This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are:

Table continues on the next page...

Table 877. iTD Buffer Pointer Page 2 (Plus) (continued)

Bit	Description
	Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro-frame. 10b Two transactions to be issued for this endpoint per micro-frame. 11b Three transactions to be issued for this endpoint per micro-frame.

Table 878. iTD Buffer Pointer Page 3-6

Bit	Description
31-12 Buffer Pointer	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-0 Reserved	These bits reserved for future use and should be set to zero.

56.6.2.4 Split transaction isochronous transfer descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

The following table shows the Split Transaction Isochronous Transfer Descriptor (siTD).

Table 879. Split Transaction Isochronous Transfer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

56.6.2.4.1 Next link pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the Next Link Pointer fields.

Table 880. Next Link Pointer

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

56.6.2.4.2 siTD endpoint capabilities/characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

The tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

Table 881. Endpoint and Transaction Translator Characteristics

Bit	Description
31	Direction (I/O).0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.

Table continues on the next page...

Table 881. Endpoint and Transaction Translator Characteristics (continued)

Bit	Description
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 882. Micro-frame Schedule Control

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the *Active* and *SplitX- state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame C-Mask* field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (mFrame S-mask). This field (along with the *Active* and *SplitX-state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame S-mask* field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

56.6.2.4.3 siTD transfer state

DWords 3-6 are used to manage the state of the transfer. The following table describes siTD transfer state fields.

Table 883. siTD Transfer Status and Control

Bit	Description
31	Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.
30	Page Select (P). Used to indicate which data page pointer should be concatenated with the *CurrentOffset* field to construct a data buffer pointer (0 selects *Page 0* pointer and 1 selects *Page 1*). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).

Table continues on the next page...

Table 883. siTD Transfer Status and Control (continued)

Bit	Description
29-26	Reserved. This field reserved for future use and should be set to zero.
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)
15-8	µFrame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.
7-0: Status—This field records the status of the transaction executed by the host controller for this slot. It is a bit vector with the encoding shown in the following rows.	
7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
2	Missed Micro-Frame. The host controller detected that a host-induced hold- off caused the host controller to miss a required complete-split transaction.
1	Split Transaction State (SplitXstate). The bit encodings are: Value Meaning 00b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask. 01b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
0	Reserved. Bit reserved for future use and should be set to zero.

56.6.2.4.4 siTD buffer pointer list (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

Table 884. Buffer Page Pointer List (plus)

Bit	Description
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K page aligned physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field *P* (see siTD transfer state) specifies the *current* active pointer.
Bits 11-0 (Page 0)	Current Offset—The 12 least significant bits of the Page 0 pointer are the current byte offset for the current page pointer (as selected with the page indicator bit (*P* field). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).
Bits 11-0 (Page 1)—The least significant bits of the Page 1 pointer are split into three subfields as shown in the following rows.	
11-5 (Page 1)	Reserved
4-3 (Page 1)	Transaction position (TP). This field is used with T-count to determine whether to send *all*, *first*, *middle*, or *last* with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: Value Meaning 00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full- speed that is greater than 188 bytes. 10B Mid. This is the *middle* payload for a full-speed OUT transaction that is larger than 188 bytes. 11b End. This is the *last* payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0 (Page 1)	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

56.6.2.4.5 siTD back link pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

Table 885. siTD Back Link Pointer

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

56.6.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head. It describes one or more USB transactions to transfer up to 20480 (5*4096) bytes. The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers. It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal utilization of on-chip buses it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The following table shows the queue element transfer descriptor data structure.

Table 886. Queue element transfer descriptor data structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Buffer Pointer (page 4)																				Reserved												1F-1C

1. 08-0F: Transfer Results

Host controller read/write Host controller read-only

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

56.6.2.5.1 Next qTD pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor. The following table describes Next qTD pointer fields.

Table 887. qTD Next Element Transfer Pointer (DWord 0)

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

56.6.2.5.2 Alternate next qTD pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next transfer descriptor on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet. The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

Table 888. TD Alternate Next Element Transfer Pointer (DWord 1)

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

56.6.2.5.3 qTD token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

Table 889. TD Token (DWord 2)

Bit	Description
31 Data Toggle	This is the data toggle sequence bit. The use of this bit depends on the setting of the *Data Toggle Control* bit in the queue head.

Table continues on the next page...

Table 889. TD Token (DWord 2) (continued)

Bit	Description	
30-16 Total Bytes to Transfer	This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that *Total Bytes To Transfer* be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).	
15 Interrupt On Complete (IOC)	If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.	
14-12 Current Page (C_Page)	This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.	
11-10 Error Counter (CERR)	This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the *Halted* bit to a one, and error status bit for the error that caused *CERR* to decrement to zero. An interrupt is generated if the *USB Error Interrupt Enable* bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD. Transaction Error - Decrement Data Buffer Error - No Decrement[3] Stalled - No Decrement[1] Babble Detected - No Decrement[1] No Error - No Decrement[2]	
	Error	Decrement Counter
	1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented
	2	If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and *PIDCode* indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset *CERR* to extend the total number of errors for this transaction. For example, *CERR* should be reset with maximum value (3) on each successful

Table continues on the next page...

Table 889. TD Token (DWord 2) (continued)

Bit	Description	
		completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b. See Split transaction interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Asynchronous - do complete split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the *PIDCode* indicates a SETUP.
	3	Data buffer errors are host problems. They don't count against the device's retries.
		NOTE Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.
9-8 PID Code	This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:	
	00b	OUT Token generates token (E1H)
	01b	IN Token generates token (69H)
	10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, µ*Frame S-mask* field in.
	11b	Reserved
7-0 Status	This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:	
	Bit	Status Field Description
	7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
	6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.

Table continues on the next page...

Table 889. TD Token (DWord 2) (continued)

Bit	Description	
	4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the *Halted* bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	2	Missed Micro-Frame. This bit is ignored unless the *QH.EPS* field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the *QH.EPS* field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split-transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are: Value Meaning 0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint. 1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.
	0	Ping State (P)/ERR. If the *QH.EPS* field indicates a High-speed device and the *PID_Code* indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are: Value Meaning 0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint. If the *QH.EPS* field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.

56.6.2.5.4 qTD buffer page pointer list

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the C_Page field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

Table 890. qTD Buffer Pointer(s) (DWords 3-7)

Bit	Description
31-12	Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.

56.6.2.6 Queue head

The table located in this section shows the Queue Head structure layout.

The following table shows the queue head structure layout.

Table 891. Queue Head Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

1. 04-0B: Static endpoint state.
2. These fields are used exclusively to support split transactions to USB 2.0 hubs
3. 10-2F: Transfer overlay.
4. 14-27: Transfer results.

Host controller read/write Host controller read-only

56.6.2.6.1 Queue head horizontal link pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The following table describes the Queue head DWord 0 fields.

Table 892. Queue Head DWord 0

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor)

Table continues on the next page...

Table 892. Queue Head DWord 0 (continued)

	11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

56.6.2.6.2 Queue head endpoint capabilities/characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint. There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

Table 893. Endpoint Characteristics: Queue Head DWord 1

Bit	Description	
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.	
27	Control Endpoint Flag (C). If the *QH.EPS* field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.	
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). The maximum value this field may contain is 0x400 (1024).	
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.	
14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition. 0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.	
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:	
	Value	Meaning
	00b	Full-Speed (12 Mbits/sec)

Table continues on the next page...

Table 893. Endpoint Characteristics: Queue Head DWord 1 (continued)

	01b	Low-Speed (1.5 Mbits/sec)
	10b	High-Speed (480 Mbits/sec)
	11b	Reserved
	This field must not be modified by the host controller.	
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.	
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See Rebalancing the periodic schedule , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the *EPS* field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the *EPS* field indicates a high-speed device yields undefined results.	
6-0	Device Address. This field selects the specific device serving as the data source or sink.	

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

Table 894. Endpoint Capabilities: Queue Head DWord 2

Bit	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro-frame. 10b Two transactions to be issued for this endpoint per micro-frame. 11b Three transactions to be issued for this endpoint per micro-frame.
29-23	Port Number. This field is ignored by the host controller unless the *EPS* field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address *Hub Addr* below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the *EPS* field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15-8	Split Completion Mask (μFrame C-Mask). This field is ignored by the host controller unless the *EPS* field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the *Active* and *SplitX-state* fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the

Table continues on the next page...

Table 894. Endpoint Capabilities: Queue Head DWord 2 (continued)

	FRINDEX register. If the FRINDEX register bits decode to a position where the µ*Frame C- Mask* field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Interrupt Schedule Mask (µFrame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the µ*Frame S-mask* field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the *EPS* field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the *PID_Code* field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the *EPS* field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

56.6.2.6.3 Transfer overlay-queue head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.

Table 895. Current qTD Link Pointer

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

Table 896. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt)µRW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from *RL* before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.

Table continues on the next page...

Table 896. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9) (continued)

6	31	Data Toggle. The *Data Toggle Control* controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the *EPS* field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the *S-bytes* field in a *qTD* is zero before activating the *qTD*. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

56.6.2.7 Periodic frame span traversal node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary. See Host controller operational model for FSTNs for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

Table 897. Frame Span Traversal Node Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Back Path Link Pointer																											0		Typ[1]		T	07-04

1. Must be set to indicate a queue head

Host controller read/write Host controller read-only

56.6.2.7.1 FSTN normal path pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

Table 898. FSTN Normal Path Pointer Field Descriptions

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (Frame Span Traversal Node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

56.6.2.7.2 FSTN back path link pointer

The second DWord of an FTSN node contains a link pointer to a queue head. If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

Table 899. FSTN Back Path Link Pointer Field Descriptions

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

56.6.3 Device data structures

This section defines the interface data structures used to communicate control, status, and data between DCD Software and the Device Controller. The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

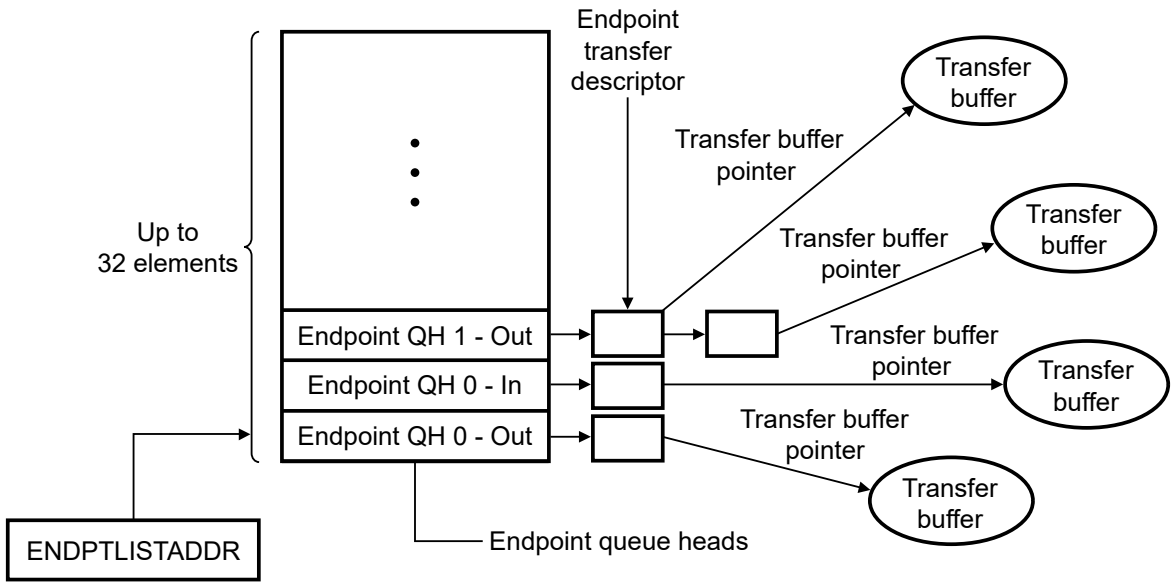

Figure 428. EndPoint Queue Head Organization

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even-numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). That is, the device queue heads in the list with even offset support receiver endpoints (OUT) and the queue heads in the list with odd offset are used for transmit endpoint(IN). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

56.6.3.1 Endpoint queue head (dQH)

The device Endpoint Queue Head (dQH) manages all transfers for a given endpoint. Data structure in the dQH has 48-byte data structure. It must have 64-byte boundaries.Priming of an endpoint includes copying the dTD (device transfer descriptor) into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, there is updation of the dTD status DWord in the dTD pointed to by the currentTD pointer. While a packet is in progress, there is use of the overlay area of the dQH as a staging area for the dTD, so that the Device Controller can access needed information with little, minimal latency.

Table 900. Endpoint Queue Head (dQH)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host controller read/write Host controller read-only

56.6.3.1.1 Endpoint capabilities/characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not modify this information when enabling the corresponding endpoint.

Table 901 describes the endpoint capabilities.

Table 901. Endpoint capabilities/characteristics

Bit	Description

Table continues on the next page...

Table 901. Endpoint capabilities/characteristics (continued)

31-30	Mult. Use this field to indicate the number of packets executed per transaction description as follows: 00 - Execute N Transactions as per the demonstration by the USB variable length packet protocol where you can compute N by using the maximum packet length (dQH) and the total bytes field (dTD) 01 Execute 1 transaction. 10 Execute 2 transactions. 11 Execute 3 transactions. **NOTE** Non-ISO endpoints must set Mult="00." ISO endpoints must set Mult="01," "10," or "11" as per need.
29	Zero-length termination select. Use this bit to terminate transfers in which the total transfer length is multiple. This bit is not relevant for Isochronous 0 - Enable zero-length packet to terminate transfers equal to a multiple of the maximum packet length. (default). 1 - Disable the zero-length packet on transfers that are equal in length to a multiple maximum packet length.
28-27	Reserved. These bit reserved for future use and should be set to 0.
26-16	Maximum packet length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt on setup (IOS). Use this bit to control type endpoints to indicate whether USBINT is set in response to receiving a setup.
14-0	Reserved. Bits reserved for future use and should be set to 0.

56.6.3.1.2 Transfer overlay-endpoint queue head

The seven DWords in the overlay area represent a transaction working space for the device controller. The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until there is completion of a transfer, you must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See Endpoint transfer descriptor (dTD) for a description of the overlay fields.

56.6.3.1.3 Current dTD pointer

The device controller uses the current dTD pointer to locate the transfer in progress. This word is for Device Controller (hardware) use only, and DCD software should not modify it.

The following table describes the dTD Pointer.

Table 902. Next dTD Pointer

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. The device controller modifies this field to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

56.6.3.1.4 Set-up buffer

There is a dedicated buffer for the 8-byte data that follows the PID set-up.

NOTE

Each endpoint has a TX and an RX dQH association with it. Use only the RX queue head for receiving setup data packets.

The following table describes the multiple mode control.

Table 903. Multiple mode control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet, and the device controller writes it for you to read.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet, and the device controller writes it for you to read.

56.6.3.2 Endpoint transfer descriptor (dTD)

The dTD describes to the chip controller where and how much data to send or receive for a given transfer. The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer. Modify this as per the discussion in Managing transfers with transfer descriptors.

The following table shows the Endpoint Transfer Descriptor (dTD).

Table 904. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host controller read/write Host controller read-only

The following table describes the dTD Pointer.

Table 905. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD for processing. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to 0.
0	Terminate (T). 1 = Pointer is invalid. 0 = Pointer is valid (points to a valid transfer element descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

Table 906. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to 0.
30-16	Total Bytes. This field specifies the total number of bytes for removal with this transfer descriptor. Decrement to this field happens by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes which five page pointers can access. Although it is possible to create a transfer up to 20K, this assumes the first offset into the first page is 0. When you cannot predetermine the offset, you can guarantee crossing past the fifth page by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H). If the value of the field is 0 when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of *Maximum Packet Length*. If you build such a transfer descriptor for an IN transfer, the last transaction will always be less than *Maximum Packet Length*.
15	Interrupt On Complete (IOC). Use this bit to indicate if you need to set USBINT in response to device controller finishing with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to 0.
11-10	Multiplier Override (MultO). Use this field to transmit ISOs (that is, ISO-IN) to override the multiplier in the QH. This field must be 0 for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, you should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and non-TX endpoints must set MultO = "00."

Table continues on the next page...

Table 906. dTD Token (continued)

9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	Status. Device Controller uses this field to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4, 2, 0 Reserved.

The following table describes the dTD Buffer Page Pointer List.

Table 907. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non-virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. Use this mostly to correlate relative completion times of packets on an ISO endpoint.

56.7 Register descriptions

There are two kinds of registers in the USB module: USB core (USBC) registers and USB noncore (USBNC) registers.

USBC registers are used to control USB core functions and are more independent of USB features. Each USB controller core has its own core registers.

USBNC registers are additional to USBC registers and are more dependent on USB features. i.MX series products vary in noncore registers.

For detailed descriptions of USBC registers, refer to Register interface.

Section USBNC memory map describes only the USBNC registers.

NOTE

- For reserved bits, preserve the value when writing (read its reset value, then write this value back).

R	Reserved								TXBURST							
W																
Reset	0	0	0	0	1	0	1	1	0	0	0	0	1	0	0	0

Fields

Field	Function
31-24 —	- Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-16 TXCHANADD	TXCHANADD TX FIFO Buffer size is: (2^TXCHANADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. For the OTG controller operating in device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoint, there are 8 of these buffers. For the OTG controller operating in Host mode, or for Host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only 1 of this buffer
15-8 —	- Reserved
7-0 TXBURST	TXBURST Default burst size for memory to TX buffer transfer. This is reset value of TXPBURST fields in BURSTSIZE.

56.7.1.1.7 RX Buffer Hardware Parameters (HWRXBUF)

Offset

Register	Offset
HWRXBUF	14h

Function

RX Buffer Hardware Parameters defined in configuration file.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RXADD								RXBURST							
W																
Reset	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

Fields

Field	Function
31-16 —	- Reserved
15-8 RXADD	RXADD Buffer total size for all receive endpoints is (2^RXADD). RX Buffer size is: (2^RXADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. There is a single Receive FIFO buffer in the USB controller. The buffer is shared for all endpoints for the OTG controller in device mode.
7-0 RXBURST	RXBURST Default burst size for memory to RX buffer transfer. This is reset value of RXPBURST bits in USB core register USB_n_BURSTSIZE. Please see BURSTSIZE .

56.7.1.1.8 General Purpose Timer #0 Load (GPTIMER0LD)

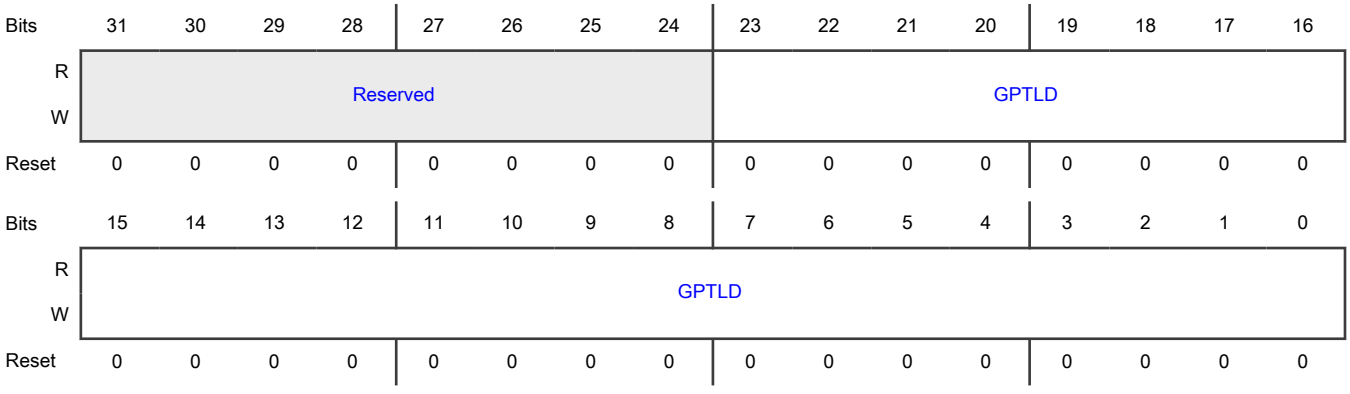
Offset

Register	Offset
GPTIMER0LD	80h

Function

This register controls load value of the count timer in register n_GPTIMER0CTRL. Please see GPTIMER0CTRL .

Diagram



Fields

Field	Function
31-24 —	- Reserved
23-0 GPTLD	GPTLD General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE** Max value is 0xFFFFFF or 16.777215 seconds.

56.7.1.1.9 General Purpose Timer #0 Controller (GPTIMER0CTRL)

Offset

Register	Offset
GPTIMER0CTRL	84h

Function

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n_USBSTS register (See USBSTS), interrupt enable bit is TIE0 bit in n_USBINTR register. (See USBINTR .)

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE** Max value is 0xFFFFFF or 16.777215 seconds.

56.7.1.1.11 General Purpose Timer #1 Controller (GPTIMER1CTRL)

Offset

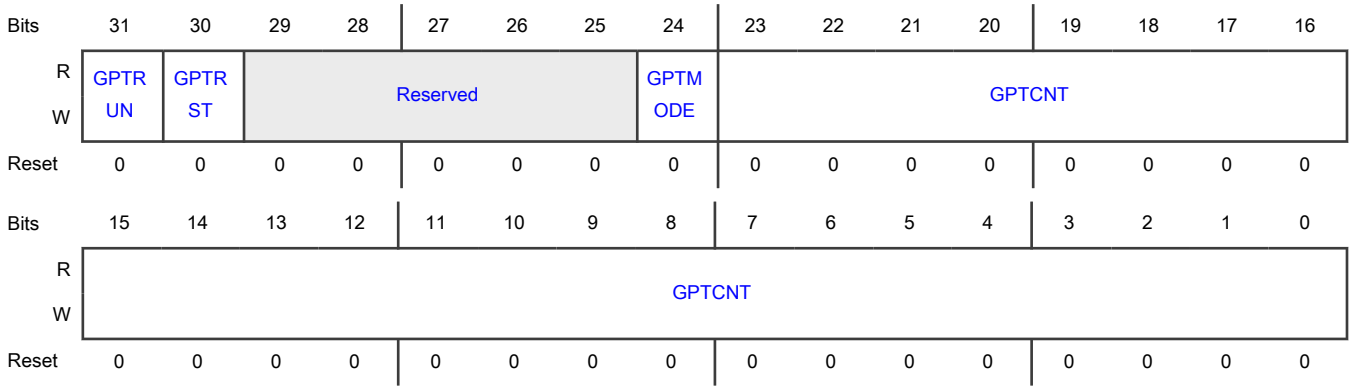
Register	Offset
GPTIMER1CTRL	8Ch

Function

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI1 bit in USB_n_USBSTS register (See USBSTS), interrupt enable bit is TIE1 bit in n_USBINTR register (See USBINTR).

Diagram



Fields

Field	Function
31 GPTRUN	GPTRUN General Purpose Timer Run GPTCNT bits are not effected when setting or clearing this bit. 0b - Stop counting 1b - Run
30 GPTRST	GPTRST General Purpose Timer Reset 0b - No action 1b - Load counter value from GPTLD bits in USB_n_GPTIMER0LD
29-25 —	- Reserved
24 GPTMODE	GPTMODE General Purpose Timer Mode In one shot mode, the timer will count down to zero, generate an interrupt, and stop until the counter is reset by software. In repeat mode, the timer will count down to zero, generate an interrupt and automatically reload the counter value from GPTLD bits to start again. 0b - One Shot Mode 1b - Repeat Mode
23-0 GPTCNT	GPTCNT General Purpose Timer Counter. This field is the count value of the countdown timer.

56.7.1.1.12 System Bus Config (SBUSCFG)

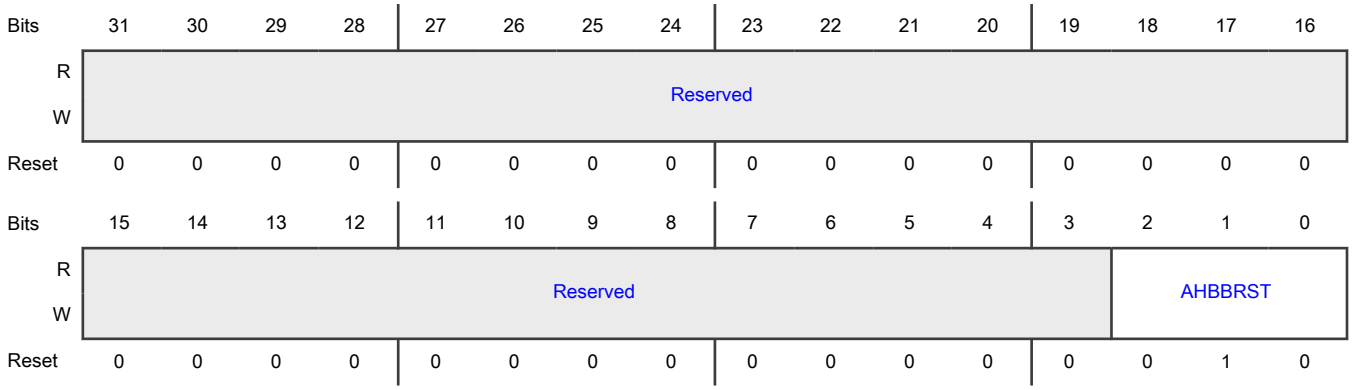
Offset

Register	Offset
SBUSCFG	90h

Function

This register defines the system bus configuration.

Diagram



Fields

Field	Function
31-3 —	- Reserved
2-0 AHBBRST	AHBBRST AHB controller interface burst configuration These bits control AHB controller transfer type sequence (or priority). **NOTE** This register overrides n_BURSTSIZE register when its value is not zero. 000b - Incremental burst of unspecified length only 001b - INCR4 burst, then single transfer 010b - INCR8 burst, INCR4 burst, then single transfer 011b - INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100b - Reserved, don't use 101b - INCR4 burst, then incremental burst of unspecified length 110b - INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111b - INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

56.7.1.1.13 Capability Registers Length (CAPLENGTH)

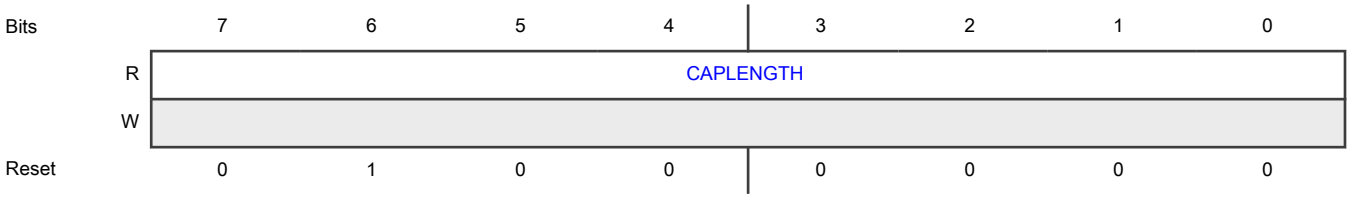
Offset

Register	Offset
CAPLENGTH	100h

Function

The Capability Registers Length register contains the address offset to the Operational registers relative to the CAPLENGTH register.

Diagram



Fields

Field	Function
7-0 CAPLENGTH	CAPLENGTH These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

56.7.1.1.14 Host Controller Interface Version (HCIVERSION)

Offset

Register	Offset
HCIVERSION	102h

Function

This is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HCIVERSION															
W																
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Fields

Field	Function
15-0 HCIVERSION	HCIVERSION Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

56.7.1.1.15 Host Controller Structural Parameters (HCSPARAMS)

Offset

Register	Offset
HCSPARAMS	104h

Function

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (n_HCSPARAMS).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	N_CC				N_PCC				Reserved			PPC	N_PORTS			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

Fields

Field	Function
31-28	-

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	Reserved
27-24 N_TT	N_TT Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23-20 N_PTT	N_PTT Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19-17 —	- Reserved
16 PI	PI Port Indicators (P INDICATOR) This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator This bit is "1b" in all controller core.
15-12 N_CC	N_CC Number of Companion Controller (N_CC). This field indicates the number of companion controllers associated with this USB2.0 host controller. These bits are '0000b' in all controller core. 0000b - There is no internal Companion Controller and port-ownership hand-off is not supported. 0001b - There are internal companion controller(s) and port-ownership hand-offs is supported.
11-8 N_PCC	N_PCC Number of Ports per Companion Controller This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. These bits are '0000b' in all controller core.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-5 —	- Reserved
4 PPC	PPC Port Power Control This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register
3-0 N_PORTS	N_PORTS Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. These bits are always set to '0001b' because all controller cores are Single-Port Host.

56.7.1.1.16 Host Controller Capability Parameters (HCCPARAMS)

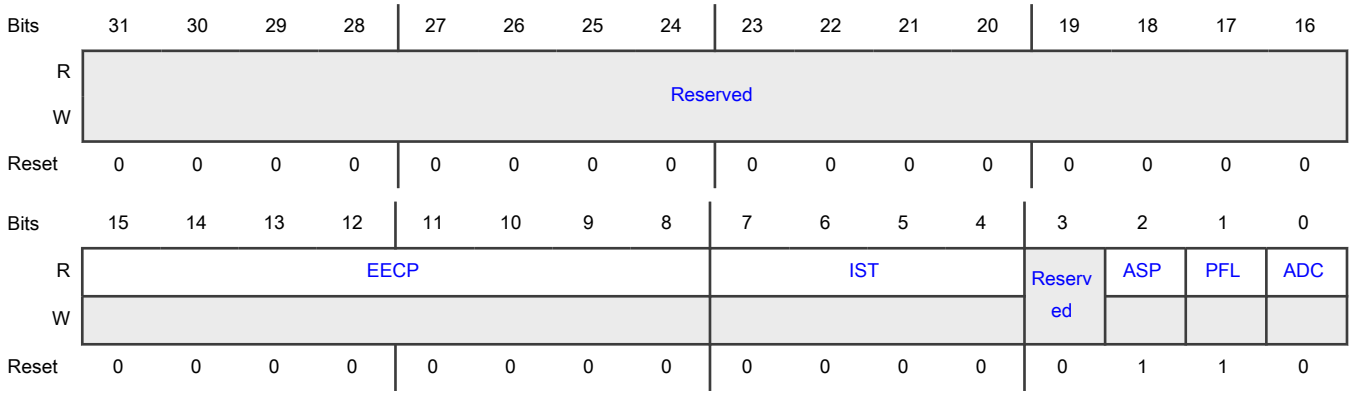
Offset

Register	Offset
HCCPARAMS	108h

Function

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Diagram



Fields

Field	Function
31-16 —	- Reserved
15-8 EECP	EECP EHCI Extended Capabilities Pointer. This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device. **NOTE** These bits are set '00h' in all controller core.
7-4 IST	IST Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. These bits are set '00h' in all controller core.
3 —	- Reserved
2 ASP	ASP Asynchronous Schedule Park Capability If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USBCMD register. **NOTE** ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core.
1 PFL	PFL Programmable Frame List Flag If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This bit is set '1b' in all controller core.

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 ADC	ADC 64-bit Addressing Capability This bit is set '0b' in all controller core, no 64-bit addressing capability is supported.

56.7.1.1.17 Device Controller Interface Version (DCIVERSION)

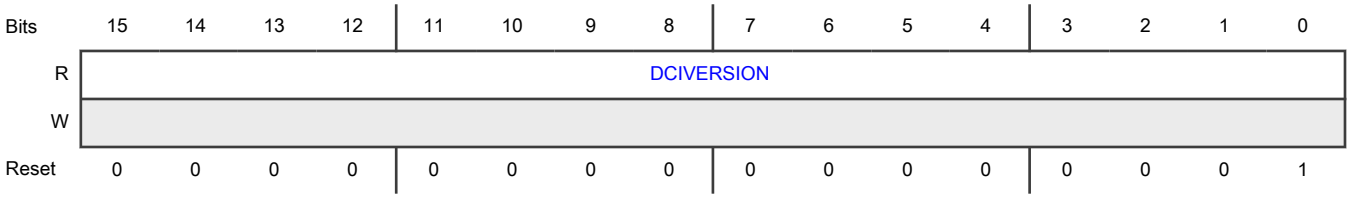
Offset

Register	Offset
DCIVERSION	120h

Function

This register indicates the two-byte BCD encoding of the device controller interface version number.

Diagram



Fields

Field	Function
15-0 DCIVERSION	DCIVERSION Device Controller Interface Version Number Default value is '01h', which means rev0.1.

56.7.1.1.18 Device Controller Capability Parameters (DCCPARAMS)

Offset

Register	Offset
DCCPARAMS	124h

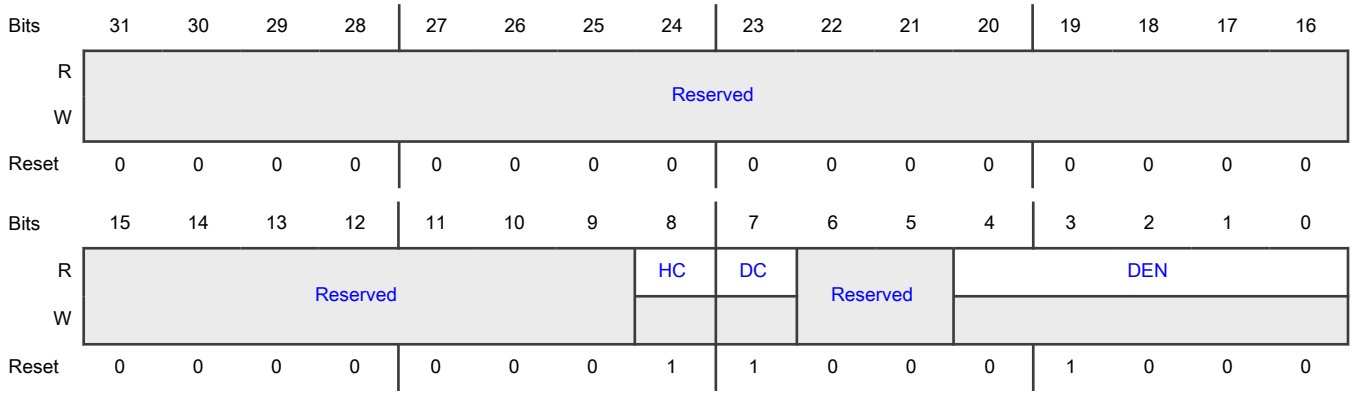
Function

These fields describe the overall device capability of the controller.

NOTE

This register is only available in OTG controller core.

Diagram



Fields

Field	Function
31-9 —	- Reserved
8 HC	HC Host Capable When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
7 DC	DC Device Capable When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6-5 —	- Reserved
4-0 DEN	DEN Device Endpoint Number This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0 - 15.

56.7.1.1.19 USB Command (USBCMD)

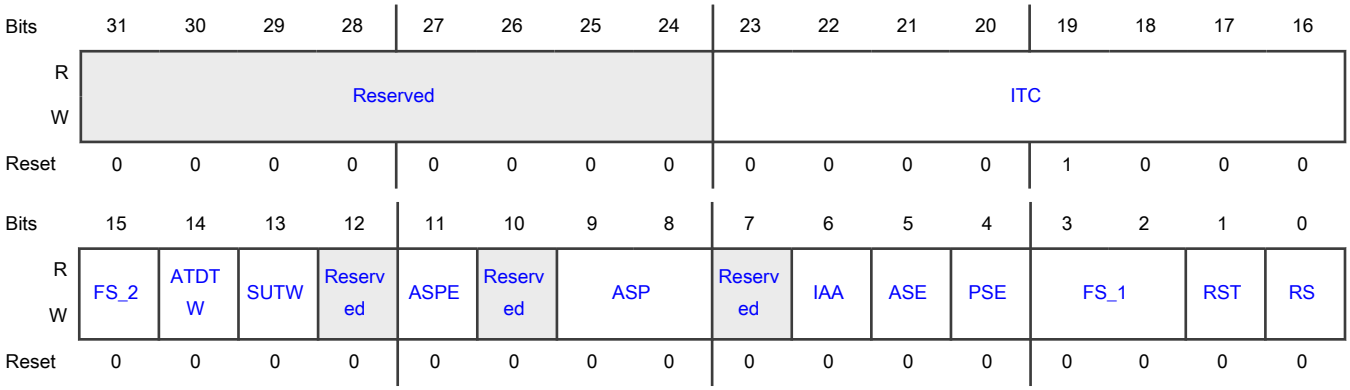
Offset

Register	Offset
USBCMD	140h

Function

Indicates the serial bus host/device controller with the command to execute. Writing to the register causes a command to be executed.

Diagram



Fields

Field	Function
31-24 —	- Reserved
23-16 ITC	ITC Interrupt Threshold Control -Read/Write. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 0000_0000b - Immediate (no threshold) 0000_0001b - 1 micro-frame 0000_0010b - 2 micro-frames 0000_0100b - 4 micro-frames 0000_1000b - 8 micro-frames 0001_0000b - 16 micro-frames 0010_0000b - 32 micro-frames 0100_0000b - 64 micro-frames
15 FS_2	FS_2 Frame List Size - (Read/Write or Read Only). [host mode only] This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field is made up from USBCMD bits 15, 3 and 2. Value Meaning 0b000 - 1024 elements (4096 bytes) Default value 0b001 - 512 elements (2048 bytes) 0b010 - 256 elements (1024 bytes) 0b011 - 128 elements (512 bytes) 0b100 - 64 elements (256 bytes) 0b101 - 32 elements (128 bytes) 0b110 - 16 elements (64 bytes) 0b111 - 8 elements (32 bytes)
14 ATDTW	ATDTW Add dTD TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software. This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.
13 SUTW	SUTW Setup TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see USBMODE) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software. This bit would also be cleared by hardware when a hazard detected.
12 —	- Reserved
11 ASPE	ASPE Asynchronous Schedule Park Mode Enable - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. **NOTE** ASPE bit reset value: '0b' for OTG controller .

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 —	- Reserved
9-8 ASP	ASP Asynchronous Schedule Park Mode Count - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when *Park Mode Enable* is a one as this will result in undefined behavior. This field is set to 3h in all controller core.
7 —	- Reserved
6 IAA	IAA Interrupt on Async Advance Doorbell - Read/Write. This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in Host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	ASE Asynchronous Schedule Enable - Read/Write. Default 0b. This bit controls whether the host controller skips processing the Asynchronous Schedule. Only the host controller uses this bit. Values Meaning 0b - Do not process the Asynchronous Schedule. 1b - Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	PSE Periodic Schedule Enable- Read/Write. Default 0b. This bit controls whether the host controller skips processing the Periodic Schedule. Only the host controller uses this bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Values Meaning 0b - Do not process the Periodic Schedule 1b - Use the PERIODICLISTBASE register to access the Periodic Schedule.
3-2 FS_1	FS_1 See description at bit 15
1 RST	RST Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	RS Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop. Host operation mode: When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one). Device operation mode: Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.

56.7.1.1.20 USB Status (USBSTS)

Offset

Register	Offset
USBSTS	144h

Function

Indicates various states of the host/device controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25 TI1	TI1 General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	TI0 General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23-17 —	- Reserved
16	NAKI

Table continues on the next page...

Table continued from the previous page...

Field	Function
NAKI	NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	AS Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	PS Periodic Schedule Status - Read Only. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
13 RCL	RCL Reclamation - Read Only. This is a read-only status bit used to detect an empty asynchronous schedule. Only used in the host operation mode.
12 HCH	HCH HCHalted - Read Only. This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error). Only used in the host operation mode. Default value is '0b' for OTG core . This is because OTG core is not operating as host in default. Please see CM bit in USB_n_USBMODE register. **NOTE** HCH bit reset value: '0b' for OTG controller core .
11	-

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	Reserved
10 ULPII	ULPII ULPI Interrupt - R/WC. This bit will be set '1b' by hardware when there is an event completion in ULPI viewport. This bit is usable only if the controller support UPLI interface mode.
9 —	- Reserved
8 SLI	SLI DCSuspend - R/WC. When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state. Only used in device operation mode.
7 SRI	SRI SOF Received - R/WC. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp. In Host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it.
6 URI	URI USB Reset Received - R/WC. When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used in device operation mode.
5 AAI	AAI Interrupt on Async Advance - R/WC. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source. Only used in host operation mode.
4	SEI

Table continues on the next page...

Table continued from the previous page...

Field	Function
SEI	System Error- R/WC. This bit is will be set to '1b' when an Error response is seen to a read on the system interface.
3 FRI	FRI Frame List Rollover - R/WC. The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles. Only used in host operation mode.
2 PCI	PCI Port Change Detect - R/WC. The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.
1 UEI	UEI USB Error Interrupt (USBERRINT) - R/WC. When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set. The device controller detects resume signaling only.
0 UI	UI USB Interrupt (USBINT) - R/WC. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

56.7.1.1.21 Interrupt Enable (USBINTR)

Offset

Register	Offset
USBINTR	148h

Function

Enables interrupts to software. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

Diagram

1 UEE	UEE USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	UE USB Interrupt Enable When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

56.7.1.1.22 USB Frame Index (FRINDEX)

Offset

Register	Offset
FRINDEX	14Ch

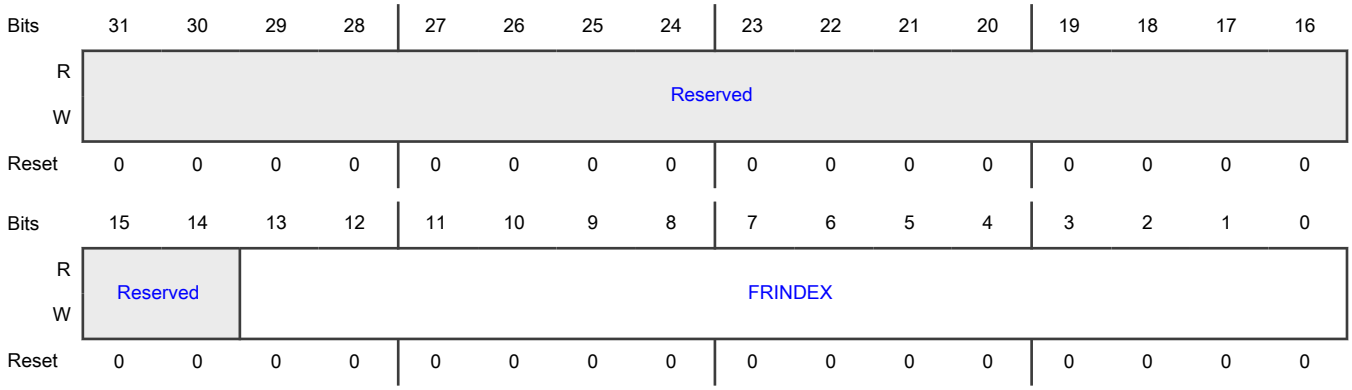
Function

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Diagram



Fields

Field	Function
31-14 —	- Reserved
13-0 FRINDEX	FRINDEX Frame Index. The value, in this register, increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in Host mode. USBCMD [Frame List Size] Number Elements N In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current microframe. The bit field values description below is represented as (Frame List Size) Number Elements N. 00_0000_0000_0000b - (1024) 12 00_0000_0000_0001b - (512) 11 00_0000_0000_0010b - (256) 10 00_0000_0000_0011b - (128) 9 00_0000_0000_0100b - (64) 8 00_0000_0000_0101b - (32) 7 00_0000_0000_0110b - (16) 6 00_0000_0000_0111b - (8) 5

56.7.1.1.23 Device Address (DEVICEADDR)

Offset

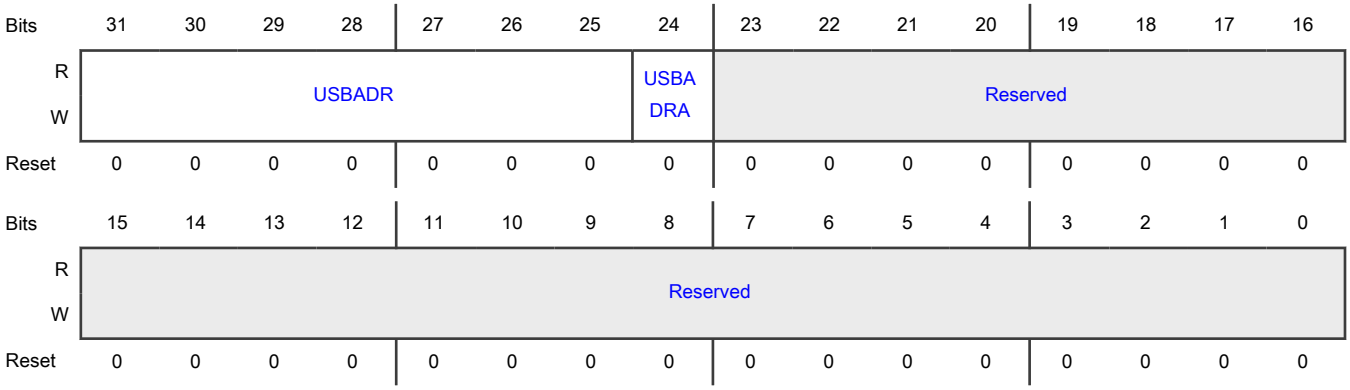
Register	Offset
DEVICEADDR	154h

Function

Device Controller only

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor.

Diagram



Fields

Field	Function
31-25 USBADR	USBADR Device Address. These bits correspond to the USB device address
24 USBADRA	USBADRA Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
23-0 —	- Reserved

56.7.1.1.24 Frame List Base Address (PERIODICLISTBASE)

Offset

Register	Offset
PERIODICLISTBASE	154h

Function

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB_n_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continued from the previous page...

Field	Function
7-0 RXPBURST	RXPBURST Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

56.7.1.1.28 TX FIFO Fill Tuning (TXFILLTUNING)

Offset

Register	Offset
TXFILLTUNING	164h

Function

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

T_s = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

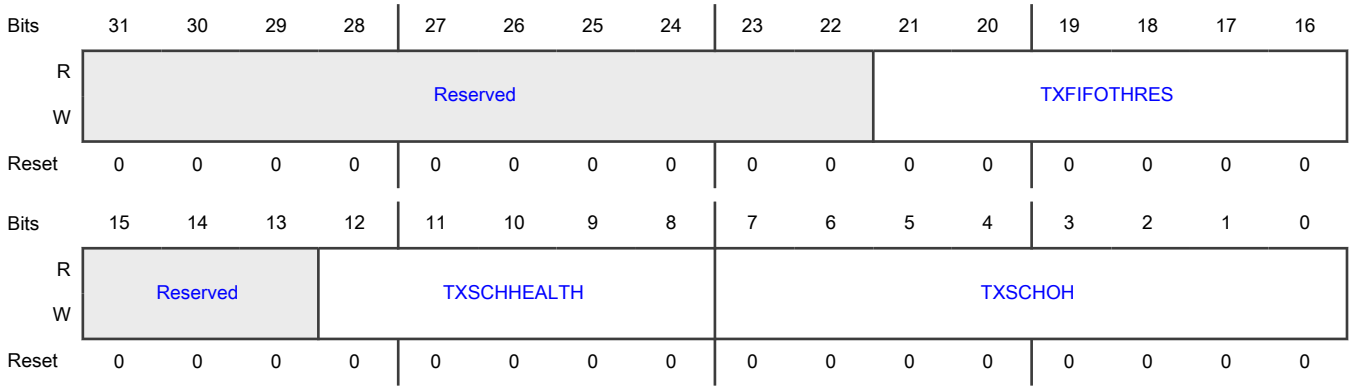
$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the n_TSCHHEALTH (T_{ff}) described below.

NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

Diagram



Fields

Field	Function
31-22 —	- Reserved
21-16 TXFIFOTHRES	TXFIFOTHRES FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in Host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USB_n_USBMODE register is set.
15-13 —	- Reserved
12-8 TXSCHHEALTH	TXSCHHEALTH Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31.
7-0 TXSCHOH	TXSCHOH Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core .

56.7.1.1.29 Endpoint NAK (ENDPTNAK)

Offset

Register	Offset
ENDPTNAK	178h

Function
Endpoint sends NAK handshake for the IN/OUT/PING token.

15-8 —	- Reserved
7-0 EPRNE	EPRNE RX Endpoint NAK Enable - R/W. Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. Bit [N] - Endpoint #[N], N is 0-7

56.7.1.1.31 Configure Flag (CONFIGFLAG)

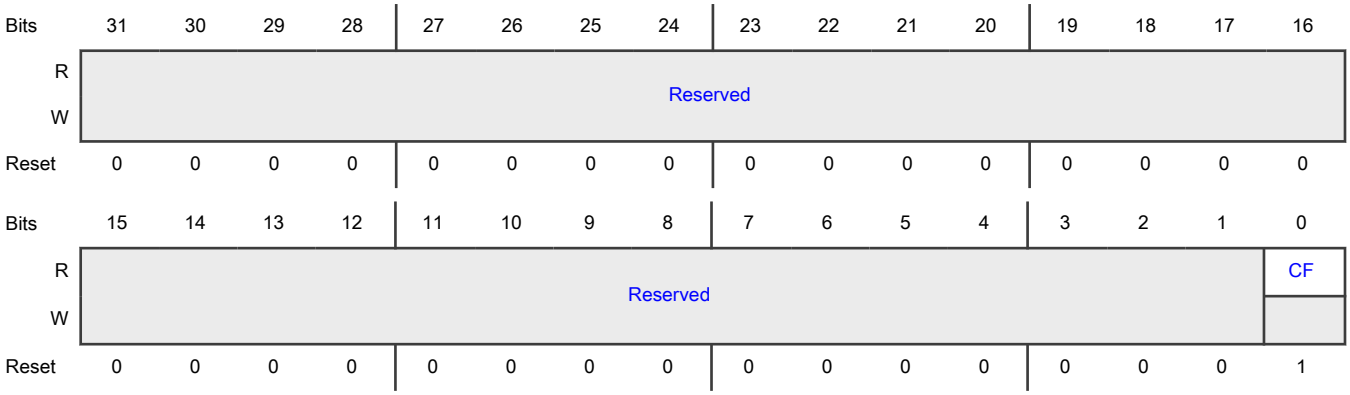
Offset

Register	Offset
CONFIGFLAG	180h

Function

This register is not used in this implementation. A read from this register returns a constant of a 00000001h to indicate that all port routings default to this host controller.

Diagram



Fields

Field	Function
31-1 —	- Reserved
0 CF	CF Configure Flag Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic. 0b - Port routing control logic default-routes each port to an implementation dependent classic host controller. 1b - Port routing control logic default-routes all ports to this host controller.

56.7.1.1.32 Port Status & Control (PORTSC1)

Offset

Register	Offset
PORTSC1	184h

Function

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTs bits in HWSPARAMs register (please see HCSPARAMS). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Diagram

Fields

Field	Function
31-30 PTS_1	PTS_1 Bit field {bit25, bit31, bit30}: "000b" UTMI/UTMI+ "001b" Reserved "010b" ULPI "011b" Serial/USB 1.1 PHY/IC-USB (FS Only) "100b" HSIC Parallel Transceiver Select (bit25, bit31, bit30). For OTG core, it's Read-Only. For Host1/Host2/Host3 core, it's Read/Write.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE All USB port interface modes are listed in this field description, but not all are supported. For detail feature of each controller core, please see Features . The behaviour is unknown when unsupported interface mode is selected.
29 STS	STS Serial Transceiver Select 1 Serial Interface Engine is selected 0 Parallel Interface signals is selected Serial Interface Engine can be used in combination with UTMI+/ULPI physical interface to provide FS/LS signaling instead of the parallel interface signals. When this bit is set '1b', serial interface engine will be used instead of parallel interface signals. This bit has no effect unless PTS bits is set to select UTMI+/ULPI interface. The Serial/USB1.1 PHY/IC-USB will use the serial interface engine for FS/LS signaling regardless of this bit value.
28 PTW	PTW Parallel Transceiver Width This bit has no effect if serial interface engine is used. 0b - Select the 8-bit UTMI interface [60MHz] 1b - Select the 16-bit UTMI interface [30MHz]
27-26 PSPD	PSPD Port Speed - Read Only. Indicates the speed at which the port is operating. 00b - Full Speed 01b - Low Speed 10b - High Speed 11b - Undefined
25 PTS_2	PTS_2 See description at bits 31-30
24 PFSC	PFSC Port Force Full Speed Connect - Read/Write. Default = 0b. When this bit is set to '1b', the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed. 0b - Normal operation

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Forced to full speed
23 PHCD	PHCD PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b. When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock. **NOTE** The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signalled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit. In Host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. 0b - Enable PHY clock 1b - Disable PHY clock
22 WKOC	WKOC Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if *Port Power(* PORTSC1 *)* is zero.
21 WKDC	WKDC Wake on Disconnect Enable (WKDSCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if *Port Power(* PORTSC1 *)* is zero or in device mode.
20 WKCN	WKCN Wake on Connect Enable (WKCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if *Port Power(* PORTSC1 *)* is zero or in device mode.
19-16 PTC	PTC Port Test Control - Read/Write. Default = 0000b. Refer to Port test mode for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE *Low speed operations are not supported as a peripheral device.* Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000b - TEST_MODE_DISABLE 0001b - J_STATE 0010b - K_STATE 0011b - SE0 (host) / NAK (device) 0100b - Packet 0101b - FORCE_ENABLE_HS 0110b - FORCE_ENABLE_FS 0111b - FORCE_ENABLE_LS 1000b-1111b - Reserved
15-14 PIC	PIC Port Indicator Control - Read/Write. Default = Ob. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used. This field is zero if *Port Power* is zero. Bit Value Meaning 00b - Port indicators are off 01b - Amber 10b - Green 11b - Undefined
13 PO	PO Port Owner-Read/Write. Default = 0. This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.
12 PP	PP Port Power (PP)-Read/Write or Read Only.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0 1b *Read Only - Host controller does not have port power control switches. Each port is hard-wired to power.* 1 1b/0b - *Read/Write. OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.* When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in all controller cores (PPC = 1).
11-10 LS	LS Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In Host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the device controller driver is not necessary. The encoding of the bits are: Bits [11:10] Meaning 00b - SE0 01b - K-state 10b - J-state 11b - Undefined
9 HSP	HSP High-Speed Port - Read Only. Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. **NOTE** HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	PR Port Reset - Read/Write or Read Only. Default = 0b. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. *This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.* In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is 0 if *Port Power (* PORTSC1 *)* is 0.
7 SUSP	SUSP Suspend - Read/Write or Read Only. Default = 0b. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the *Force Port Resume* bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (that is, *Port enabled* bit is a zero) the results are undefined. This field is 0 if *Port Power (* PORTSC1 *)* is 0 in Host mode. In Device Mode: Read Only. In device mode this bit is a read only status bit.
6 FPR	FPR Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. Default = 0. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the *Port Change Detect* bit in the USBSTS register is also set to one. *This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.*

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle. This field is zero if *Port Power(* PORTSC1 *)* is zero in Host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit will be cleared because a K-to-J transition detected, the *Port Change Detect* bit in the USBSTS register is also set to one.
5 OCC	OCC Over-current Change-R/WC. Default=0. This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.
4 OCA	OCA Over-current Active-Read Only. Default 0. This bit will automatically transition from one to zero when the over current condition is removed. 0b - This port does not have an over-current condition. 1b - This port currently has an over-current condition
3 PEC	PEC Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0 = No change. Default = 0. In Host Mode: For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is 0 if *Port Power (* PORTSC1 *)* is 0. In Device mode: The device port is always enabled, so this bit is always '0b'.
2 PE	PE Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0. In Host Mode:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is 0 if *Port Power(* PORTSC1 *)* is 0 in Host mode. In Device Mode: The device port is always enabled, so this bit is always '1b'.
1 CSC	CSC Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0. In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. This field is 0 if *Port Power (* PORTSC1 *)* is 0 in Host mode. In Device Mode: This bit is undefined in device controller mode.
0 CCS	CCS Current Connect Status-Read Only. In Host Mode: 1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the *Connect Status Change* bit (Bit 1) to be set. This field is 0 if *Port Power (* PORTSC1 *)* is 0 in Host mode. In Device Mode: 1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.

56.7.1.1.33 On-The-Go Status & control (OTGSC)

Offset

Register	Offset
OTGSC	1A4h

Function

This register is available only in OTG controller core. It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also USBMODE.

26 ASVIE	ASVIE A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	AVVIE A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	IDIE USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 —	- Reserved
22 DPIS	DPIS Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 STATUS_1MS	STATUS_1MS 1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	BSEIS B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit.
19 BSVIS	BSVIS B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold. Software must write a one to clear this bit.
18 ASVIS	ASVIS A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Software must write a one to clear this bit.
17 AVVIS	AVVIS A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold on an A device. Software must write a one to clear this bit.
16 IDIS	IDIS USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.
15 —	- Reserved
14 DPS	DPS Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 TOG_1MS	TOG_1MS 1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	BSE B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	BSV B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	ASV A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	AVV A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8	ID

Table continues on the next page...

Table continued from the previous page...

Field	Function
ID	USB ID - Read Only. 0 = A device, 1 = B device
7-6 —	- Reserved
5 IDPU	IDPU ID Pullup - Read/Write This bit provide control over the ID pull-up resistor; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	DP Data Pulsing - Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OT OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 —	- Reserved
1 VC	VC VBUS Charge - Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VD VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

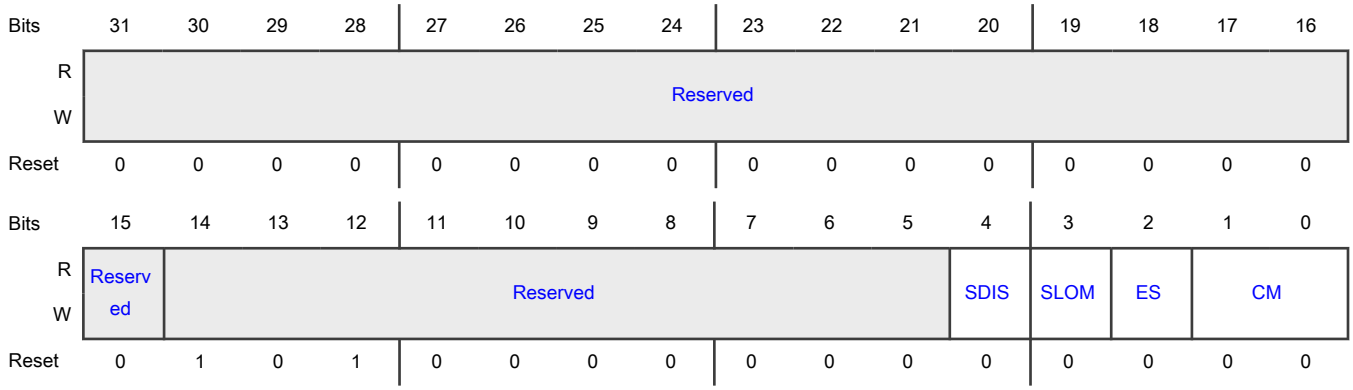
56.7.1.1.34 USB Device Mode (USBMODE)

Offset

Register	Offset
USBMODE	1A8h

Function
USB Mode Selection

Diagram



Fields

Field	Function
31-16 —	- Reserved
15 —	- Reserved
14-5 —	- Reserved
4 SDIS	SDIS Stream Disable Mode. (0 - Inactive [default]; 1 - Active) Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active. Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE** Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TXFILLTUNING and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature. **NOTE** The use of this feature substantially limits of the overall USB performance that can be achieved.
3	SLOM

Table continues on the next page...

Table continued from the previous page...

Field	Function
SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See Control endpoint operation model . 0b - Setup Lockouts On (default); 1b - Setup Lockouts Off. DCD requires use of Setup Data Buffer Tripwire in USBCMD.
2 ES	ES Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. Bit Meaning 0b - Little Endian [Default] 1b - Big Endian
1-0 CM	CM Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the *RESET* bit in the USBCMD register before reprogramming this register. For OTG controller core, reset value is '00b'. 00b - Idle [Default for combination host/device] 01b - Reserved 10b - Device Controller [Default for device only controller] 11b - Host Controller [Default for host only controller]

56.7.1.1.35 Endpoint Setup Status (ENDPTSETUPSTAT)

Offset

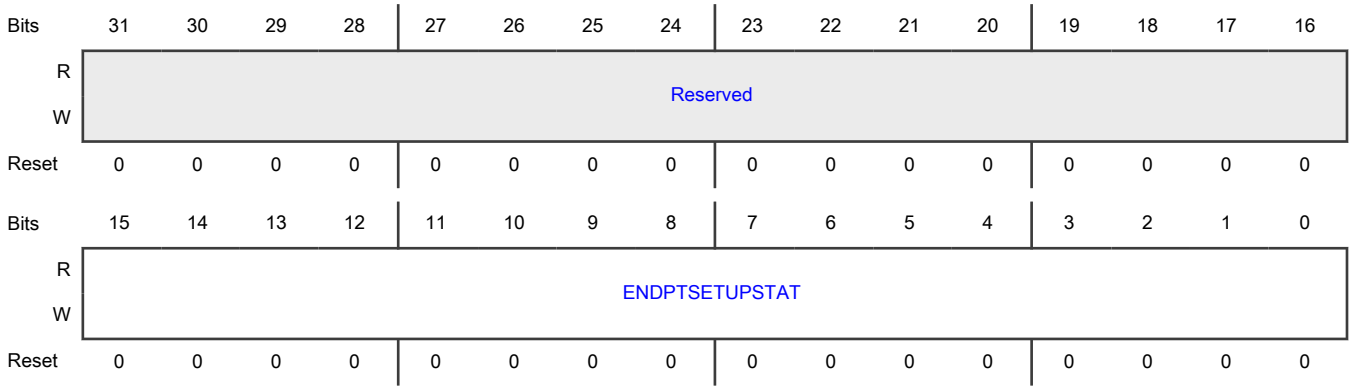
ENDPTSETUPSTAT	1ACh

Function
Endpoint Setup Status

Diagram



Fields

Field	Function
31-16 —	- Reserved
15-0 ENDPTSETUPSTAT	ENDPTSETUPSTAT Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See Managing endpoints in the Device Operational Model. This register is only used in device mode.

56.7.1.1.36 Endpoint Prime (ENDPTPRIME)

Offset

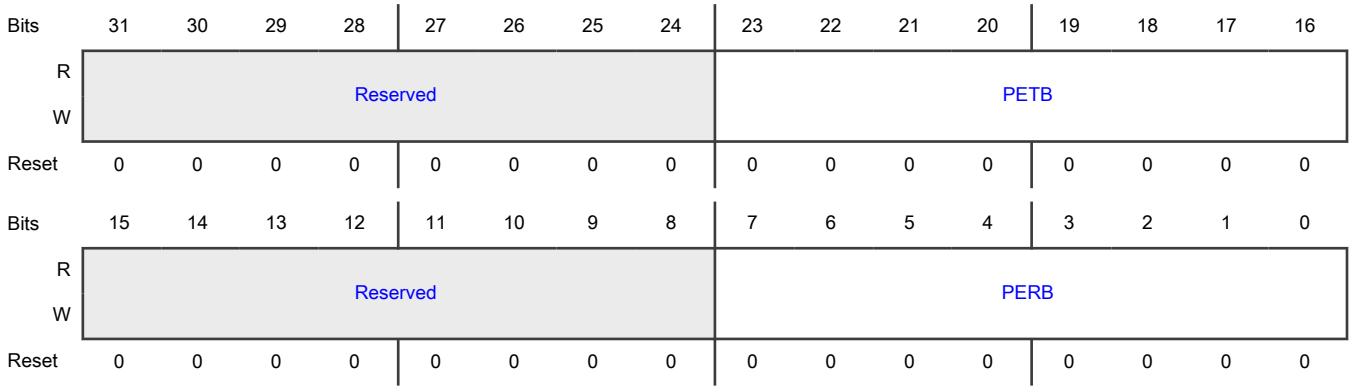
Register	Offset
ENDPTPRIME	1B0h

Function

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

Diagram



Fields

Field	Function
31-24 —	- Reserved
23-16 PETB	PETB Prime Endpoint Transmit Buffer - R/WS. For each endpoint a corresponding bit is used to request that a buffer is prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PETB[N] - Endpoint #N, N is in 0..7
15-8 —	- Reserved
7-0 PERB	PERB Prime Endpoint Receive Buffer - R/WS. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PERB[N] - Endpoint #N, N is in 0..7

56.7.1.1.37 Endpoint Flush (ENDPTFLUSH)

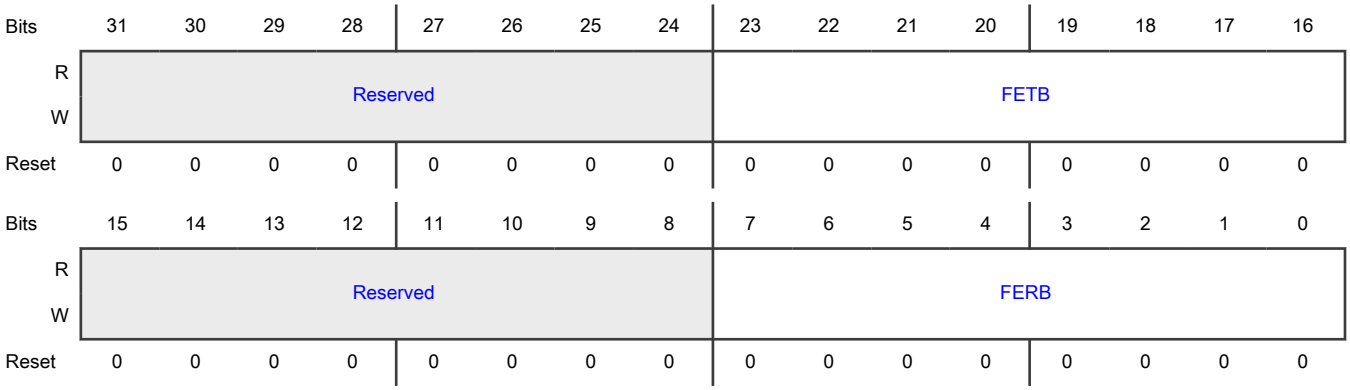
Offset

Register	Offset
ENDPTFLUSH	1B4h

Function

This register is only used in device mode.

Diagram



Fields

Field	Function
31-24 —	- Reserved
23-16 FETB	FETB Flush Endpoint Transmit Buffer - R/WS. Writing one to a bit(s) in this register causes the associated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FETB[N] - Endpoint #N, N is in 0..7
15-8 —	- Reserved
7-0 FERB	FERB Flush Endpoint Receive Buffer - R/WS. Writing one to a bit(s) causes the assocUOGiated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FERB[N] - Endpoint #N, N is in 0..7\

56.7.1.1.38 Endpoint Status (ENDPTSTAT)

Offset

Register	Offset
ENDPTSTAT	1B8h

Function

This register is only used in device mode.

Diagram

Field	Function
3-2 RXT	RXT RX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
1 RXD	RXD RX Endpoint Data Sink - Read/Write 0 Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
0 RXS	RXS RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled This bit is set automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpointand this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints. **NOTE** [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.

56.7.1.1.45 Endpoint Control 5 (ENDPTCTRL5)

Offset

Register	Offset
ENDPTCTRL5	1D4h

Function

This is endpoint control register for endpoint 5 in device operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

57.2 Overview

USBDCD works with the USB transceiver to detect whether the USB device is attached to a Charging Port, either a Dedicated Charging Port (DCP) or a Charging Downstream Port (CDP). System software coordinates the detection activities of the module and controls an off-chip integrated circuit that performs the battery charging.

The use of the term "USB transceiver" in this module documentation applies to the USB physical layer instance on the chip, whether it is an Full Speed (FS)/Low Speed (LS) only transceiver or an High Speed (HS)/FS/LS capable PHY.

57.2.1 Block diagram

The following figure is a high-level block diagram of the module.

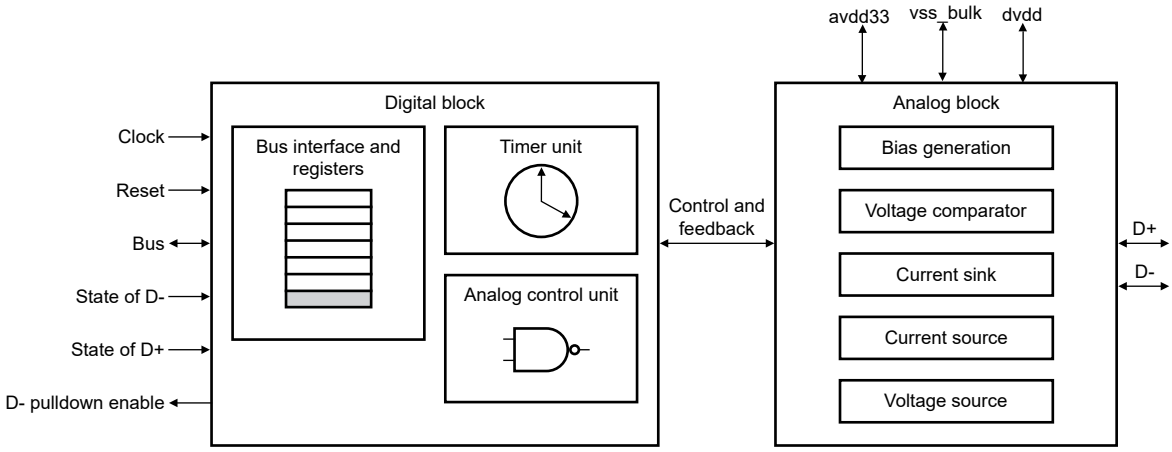

Figure 429. Block diagram

USBDCD consists of two main blocks:

- A Digital block provides the programming interface (memory-mapped registers) and includes the Timer unit and the Analog control unit.
- An Analog block provides the circuitry for the physical detection of the charger that includes the Bias generation, Voltage source, Current source, Current sink, and Voltage comparator circuitry. This block also contains necessary muxes between the source/sink circuits and the D- and D+ pins.

57.2.2 Features

- Compliant with the latest industry-standard specifications: *USB Battery Charging Specification, Revisions 1.1 and 1.2*
- Supports programmable timing parameters:
  - By default set to values required by the industry standards to allow easy configuration. You only need to set the clock frequency before enabling the module.
  - Updates of the standards are programmable.

57.3 Functional description

Several hardware components are involved in the sequence of detecting the presence of the charging port and type of the charging port. System software coordinates this activity. This collection of interacting hardware and software is called USB battery charging subsystem. The following figure shows USBDCD as a component of the subsystem.

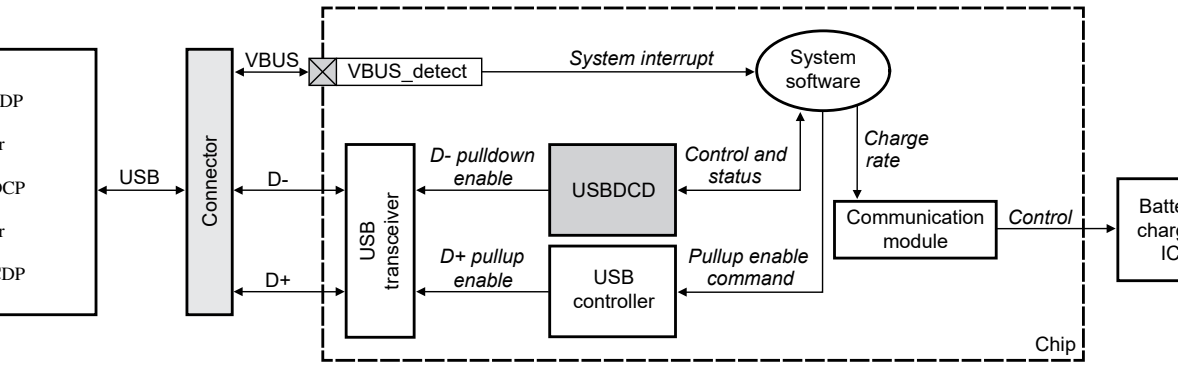

Figure 430. USB battery charging subsystem

The following table describes the components.

Table 909. USB battery charger subsystem components

<table>
<tr><th>Component</th><th>Description</th></tr>
<tr><td>Battery Charger IC</td><td>The external battery charger IC regulates the charge rate to the rechargeable battery. System software is responsible for communicating the appropriate charge rates.

<table><tr><th>Charger</th><th>Maximum current drawn</th></tr><tr><td>Standard Downstream Port (SDP)</td><td>up to 500 mA (I_{CFG_MAX})[1]</td></tr><tr><td>CDP</td><td>up to 1500 mA (I_{DEV_CHG})</td></tr><tr><td>DCP</td><td>up to 1500 mA (I_{DEV_CHG})</td></tr></table>
1. If a USB SDP host has suspended the USB device, the current drawn by the device has to follow the rules of the Dead Battery Provision in the USB Battery Charging Specification, Rev. 1.2.</td></tr>
<tr><td>Comm Module</td><td>A communications module on the device can be used to control the charge rate of the battery charger IC.</td></tr>
<tr><td>System software</td><td>Coordinates the detection activities of the subsystem.</td></tr>
<tr><td>USB Controller</td><td>The D+ pullup enable control signal plays a role during the charger type detection phase. System software must issue a command to the USB controller to assert this signal. After this pullup is enabled, the device is considered to be connected to the USB bus. The host then attempts to enumerate it.

NOTE
In general, the USB controller is used only for USB device applications when using USBDCD. For USB host applications, USBDCD must be disabled.</td></tr>
<tr><td>USB Transceiver</td><td>The USB transceiver contains the pullup resistor for the USB D+ signal and the pulldown resistors for the USB D+ and D– signals. The D+ pullup and the D– pulldown are both used during the charger detection sequence in BC1.1, but it is not used during charger detection in BC1.2. The USB transceiver also outputs the digital state of the D+ and D– signals from the USB bus.

The pullup and pulldown enable signals are controlled by other modules during the charger detection sequence in BC1.1: The D+ pullup enable is output from the USB controller and is under software control. USBDCD controls the D– pulldown enable.</td></tr>
<tr><td>USBDCD</td><td>Detects whether the device has been plugged into either an SDP, a CDP, or a DCP.</td></tr>
<tr><td>VBUS_detect</td><td>This interrupt pin connected to the USB VBUS signal detects when the device has been plugged into or unplugged from the USB bus. If the system requires waking up from a low-power mode on being plugged into the USB port, this interrupt should also be a low-power wakeup source. If this pin multiplexes other functions, such as GPIO, the pin can be configured as an interrupt so that the USB plug or unplug event can be detected.</td></tr>
</table>

57.3.1 Modes of operation

The operating modes of the USBDCD module are shown in the following table.

Table 910. Module modes and their conditions

Module mode	Description	Conditions when used
Enabled for Charger Detection	The module performs the charger detection sequence.	System software must enable the module only if all of the following conditions are true: • The system is using a rechargeable battery or is otherwise capable of being powered up by an SDP or a Charging Port. • The device is being used in a USB device application. • The device is attached to the USB cable.
Enabled for Signal Overrides	Module bias circuits are enabled for special signaling on DP/DM pins.	See SIGNAL_OVERRIDE[PS].
Disabled	The module is not active and is held in a low-power state.	System software must disable the module when either of the following conditions is true: • The charger detect sequence is complete. • The conditions for being enabled are not met.
Powered Off	The digital supply voltage dvdd is removed.	Low system performance requirements allow putting the device into a very low-power stop mode.

Operating mode transitions are shown in the following table.

Table 911. Entering and exiting module modes

Module mode	Entering	Exiting	Mode after exiting
Enabled	Set CONTROL[START].	Set CONTROL[SR]. [1]	Disabled
Disabled	Take *either* of the following actions: • Set CONTROL[SR].[1] • Reset the module. By default, the module is disabled.	Set CONTROL[START].	Enabled
Powered Off	Perform the following actions: 1. Put the device into very low-power stop mode. 2. Adjust the supply voltages.	Perform the following actions: 1. Restore the supply voltages. 2. Take the device out of very low-power stop mode.	Disabled

1. The effect of setting the CONTROL[SR] field is immediate; that is, the module is disabled even if the sequence has not completed.

57.3.2 The charger detection sequence

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.2*.

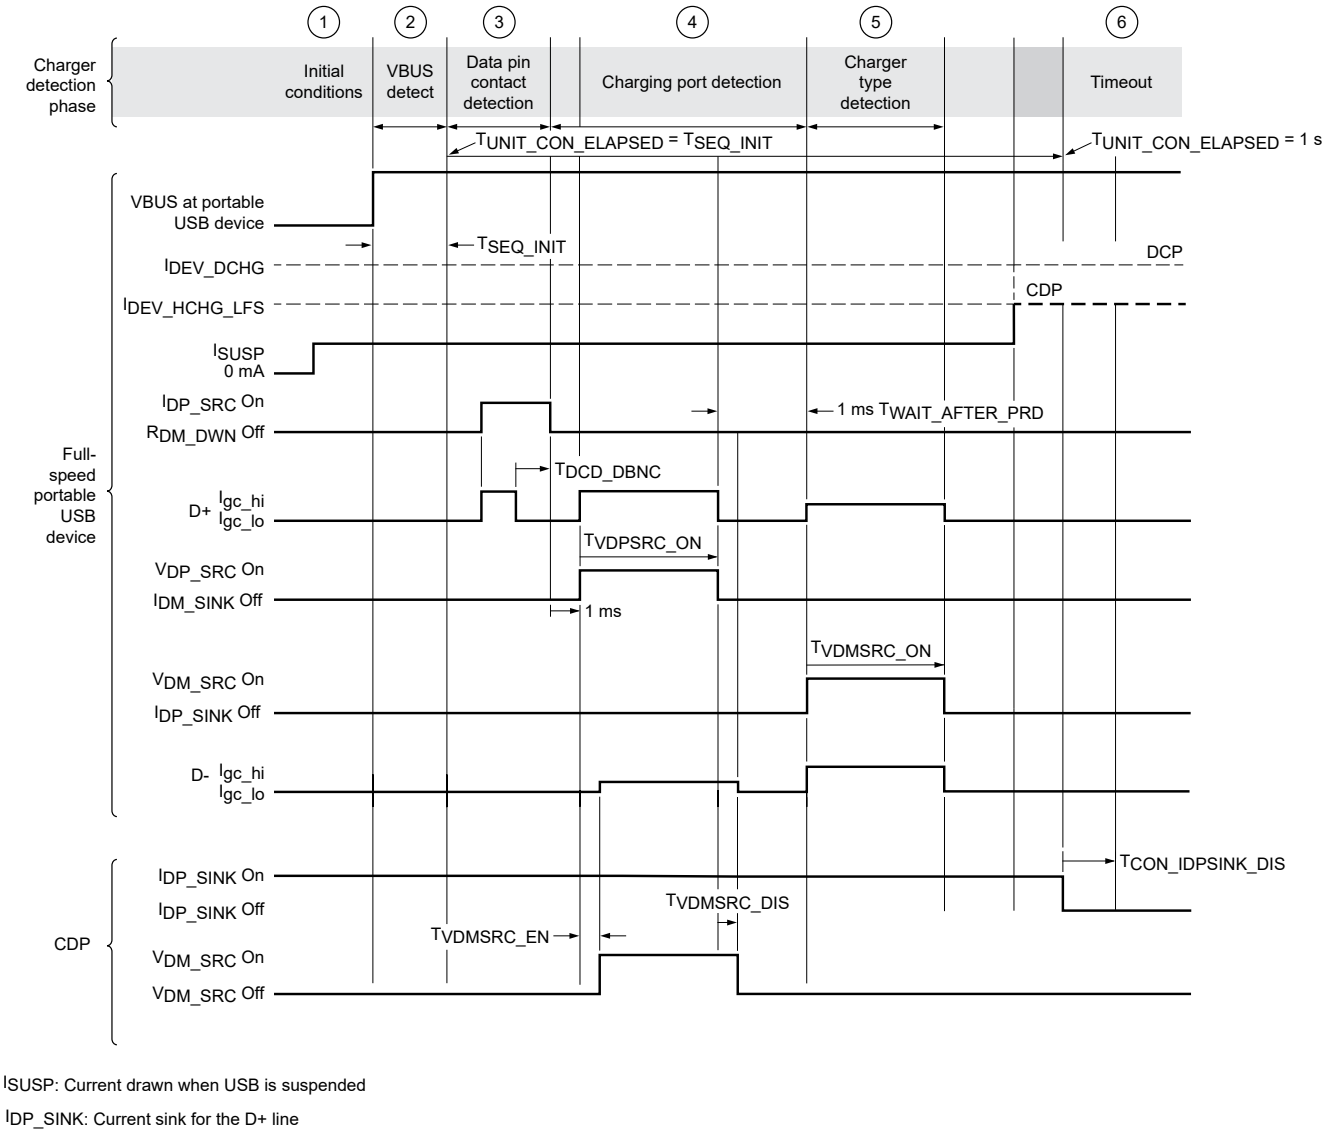

Figure 431. FS charger detection timing for BC1.2

Timing parameter values used in this module for BC1.2 are listed in the following table.

Table 912. Timing parameters for the charger detection sequence for BC1.2

Parameter	USB Battery Charging Spec	Module default	Module programmable range
T_{DCD_DBNC} [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
$T_{WAIT\_AFTER\_PRD}$	N/A	1 ms	0– 1023 ms
T_{VDMSRC_ON}	40 ms	40 ms	0 –1023 ms

Table continues on the next page...

Table 912. Timing parameters for the charger detection sequence for BC1.2 (continued)

Parameter	USB Battery Charging Spec	Module default	Module programmable range
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 – 20 ms	From the USB host	N/A
$T_{CON\_IDPSINK\_DIS}$ [1]	0 – 10 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.2*.

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.1*.

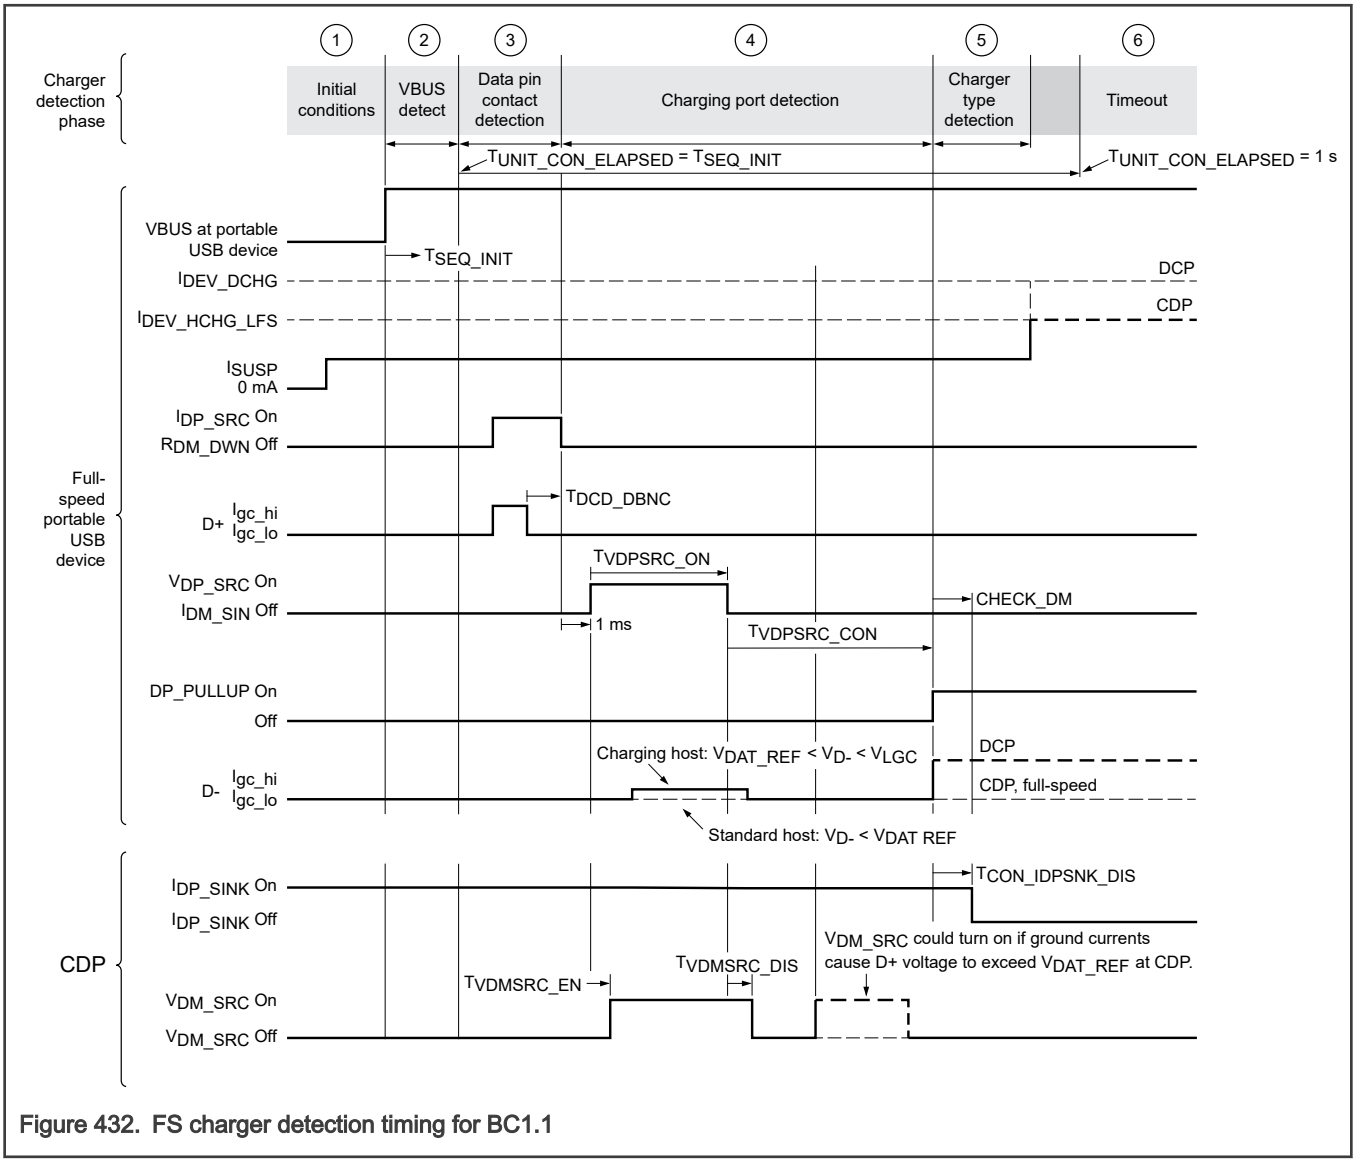

Figure 432. FS charger detection timing for BC1.1

Timing parameter values used in this module for BC1.1 are listed in the following table.

Table 913. Timing parameters for the charger detection sequence for BC1.1

Parameter	USB Battery Charging Spec	Module default	Module programmable range
T_{DCD_DBNC} [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
T_{VDPSRC_CON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
CHECK_DM	N/A	1 ms	0– 15 ms
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 –20 ms	From the USB host	N/A
$T_{CON\_IDPSINK\_DIS}$ [1]	0– 20 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.1*.

The following table provides an overview description of the charger detection sequence shown in the preceding figure.

Table 914. Overview of the charger detection sequence

Phase		Overview description	Full description
1	Initial conditions	Initial system conditions that need to be met before the detection sequence is initiated.	Initial system conditions
2	VBUS detection	System software detects contact of the VBUS signal with the system interrupt pin VBUS_detect.	VBUS contact detection
3	Data pin contact detection	The USBDCD module detects that the USB data pins D+ and D– have made contact with the USB port.	Data pin contact detection
4	Charging port detection	The USBDCD module detects if the port is an SDP or either type of charging port, that is CDP or DCP.	Charging port detection
5	Charger type detection	The USBDCD module detects the type of charging port, if applicable.	Charger type detection
6	Sequence timeout	The USBDCD module did not finish the detection sequence within the timeout interval. The sequence will continue until halted by software.	Charger detection sequence timeout

57.3.2.1 Initial system conditions

The USBDCD module is intended for use with USB device applications using a rechargeable battery. The module does not have support for interfacing with ACA or ACA-Dock equipment as defined in the *USB Battery Charging Specification, Revision 1.2*. It cannot be used with USB applications that are embedded host or OTG.

In addition, before the USBDCD module's charger detection sequence can be initiated, the system must be:

- Powered-up and in run mode. The USBDCD instantiation of this module for the High-Speed port does not directly depend on the VBUS voltage and can operate as long as the avdd33 supply is in a valid range.
- Recently plugged into a USB port.
- Drawing not more than 2.5 mA total system current from the USB bus, except as allowed by the *USB 2.0 Connect Timing Update ECN*.

Examples of allowable precursors to this set of initial conditions include:

- A powered-down device is subsequently powered-up upon being plugged into the USB bus.
- A device in a low-power mode subsequently enters run mode upon being plugged into the USB bus.

57.3.2.2 VBUS contact detection

Once the device is plugged into a USB port, the VBUS_detect system interrupt is triggered. System software must do the following to initialize the module and start the charger detection sequence:

1. Restore power if the module is powered-off.
2. Set CONTROL[SR] to initiate a software reset.
3. Configure the USBDCD module by programming the CLOCK register and the timing parameters as needed.
4. Set CONTROL[IE] to enable interrupts, or clear CONTROL[IE] if the software polling method is used.
5. Program CONTROL[BC12] based on which revision of the USB Battery Charging Specification is needed.
6. Set CONTROL[START] to start the charger detection sequence.

57.3.2.3 Data pin contact detection

The module must ensure that the data pins have made contact because the detection sequence depends upon the state of the USB D+ and D- signals. USB plugs and receptacles are designed such that when the plug is inserted into the receptacle, the power pins make contact before the data pins make contact. See the following figure.

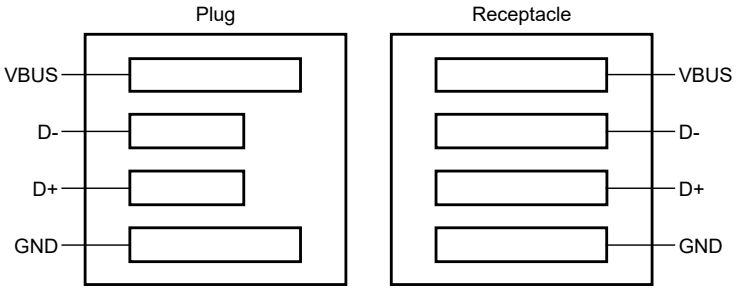

Figure 433. Relative pin positions in USB plugs and receptacles

As a result, when a portable USB device is attached to an upstream port, the portable USB device detects VBUS before the data pins have made contact. The time between power pins and data pins making contact depends on how fast the plug is inserted into the receptacle. Delays of several hundred milliseconds are possible.

57.3.2.3.1 Debouncing the data pin contact

When system software has initiated the charger detection sequence, as described in Initial system conditions, the USBDCD module turns on the I_{DP_SRC} current source and enables the R_{DM_DWN} pulldown resistor. If the data pins have not made contact, the D+ line remains high. After the data pins make contact, the D+ line goes low and debouncing begins.

After the D+ line goes low, the module continuously samples the D+ line over the duration of the T_{DCD_DBNC} debounce time interval. By default, T_{DCD_DBNC} is 10 ms, but it can be programmed in the TIMER0[TDCD_DBNC] field. See the description of TIMER0 for details.

When it has remained low for the entire interval, the debouncing is complete. However, if the D+ line returns high during the debounce interval, the module waits until the D+ line goes low again to restart the debouncing. This cycle repeats until either of the following happens:

- The data pin contact has been successfully debounced (see Success in detecting data pin contact (phase completion)).
- A timeout occurs (see Charger detection sequence timeout).

57.3.2.3.2 Success in detecting data pin contact (phase completion)

After successfully debouncing the D+ state, the module does the following:

- Updates the STATUS register to reflect phase completion (See Table 920 for field values.)
- Directly proceeds to the next step in the sequence: detection of a charging port (See Charging port detection.)

57.3.2.4 Charging port detection

After it detects that the data pins have made contact, the module waits for a fixed delay of 1 ms, and then attempts to detect whether it is plugged into a charging port. The module connects the following analog units to the USB D+ or D– lines during this phase:

- The voltage source V_{DP_SRC} connects to the D+ line
- The current sink I_{DM_SINK} connects to the D– line
- The voltage comparator connects to the USB D– line, comparing it to the voltage V_{DAT_REF}.

After a time of T_{VDPSRC_ON}, the module samples the D– line. The T_{VDPSRC_ON} parameter is programmable and defaults to 40 ms. After sampling the D– line, the module disconnects the voltage source, current sink, and comparator.

The next steps in the sequence depend on the voltage on the D– line as determined by the voltage comparator. See the following table.

Table 915. Sampling D– in the charging port detection phase

If the voltage on D- is...	Then...	See...
Below V_{DAT_REF}	The port is an SDP that does not support using charging currents above I_{CFG_MAX}.	SDP
Above V_{DAT_REF} but below V_{LGC}	The port is a charging port.	Charging port
Above V_{LGC}	This is an error condition.	Error in charging port detection

57.3.2.4.1 SDP

As part of the charger detection handshake with a standard USB host, the module does the following without waiting for the interval ($T_{WAIT\_AFTER\_PRD}$ or T_{VDPSRC_CON}) to elapse:

- Updates the STATUS register to reflect that an SDP is detected with SEQ_RES = 01b. See Table 920 for field values.
- Sets CONTROL[IF].

- Generates an interrupt if enabled in CONTROL[IE].

At this point, control is passed to system software via the interrupt. The rest of the sequence, which detects the type of charging port, is not applicable, so software must perform the following steps:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 909.

57.3.2.4.2 Charging port

As part of the charger detection handshake with any type of USB host, the module waits until the interval ($T_{WAIT\_AFTER\_PRD}$ or T_{VDPSRC_CON}) has elapsed before it does the following:

For *USB Battery Charging Specification, Rev. 1.2*:

- Enables V_{DM_SRC}.
- Updates the STATUS register to reflect that a charging port is detected with SEQ_RES = 10b. See Table 920 for field values.
- At this point the detection sequence progresses to Charger type detection without needing software interaction.

For *USB Battery Charging Specification, Rev. 1.1*:

- Updates the STATUS register to reflect that a charging port is detected with SEQ_RES = 10b. See Table 920 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].
- At this point, control is passed to system software via the interrupt. Software must:
  1. Read the STATUS register.
  2. Set CONTROL[IACK] to acknowledge the interrupt.
  3. Issue a command to the USB controller to pullup the USB D+ line.
  4. Wait for the module to complete the final phase of the sequence. See Charger type detection.

57.3.2.4.3 Error in charging port detection

For this error condition, the module does the following:

- Updates the STATUS register to reflect the error with SEQ_RES = 00b. See Table 920 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

Note that in this case the module does not wait for the interval ($T_{WAIT\_AFTER\_PRD}$ or T_{VDPSRC_CON}) to elapse.

At this point, control has been passed to system software via the interrupt. The rest of the sequence (detecting the type of charging port) is not applicable, so software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

57.3.2.5 Charger type detection

For *USB Battery Charging Specification, Rev. 1.2*:

After the USBDCD module enables the V_{DM_SRC}, the module starts the T_{VDMSRC_ON} timer counting down the time interval programmed into the TIMER2[T_{VDMSRC_ON}] field.

Once the T_{VDMSRC_ON} timer is elapsed, the module samples the USB D+ line to determine the type of charger. See the following table.

Table 916. Sampling D+ in the charger type detection phase (BC1.2)

If the voltage on D+ is...	Then...	See...
High (D+>V_{DAT_REF})	The port is a DCP. [1]	DCP
Low (D+<V_{DAT_REF})	The port is a CDP. [2]	CDP

1. In a DCP, the D+ and D– lines are shorted together through a small resistor.
2. In a CDP, the D+ and D– lines are not shorted.

For *USB Battery Charging Specification, Rev. 1.1*:

After software enables the D+ pullup resistor, the module is notified automatically (via internal signaling) to start the CHECK_DM timer counting down the time interval programmed in the TIMER2[CHECK_DM] field.

After the CHECK_DM time is elapsed, the module samples the USB D– line to determine the type of charger. See the following table.

Table 917. Sampling D– in the charger type detection phase (BC1.1)

If the voltage on D– is...	Then...	See...
High	The port is a DCP. [1]	DCP
Low	The port is a CDP. [2]	CDP

57.3.2.5.1 DCP

For a DCP, the module does the following:

- Updates the STATUS register to reflect that a dedicated charging port is detected with SEQ_RES = 11b. See Table 920 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE] field.

The *USB Battery Charging Specification, Rev. 1.2* indicates that additionally if the detection sequence determines an attachment to a DCP, then the USB device should signal on the D+ pin by either enabling the D+ pullup resistor or enabling V_{DP_SRC}.

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Disable the USB controller to prevent transitions on the USB D+ or D– lines from causing spurious interrupt or wakeup events to the system.
3. Set CONTROL[IACK] to acknowledge the interrupt.
4. Set CONTROL[SR] to issue a software reset to the module.
5. Disable the module.

6. Enable signaling on the D+ pin. This can be done by enabling the Transceiver D+ pullup resistor through configuration of the register fields in the USB controller instance for this USB port. For USBHSDCD instantiation of USBDCD, this signaling can alternatively be done by enabling V_{DP_SRC} through setting the SIGNAL_OVERRIDE[PS] field to a value of 010b.
7. Communicate the appropriate charge rate to the external battery charger IC; see Table 909.

57.3.2.5.2 CDP

For a CDP, the module does the following:

- Updates the STATUS register to reflect that a CDP is detected with SEQ_RES = 10b. See Table 920 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control is passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 909.

57.3.2.6 Charger detection sequence timeout

The maximum time allowed to connect according to the *USB Battery Charging Specification* is one second. If the Unit Connection Timer reaches the one second limit and the sequence is still running as indicated by the STATUS[ACTIVE] field, the module does the following:

- Updates the STATUS register to reflect that a timeout error has occurred. See Table 920 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].
- The detection sequence continues until explicitly halted by software setting CONTROL[SR].
- The Unit Connection Timer continues counting. See the description of TIMER0.

At this point, control is passed to the system software via the interrupt, which has two options: ignore the interrupt and allow more time for the sequence to complete, or halt the sequence. To halt the sequence, software must:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

This timeout function is also useful in case software does not realize that the USB device is unplugged from USB port during the charger detection sequence. If the interrupt occurs but the V_{BUS_DETECT} input is low, software can disable and reset the module.

System software might allow the sequence to run past the timeout interrupt under these conditions:

1. The USB Battery Charging Spec is amended to allow more time. In this case, software should poll TIMER0[$T_{UNITCON}$] periodically to track elapsed time after 1s; or
2. For debug purposes.

Note that the $T_{UNITCON}$ register field will stop incrementing when it reaches its maximum value so it will not roll over to zero and start counting up again.

57.3.2.7 Dead Battery Provision signaling

If the system needs to operate under the Dead Battery Provision of the *USB Battery Charging Specification, Revision 1.2*, the USBDCD module must be configured to signal V_{DP_SRC} on the USB_DP pin.

For information on Dead Battery Provision conditions and signaling, see the Dead or weak battery later in this chapter.

57.3.3 Clocking

The following table describes the clock sources for the USBDCD module. Refer to the chip's clocking chapter for clock setting, configuration, and gating information.

Note these clocks share same name with the USB PHY.

Table 918. USBDCD clocks

Clock name	Description
MODULE_CLK	Peripheral clock
MODULE_CLK_S	Peripheral access clock

57.3.4 Resets

There are two ways to reset various register contents in this module: hardware resets and a software reset.

57.3.4.1 Hardware resets

Hardware resets originate at the system or device level and propagate down to the individual module level. They include start up reset, low-voltage reset, and all other hardware reset sources.

Hardware resets cause the register contents to be restored to their default state as listed in the register descriptions.

57.3.4.2 Software reset

A software reset re-initializes the module's status information, but leaves configuration information unchanged. The software reset allows software to prepare the module without needing to reprogram the same configuration each time the USB device is plugged into a USB port.

Setting CONTROL[SR] initiates a software reset. The following table shows all register fields that are reset to their default values by a software reset.

Table 919. Software reset and register fields affected

Register	Fields affected	Fields not affected
CONTROL[1]	IF	IE, START
STATUS	All	None
CLOCK	None	All
TIMER*n*	TUNITCON	All other

1. CONTROL[SR] and CONTROL[IACK] are self-clearing.

A software reset also returns all internal logic, timers, and counters to their reset states. If the module is already active (STATUS[ACTIVE] = 1b), a software reset stops the sequence.

NOTE

Software must always initiate a software reset before starting the sequence to ensure the module is in a known state.

57.3.5 Interrupts

The USBDCD module has an interrupt to alert system software of certain events, which are listed in the following table. All events except the Phase Complete event for the Data Pin Detection phase can trigger an interrupt.

Table 920. Events triggering an interrupt by sequence phase

Sequence phase	Event	Event description	STATUS fields [1]	Phase description
Data Pin Detection	Phase Complete	The module has detected data pin contact. *No interrupt occurs*: CONTROL[IF] = 0b.	ERR = 0b SEQ_STAT = 01b SEQ_RES = 00b TO = 0b	VBUS contact detection
Charging Port Detection	Phase Complete	The module has completed the process of identifying if the USB port is a charging port or not. **NOTE:** An interrupt is triggered at completion of this phase for BC 1.1 operation whether an SDP or a Charging port is detected. For BC 1.2 operation, if an SDP is detected an interrupt is triggered but if a Charging port is detected the sequence goes directly to the Charger Type Detection phase.	ERR = 0b SEQ_STAT = 10b SEQ_RES = 01b or 10b TO = 0b	Charging port detection
	Error	The module cannot identify the type of port because the D– line is above the USB's VLGC threshold.	ERR = 1b SEQ_STAT = 10b SEQ_RES = 00b TO = 0b	Error in charging port detection
Charger Type Detection	Phase Complete	The module has completed the process of identifying the charger type detection. **NOTE:** The ERR flag always reads zero because no known error conditions are checked during this phase.	ERR = 0b SEQ_STAT = 11b SEQ_RES = 11b or 10b TO = 0b	Charger type detection
Sequence Timeout	Error	The timeout interval from the time the USB device attaches to a USB port until it connects has elapsed.	ERR = 1b SEQ_STAT = last value [2] SEQ_RES = last value [2] TO = 1b	Charger detection sequence timeout

1. See the description of the Status register for register information.
2. The SEQ_STAT and SEQ_RES fields retain the values held at the time of the timeout error.

57.3.5.1 Interrupt handling

Software reads which event caused the interrupt from the STATUS register during the interrupt service routine.

An interrupt is generated only if CONTROL[IE] is set. The CONTROL[IF] field is always set under interrupt conditions, even if CONTROL[IE] is cleared. In this case, software can poll CONTROL[IF] to determine if an interrupt condition is pending.

Writes to CONTROL[IF] are ignored. To reset CONTROL[IF], set CONTROL[IACK] to acknowledge the interrupt. Writing to CONTROL[IACK] when CONTROL[IF] is cleared has no effect.

57.4 External signals

This section describes the module signals. The following table shows a summary of module signals that interface with the pins of the device.

Table 921. Signal descriptions

Signal	Description	I/O
USB_DM	USB D– analog data signal. The analog block interfaces directly to the D– signal on the USB bus.	I/O
USB_DP	USB D+ analog data signal. The analog block interfaces directly to the D+ signal on the USB bus.	I/O
avdd33 [1]	3.3 V regulated analog supply	POWER
vss_bulk	Digital/Analog ground	POWER
dvdd	Core voltage digital supply	POWER

1. Voltage must be 3.3 V ± 10% for full functionality of the module. That is, the charger detection function does not work when this voltage is below 3.0 V, and the CONTROL[START] field should not be set.

NOTE

The transceiver module also interfaces to the USB_DM and USB_DP signals. Both modules and the USB host/hub use these signals as bidirectional, tristate signals.

Information about the signal integrity aspects of the lines including shielding, isolated return paths, input or output impedance, packaging, suggested external components, ESD, and other protections can be found in the USB 2.0 Specification and in Application information.

57.5 Initialization

This module is designed for minimal configuration while retaining significant programmability. To initialize USBDCD:

1. Initialize the CLOCK register to the actual system clock frequency, unless the default value already matches the system requirements.
2. Reset ANACTRL[DEV_PULLDOWN] to 0b when this module is in use for the proper operation of the USBHSDCD instantiation of USBDCD.

   For more information, see the "USB PHY Analog Control Register (ANACTRL)" section of the "Universal Serial Bus 2.0 Integrated PHY (USB-PHY)" chapter.
3. Do not modify other registers, as they default to the values that comply with the USB Battery Charging Specification.
4. Configure timing parameters to obtain flexibility as per the requirements of a specific system.

All module configuration must occur *before* initiating the charger detection sequence. Configuration changes made *after* setting CONTROL[START] result in undefined behavior.

57.6 Application information

This section provides application information.

57.6.1 External pullups

Any external pullups applied to the USB D+ or D- data lines must be capable of being disabled to prevent incorrect pullup values or incorrect operation of the USB subsystem.

57.6.2 Dead or weak battery

According to the *USB Battery Charging Specification, Revision 1.2*, a USB device with a dead or weak battery that is attached to an SDP can draw charging current from VBUS without connecting for several minutes, until the battery is charged to the point that the USB device can connect. The conditions for this operation are referred to as the Dead Battery Provision.

The *USB Battery Charging Specification, Revision 1.2* limits this charging condition to 100 mA for a duration of 45 minutes. The later *USB 2.0 Connect Timing Update ECN* modifies this charging condition to 500 mA for a duration of 2 minutes. Customers designing systems to take advantage of the Dead Battery Provision should study both specifications closely.

The USBDCD module is compatible with systems that do not check the strength of the battery. Therefore, this module assumes that the battery is good, so the USB device must immediately connect to the USB bus by pulling the USB_DP pin high after the USBDCD module has determined that the device is attached to an SDP or CDP. (By definition, a DCP does not support connection but still requires a signaling event, see DCP.)

The module is also compatible with systems that have other circuitry to check the strength of the battery. In these systems, if it is known that the battery is weak or dead, software can delay connecting to the USB while charging using the Dead Battery Provision. Once the battery is charged to the good battery threshold, software must then connect to the USB host by pulling the USB_DP pin high.

While using the Dead Battery Provision, the USB_DP pin must signal by enabling V_{DP_SRC}. On this product that signaling can be done most simply by setting the SIGNAL_OVERRIDE[PS] field to value 10b.

57.6.3 Handling unplug events

If the device is unplugged from the USB bus during the charger detection sequence, the contents of the STATUS register must be ignored and the USBDCD module must get a Software Reset, as described in Software reset.

57.7 USBDCD register descriptions

57.7.1 USBDCD memory map

USBHSDCD1 base address: 42CA_0800h

Field	Function
31-23 —	Reserved
22 ACTIVE	Active Status Indicator Indicates whether the sequence is running. 0b - The sequence is not running. 1b - The sequence is running.
21	Timeout Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
TO	Indicates whether the detection sequence is passed the timeout threshold. 0b - The detection sequence is not running for over 1 s. 1b - It is over 1 s since the data pin contact was detected and debounced.
20 ERR	Error Flag Indicates whether there is an error in the detection sequence. 0b - No sequence errors. 1b - Error in the detection sequence. See STATUS[SEQ_STAT]to determine the phase in which the error occurred.
19-18 SEQ_STAT	Charger Detection Sequence Status Indicates the status of the charger detection sequence. 00b - The module is either not enabled, or the module is enabled but the data pins have not yet been detected. 01b - Data pin contact detection is complete. 10b - Charging port detection is complete. 11b - Charger type detection is complete.
17-16 SEQ_RES	Charger Detection Sequence Results Reports how the charger detection is attached. 00b - No results to report. 01b - Attached to an SDP. Must comply with USB 2.0 by drawing only 2.5 mA (max) until connected. 10b - Attached to a charging port. The exact meaning depends on the STATUS[SEQ_STAT] field (value 0: Attached to either a CDP or a DCP. The charger type detection has not completed. value 1: Attached to a CDP. The charger type detection has completed.) 11b - Attached to a DCP.
15-0 —	Reserved **NOTE** Fields do not always read as 0.

57.7.5 Signal Override (SIGNAL_OVERRIDE)

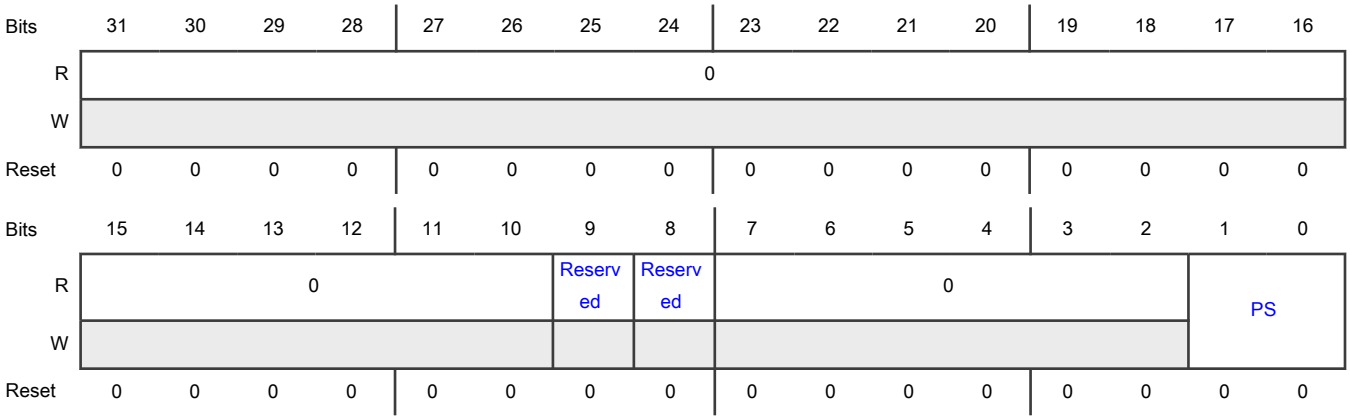
Offset

Register	Offset
SIGNAL_OVERRIDE	Ch

Function

Provides a way for the customer to enable signaling required by the USB BC Rev. 1.2 Specification after the battery charger detection sequences is completed.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 —	Reserved Reserved, not for customer use. The value of this field may change during module operation.
8 —	Reserved Reserved, not for customer use. The value of this field may change during module operation.
7-2 —	Reserved
1-0 PS	Phase Selection Enables specified voltage and current source circuits on the USB_DP and USB_DM pins. Use of the override value below enables the charger detection bias circuits without needing to set CONTROL[START]. Customers may set this field to 10b for required signaling if attached to a Dedicated Charging Port, or during operation under the Dead Battery Provision. 00b - No overrides. Field must remain at this value during normal USB data communication to prevent unexpected conditions on USB_DP and USB_DM pins. (Default) 01b - Reserved, not for customer use. 10b - Enables VDP_SRC voltage source for the USB_DP pin and IDM_SINK current source for the USB_DM pin. 11b - Reserved, not for customer use.

57.7.6 TIMER0 (TIMER0)

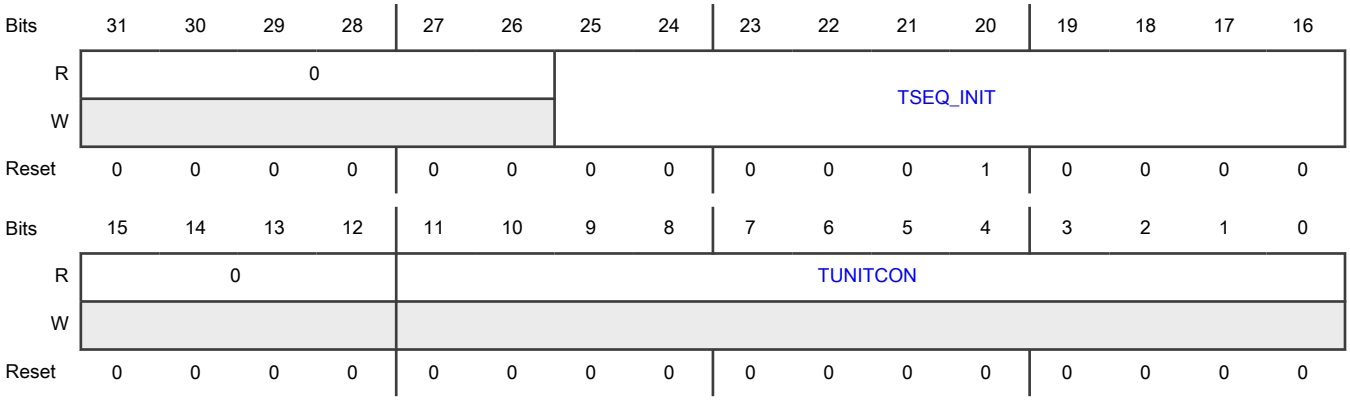
Offset

Register	Offset
TIMER0	10h

Function

Represents the system latency in ms using the TSEQ_INIT field.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 TSEQ_INIT	Sequence Initiation Time TSEQ_INIT represents the system latency (in ms) measured from the time VBUS goes active to the time system software initiates the charger detection sequence in the USBDCD module. When software sets CONTROL[START], the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0-1023, but the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1 s or less. 00_0000_0000b-11_1111_1111b - 0 ms - 1023 ms
15-12 —	Reserved
11-0 TUNITCON	Unit Connection Timer Elapse (in ms) Displays the amount of elapsed time since the event of setting CONTROL[START] plus the value of TSEQ_INIT. The timer is automatically initialized with the value of TSEQ_INIT before starting to count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This timer enables compliance with the maximum time allowed to connect T_{UNIT_CON} under the USB Battery Charging Specification. If the timer reaches the one second limit, the module triggers an interrupt and sets the error flag STATUS[ERR]. The timer continues counting throughout the charger detection sequence, even when control has been passed to software. As long as the module is active, the timer continues to count until it reaches the maximum value of FFFh (4095 ms). The timer does not roll over to zero. A software reset clears the timer.

57.7.7 TIMER1 (TIMER1)

Offset

Register	Offset
TIMER1	14h

Function

Contains timing parameters.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

58.2 Overview

USBPHY interfaces with the USB host and device system at a low-speed (LS) rate of 1.5 Mbit/s, full-speed (FS) rate of 12 Mbit/s, or USB 2.0 high-speed (HS) rate of 480 Mbit/s. The following sections describe the external and internal interfaces, major blocks, and programmable registers that comprise the integrated USBPHY.

58.2.1 Block diagram

The integrated PHY provides a standard USB transceiver macrocell interface (UTMI). The DP and DN pins (as shown in the following figure) connect directly to a USB connector.

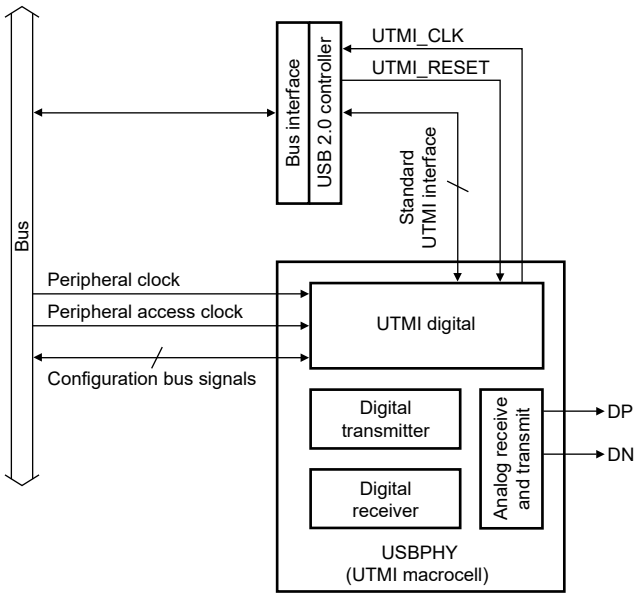

Figure 434. Block diagram

58.2.2 Features

- Supports HS and FS in Device mode
- Supports HS, FS, and LS in Host mode
- Complies with the UTMI+ standard, having a 16-bit data interface to the USB controller
- Provides an integrated 480 MHz PLL
- Provides an integrated USBDCD (see the "USB Device Charger Detection Module (USBDCD)" chapter) with features of *USB Battery Charging Specification, Revision 1.2*

58.3 Functional description

This section covers the USBPHY core components.

- The digital portions of USBPHY include the UTMI, digital transmitter, digital receiver, and programmable registers.
- The analog transceiver comprises an analog receiver and analog transmitter, as shown in Figure 435.

58.3.1 UTMI

The UTMI block handles the LineState bits, reset buffering, suspend distribution, transceiver speed selection, transceiver termination selection, and clock generation logic for the clocks derived from the PHY's USB PLL.

The PLL in USBPHY supplies a 480 MHz clock to the UTMI digital block that divides the clock to generate the 30 MHz clock (UTMI_CLK) used in the interface.

58.3.2 Digital transmitter

The digital transmitter receives a 16-bit transmit data from the USB controller and handles the TX_VALID, TX_VALIDH, and TX_READY handshake. Additionally, it contains the transmit serializer that converts 16-bit parallel words, at a frequency of 30 MHz, to a single bitstream at 480 Mbit/s for HS, 12 Mbit/s for FS, or 1.5 Mbit/s for LS. The digital transmitter does this while implementing the bit-stuffing algorithm and NRZI encoder that you use to remove the DC component from the serial bitstream. The output of this encoder is sent to the LS, FS, or HS drivers in the analog transceiver section's transmitter block.

58.3.3 Digital receiver

The digital receiver receives the raw serial bitstream from the LS differential transceiver, FS differential transceiver, and 480 MHz sampled data from the HS differential transceiver. As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give an appropriate sample of the incoming 480 Mbit/s bitstream. Because this sample point shifts relative to the PLL phase that the digital logic uses, a rate-matching elastic buffer is provided to cross this clock domain boundary.

After the bitstream is in the local clock domain, an NRZI decoder and a bit unstuffer restore the original payload data bitstream and pass it to a deserializer and holding register. The RX state machine handles the RX_READY and RX_VALIDH signals, and a handshake with the USB controller. The handshake is not interlocked, with no RX_READY signal coming from the controller, which must take each 16-bit value that the PHY presents. The RX state machine provides an RX_ACTIVE signal to the controller that indicates whether it is inside a valid packet (synchronization detected, for example).

58.3.4 Analog receiver

The following figure illustrates the analog receiver that comprises differential receivers—two single-ended ones, a 9X, and a 480 MHz HS data sampling module.

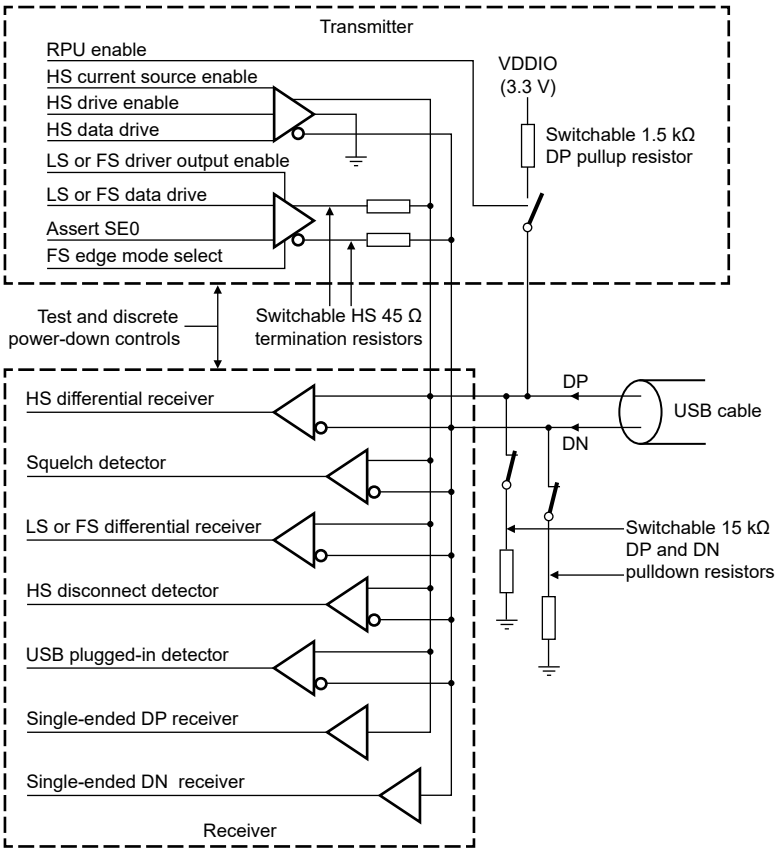

Figure 435. Analog transceiver block diagram

58.3.4.1 HS differential receiver

The HS differential receiver is both a differential analog receiver and threshold comparator. Its output is high (1b) if the differential signal is greater than a 0 V threshold. Otherwise, its output is low (0b). The purpose of the HS differential receiver is to discriminate the ± 400 mV differential voltage resulting from the HS drivers' current flow into the dual 45 Ω terminations found on each pin of the differential pair. The envelope or squelch detector (see Squelch detector) ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

58.3.4.2 Squelch detector

The squelch detector is a differential analog receiver and threshold comparator. Its output is high (1b) if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is low (0b). The purpose of the squelch detector is to invalidate the HS differential receiver if the incoming signal is too low for appropriate reception.

58.3.4.3 LS or FS differential receiver

The LS or FS differential receiver is both a differential analog receiver and threshold comparator. The crossover voltage lies between 1.3 V and 2.0 V. Its output is 1 if the DP line is above the crossover point and the DN line is below the crossover point. The digital receiver section decodes the receiver data into the J or K state, according to the speed.

58.3.4.4 HS disconnect detector

The HS disconnect detector is a differential analog receiver and threshold comparator. Its output is high when the differential magnitude is greater than a nominal 575 mV threshold. Otherwise, its output is low.

58.3.4.5 USB plugged-in detector

When operating in Device mode, USBPHY provides the following methods for the local USB device to detect the attachment of a cable to a remote USB host or hub. You must deploy only one of these methods at a time when waiting to identify the cable attachment event, and disable all methods during USB data communication:

- USB plugged-in detector: This method looks for both DP and DN to be high. A large pair of on-chip pullup resistors (200 kΩ) hold both the DP and DN pins high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case. When operating in Device mode, the upstream port in the host or hub interface contains a 15 kΩ pulldown resistor that could easily override the 200 kΩ pullup resistor. When plugged in, at least one signal in the pair is low, which forces the plugged-in detector's output to become high.

  CTRL[ENDEVPLUGINDETECT] controls the USB plugged-in detector, and you can observe the results through STATUS[DEVPLUGIN_STATUS].

- Data contact detect: This method functions according to *USB Battery Charging Specification, Revision 1.2*. See the "USB Device Charger Detection (USBDCD)" chapter that describes the usage of this method.

58.3.4.6 Single-ended DP receiver

The single-ended DP receiver output is high whenever the DP input is above its nominal 1.8 V threshold.

58.3.4.7 Single-ended DN receiver

The single-ended DN receiver output is high whenever the DN input is above its nominal 1.8 V threshold.

58.3.5 Analog transmitter

The analog transmitter comprises two differential drivers: one for HS signaling and another for FS signaling. It also contains the switchable 1.5 kΩ pullup resistor (see Figure 436).

58.3.5.1 Switchable HS 45 Ω termination resistors

The HS current mode differential signaling requires a 90 Ω differential termination at each end of the USB cable. This results from switching in 45 Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is terminated in parallel with 45 Ω at each end, each driver sees a 22.5 Ω load. This load impedance is too low for FS signaling levels, generating the need for switchable HS terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance for each device, as shown in Figure 436.

TX[TXCAL45DP], for example, allows one of the trimming resistor values to be placed in parallel with the 45 Ω terminator on the DP signal.

58.3.5.2 LS or FS differential driver

The LS or FS differential drivers are essentially a pair of low-impedance pullup and pulldown devices that are switched in a differential mode for most LS or FS signaling. One output is driven high while the other output is driven low to signal the "J" state or the "K" state. Both outputs are driven low for the LS or FS "SE0" state.

58.3.5.3 HS differential driver

The HS differential driver receives a 17.78 mA current from the constant current source (IREF) and essentially steers it down either the DP signal or DN signal, or alternatively to the ground. This current produces an approximately 400 mV drop across the 22.5 Ω termination that the driver sees when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (Vbg) circuit.

58.3.5.4 Switchable 1.5 kΩ DP pullup resistor

This chip contains a switchable 1.5 kΩ pullup resistor on the DP signal. You switch the register on to indicate to the host or hub controller that an FS-capable device is on the USB cable, powered on, and ready. You switch this resistor off at POR so that the host does not recognize a USB device until the processor software enables the announcement of an FS device.

58.3.5.5 Switchable 15 kΩ DP and DN pulldown resistors

This chip contains switchable 15 kΩ pulldown resistors on both DP and DN signals. You enable them in Host mode to indicate to the device controller that a host is present.

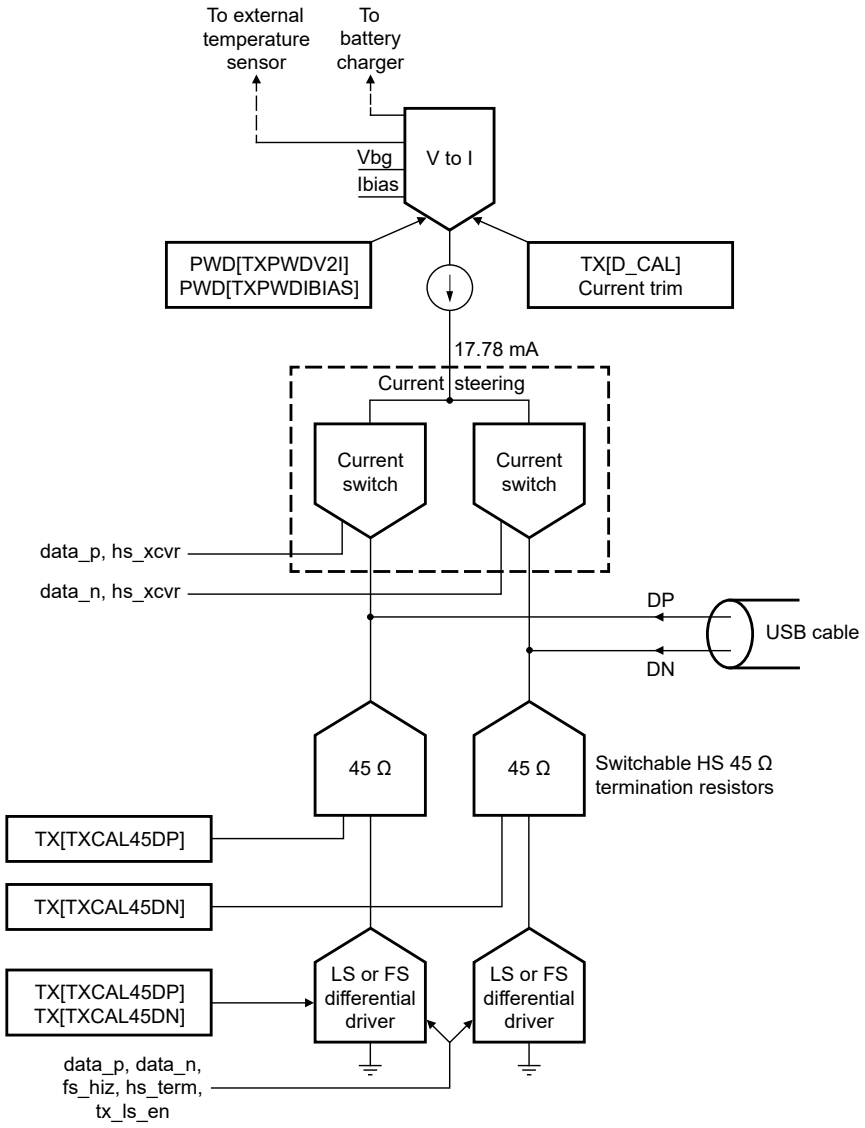

Figure 436. USBPHY transmitter block diagram

58.3.6 Low-Power mode

USBPHY includes a low-power mode (Suspend mode) to save power consumption.

When the USB bus is idle, you can place the transceiver in Low-Power mode (suspend it), after which the clocks to USBPHY can be stopped. The 32 kHz low-power clock must remain active because you need it for wake-up detection.

The USB HS controller monitors USBPHY's entry and exit into Low-Power mode:

- If USB.PORTSC1[SUSP] is 1, the UTMI interface is driven to the FS or LS state.
- If USB.PORTSC1[PHCD] is 1, the UTMI signal "SuspendM" goes low.
- If CTRL[ENAUTOCLR_PHY_PWD] and CTRL[ENAUTOCLR_CLKGATE] are 1, the UTMI clock and PHY transmitter are automatically enabled when the "SuspendM" signal goes high.

USBPHY enters Low-Power mode under the control of the driver software. See the "Universal Serial Bus Controller (USB)" chapter for details.

58.3.7 Clocking

The following table describes the clock sources for USBPHY. See the chip's clocking chapter for clock setting, configuration, and gating information.

Table 923. USBPHY clocks

Clock name	Description
Peripheral clock	Free running IPS bus clock for register configuration
Peripheral access clock	Gated IPS bus clock

58.3.8 Reset

Table 924. USBPHY resets

Reset	How it works
Chip	USBPHY's logic and registers are reset to their default states.
UTMI	UTMI_RESET signal from the USB controller resets the UTMI state machines, FIFO, and so on.
Software	A soft reset (SFTRST) of USBPHY's USBPHY Powerdown (PWD), USBPHY Transmitter Control (TX), USBPHY Receiver Control (RX), USBPHY General Control (CTRL), STATUS[OTGID_STATUS], DEBUG0_STATUS[UTMI_RXERROR_FAIL_COUNT], USBPHY Debug (DEBUG), and UTMI Debug Status 1 (DEBUG1) registers and fields takes place when you write 1 to CTRL[SFTRST]. This also resets state machines in the PHY. Write 0 to CTRL[SFTRST] to release the PHY from reset. **NOTE** A soft reset can take multiple clock periods to complete; therefore, do not write 1 to CTRL[CLKGATE] when writing 1 to CTRL[SFTRST]. The reset process gates the clocks automatically.

58.3.9 Interrupts

Table 925. USBPHY interrupts

Flag or event	Interrupt enable	Description
CTRL[DEVPLUGIN_IRQ]	CTRL[ENIRQDEVPLUGIN]	Indicates nonstandard resistive plugged-in detection
CTRL[RESUME_IRQ]	CTRL[ENIRQRESUMEDETECT]	Indicates that the host is sending a "resume" signal after a "suspend" signal
CTRL[WAKEUP_IRQ]	CTRL[ENIRQWAKEUP]	Indicates that the USB controller has stopped driving the "SuspendM" signal in its active-low state to the PHY

Table continues on the next page...

Table 925. USBPHY interrupts (continued)

Flag or event	Interrupt enable	Description
CTRL[OTG_ID_CHG_IRQ]	CTRL[ENOTG_ID_CHG_IRQ]	Indicates that the value of the OTG ID pin has changed
CTRL[HOSTDISCONDETECT_IRQ]	CTRL[ENIRQHOSTDISCON]	Indicates that the host has detected disconnection of the device in HS mode
USBDCD interrupt	USBDCD interrupt enable	See the "Interrupts" section in the "USB Device Charger Detection Module (USBDCD)" chapter for details
DP changes	USB.CTRL1[WKUP_DPDM_EN]	Wake-up on DP changes—only for the USB device
DN changes	USB.CTRL1[WKUP_DPDM_EN]	Wake-up on DN changes—only for the USB device
ID changes	USB.CTRL1[WKUP_ID_EN]	Wake-up on ID changes
VBUS valid	USB.CTRL1[WKUP_VBUS_EN]	Wake-up on VBUS valid
Session valid	USB.CTRL1[WKUP_VBUS_EN]	Wake-up on session valid

58.4 External signals

Table 926. USBPHY external signals

Signal	Description	Direction
DP	D+ pin	I/O
DN	D- pin	I/O
USB_ID	ID pin	Input
VBUS	VBUS pin	Power

58.5 Initialization

Perform the following procedure to initialize the internal 480 MHz USB PLL clock:

1. Enable the reference clock for USB PLL.
2. Enable the USBPHY PLL regulator.
3. Release the PHY from reset.
4. Power up the PLL.
5. Configure PLL_SIC[PLL_DIV_SEL] appropriately, according to the selected external reference. The system oscillator ranges from 16 MHz to 32 MHz.

58.6 Application information

58.6.1 Recommended register configuration for USB certification

USBPHY has programmability to adjust several transceiver parameters. You can:

- Adjust the TX HS driver termination impedance, FS driver output impedance, and HS driver output currents by using USBPHY Transmitter Control (TX).

- Adjust the HS RX thresholds for the envelope detector or squelch comparator and the host disconnect comparator by using USBPHY Receiver Control (RX).

The default values of the transceiver parametric trim fields are centered with no changes needed for USB certification testing when the chip is used with boards optimized for signal integrity on the HS USB port.

It may be useful to make changes to the parametric trim fields in cases where external components are inserted between the USB DP and DN pins, or compromises are made on USB DP and DN signal routing.

58.6.2 Register macro usage

A read-modify-write (RMW) operation involves updating a field without disrupting the contents of the remaining fields in the register. In this operation, the CPU reads the register, modifies the target field, and then writes the results back to the register. Because of the initial register read, this is an expensive operation in terms of CPU cycles.

To address this issue, you can implement some USBPHY registers as a group, including registers that can be used to either set, clear, or toggle (SCT) individual fields of the primary register. When writing to an SCT register, all fields that are 1 perform the associated operation on the primary register, while all fields that are 0 are not affected. The SCT registers always read back 0, and must have the write-only access type. You cannot implement SCT registers if the primary register has a read-only access type.

With this architecture, you can update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, and then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have a potential drawback—whenever a field is modified, USBPHY sees a value of 0 before you write the final value. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something you must consider when using a CS operation.

Also, you do not require a CS operation for fields that are 1-bit wide. While the CS operation works in this case, it is more appropriate to set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

NOTE

All macros for SCT are not atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of RMW operations. You must remember this when an atomic operation is required because an unexpected behavior may take place if an interrupt occurs during a critical update sequence.

58.7 USBPHY register descriptions

USBPHY does not generate transfer errors when accessing unimplemented registers in its register space.

Also, the SCT feature is implemented for some registers (see Register macro usage for information about this feature).

58.7.2 USBPHY Powerdown (PWD)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

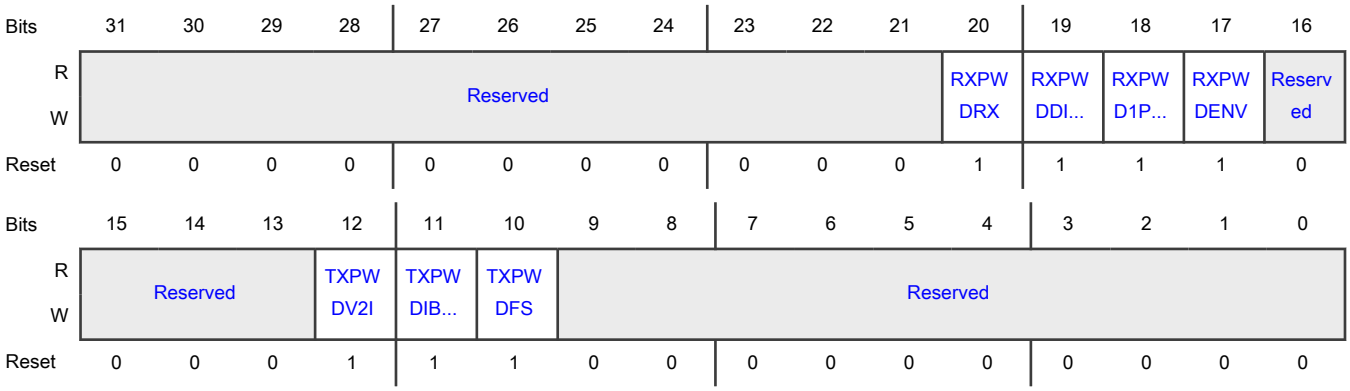
Register	Offset	Description
PWD	0h	USBPHY Powerdown
PWD_SET	4h	Writing 1 to a bit in this register ensures that the corresponding bit in PWD is 1
PWD_CLR	8h	Writing 1 to a bit in this register ensures that the corresponding bit in PWD is 0
PWD_TOG	Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in PWD

Function

Provides an overall control of the PHY power state.

You must enable the PHY clocks before programming this register.

Diagram



Fields

Field	Function
31-21 —	Reserved
20 RXPWDRX	Receiver Powerdown Disables the HS RX differential receiver, HS envelope detector, and HS host disconnect comparator along with their RX current mirror bias circuits. The overall control of the RX current bias block is shared with the battery charge circuit, but this field powers down the other aforementioned RX circuits (the entire USBPHY receiver block) unconditionally, except for the FS differential receiver. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Disable or power down RX circuits
19 RXPWDDIFF	HS Receiver Powerdown Disables the USB HS RX differential receiver that is used for data reception in HS operation. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation 1b - Disable or power down
18 RXPWD1PT1	FS Receiver Powerdown Disables the USB FS RX differential receiver that is used for data reception in both FS and LS operations. This field does not affect the bias and operation of the FS differential receiver. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation 1b - Disable or power down
17 RXPWDENV	Receiver Envelope Powerdown Disables the USB HS RX envelope detector that generates the squelch signal to qualify the HS RX data. The host disconnect comparator is used in Host mode to check for a disconnection from the remote device. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation 1b - Disable or power down
16-13 —	Reserved
12 TXPWDV2I	USBPHY TX V-I Converter and Current Mirror Powerdown Disables the USBPHY TX V-I converter that provides currents used in the HS TX drivers. The converter depends on both USBPHY's bias module and the bias current block. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation 1b - Disable or power down
11 TXPWDIBIAS	Transmitter Bias Powerdown Disables the USBPHY current bias block for the transmitter that provides mirrored currents to track USBPHY's bias module reference current generator for several functions in the TX, RX, and detector sections. Control of the current bias block is shared with the battery charge circuit. Writing 1 to this field does not power down the circuit unless the value of the corresponding field in the battery charge control is also 1 for power down. The field must be 1 only when the USB is in the Suspend bus state. This effectively powers down the entire USB transmit path. The field must become 1 only when the USB is in Suspend mode. This effectively powers down the entire USB transmit path. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. **NOTE** These circuits are shared with the battery charge circuit. Writing 1 to this field does not power down these circuits, unless the corresponding field in the battery charger is also configured as 1 for a power down. 0b - Enable for normal operation 1b - Disable or power down
10 TXPWDFS	FS Transmitter Powerdown Disables the USB FS TX drivers that must have their bias enabled during USB data communication, including resume and bus reset signaling. They are used in HS, FS, and LS because pulldown of the FS TX drivers provides local HS termination. If this field is 1, it turns off the current starvation sources and puts the drivers into high-impedance output. This field becomes 0 in case of a wake-up event if USB is suspended when CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Provide bias to enable for normal operation 1b - Disable or power down
9-0 —	Reserved

58.7.3 USBPHY Transmitter Control (TX)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
TX	10h	USBPHY Transmitter Control
TX_SET	14h	Writing 1 to a bit in this register ensures that the corresponding bit in TX is 1
TX_CLR	18h	Writing 1 to a bit in this register ensures that the corresponding bit in TX is 0
TX_TOG	1Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in TX

Function

Allows adjustment of transmit parametric values.

3 —	Reserved
2-0 ENVADJ	Envelope Adjustment Adjusts the trip point for the envelope detector. The field values are trip-level voltages in nominal DC settings to indicate the effect of changing these fields. AC values measured during compliance testing are a bit higher. 000b - 0.1000 V 001b - 0.1125 V 010b - 0.1250 V 011b - 0.0875 V 1xxb - Reserved

58.7.5 USBPHY General Control (CTRL)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL	30h	USBPHY General Control
CTRL_SET	34h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 1
CTRL_CLR	38h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 0
CTRL_TOG	3Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL

Function

Handles OTG and host controls.

This register also includes interrupt enables, connectivity detect enables, and results.

Fields

Field	Function
31 SFTRST	Software Reset Soft-resets USBPHY Powerdown (PWD), USBPHY Transmitter Control (TX), USBPHY Receiver Control (RX), and USBPHY General Control (CTRL). 0b - Release from reset 1b - Reset
30 CLKGATE	Clock Gating Gates UTMI clocks. Write 1 to this field to save power when the USB is not actively used. Retain the configuration state when the clock is gated. **NOTE** This field can automatically become 0 in case of a wake-up event when USB is suspended, if ENAUTOCLR_CLKGATE is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Run clocks 1b - Gate clocks
29 UTMI_SUSPENDM	UTMI Suspend Mode Indicates a power-down state. UTMI_SUSPENDM is negative logic, as the UTMI specification requires it to be. If this field is 0, all powerdown fields in USBPHY Powerdown (PWD) are enabled. If this field is 0, the USB controller enters Suspend mode. 0b - Suspended 1b - Not suspended
28 HOST_FORCE_LS_SE0	FS EOP LS Timing Works with DEBUG[HOST_RESUME_DEBUG] and forces the next FS packet that is transmitted to have an EOP with LS timing. This field is used in Host mode for the resume sequence. After the packet is transferred, the field becomes 0. You can use this function to force the LS SE0 or use UTMI_SUSPENDM to trigger this event when existing the Suspend state. 0b - Do not force the next FS packet 1b - Force the next FS packet
27 OTG_ID_VALUE	ID Value Indicates the results of the USB_ID pin while monitoring the cable plugged into the Micro- or Mini-AB receptacle. If this field is 0, the ID resistance is less than Ra_Plug_ID, indicating host (A) side. If this field is 1, the ID resistance is greater than Rb_Plug_ID, indicating device (B) side. The functioning of this field is similar to that of STATUS[OTGID_STATUS]; however, this field includes debounce and system clock synchronization logic to filter the glitches on the USB ID pad. 0b - Lesser ID resistance than Ra_Plug_ID 1b - Greater ID resistance than Rb_Plug_ID
26-25 —	Reserved
24 FSDLL_RST_EN	FSDLL Reset Enable Enables resetting of the FSDLL lock detection logic at the end of each TX packet. 0b - Disables 1b - Enables
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21 —	Reserved
20 ENAUTOCLR_PHY_PWD	PHY PWD Auto Clear Enable Enables automatic writing of 0 to the fields in USBPHY Powerdown (PWD) in case of a wake-up event while USB is suspended. You must write 1 to this field if auto wake-up is required without software interaction. 0b - Disables 1b - Enables
19 ENAUTOCLR_CLKGATE	Clock Gating Auto Clear Enable Enables automatic writing of 0 to CLKGATE in case of a wake-up event while USB is suspended. You must write 1 to this field if auto wake-up is required without software interaction. 0b - Disables 1b - Enables
18 AUTORESUME_EN	Auto Resume Enable Enables the auto resume feature. If this field is 1, USBPHY uses a 32 kHz clock to send resume signaling to respond to the USB device remote wakeup (for Host mode only). The field functionality is useful when PLL is off and the reference clock is powered down. 0b - Disables 1b - Enables
17 WAKEUP_IRQ	Wake-Up Interrupt Specifies whether a wake-up event exists. Reset this field by writing 1 to the clear address space, and not by a general write. 0b - No wake-up event exists 1b - Wake-up event exists
16 ENIRQWAKEUP	Wake-Up Interrupt Enable Enables interrupts for wake-up events. 0b - Disables 1b - Enables
15 ENUTMILEVEL3	UTMI Level 3 Enable Enables UTMI+ level 3 operation for USBPHY. You must write 1 to this field if an embedded host use case needs to support an external FS hub with an LS device connected. 0b - Disables

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enables
14 ENUTMILEVEL2	UTMI Level 2 Enable Enables UTMI+ level 2 operation for USBPHY. You must write 1 to this field if an embedded host use case needs to support an LS device. 0b - Disables 1b - Enables
13 —	The value of this reserved bit must remain 0b.
12 DEVPLUGIN_IRQ	Device Plug-In Interrupt Indicates that the device is connected. Reset this field by writing 1 to the SCT clear address space, and not by a general write. 0b - Not connected 1b - Connected
11 ENIRQDEVPLUGIN	Device Plug-In Interrupt Enable Enables an interrupt for the detection of connectivity to the USB line. 0b - Disables 1b - Enables
10 RESUME_IRQ	Interrupt Resume Specifies whether the host is sending a wake-up signal after suspend signaling. This field also becomes 1 after a reset during Suspend mode. Use this field to wake up the USB device from Suspend mode for either the host resume or host reset case. You must reset this field by writing 1 to the clear address space, and not by a general write. 0b - No resume interrupt 1b - Resume interrupt
9 ENIRQRESUMEDETECT	Resume Detection Interrupt Enable Enables an interrupt for detection of a non-J state on the USB line. You must write 1 to this field only after the USB device has entered Suspend mode. 0b - Disables 1b - Enables
8 RESUMEIRQSTICKY	RESUME_IRQ Sticky Specifies until when RESUME_IRQ remains 1 during the resume or reset state signaling period. 0b - Remains 1 during the wake-up period 1b - Remains 1 until you write 0 to it

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 ENOTGIDDETECT	Enable Internal OTG ID Detector Enables the circuit to detect resistance of the Mini-AB ID pin. 0b - Disables 1b - Enables
6 OTG_ID_CHG_IRQ	OTG ID Change Interrupt Indicates that the value of the OTG ID pin has changed. 0b - No ID change interrupt 1b - ID change interrupt
5 DEVPLUGIN_POLARITY	Device Plug-In Polarity Specifies whether to trip the interrupt when the USB device is plugged in or when it is unplugged. If this field is 0, it trips the interrupt when the USB cable from the host to the device is plugged in. If this field is 1, it trips the interrupt if the USB cable from the host to the device is unplugged. 0b - Plugged in 1b - Unplugged
4 ENDEVPLUGINDETECT	Nonstandard Resistive Plugged-In Detection Enable Controls connection of nominal 200 kΩ pullup resistors with both the DP and DN pins as a method of detecting, in Device mode, when a USB cable is attached. This field must remain 0 for normal USB data communication, or when using USBHSDCD for battery charger detection, according to *USB Battery Charger Specification Revision 1.2* or any other detection mechanism for USB cable plugin. STATUS[DEVPLUGIN_STATUS] reports the results of this detection method. 0b - Disables 1b - Enables
3 HOSTDISCONDETECT_IRQ	Host Disconnect Detection Interrupt Specifies whether the device is disconnected in HS Host mode. Reset this field by writing 1 to the SCT clear address space, and not by a general write. 0b - Connected 1b - Disconnected
2 ENIRQHOSTDISCON	Host Disconnect Interrupt Enable Enables an interrupt for detection of device disconnection when in HS Host mode. You must write 1 to this field after writing 1 to ENDEVPLUGINDETECT. 0b - Disables 1b - Enables

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 ENHOSTDISCONDETECT	Host Disconnect Detection Enable Enables the HS disconnect detector for Host mode. This signal allows the override of detection enabling, which the UTMI controller normally performs. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet. Write 1 to this field when an HS device is connected. This is suggested during a bus reset. Ensure that this field is not 1 at the end of resume signaling; otherwise, a wrong disconnect status may be detected. 0b - Disables 1b - Enables
0 ENOTG_ID_CHG_IRQ	ID Change Interrupt Enable Enables the interrupt for ID change. 0b - Disables 1b - Enables

58.7.6 USBPHY Status (STATUS)

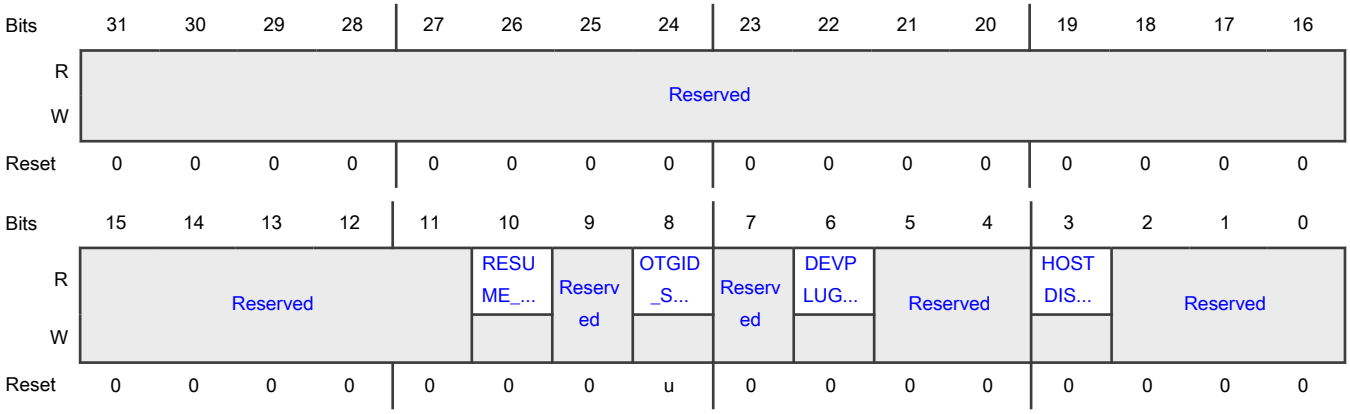
Offset

Register	Offset
STATUS	40h

Function

Holds results of IRQ and other detects.

Diagram



Fields

Field	Function
31-11 —	Reserved
10 RESUME_STATUS	Resume Status Indicates whether the line state is in J state. This field provides a valid indication of resume signaling only when operating in FS or HS mode, after being in the Suspend bus state. This status field may toggle during USB data packet communication. Also, it does not indicate resume signaling when operating as a host that is directly attached to an LS device. 0b - Is in J state 1b - Is not in J state
9 —	Reserved
8 OTGID_STATUS	OTG ID Status Indicates the results of the USB_ID pin on the USB cable plugged into the local Micro-AB or Mini-AB receptacle. If this field is 0, the ID resistance to ground is less than Ra_Plug_ID, indicating host (A) side. If this field is 1, the ID resistance is greater than Rb_Plug_ID, indicating device (B) side. 0b - Lesser ID resistance 1b - Greater ID resistance
7 —	Reserved
6 DEVPLUGIN_STATUS	Status Indicator for Nonstandard Resistive Plugged-In Detection Indicates whether the device is connected on the DP and DN lines using the nonstandard resistive plugged-in detection method that CTRL[ENDEVPLUGINDETECT] controls. When a USB cable attached to a remote host is attached to the local device, the 15 kΩ host pulldowns override the high value resistors used in this detection method. 0b - No attachment detected 1b - Cable attachment detected
5-4 —	Reserved
3 HOSTDISCONDETECT_STATUS	Host Disconnect Detection Status Detects at the local host (downstream) port that the USB cable is disconnected when in HS mode. 0b - Do not detect 1b - Detect

2-0 —	Reserved

58.7.7 USBPHY Debug (DEBUG)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
DEBUG	50h	USBPHY Debug
DEBUG_SET	54h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG is 1
DEBUG_CLR	58h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG is 0
DEBUG_TOG	5Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in DEBUG

Function

Debugs USBPHY.

Fields

Field	Function
31 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 CLKGATE	Clock Gating Gates the test clocks. To save power while the USB is not being actively used, retain the value of 1 in this field. The configuration state is maintained when the clock is gated. 0b - Run clocks 1b - Gate clocks
29 HOST_RESUME_DEBUG	Host Resume Selects the method used to generate the LS SE0 at the end of host resume signaling. The default method triggers from a change to the UTMI_SUSPENDM signal from the USB controller to the PHY. The other method depends on programming CTRL[HOST_FORCE_LS_SE0] at an appropriate time. If this field is 0, it generates LS SE0 at the end of host resume based on CTRL[HOST_FORCE_LS_SE0]. If this field is 1, it generates LS SE0 at the end of host resume based on the state of CTRL[UTMI_SUSPENDM]. 0b - Based on CTRL[HOST_FORCE_LS_SE0] 1b - Based on CTRL[UTMI_SUSPENDM]
28-25 SQUELCHRESETLENGTH	Squelch Reset Length Indicates the number of 480 MHz clock intervals used for the delay time. The changes you make to this field are used only for a specific HS RX debug mode that ENSQUELCHRESET enables. This field adjusts the delay time between the detection of valid HS RX data and release of squelch for that debug mode. The field value indicates the number of 480 MHz clock intervals used for the delay time.
24 ENSQUELCHRESET	Enable Squelch Reset Enables squelch reset. Let the value of this field be 1 to allow normal operation of the squelch state machine for qualification of HS receive data. Writing 0 to this field freezes the functional mode squelch state machine in its reset state, and must be done only for a specific HS RX debug mode. 0b - Disables 1b - Enables
23-21 —	Reserved
20-16 SQUELCHRESETCOUNT	Squelch Reset Count Adjusts the delay time, in 480 MHz clock intervals, between the detection of squelch to the reset of HS RX state machines. Any changes that you make to this field must only be used for a specific HS RX debug mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-13 —	Reserved
12 ENTX2RXCOUNT	Enable Countdown from TX to RX Packets for Debug Enables a countdown to transition between the TX and RX packets for debug. 0b - Disables 1b - Enables
11-8 TX2RXCOUNT	Set Countdown Delay Value from TX to RX Packets for Debug Specifies the delay between the end of transmit to the beginning of receive packets for debug. This is a Johnson counter value and therefore counts to 8.
7-6 —	Reserved
5-4 ENHSTPULLDOWN	Enable Host Pulldown Overdrive Mode Selects whether to override the control of DP and DN pins. This field selects Host Pulldown Overdrive mode. Write 1b to bit 5 to override the control of the DP 15 kΩ pulldown, which the USB controller normally performs. Write 1b to bit 4 to override the control of the DN 15 kΩ pulldown, which the USB controller normally performs. Write 00b to both the bits to disable Host Pulldown Overdrive mode and return the control of the pulldown resistors to the USB controller. When in Host Pulldown Overdrive mode, HSTPULLDOWN further controls the connection of the individual pulldown resistors. Both pulldown resistors are also unconditionally enabled when ANACTRL[DEV_PULLDOWN] becomes 1 without considering the value of this field. 00b - Disable Host Pulldown Overdrive mode 01b - Override the control of DN 15 kΩ pulldown 10b - Override the control of DP 15 kΩ pulldown 11b - Override the control of DP and DN 15 kΩ pulldown
3-2 HSTPULLDOWN	Select DP and DN Pulldown Resistors in Host Pulldown Overdrive Mode Selects whether to connect pulldown resistors on the DP and DN pins if Host Pulldown Overdrive mode is enabled through ENHSTPULLDOWN. Write 1b to bit 3 of this field to connect the 15 kΩ pulldown on the DP line, and write 1b to bit 2 to connect the 15 kΩ pulldown on the DN line. Write 00b to both the bits to disconnect the resistors in Host Pulldown Override mode. 00b - Disconnect the resistors 01b - Connect 15 kΩ pulldown on DN 10b - Connect 15 kΩ pulldown on DP 11b - Connect 15 kΩ pulldown on DP and DN

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 —	Reserved
0 OTGIDPIOLOCK	Hold OTG_ID Holds OTG ID value. After the OTG ID status is acquired from STATUS[OTGID_STATUS], use this field to hold the OTG ID value. This is to save power for the comparators that are used to determine the ID status.

58.7.8 UTMI Debug Status 0 (DEBUG0_STATUS)

Offset

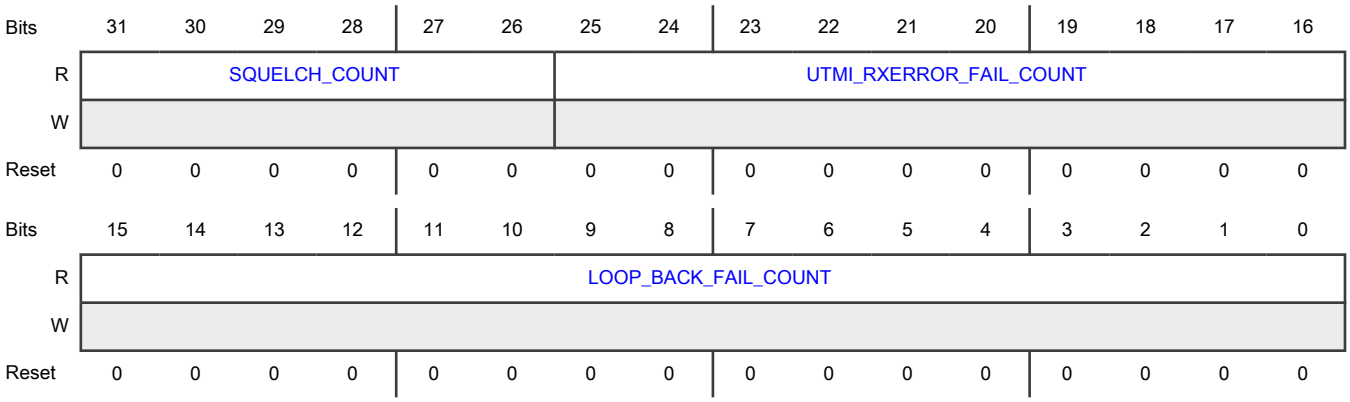
Register	Offset
DEBUG0_STATUS	60h

Function

Holds multiple views for counters and status of state machines.

This field works with DEBUG1[DBG_ADDRESS] to select the function to view. The default settings used to count errors are described in this register.

Diagram



Fields

Field	Function
31-26 SQUELCH_COUNT	Squelch Count Indicates the running count of the squelch reset instead of the normal end for HS RX.

Table continues on the next page...

Table continued from the previous page...

Field	Function
25-16 UTMI_RXERROR_FAIL_COUNT	UTMI Receive Error Fail Count Indicates the running count of UTMI_RXERROR.
15-0 LOOP_BACK_FAIL_COUNT	Loopback Fail Count Indicates the running count of the failed pseudo-random generator loopback. Each time it enters Test mode, the counter goes to 900D and counts up for every detected packet failure in digital and analog loopback tests.

58.7.9 UTMI Debug Status 1 (DEBUG1)

Offset

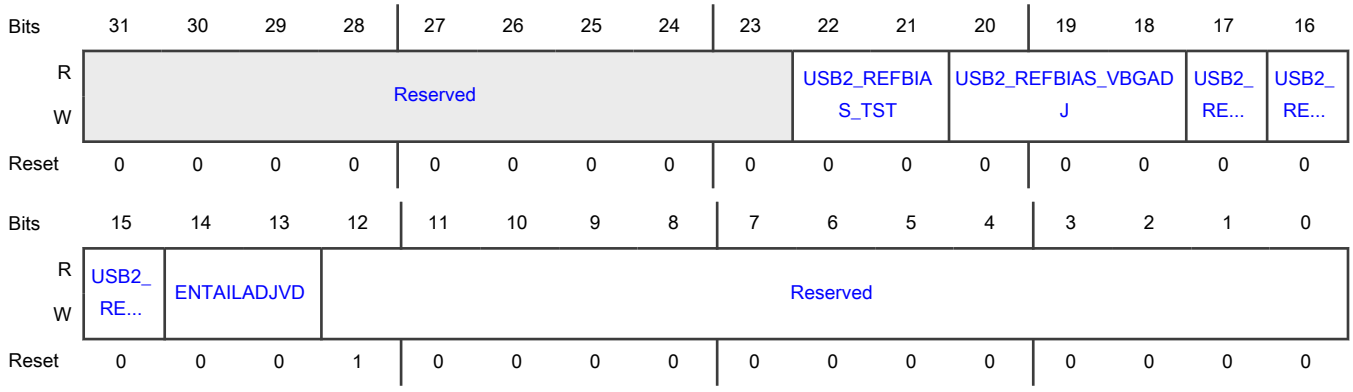
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
DEBUG1	70h	UTMI Debug Status 1
DEBUG1_SET	74h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG1 is 1
DEBUG1_CLR	78h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG1 is 0
DEBUG1_TOG	7Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in DEBUG1

Function

Selects the muxing of USBPHY Debug (DEBUG) to be indicated in UTMI Debug Status 0 (DEBUG0_STATUS).

Diagram



Fields

Field	Function
31-23 —	Reserved
22-21 USB2_REFBIAS_TST	Bias Current Control Adjustment Specifies the main current trim for the USBPHY bias module current reference generator. Use this field to trim the PHY's current reference when TRIM_OVERRIDE_EN[TRIM_REFBIAS_TST_OVERRIDE] is 1. If TRIM_OVERRIDE_EN[TRIM_REFBIAS_TST_OVERRIDE] becomes 0, the current trim values in TRIM_OVERRIDE_EN[TRIM_USB2_REFBIAS_TST] are used instead. 00b - ≈ 10 µA reference current; nominal 01b - ≈ 0.9x compared to nominal 10b - ≈ 0.8x compared to nominal 11b - ≈ 1.1x compared to nominal
20-18 USB2_REFBIAS_VBGADJ	Bandgap Voltage Adjustment Specifies the voltage adjustment trim on USBPHY bias module bandgap generator. Use this field to trim the PHY's bandgap voltage when TRIM_OVERRIDE_EN[TRIM_REFBIAS_VBGADJ_OVERRIDE] is 1. If TRIM_OVERRIDE_EN[TRIM_REFBIAS_VBGADJ_OVERRIDE] becomes 0, the voltage trim values in TRIM_OVERRIDE_EN[TRIM_USB2_REFBIAS_VBGADJ] are used instead. 000b - Nominal bandgap voltage; flattest temperature coefficient 001b - ≈ +10 mV compared to nominal 010b - ≈ +20 mV compared to nominal 011b - ≈ +30 mV compared to nominal; most-positive temperature coefficient 100b - ≈ -10 mV compared to nominal 101b - ≈ -20 mV compared to nominal 110b - ≈ -30 mV compared to nominal 111b - ≈ -40 mV compared to nominal; most-negative temperature coefficient
17 USB2_REFBIAS_LOWPWR	Reference Bias Low Power Configuration Configures the bias currents in the bandgap reference amplifier in the USBPHY bias module. If this field is 0, the bandgap amplifier for a nominal bias current is configured. If this field is 1, the bandgap amplifier for 50% of the nominal bias current is configured. The field must remain 0 for normal operation. Writing 1 is only intended for lab characterization purposes. 0b - Nominal bias current 1b - 50% of nominal bias current
16	Bandgap Voltage Status Comparator Powerdown

Table continues on the next page...

Table continued from the previous page...

Field	Function
USB2_REFBIAS_PWDVBGUP	Disables the VBGUP comparator to save its bias current after the bandgap voltage is valid and stable. The VBGUP comparator monitors the USBPHY bias module bandgap voltage to check that the voltage is in the valid range. If this field is 1, MISC[VBGUP] is also forced to become 1. You cannot detect a bandgap voltage problem if this field is 1, and the PHY does not automatically restore the VBGUP comparator if such a problem occurs. Therefore, it is not recommended to make changes to this field. 0b - Enables 1b - Disables
15 USB2_REFBIAS_SELFBIASOFF	Self-Bias Off for Reference Bias Amplifiers and Comparators Selects the local bias sources to use for the amplifiers and comparators in the USBPHY bias module. If this field is 0, self-bias is used for bias reference amplifier and comparator circuits. If this field is 1, the current reference bias is used for amplifier and comparator circuits. Self-bias is required at reference generator startup. After the bandgap voltage and reference current generator are stable, bias from the reference generator's own regulated currents can be used instead. You must let the value of this field be 0 during a ramp of the 1.8 V power domain and during any time that the USBPHY bias reference circuit transitions from the disabled to enabled state. Switching to the current reference bias after the bandgap voltage is stable may somehow improve bandgap voltage stability, but could cause problems if the 1.8 V power is interrupted. You must monitor MISC[VBGUP]; intervention is mandatory if the value of this field changes. You must also note the interaction of USB2_REFBIAS_PWDVBGUP and MISC[VBGUP]. 0b - Self-bias 1b - Current reference bias
14-13 ENTAILADJVD	HS RX Squelch Rise Time Delay Trim Adjusts the squelch rise time delay for the squelch signal, from the HS RX envelope detector, when TRIM_OVERRIDE_EN[TRIM_ENV_TAIL_ADJ_VD_OVERRIDE] is 1. If TRIM_OVERRIDE_EN[TRIM_ENV_TAIL_ADJ_VD_OVERRIDE] becomes 0, the squelch rise time trim values in TRIM_OVERRIDE_EN[TRIM_USB_REG_ENV_TAIL_ADJ_VD] are used instead. 00b - Squelch rising edge delay is nominal 01b - +20% delay compared to nominal 10b - -20% delay compared to nominal 11b - -40% delay compared to nominal
12-0 —	The value of this reserved bit must remain 0b.

58.7.10 USBPHY Version (VERSION)

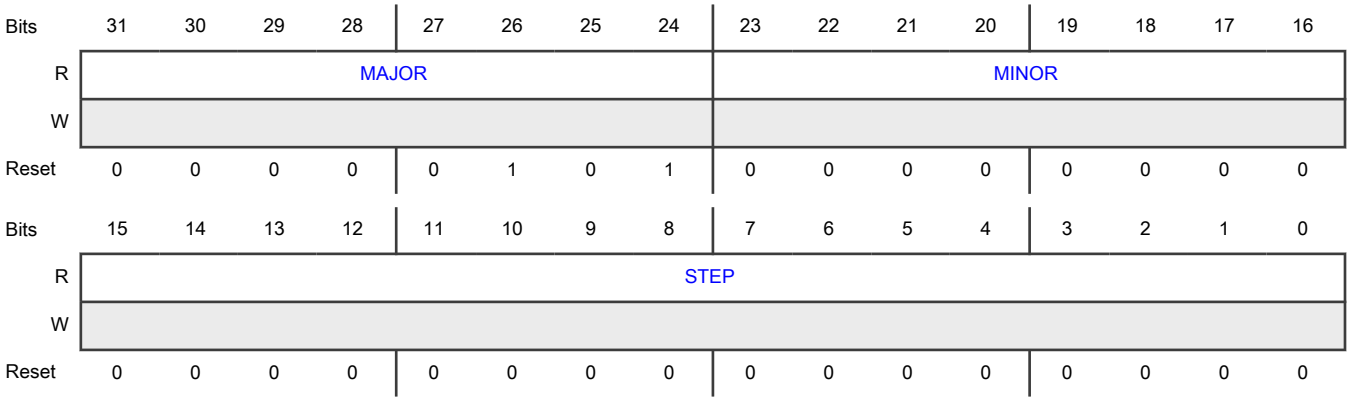
Offset

Register	Offset
VERSION	80h

Function

Indicates the version of USBPHY.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Indicates the "Major" field of the USBPHY version.
23-16 MINOR	Minor Indicates the "Minor" field of the USBPHY version.
15-0 STEP	Step Indicates the stepping of the USBPHY version.

58.7.11 USBPHY PLL Control and Status (PLL_SIC)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
PLL_SIC	A0h	USBPHY PLL Control and Status

Table continues on the next page...

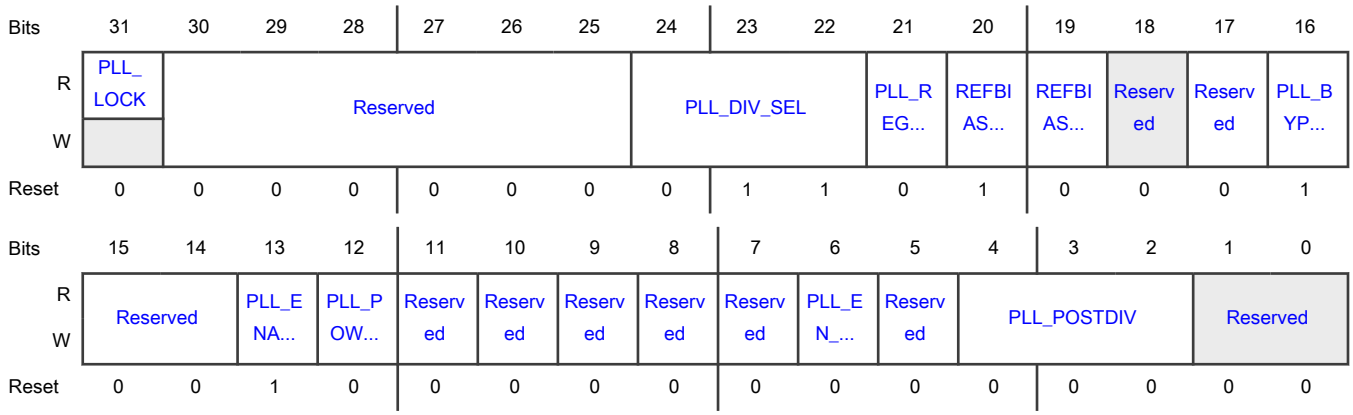
Table continued from the previous page...

Register	Offset	Description
PLL_SIC_SET	A4h	Writing 1 to a bit in this register ensures that the corresponding bit in PLL_SIC is 1
PLL_SIC_CLR	A8h	Writing 1 to a bit in this register ensures that the corresponding bit in PLL_SIC is 0
PLL_SIC_TOG	ACh	Writing 1 to a bit in this register inverts the value of the corresponding bit in PLL_SIC

Function

Configures the 480 MHz USBPHY PLL.

Diagram



Fields

Field	Function
31 PLL_LOCK	PLL Lock Indicates the current status of the USB PLL lock. 0b - Not locked 1b - Locked
30-25 —	Reserved
24-22 PLL_DIV_SEL	PLL Divider Selection Controls the USB PLL feedback loop divider. The valid range for divider values is 13–240. (Fout = Fin × div_select). The USB PLL produces a 480 MHz output clock. This field allows the use of different frequency signals for the PLL reference clock input connected to the OSCCLK signal from the system oscillator. If TRIM_OVERRIDE_EN[TRIM_DIV_SEL_OVERRIDE] is 1, the USB PLL uses this register value.

58.7.12 USBPHY VBUS Detect Control (USB1_VBUS_DETECT)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
USB1_VBUS_DETECT	C0h	USBPHY VBUS Detect Control
USB1_VBUS_DETECT_SET	C4h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_VBUS_DETECT is 1
USB1_VBUS_DETECT_CLR	C8h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_VBUS_DETECT is 0
USB1_VBUS_DETECT_TOG	CCh	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_VBUS_DETECT

Function

Defines controls for USB VBUS detect and some additional out-of-band signaling functions.

Diagram

Fields

Field	Function
31 EN_CHARGER_RESISTOR	Charger Resistor Enable Enables a nominal 125 kΩ pullup on DP and a nominal 375 kΩ pulldown on DN. This allows resistive battery charger detection according to *USB Battery Charging Specification Revision 1.0*, which is now obsolete. With this method, you perform the detection of the DN and DP pin states by using USB1_CHRG_DET_STAT[DN_STATE] and USB1_CHRG_DET_STAT[DP_STATE], respectively. This field must remain 0 for normal USB data communication, or when using the USBHSDCD module for battery charger detection, according to *USB Battery Charger Specification Revision 1.2* or any other detection mechanism for USB cable plugin. 0b - Disables 1b - Enables
30-28 —	Reserved
27 —	Reserved
26 DISCHARGE_VBUS	VBUS Discharge Resistor Controller Enables (controls) a nominal 22 kΩ resistor between the USB1_VBUS pin and the ground that can be used to accelerate the fall of the VBUS signal at the end of a session. 0b - Disables 1b - Enables
25-23 —	Reserved
22-20 PWRUP_CMPS	VBUS_VALID Comparator Enable Enables (powers up) the comparator used for the VBUS_VALID detector. You can reset this field to 0 to save power if the internal VBUS_VALID comparator is not used. The default value is 111b. 000b - Disable the VBUS_VALID comparator 001b - Enable the SESS_VALID comparator 010b - Enable 3V detection
19 —	Reserved
18 VBUSVALID_TO_SESSVALID	VBUS_VALID Comparator Selection Controls the comparator that is used to report the VBUS_VALID results of the VBUS_VALID comparator and session valid comparators, in USB1_VBUS_DETECT[ID_OVERRIDE_EN].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0, the VBUS_VALID comparator for the VBUS_VALID results is used. If this field is 1, the session end comparator for the VBUS_VALID results is used. The session end threshold is > 0.8 V and < 4.0 V. The VBUS_VALID comparator is the most accurate and has a programmable threshold that VBUSVALID_THRESH defines. The session valid comparator may be useful in systems using nonstandard VBUS voltages. The mux selection in this field happens before any VBUS_VALID selection controlled by VBUSVALID_SEL and VBUS_SOURCE_SEL. 0b - VBUS_VALID comparator for the VBUS_VALID results 1b - Session end comparator for the VBUS_VALID results
17-13 —	Reserved
12 ID_OVERRIDE	ID Pin Status Local Override Value Specifies the ID pin status local override value. If ID_OVERRIDE_EN is 1, the value of this field is used for the IDDIG signal and also reported in STATUS[OTGID_STATUS]. This field has no impact if ID_OVERRIDE_EN becomes 0. See the description of STATUS[OTGID_STATUS] to understand the state assignment convention of the ID pin value.
11 ID_OVERRIDE_EN	Enable Local ID Pin Status Override Allows local override of the ID pin detection status. If this field is 0, USBPHY's ID pin detector for ID status is used. If this field is 1, the value of ID_OVERRIDE is used for the reported ID pin status. 0b - Do not allow override 1b - Allow override
10-9 VBUS_SOURCE_SEL	VBUS_VALID Source Selection Selects the source of the VBUS_VALID signal reported to the USB controller. If this field is 0b, by default, the VBUS_VALID comparator results for the signal reported to the USB controller are used. If this field is 1b or 10b, the session valid comparator results for the signal reported to the USB controller are used. The VBUS_VALID source selections in this field take effect only if both VBUSVALID_SEL and VBUS_OVERRIDE_EN are 0. This field does not impact the value of USB1_VBUS_DET_STAT[VBUS_VALID]. 00b - VBUS_VALID comparator results 01b - Session valid comparator results

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Session valid comparator result 11b - Reserved; do not use
8 VBUSVALID_SEL	VBUS_VALID Source Selection Selects the source of the VBUS_VALID signal reported to the USB controller. If this field is 0, by default, the VBUS_VALID comparator results for the signal reported to the USB controller are used. If this field is 1, the VBUS_VALID_3V detector results for the signal reported to the USB controller are used. The VBUS_VALID source selection in this field only takes effect if VBUS_VALID is 0 . This field does not impact the value of USB1_VBUS_DET_STAT[VBUS_VALID]. 0b - VBUS_VALID comparator results 1b - VBUS_VALID_3V detector results
7 VBUSVALID_OVERRIDE	Override Value for the VBUS_VALID Signal Provides the value of USB1_VBUS_DET_STAT[VBUS_VALID] reported to the USB controller if the value of VBUS_OVERRIDE_EN is 1. This field does not impact the value of USB1_VBUS_DET_STAT[VBUS_VALID]. 0b - Overridden to 0 1b - Overridden to 1
6 AVALID_OVERRIDE	Override Value for A-Device Session Valid Provides the value for USB1_VBUS_DET_STAT[AVALID] if the value of VBUS_OVERRIDE_EN is 1. 0b - Overridden to 0 1b - Overridden to 1
5 BVALID_OVERRIDE	Override Value for B-Device Session Valid Provides the value for USB1_VBUS_DET_STAT[BVALID] if the value of VBUS_OVERRIDE_EN is 1. 0b - Overridden to 0 1b - Overridden to 1
4 SESSEND_OVERRIDE	Override Value for SESSEND Provides the value for USB1_VBUS_DET_STAT[SESSEND] if the value of VBUS_OVERRIDE_EN is 1. 0b - Overridden to 0 1b - Overridden to 1
3 VBUS_OVERRIDE_EN	VBUS Detect Signal Override Enable Allows you to override the results from VBUS_VALID and session valid comparators using the values in USB1_VBUS_DETECT[7:4].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0, by default, the results of the internal VBUS_VALID and session valid comparators for VBUS_VALID, AVALID, BVALID, and SESSEND are used. If this field is 1, the override values for VBUS_VALID, AVALID, BVALID, and SESSEND are used. The VBUS_VALID, AVALID, BVALID, and SESSEND signals sent to the USB controller are affected by these bit selections. The values reported for USB1_VBUS_DET_STAT[AVALID], USB1_VBUS_DET_STAT[BVALID], and USB1_VBUS_DET_STAT[SESSEND] are also affected but the value of USB1_VBUS_DET_STAT[VBUS_VALID] is not affected. This override method may be useful if you do not perform VBUS detection using the internal VBUS_VALID or session end comparators. 0b - Results of VBUS_VALID and session valid comparators for VBUS_VALID, AVALID, BVALID, and SESSEND 1b - Override values for VBUS_VALID, AVALID, BVALID, and SESSEND
2-0 VBUSVALID_THRESH	VBUSVALID Threshold Sets the threshold for the VBUSVALID comparator, which is the most accurate method to determine the presence of 5 V, and includes hysteresis to minimize the need for software debounce of the detection. This comparator has ~50 mV of hysteresis to prevent chattering at the comparator trip point. 000b - 4.0 V 001b - 4.1 V 010b - 4.2 V 011b - 4.3 V 100b - 4.4 V 101b - 4.5 V 110b - 4.6 V 111b - 4.7 V

58.7.13 USBPHY VBUS Detector Status (USB1_VBUS_DET_STAT)

Offset

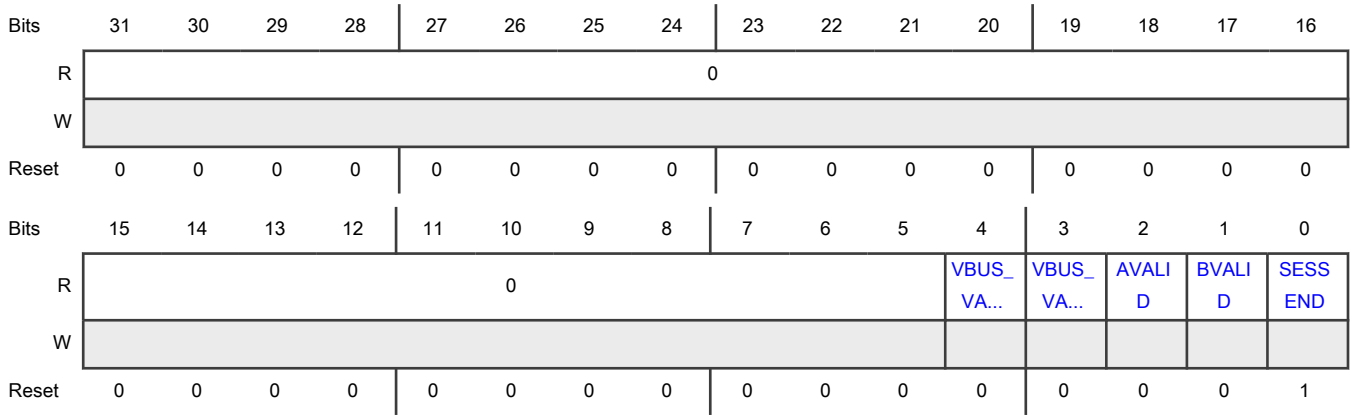
Register	Offset
USB1_VBUS_DET_STAT	D0h

Function

Allows status observation for USB VBUS detect functions.

The APB clock synchronizes the values reported in this register.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 VBUS_VALID_3V	VBUS_VALID_3V Detector Status Indicates the status of the VBUS_VALID_3V detector. If this field is 0, the VBUS voltage is below the VBUS_VALID_3V threshold. If this field is 1, the VBUS voltage is above the VBUS_VALID_3V threshold. The VBUS_VALID_3V detector has a lower threshold for the voltage on the USB1_VBUS pin than either the session valid or VBUS_VALID comparators. This signal may be useful for applications using a nonstandard VBUS voltage. 0b - Below threshold 1b - Above threshold
3 VBUS_VALID	VBUS Voltage Status Indicates the result of VBUS_VALID detection for the USB1_VBUS pin. If this field is 0, the VBUS voltage is below the comparator threshold. If this field is 1, the VBUS voltage is above the comparator threshold. USB1_VBUS_DETECT[VBUSVALID_TO_SESSVALID] selects the VBUS_VALID comparator used. You cannot overwrite the VBUS_VALID source, which is not affected by the values of USB1_VBUS_DETECT[VBUSVALID_OVERRIDE] and USB1_VBUS_DETECT[VBUS_OVERRIDE_EN]. 0b - Below threshold 1b - Above threshold
2 AVALID	A-Device Session Valid Status Indicates A-device session valid status that the session valid comparator determines. If this field is 0, the VBUS voltage is below the session valid threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, the VBUS voltage is above the session valid threshold. The voltage on the USB1_VBUS pin determines the default value of this field. You can overwrite this field by using USB1_VBUS_DETECT[AVALID_OVERRIDE] and USB1_VBUS_DETECT[VBUS_OVERRIDE_EN]. 0b - Below threshold 1b - Above threshold
1 BVALID	B-Device Session Valid Status Indicates B-device session valid status that the session valid comparator determines. If this field is 0, the VBUS voltage is below the session valid threshold. If this field is 1, the VBUS voltage is above the session valid threshold. The voltage on the USB1_VBUS pin determines the default value of this field. You can overwrite this field by using USB1_VBUS_DETECT[BVALID_OVERRIDE] and USB1_VBUS_DETECT[VBUS_OVERRIDE_EN]. 0b - Below threshold 1b - Above threshold
0 SESSEND	Session End Indicator Indicates session end status, the value inverted from the session valid comparator. If this field is 0, the VBUS voltage is above the session valid threshold. If this field is 1, the VBUS voltage is below the session valid threshold. The voltage on the USB1_VBUS pin determines the default value of this field. You can overwrite this field by using USB1_VBUS_DETECT[SESSEND_OVERRIDE] and USB1_VBUS_DETECT[VBUS_OVERRIDE_EN]. 0b - Above threshold 1b - Below threshold

58.7.14 USBPHY Charger Detect Control (USB1_CHRG_DETECT)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
USB1_CHRG_DETECT	E0h	USBPHY Charger Detect Control
USB1_CHRG_DETECT_SET	E4h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_CHRG_DETECT is 1

Table continues on the next page...

Table continued from the previous page...

Register	Offset	Description
USB1_CHRG_DETECT_CLR	E8h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_CHRG_DETECT is 0
USB1_CHRG_DETECT_TOG	ECh	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_CHRG_DETECT

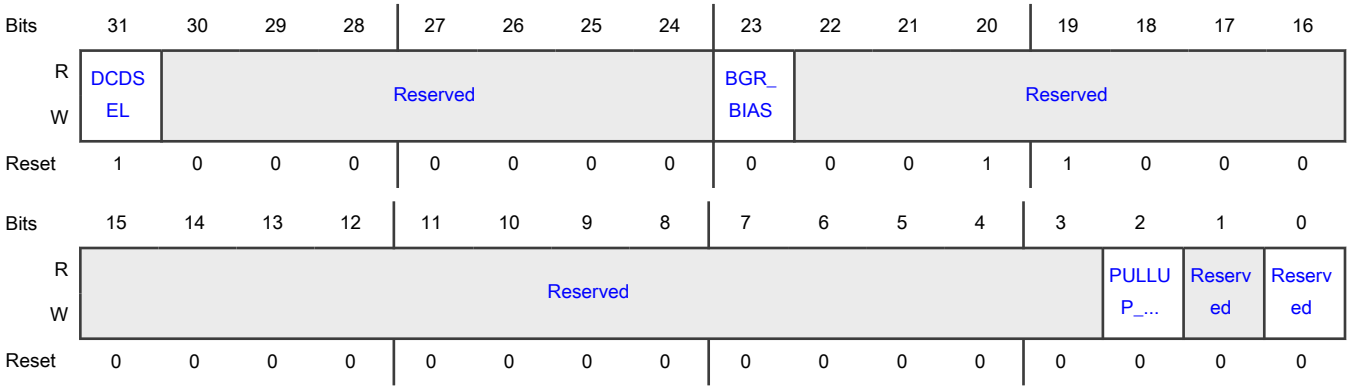
Function

Defines controls for USB battery charging detection functions.

USBDCD controls the USB battery charging detection functions (see the "USB Device Charger Detection Module (USBDCD)" chapter for more information).

You must not change the values of this field except for characterization tasks.

Diagram



Fields

Field	Function
31 DCDSEL	DCD Selection Selects the control source for battery charging detection. If this field is 0, USBPHY Charger Detect Control (USB1_CHRG_DETECT) controls the BC 1.2 functionality. If this field is 1, fields and state machines in USBHSDCD control the BC 1.2 functionality (see the "USB Device Charger Detection Module (USBDCD)" chapter for more information). You can control several of the USBPHY analog circuits associated with the USB battery charging v1.2 functions by either using control fields in USBPHY Charger Detect Control (USB1_CHRG_DETECT) or by using the USBHSDCD module's registers. Use of USBHSDCD is recommended for software simplification, for device mode charger detection because USBHSDCD can auto-sequence through the detection states. 0b - Fields in the USB1_CHRG_DETECT register 1b - Fields and state machines in the USBHSDCD module

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-24 —	Reserved
23 BGR_BIAS	BGR Bias Selects the bias method deployed for the voltage and current sources used for the analog circuits associated with USB battery charging detection in the USBHSDCD instantiation of USBDCD (see the "USB Device Charger Detection Module (USBDCD)" chapter for more information). If this field is 0, by default, the local bias powered from VBUS for 10 µA reference is used. If this field is 1, the bandgap bias powered from VREGIN0 or VREGIN1 for 10 µA reference is used. The V_{DP_SRC} and V_{DN_SRC} bias is generated from the USB1_VBUS voltage, independent of the value of this field. 0b - Local bias 1b - Bandgap bias
22-3 —	Reserved
2 PULLUP_DP	DP Pullup Resistor Enable Override Control Enables FS Device mode operation that is normally controlled using the UTMI bus signals that the USB controller sends to USBPHY. If this field is 1, the pullup resistor is enabled independently of the UTMI signals to the PHY. The USB software stack uses this capability during charger type detection, according to the obsolete *USB Battery Charging Specification Revision 1.1*. For USB battery charging detection and normal USB data communication (associated with the USB battery charging v1.2), retain 0 as the value of this field. 0b - Disables 1b - Enables
1 —	Reserved
0 —	This value of this bit must remain 0b to avoid interference with USB battery charging detection.

58.7.15 USBPHY Charger Detect Status (USB1_CHRG_DET_STAT)

Offset

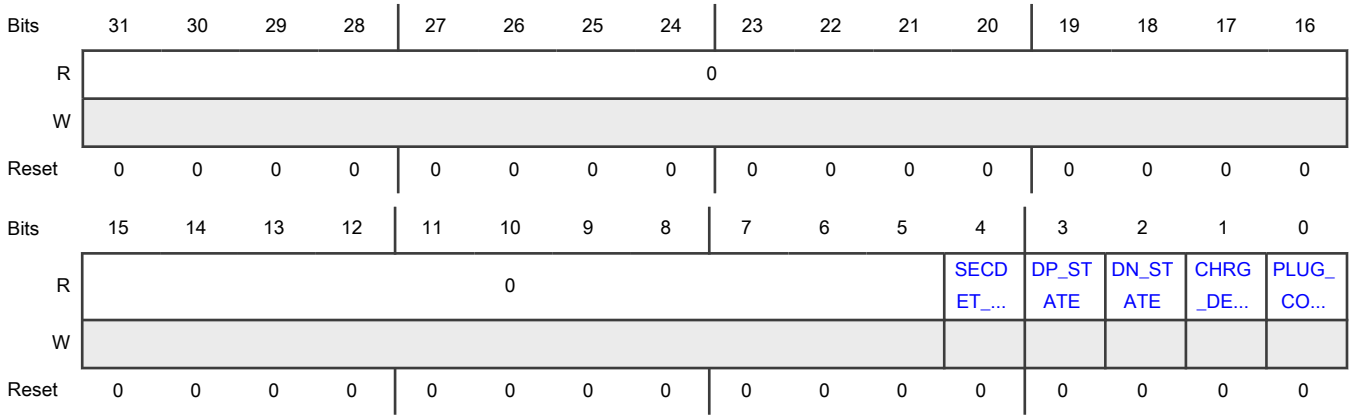
Register	Offset
USB1_CHRG_DET_STAT	F0h

Function

Indicates the USBPHY charger detect status.

Use the USBHSDCD registers for USB battery charging detection functions and standards-based charger detection purposes.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 SECDET_DCP	Battery Charging Secondary Detection Phase Output Indicates the type of charging port detected—charging downstream port (CDP) or downstream charging port (DCP)—during the USB battery charging secondary detection phase, using the USBHSDCD module. 0b - CDP detected 1b - DCP detected
3 DP_STATE	DP State Indicates the single-ended receiver output for the DP pin, from charger detection circuits. 0b - < 0.8 V 1b - > 2.0 V
2 DN_STATE	DN State Indicates the single-ended receiver output for the DN pin, from charger detection circuits. 0b - < 0.8 V 1b - > 2.0 V
1 CHRG_DETECTED	Battery Charging Primary Detection Phase Output Indicates whether a standard downstream port (SDP) or charging port is detected during the USB battery charging primary detection phase.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - SDP detected 1b - Charging port detected
0 PLUG_CONTACT	Battery Charging Data Contact Detection Phase Output Indicates whether an attached USB cable is detected between the remote host and the local device during the data contact detection phase, according to *USB Battery Charging Specification Revision 1.2* (using the USBHSDCD module). 0b - Not detected 1b - Detected

58.7.16 USBPHY Analog Control (ANACTRL)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
ANACTRL	100h	USBPHY Analog Control
ANACTRL_SET	104h	Writing 1 to a bit in this register ensures that the corresponding bit in ANACTRL is 1
ANACTRL_CLR	108h	Writing 1 to a bit in this register ensures that the corresponding bit in ANACTRL is 0
ANACTRL_TOG	10Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in ANACTRL

Function

Includes fields for adding pre-emphasis to the USB HS TX output drivers.

Diagram

Field	Function
—	
10 DEV_PULLDOWN	Device Pulldown Enables the 15 kΩ pulldown resistors on both DP and DN pins in Device mode. You can use this feature in Device mode, while the USB cable is disconnected, to retain the data pins at known values, avoiding unnecessary interrupts from single-ended receivers. This field must be reset to 0 during normal USB data communication in Device mode, or during battery charger detection, using the USBHSDCD module. 0b - Disables 1b - Enables
9-1 —	Reserved
0 —	The value of this reserved bit must remain 0b for normal operation.

58.7.17 USBPHY Loopback Control and Status (USB1_LOOPBACK)

Offset

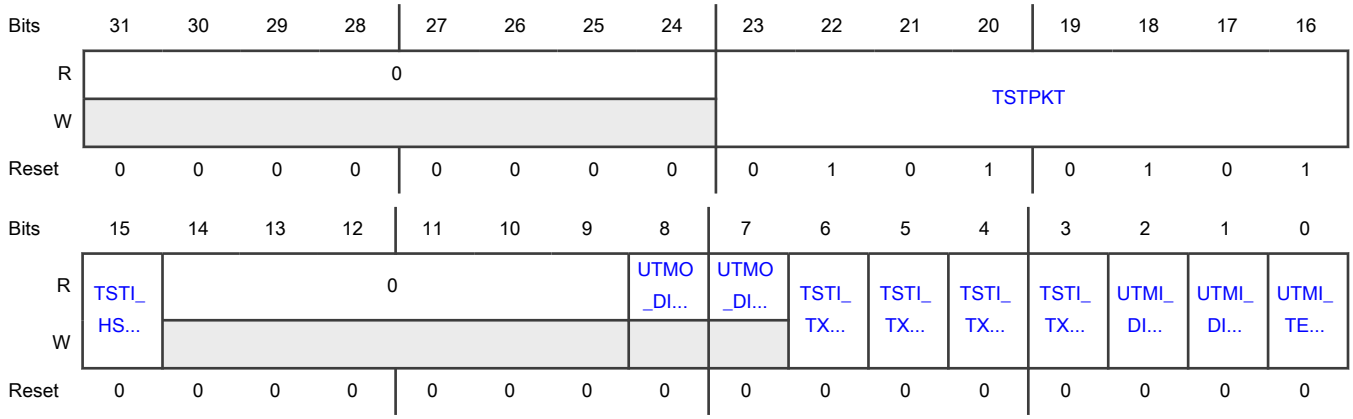
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
USB1_LOOPBACK	110h	USBPHY Loopback Control and Status
USB1_LOOPBACK_SET	114h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_LOOPBACK is 1
USB1_LOOPBACK_CLR	118h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_LOOPBACK is 0
USB1_LOOPBACK_TOG	11Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_LOOPBACK

Function

Controls loopback testing for USBPHY. Loopback mode is for test purposes only; you cannot use it for normal USB data communication.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 TSTPKT	Testing Packet Selects the packet data byte used for USB loopback testing in Pulse mode. Pulse mode is selected if you write 01b to UTMI_DIG_TST0 and UTMI_DIG_TST1. The default value produces a data inversion at each unit interval.
15 TSTI_HSFS_MODE_EN	Loopback Test HS-FS Mode Enable Enables the loopback test to dynamically change the packet speed. It sends a number of HS packets determined by USB1_LOOPBACK_HSFSCNT[TSTI_HS_NUMBER], followed by a number of FS packets determined by USB1_LOOPBACK_HSFSCNT[TSTI_FS_NUMBER]. 0b - Disables 1b - Enables
14-9 —	Reserved
8 UTMO_DIG_TST1	UTMO Digital Test 1 Indicates USB loopback test results. Test results are only valid when UTMI_TESTSTART is 1. 0b - Not passing 1b - Passing
7 UTMO_DIG_TST0	UTMO Digital Test 0 Indicates USB loopback test results. Test results are only valid when UTMI_TESTSTART is 1.

58.7.18 USBPHY Loopback Packet Number Selection (USB1_LOOPBACK_HSFSCNT)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

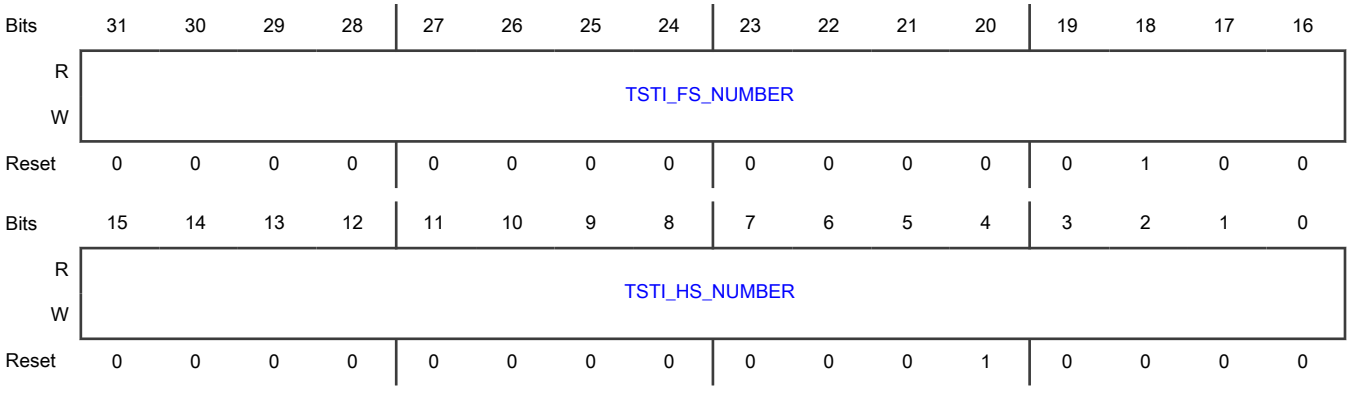
Register	Offset	Description
USB1_LOOPBACK_HSFSCNT	120h	USBPHY Loopback Packet Number Selection
USB1_LOOPBACK_HSFSCNT_SET	124h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_LOOPBACK_HSFSCNT is 1
USB1_LOOPBACK_HSFSCNT_CLR	128h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_LOOPBACK_HSFSCNT is 0
USB1_LOOPBACK_HSFSCNT_TOG	12Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_LOOPBACK_HSFSCNT

Function

Selects the packet counts used for the specific loopback test mode that dynamically alternates the transmit speed.

See USBPHY Loopback Control and Status (USB1_LOOPBACK) for other configuration of this mode.

Diagram



Fields

Field	Function
31-16 TSTI_FS_NUMBER	Loopback Test FS Packet Number Specifies the FS packet number, used when USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is 1.
15-0 TSTI_HS_NUMBER	Loopback Test HS Packet Number Specifies the HS packet number, used when USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is 1.

58.7.19 USBPHY Trim Override Enable (TRIM_OVERRIDE_EN)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
TRIM_OVERRIDE_EN	130h	USBPHY Trim Override Enable
TRIM_OVERRIDE_EN_SET	134h	Writing 1 to a bit in this register ensures that the corresponding bit in TRIM_OVERRIDE_EN is 1
TRIM_OVERRIDE_EN_CLR	138h	Writing 1 to a bit in this register ensures that the corresponding bit in TRIM_OVERRIDE_EN is 0
TRIM_OVERRIDE_EN_TOG	13Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in TRIM_OVERRIDE_EN

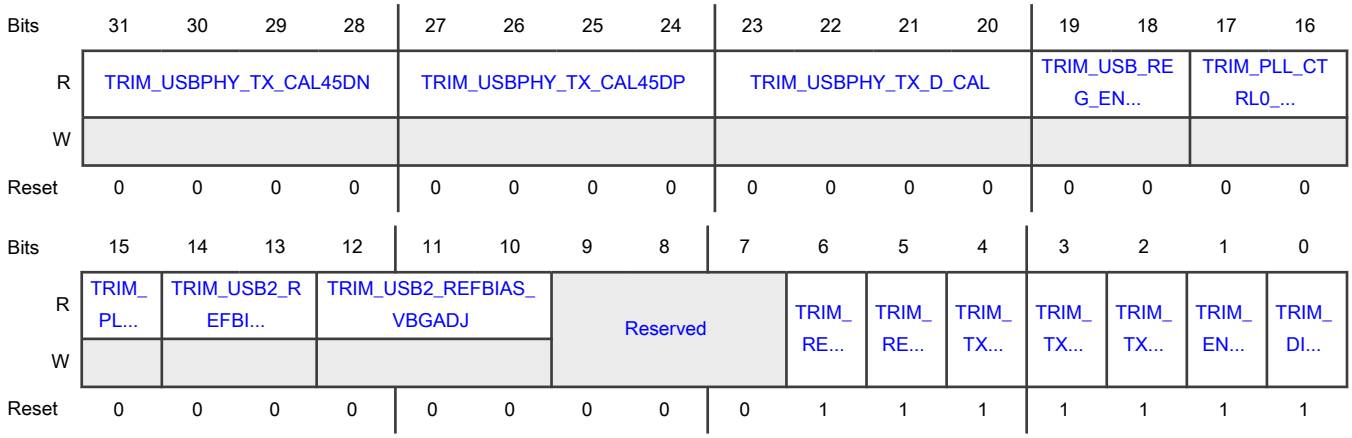
Function

Allows observation of the default IFR settings of the PHY parameters for the following fields:

- TRIM_USBPHY_TX_CAL45DN
- TRIM_USBPHY_TX_CAL45DP
- TRIM_USBPHY_TX_D_CAL
- TRIM_USB_REG_ENV_TAIL_ADJ_VD
- TRIM_PLL_CTRL0_DIV_SEL

Additional fields also determine whether you can overwrite those values by using the settings defined in USBPHY Transmitter Control (TX), UTMI Debug Status 1 (DEBUG1), and USBPHY PLL Control and Status (PLL_SIC).

Diagram



Fields

Field	Function
31-28 TRIM_USBPHY_TX_CAL45DN	DN Series Termination Resistance Trim Bits from Outside USBPHY Trims the termination resistance if TRIM_TX_CAL45DN_OVERRIDE is 0. If TRIM_TX_CAL45DN_OVERRIDE is 1, the resistance trim values in TXCAL45DN are used instead. Decode to trim the nominal 45 Ω series termination resistance to the DN output pin, with values loaded using signals outside USBPHY. The methods used to load the read-only values into this field during reset and boot are chip-specific. The maximum resistance is at value 0000b and minimum resistance is at value 1111b (resistance is centered at value 0111b). For USBPHY, each incrementally increasing trim value decreases the target resistance by approximately 3.5%, compared to the next lower value. Trimming this resistance impacts both the overshoot and undershoot of the FS TX output and the amplitude of the HS TX output. The methods used to load the read-only values into this field during reset and boot are chip-specific.
27-24 TRIM_USBPHY_TX_CAL45DP	DP Series Termination Resistance Trim Bits from Outside USBPHY Trims the termination resistance when TRIM_TX_CAL45DP_OVERRIDE is 0. If TRIM_TX_CAL45DP_OVERRIDE is 1, the resistance trim values in TX[TXCAL45DP] are used instead. Decode to trim the nominal 45 Ω series termination resistance to the DP output pin, with values loaded using signals outside USBPHY. The methods used to load the read-only values into this field during reset and boot are chip-specific. The maximum resistance is 0000b and minimum resistance is 1111b (the resistance is centered at value 0111b). For USBPHY, each incrementally increasing trim value decreases the target resistance by approximately 3.5%, compared to the next lower value. Trimming this resistance impacts both the overshoot and undershoot of the FS TX output and amplitude of the HS TX output. The methods used to load the read-only values into this field during reset and boot are chip-specific.
23-20	HS TX Output Current Trim Bits from Outside USBPHY

Table continues on the next page...

Table continued from the previous page...

Field	Function
TRIM_USBPHY_TX_D_CAL	Trims the output current if TRIM_TX_D_CAL_OVERRIDE is 0. In this case, the current trim values in TX[D_CAL] are used instead. Decode to trim the nominal 17.78 mA current source for the HS TX drivers on DP and DN, with values loaded using signals from outside the PHY. This current is directly proportional to the amplitude of the HS TX eye diagram. The methods used to load the read-only values into this field during reset and boot are chip-specific. 0000b - Maximum current; approximately 19% above nominal 0111b - Nominal 1111b - Minimum current; approximately 19% below nominal
19-18 TRIM_USB_REG_ENV_TAIL_ADJ_VD	HS RX Squelch Rise Time Delay Trim Bits from Outside USBPHY Allows you to adjust the squelch rise time if TRIM_ENV_TAIL_ADJ_VD_OVERRIDE is 0. In this case, the squelch rise time trim values in DEBUG1[ENTAILADJVD] are used instead. This field defines the delay adjustment for the rise time of the squelch signal from the HS RX envelope detector, with values loaded using signals from outside the PHY. The methods used to load the read-only values into this field during reset and boot are chip-specific. See DEBUG1[ENTAILADJVD] to understand the available trims.
17-15 TRIM_PLL_CTRL0_DIV_SEL	PLL Divider Value Configuration Bits from Outside USBPHY Controls the PLL feedback loop divider if TRIM_DIV_SEL_OVERRIDE is 0. USBPHY's PLL produces a 480 MHz output clock. This field allows the use of different frequency signals for the PLL reference clock input connected to the OSCCLK signal from the system oscillator, with values loaded from outside USBPHY. If TRIM_DIV_SEL_OVERRIDE is 0, the PLL divider values in PLL_SIC[PLL_DIV_SEL] are used instead. See the field value descriptions for PLL_SIC[PLL_DIV_SEL] to understand the available input frequency settings. The methods used to load the read-only values into this field during reset and boot are chip-specific.
14-13 TRIM_USB2_REFBIAS_TST	Bias Current Control Adjustment Bits from Outside USBPHY Trims the PHY's current reference when TRIM_REFBIAS_TST_OVERRIDE is 0. If TRIM_REFBIAS_TST_OVERRIDE is 1, the current trim values in DEBUG1[USB2_REFBIAS_TST] are used instead. This field defines the main current trim for the USBPHY bias module current reference generator, with values loaded using signals from outside the PHY.
12-10 TRIM_USB2_REFBIAS_VBGADJ	Bandgap Voltage Adjustment Bits from Outside USBPHY Trims the PHY's bandgap voltage if TRIM_REFBIAS_VBGADJ_OVERRIDE is 0. In this case, the voltage trim values in DEBUG1[USB2_REFBIAS_VBGADJ] are used instead. This field defines voltage adjustment trim on the USBPHY bias module bandgap generator, with values loaded using signals from outside the PHY.

59.2 Overview

FlexCAN is a communication controller implementing the CAN protocol according to the ISO 11898-1:2015 standard and CAN 2.0 Part B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the electromagnetic interference (EMI) environment of a vehicle. FlexCAN is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN version 2.0 Part B protocol. It supports both standard and extended message frames and long payloads.

NOTE

Legacy Receive (RX) FIFO cannot be used in Flexible Data (FD) mode.

NOTE

In CAN FD mode, use the Enhanced Receive FIFO feature instead of the Legacy Receive FIFO.

NOTE

FD mode is limited to Message Buffer (MB) mode only, the Enhanced Receive FIFO with DMA is supported.

59.2.1 Block diagram

Figure 437 shows the main submodules implemented in FlexCAN.

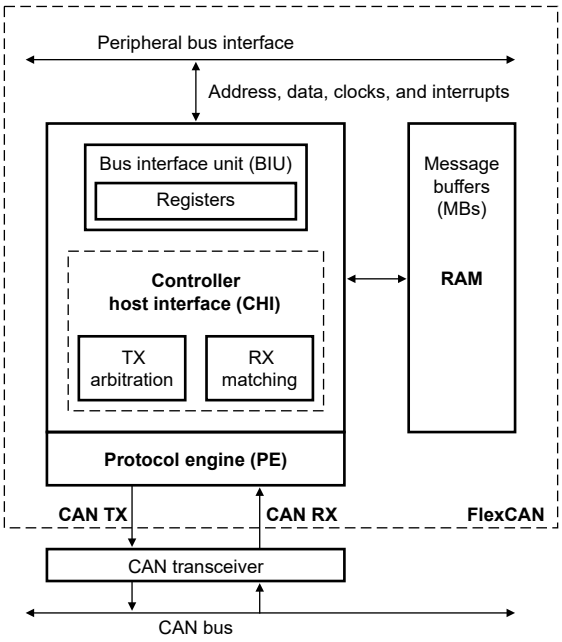

Figure 437. Block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- RAM access for receiving and transmitting message frames
- Receive message validation
- Error handling.
- CAN FD message detection

The Controller Host Interface (CHI) submodule manages:

- Message buffer (MB) selection for reception and transmission
- Arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus to establish connection to the CPU and to other blocks. The BIU manages access to:

- Clocks
- Address and data buses
- Interrupt outputs
- DMA
- Test signals

59.2.2 Features

- Full implementation of *CAN with Flexible data rate (CAN FD) protocol specification* and *CAN Specification Version 2.0, Part B*
  - Standard data frames
  - Extended data frames
  - Data length of 0–64 bytes
  - Content-related addressing

- Compliance with ISO 11898-1:2015 standard
- Flexible message buffers that can be configured to store a payload of 0, 8, 16, 32, or 64 bytes
  - Increasing the payload size decreases the number of supported message buffers (see FlexCAN memory partition for CAN FD).
  - Message buffers are configurable as receive or transmit, supporting standard and extended messages.
- Individual Receive Mask registers for each message buffer
- Full-featured Legacy RX FIFO with storage capacity for six frames and automatic internal pointer handling with DMA support
- Full-featured Enhanced RX FIFO with storage capacity of 20 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Programmable clock source to CAN Protocol Interface, either peripheral clock or oscillator clock
- Optional general purpose RAM space, using RAM not used by reception or transmission structures
- Listen-Only mode
- Programmable loopback mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Timestamp based on 32-bit free-running timer, with optional external time tick
- Global network time, synchronized by specific message
- Maskable interrupts
- Independence from transmission medium (external transceiver is assumed)
- Short latency time due to arbitration scheme for high-priority messages
- Low-power modes, with programmable wake-up on bus activity
- Transceiver delay compensation when transmitting CAN FD messages at faster data rates
- Management of remote request frames, automatically or by software
- Restriction only to write CAN bit time settings and configuration bits in Freeze mode
- Transmit message buffer status (lowest-priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- ESR1[SYNCH] to indicate module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy RX FIFO Global Mask register
- Selectable priority between message buffers and receive FIFO during matching process
- Powerful Legacy RX FIFO ID filtering, capable of matching incoming IDs against either 128 extended IDs, 256 standard IDs, or 512 partial (8-bit) IDs, with 32 individual masking capability
- Powerful Enhanced RX FIFO ID filtering, capable of matching incoming IDs against either 64 extended or 128 standard ID filter elements with three filtering schemes: mask plus filter, range, and two filters without mask.
- Complete backward compatibility with previous FlexCAN version
- Detection and correction of errors in memory read accesses.
  - Each byte of FlexCAN memory is associated to five parity bits.
  - The error correction mechanism ensures that errors in one bit of this 13-bit word can be corrected (correctable errors).

— Errors in two bits can be detected but not corrected (noncorrectable errors).

59.3 Functional description

FlexCAN is a CAN protocol engine with a flexible message buffer system for transmitting and receiving CAN frames. The system is a set of message buffers (MBs) that stores configuration and control data, timestamp, message ID, and data (see Message buffer structure).

For classical CAN frames, FlexCAN supports simultaneous reception through Legacy FIFO and message buffer. For CAN FD frames, FlexCAN supports reception through message buffer and enhanced receive FIFO.

For message buffer reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by three local priority bits) or the message buffer ordering.

A message buffer is active at a given time if it can participate in both the matching and arbitration processes. A receive message buffer with a 0b code is inactive (see Table 965). A transmit message buffer with a 1000b or 1001b code is also inactive (see Table 966).

FlexCAN can receive and transmit messages in CAN FD format. The message buffers are sized to store the quantity of data bytes selected by FDCTRL[MBDSRn]. The quantity of FD message buffers available for a given quantity of data bytes is described in the CAN FD Control (FDCTRL) register. See also FlexCAN memory partition for CAN FD.

59.3.1 Modes of operation

FlexCAN has these functional modes:

Table 928. Functional modes

Mode	Description
Normal (User or Supervisor)	In Normal mode, FlexCAN receives and transmits message frames, manages errors normally, and enables all CAN Protocol functions. User and Supervisor modes differ in the access to some restricted control registers.
Freeze	Freeze mode is enabled when MCR[FRZ] = 1. If enabled, FlexCAN enters Freeze mode when MCR[HALT] is 1 or when Debug mode is requested at chip level and FlexCAN writes 1 to MCR[FRZACK]. In this mode, no transmission or reception of frames is done, and synchronicity to the CAN bus is lost. See Freeze mode.
Loopback	FlexCAN enters this mode when CTRL1[LPB] becomes 1. In this mode, FlexCAN performs an internal loopback that can be used for self-test. The bit stream output of the transmitter is internally fed back to the receiver input. The receiving CAN input pin is ignored and the transmitting CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. To ensure proper reception of its own message, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. Both transmit and receive interrupts are generated.
Listen-Only	FlexCAN enters this mode when CTRL1[LOM] becomes 1. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.
CAN FD Active	In this mode, FlexCAN can transmit and receive all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can put FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

Some features available in classical CAN are unavailable in CAN FD mode.

Table 929. Differences between classical CAN and CAN FD

Feature	Classical CAN	CAN FD
Legacy RX FIFO DMA	Yes	No
Legacy RX FIFO	Yes	No
Enhanced RX FIFO DMA	Yes	Yes
Enhanced RX FIFO	Yes	Yes

FlexCAN can operate in these low-power modes:

Table 930. Low-power modes

Mode	Description
Module Disable	FlexCAN enters this mode when the CPU writes 1 to MCR[MDIS] and FlexCAN writes 1 to MCR[LPMACK]. After FlexCAN is disabled, it issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Writing 0 to MCR[MDIS] exits this mode. See Module Disable mode.
Doze	FlexCAN enters this mode when MCR[DOZE] is 1, Doze mode is requested at chip level, and FlexCAN writes 1 to MCR[LPMACK]. When in Doze mode, FlexCAN issues a request to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. This mode is exited when: • MCR[DOZE] becomes 0 • The chip is removed from Doze mode • Or activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Doze mode.
Stop	FlexCAN enters this mode when Stop mode is requested at chip level and FlexCAN writes 1 to MCR[LPMACK]. When in Stop mode, FlexCAN puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode occurs when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Stop mode.

59.3.1.1 Modes of operation details

FlexCAN has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following subsections contain functional details about Freeze mode and low-power modes.

CAUTION

FlexCAN does not support "Permanent Dominant" failure on the CAN bus line. If a Low-Power request or Freeze mode request occurs during a "Permanent Dominant" condition, the corresponding acknowledgment field can never be 1.

59.3.1.1.1 Freeze mode

This mode is requested either by the CPU writing 1 to MCR[HALT] or when the chip is put into Debug mode. MCR[FRZ] must be 1 and the module must not be in a low-power mode.

When MECR[NCEFAFRZ] becomes 1 and a noncorrectable error is detected in a memory read access performed by FlexCAN internal processes (see Error response), FlexCAN also requests Freeze mode. This request occurs via both MCR[HALT] and MCR[FRZ] automatically becoming 1.

To obtain acknowledgment, FlexCAN writes 1 to MCR[FRZACK]. The CPU must only consider FlexCAN to be in Freeze mode when both request and acknowledgment conditions are satisfied.

When Freeze mode is requested, FlexCAN:

1. Waits to be in either Intermission, Error Passive, Bus Off, or Idle state.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
3. Ignores the receive input pin and drives the transmit pin as recessive.
4. Stops the prescaler, halting all CAN protocol activities.
5. Grants write access to the Error Counters register, which is read-only in other modes.
6. Writes 1 to MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, you must wait for MCR[FRZACK] to become 1 before executing any other action, otherwise FlexCAN may operate unpredictably. In Freeze mode, all memory-mapped registers are accessible, except for CTRL1[CLKSRC], which can be read but cannot be written.

Freeze mode is exited in one of these conditions:

- CPU writes 0 to MCR[FRZ].
- The chip is removed from Debug mode or the MCR[HALT] becomes 0.

MCR[FRZACK] becomes 0 after the protocol engine recognizes the negation of the freeze request. After leaving Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

59.3.1.1.2 Module Disable mode

This low-power mode is normally used to disable a complete FlexCAN block temporarily, with no power consumption. The CPU requests this mode by writing 1 to MCR[MDIS], and FlexCAN acknowledges the request by writing 1 to MCR[LPMACK]. The CPU must only consider FlexCAN to be in Disable mode when both the request and acknowledgment conditions are satisfied.

If FlexCAN is disabled during Freeze mode, the module requests to disable the clocks to the PE and CHI submodules, writes 1 to MCR[LPMACK] and writes 0 to MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and then checks that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Shuts down the clocks to the PE and CHI submodules.
5. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].

In this mode, the Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except for:

- The Receive Message Buffers Global Mask registers
- The Receive Buffer 14 Mask register
- The Receive Buffer 15 Mask register

When in Disable mode, these items may not be accessed:

- The message buffers
- The Receive Individual Mask registers
- The reserved words within RAM

To exit this mode, the CPU writes 0 to MCR[MDIS], causing FlexCAN to request to resume the clocks and write 0 to MCR[LPMACK]. This write occurs after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

59.3.1.1.3 Doze mode

This is a system low power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, MCR[DOZE] needs to have been asserted previously for Doze mode to be triggered. The acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN to be in Doze mode when both request and acknowledgement conditions are satisfied.

If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK]. If Doze mode is triggered during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register. The the message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Doze mode.

Exiting Doze mode is done in one of the following ways:

- CPU removing the Doze mode request
- CPU negating MCR [DOZE]
- Self Wake mechanism

In the Self Wake mechanism, if MCR[SLFWAK] was set at the time FlexCAN entered Doze mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN negates the DOZE bit, requests to resume its clocks and negates the LPMACK after the CAN protocol engine recognizes the negation of the Doze mode request. It also sets ESR [WAKINT] and, if enabled by MCR[WAKMSK], generates a Wake-Up interrupt to the CPU. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK upon wakeup from Doze mode.

Table 931. Wakeup from Doze mode

SLFWAK	WAKINT	WAKMSK	FlexCAN clocks enabled	Wakeup interrupt generated
0	-	-	No	No
0	-	-	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	Yes	No
1	1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line when in Doze mode. (See MCR[WAKSRC].) This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

59.3.1.1.4 Stop mode

In this low-power mode for the system, all chip clocks can be stopped for maximum power savings. Stop mode is globally requested by the CPU and FlexCAN writes 1 to a Stop Acknowledgment signal to indicate acknowledgment. The CPU must only consider FlexCAN to be in Stop mode when both request and acknowledgment conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it shuts down the clocks globally by:

1. Writing 1 to MCR[LPMACK].
2. Writing 0 to MCR[FRZACK].
3. Sending the Stop Acknowledge signal to the CPU.

If Stop mode is requested during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and verifies that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].
5. Sends a Stop Acknowledge signal to the CPU, so that the CPU can shut down the clocks globally.

FlexCAN exits Stop mode when the CPU resumes the clocks and removes the Stop mode request. This exit can occur as a result of the Self-Wake mechanism.

In Self-Wake, if MCR[SLFWAK] = 1 when FlexCAN enters Stop mode, then upon detecting a recessive-to-dominant transition on the CAN bus, FlexCAN writes 1 to ESR1[WAKINT]. If enabled by MCR[WAKMSK], FlexCAN generates a wake-up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up. Table 932 details the effect of MCR[SLFWAK] and MCR[WAKMSK] upon wakeup from Stop mode. Waking from Stop mode only works when both fields are 1.

After the CAN protocol engine recognizes the negation of the Stop mode request, FlexCAN writes 0 to MCR[LPMACK]. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up.

Table 932. Waking from Stop mode

SLFWAK	WAKINT	WAKMSK	Chip clocks enabled	Wake-up interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the receive CAN input line when in Stop mode. (See the description in MCR[WAKSRC].) This feature can protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

NOTE

When FlexCAN is in the Bus Off state and Low-Power mode, FlexCAN may take an extra 128 IDLE cycles to leave the Bus Off state after exiting Low-Power mode.

59.3.2 Transmission process

NOTE

Instances of MB_CS in this topic refer to items in message buffers. See Message buffer structure for details.

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt flag is set, and clear it if necessary.
2. If the message buffer is active (transmission pending), request an abort of the transmission. Write the ABORT code (1001b) to the CODE field of the Control and Status word.
3. Poll the IFLAG register until the corresponding IFLAG flag is set, or wait for the interrupt request (if enabled by the respective IMASK field).
4. Read the CODE field to identify whether the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIOEN]).
7. Write payload data bytes.
8. Configure the Control and Status word as needed.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] = 1, configure MB_CS[EDL] and MB_CS[BRS]. For details about the relationship between the written value and transmitted value of MB_CS[ESI], see Table 942.[7]
    d. Configure Data Length Code in bytes via MB_CS[DLC]. See Table 969 for detailed information.
    e. To transmit the CAN frame, activate the message buffer by writing Ch to MB_CS[CODE].

NOTE

To maximize software performance, configure all the fields in the MB_CS word in a single 32-bit write operation. If the fields are configured in separate writes, MB_CS[CODE] must be the last write in the Control and Status word.

When the MB is activated, it participates in the arbitration process and its contents are eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission exceeds the MB payload size, FlexCAN completes the expected DLC by adding a constant CCh pattern.

After a successful transmission:

1. The value of the free-running timer is written into the timestamp field.
2. The CODE field in the Control and Status word is updated.
3. Both Cyclic Redundancy Check (CRCR) and CAN FD CRC (FDCRC) are updated.
4. A status flag is set in the Interrupt Flag register.
5. If allowed by the corresponding Interrupt Mask Register field, an interrupt is generated.

After transmission, the new CODE field depends on the code used to activate the message buffer (see Table 965 and Table 966 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is 1), after the Interrupt flag is set for an MB configured as transmit buffer, the message buffer is blocked. The CPU cannot update the message buffer until the Interrupt Flag is cleared by the CPU. The CPU must clear the corresponding IFLAG flag before preparing this MB for a new transmission or reception.

[7] There is no need to write the ESI field; it is automatically transmitted as dominant by error active nodes and as recessive by error passive nodes. If FlexCAN is operating as a network gateway, however, the CPU writes MB_CS[ESI] according to the error status of the node that sent the message.

NOTE

For backward compatibility (MCR[AEN] is 0), write the INACTIVE code (1000b) to the CODE field to deactivate the MB. In this case, the pending frame may be transmitted without notification (see Message buffer inactivation).

59.3.3 Arbitration process

The arbitration process scans the message buffers, searching for the transmission MB that holds the message to be sent at the next opportunity. This MB is called the arbitration winner. The scan starts from the lowest number MB and continues to the higher ones.

The arbitration process is triggered when at least one of the following occur:

- CRC field of the CAN frame arrives. The starting point depends on the value of CTRL2[TASD].
- Error Delimiter field of a CAN frame is in progress.
- Overload Delimiter field of a CAN frame is in progress.
- The winner of the arbitration is deactivated, and the CAN bus has not reached the first bit of the Intermission field.
- CPU writes to the Control and Status word of a winner MB, and the CAN bus has not reached the first bit of the Intermission field.
- CHI is in the Idle state and the CPU writes to the Control and Status word of any message buffer.
- FlexCAN exits Bus Off state.
- FlexCAN leaves Freeze mode or a low-power mode.

If the arbitration process does not evaluate all message buffers before the CAN bus reaches the first bit of the Intermission field, the temporary arbitration winner is invalidated. FlexCAN will not compete for the CAN bus at the next opportunity.

The arbitration process selects the winner among the active transmission message buffers at the end of the scan according to the values of CTRL1[LBUF] and MCR[LPRIOEN].

See Arbitration process (continued) for more information about this process.

59.3.3.1 Lowest-number message buffer first

If CTRL1[LBUF] is 1, the first (lowest number) active transmission message buffer found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is 1.

59.3.3.2 Highest-priority message buffer first

If CTRL1[LBUF] is 0, the arbitration process searches for the active transmission message buffer with the highest priority. The frame of this message buffer has a higher probability of winning the arbitration on the CAN bus when multiple external nodes compete for the bus simultaneously.

The sequence of bits considered for this arbitration is called the arbitration value of the message buffer. The transmission message buffer with the lowest arbitration value among all transmission message buffers has the highest priority.

If two or more message buffers have equivalent arbitration values, the message buffer with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN].

59.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] = 0, the arbitration value is built using the exact sequence of bits that would be transmitted in a CAN frame where local priority is disabled.

Table 933. Composition of the arbitration value when local priority is disabled

Format	Message buffer arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

59.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be 1. In this case, the message buffer PRIO field (see Message buffer structure) is included at the very left of the arbitration value.

Table 934. Composition of the arbitration value when local priority is enabled

Format	Message buffer arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, message buffers with low PRIO values have higher priority than message buffers with high PRIO values. This priority is maintained regardless of the rest of their arbitration values.

The PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

59.3.3.3 Arbitration process (continued)

After the arbitration winner is found (see Arbitration process), its content is copied to a hidden auxiliary message buffer called a transmit serial message buffer (TX SMB). The TX SMB has the same structure as a normal message buffer, but is not user-accessible. This copy operation is called move-out. After it is done, write access to the Control and Status word of the corresponding MB is blocked (if MCR[AEN] = 1). Write access is restored in one of the following events:

- The CPU clears the corresponding IFLAG flag after the message buffer is transmitted.
- FlexCAN enters Freeze mode or Bus Off state.
- FlexCAN loses the bus arbitration, or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the TX SMB is transmitted according to the CAN protocol rules.

The arbitration process can be triggered under the following conditions:

- During RX and TX frames from CAN CRC field to end of frame. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT = 124 to 128. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During Control and Status write by CPU in Bus Idle. The first Control and Status write starts the arbitration process, and a second Control and Status write during this same arbitration restarts the process. If other Control and Status writes are performed, the transmission arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case, the first and second Control and Status writes in Bus Idle do not restart the arbitration process. If there is not enough time to finish arbitration in the Wait For Bus Idle state and the next state is Idle, the scan is not interrupted. That scan is completed during Bus Idle state. During this arbitration, a Control and Status write does not cause an arbitration restart.

- Deactivation of an arbitration winner during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If a resynchronization occurs during Wait For Bus Idle, the arbitration process is restarted.

The arbitration process stops when:

- All message buffers are scanned.
- A transmission message buffer is found (if lowest buffer feature is enabled).
- An arbitration winner deactivates or aborts during any arbitration process.
- There is not enough time to finish the transmission arbitration process (for instance, when a deactivation is performed near the end of frame). In this case, the arbitration process is pending.
- An error or overload flag occurs in the bus.
- A low-power or Freeze mode request occurs in Idle state.

Arbitration is considered pending when:

- It is not possible to finish arbitration process in time.
- A Control and Status write occurs during arbitration, when that write is performed in an MB whose number is lower than the transmission arbitration pointer.
- Any Control and Status write occurs when there is no transmission arbitration process in progress.
- RX Match has updated an RX code to TX code.
- FlexCAN enters the Bus Off state.

If a Control and Status write is performed in the arbitration winner, a new process is restarted immediately.

If a Control and Status write is performed in an MB whose number is higher than the transmission arbitration pointer, the ongoing arbitration process scans this MB as normal.

59.3.4 Receive process

To be able to receive CAN frames into a message buffer, the CPU must prepare it for reception by executing the following steps:

1. If the message buffer is active (either TX or RX), deactivate it (see Message buffer inactivation), preferably with a safe deactivation (see Transmission abort mechanism).
2. Write the ID word into the message buffer.
3. To activate the message buffer, write the EMPTY code (0100b) to the CODE field of the Control and Status word. No setup is required for EDL, BRS, and ESI fields. The respective fields in the received message overwrite these fields.

After the MB is activated, it can receive frames that match the programmed filter. At the end of a successful reception, the move-in process updates the message buffer (see Move-in) as follows:

1. The received data field (up to eight bytes for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the free-running timer when the second bit of the Identifier field of the frame is written into the Timestamp field of the MB.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 965 and Table 966 in Section Message buffer structure).
6. If allowed by the corresponding Interrupt Mask field, a status flag is set in the Interrupt Flag register and an interrupt is generated.

The recommended way for the CPU to service (read) the frame received in a message buffer is:

1. Read the Control and Status word of that message buffer.
2. Verify that the BUSY bit is 0, indicating that the message buffer is locked. If it is not 0, repeat step 1 until it becomes 0. See Message buffer lock mechanism.
3. Read the contents of the message buffer. After the message buffer is locked, FlexCAN move-in processes do not modify its contents. See Move-in.
4. Acknowledge the proper flag in the IFLAG registers.
5. Unlock the message buffer by reading the free-running timer.

To verify frame reception, the CPU should poll the status flag bit for that specific message buffer in one of the IFLAG registers, not the CODE field of that message buffer. Polling the CODE field does not work in this case. After a frame is received and the CPU services the message buffer (by reading the Control and Status word and unlocking the message buffer), the CODE field does not return to EMPTY. It remains FULL, as explained in Table 965. If the CPU tries to work around this behavior by writing to the Control and Status word to force an EMPTY code after reading the message buffer without a prior safe deactivation, a newly received frame matching the filter of that message buffer may be lost.

CAUTION

In summary: never poll by reading the Control and Status word of the message buffers directly. Instead, read the IFLAG registers.

The Identifier field of the received frame is always stored in the matching message buffer. If the match was due to masking, the contents of the ID field in a message buffer may change. When MCR[SRXDIS] becomes 1, FlexCAN does not store frames transmitted by itself in any MB, even if it contains a matching receive MB. Also, no interrupt flag or interrupt signal is generated. Otherwise, when MCR[SRXDIS] becomes 0, if a matching receive MB exists, FlexCAN can receive frames transmitted by itself.

When MCR[DMA]) becomes 1, upon receiving a frame in the Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy RX FIFO in DMA Operation). The IMASK1 fields in the Legacy RX FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).

59.3.5 Matching process

The matching process scans the message buffer memory for RX MBs programmed with the same ID as the one received from the CAN bus. . The matching starts from the lowest number message buffer and continues toward the higher-numbered ones.

For enhanced RX FIFO, see Enhanced RX FIFO.

For legacy RX FIFO, see Legacy RX FIFO.

As the frame is received, it is stored in a hidden auxiliary MB called Receive Serial Message Buffer (RX SMB).

The starting point of the matching process depends on the following conditions:

- If the received frame is a remote frame, the starting point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the starting point is the CRC field of the frame.
- If the received frame is a data frame and the DLC field has a nonzero value, the starting point is the DATA field of the frame.

If a matching ID is found in one of the message buffers, the move-in process transfers the contents of the RX SMB to the matched MB. If any CAN protocol error is detected, no match results are transferred to the matched MB at the end of reception.

The matching process scans all matching elements of the the active receive MBs (CODE is EMPTY, FULL, OVERRUN, or RANSWER). The process searches for a successful comparison to the matching elements of the RX SMB that is receiving the frame on the CAN bus. The RX SMB has the same structure as a message buffer. The reception structures (message buffers)

associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures. The matching winner depends on conditions described in Table 935.

Table 935. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Message buffer	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY, FULL, or OVERRUN
Message buffer	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	0	—	cmp	no_cmp	cmp	RANSWER
Message buffer	1	1	0	cmp	no_cmp	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN

1. For message buffer structure, if SMB[IDE] is 1, the ID is 29 bits (ID Standard plus ID Extended). If SMB[IDE] is 0, the ID is 11 bits (ID Standard). For Legacy RX FIFO structure, the ID depends on IDAM.
2. cmp: Compares the RX SMB contents to the MB contents regardless of masks.
3. no_cmp: The RX SMB contents are not compared to the MB contents.
4. cmp_msk: Compares the RX SMB contents to MB contents, accounting for masks.

NOTE

For Enhanced RX FIFO, see Enhanced RX FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the message buffer is EMPTY.
- The CODE field of the message buffer is either FULL or OVERRUN, and it has already been serviced (the CPU has read the Control and Status word and unlocked it as described in Message buffer lock mechanism).
- The CODE field of the message buffer is either FULL or OVERRUN and an inactivation (see Message buffer inactivation) is performed.

The scan order for message buffers is from the matching element with the lowest number to the higher ones.

59.3.5.1 Matching priority

MCR[IRMQ] affects the matching winner search for MBs. If the field is 0, the matching winner is the first matched MB whether it is free-to-receive or not. If it is 1, the matching winner is selected according to this priority:

1. The first free-to-receive matched message buffer
2. The last non-free-to-receive matched message buffer

59.3.5.2 Special cases

If a non-safe MB inactivation (see Message buffer inactivation) occurs during the matching process and the inactivated MB is the temporary matching winner, the temporary matching winner is invalidated. The matching elements scan is not stopped and

not restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist. In this case, a message may be lost.

Consider an example where:

- MCR[IRMQ] is 1.
- There are two message buffers with the same ID: the second and fifth MBs in the array.
- FlexCAN starts receiving messages with that ID.

When the first message arrives, the matching algorithm finds the first match in message buffer number 2. The code of this message buffer is EMPTY, so the message is stored in that MB. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive." It continues looking, finds MB number 5, and stores the message in that MB. If yet another message with the same ID arrives, the matching algorithm finds no matching free-to-receive MBs, so it overwrites the last matched message buffer (MB number 5). In doing so, it updates the CODE field of the message buffer to OVERRUN.

The ability to match the same ID in more than one MB can be used to implement a reception queue to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the message buffers. The CPU can examine the Timestamp field of the message buffers to determine the order in which the messages arrived.

Matching a range of IDs is possible via ID acceptance masks. FlexCAN supports individual masking per message buffer (see Receive Individual Mask (RXIMR0 - RXIMR95)). During the matching algorithm, if a mask field is 1, the corresponding ID bit is compared. If the mask field is 0, the corresponding ID bit is a "don't care". Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, the module blocks them.

FlexCAN also supports an alternate masking scheme with only RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), and Receive 15 Mask (RX15MASK) for backward compatibility with legacy applications. This alternate masking scheme is enabled when the MCR[IRMQ] = 0.

59.3.6 Move process

There are two types of move process: move-in and move-out.

59.3.6.1 Move-in

The move-in process is the copying of a message received by an RX SMB to an RX message buffer that has matched it. Each RX SMB has its own move-in process, but only one is performed at a given time. The move-in starts only when the message held by the RX SMB has a corresponding match (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the RX SMB.
  - The first bit of an overload frame next to the frame that carried the message in the RX SMB.
- There is no ongoing matching process.
- The CPU is not locking the destination message buffer.
- No move-in process from another RX SMB is ongoing. If more than one move-in process is to be started at the same time, both are performed and the newest process substitutes for the oldest.

The term "pending move-in" is used throughout the documentation and stands for a move-to-be that does not satisfy all of the above conditions.

If any of the following conditions is satisfied, the move-in is canceled and the RX SMB is able to receive another message:

- The destination message buffer is inactivated after the CAN bus has reached the first bit of the Intermission field next to the frame that carried the message. Also, its matching process has finished.
- There is a previous pending move-in to the same destination message buffer.
- The RX SMB is receiving a frame transmitted by FlexCAN itself and self-reception is disabled (MCR[SRXDIS] = 1).
- Any CAN protocol error is detected.

If the module enters Freeze or Low-Power mode, the pending move-in is not canceled. It remains on hold, waiting for Freeze and Low-Power mode to be exited and for the module to be unlocked. If a message buffer is unlocked during Freeze mode, the move-in occurs immediately.

The move-in process is FlexCAN executing the following steps:

1. Read all data words from the RX SMB in accordance with the selected payload size for the RX storage element.
2. Write all data words to the RX message buffer according to the selected payload size for the RX storage element. If the data size of the storage element is smaller than the original payload size described in the DLC field of the message, the payload is truncated. The high-order bytes that do not fit the destination size are lost.
3. Read the Control and Status and ID words from the RX SMB.
4. Write the Control and Status and ID words to the RX message buffer, and update the CODE field.

The move-in process is not atomic; the inactivation of the destination message buffer immediately cancels it (see Message buffer inactivation). In this case, the message buffer may remain partially updated, and therefore incoherent.

To alert the CPU that the message buffer content is temporarily incoherent, the BUSY Bit (least significant bit of the CODE field) of the destination message buffer becomes 1 during move-in.

59.3.6.2 Move-out

The move-out process is the copying of content from a TX message buffer to the TX SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- In the first bit of Intermission field
- During the Bus Off state, when TX Error Counter is in the 124 to 128 range
- During the Bus Idle state
- During the Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently outside the Bus Idle state. In Bus Idle, the move-out has the lowest priority of the concurrent memory accesses.

59.3.7 Data coherence

In order to maintain data coherency and proper FlexCAN operation, the CPU must obey the rules described in Transmission process and Receive process.

59.3.7.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU whether the transmission was aborted or the frame could not be aborted and was transmitted instead.

These primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be 1.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active message buffers configured for transmission must be aborted before they can be updated. The write operation is blocked and the transmission is not disturbed when the abort code is written to:

- A message buffer currently being transmitted.
- A message buffer that was already loaded into the TX SMB for transmission.

In this case, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.

- The module enters the Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

1. The message buffer is transmitted correctly.
2. The interrupt flag is set in the proper IFLAG register.
3. If enabled, an interrupt to the CPU is generated.

The abort request is automatically cleared when the interrupt flag is set. If only one of the above conditions is reached, the frame is not transmitted. In this case:

1. The abort code is written into the CODE field.
2. The interrupt flag is set in the proper IFLAG register.
3. Optionally, an interrupt is generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, the write operation is not blocked. The MB is updated and the interrupt flag is set. In this way, the CPU only needs to read the abort code to verify that the active MB was safely inactivated. In this case, although MCR[AEN] = 1 and the CPU wrote the abort code, the MB is inactivated and not aborted, because the transmission did not start yet. A message buffer is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

59.3.7.2 Message buffer inactivation

Inactivation protects the message buffer against updates by FlexCAN internal processes. It allows the CPU to rely on message buffer data coherence after having updated it, even in Normal mode.

Inactivation of transmission message buffers must be performed only when MCR[AEN] = 0.

If a message buffer is inactivated, it does not participate in the arbitration process or the matching process until it is reactivated. See Transmission process and Receive process for detailed instructions on how to inactivate and reactivate a message buffer.

To inactivate a message buffer, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you cannot synchronize the CODE field update with FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of an inactivated RX message buffer may be lost without notice. This loss can occur even if there are other message buffers with the same filter.
- A frame containing the message within an inactivated TX message buffer may be transmitted without setting the respective IFLAG flag.

To perform a safe inactivation and avoid the above consequences for TX message buffers, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the message buffer (see Message buffer lock mechanism).

59.3.7.3 Message buffer lock mechanism

In addition to message buffer inactivation, FlexCAN uses a message buffer lock mechanism to maintain data coherence for the receive process. When the CPU reads the Control and Status word of an RX message buffer with codes FULL or OVERRUN, FlexCAN is configured to allow the CPU to read the whole message buffer in an atomic operation. FlexCAN sets an internal lock flag for that message buffer.

The lock is released in any of the following events:

- The CPU reads the free-running timer (global unlock operation).
- The CPU reads the Control and Status word of another message buffer, regardless of its code.

- The CPU writes into the Control and Status word. This procedure is not recommended for normal unlocking, because it cancels a pending move and may lose a received message.

The message buffer lock prevents a new frame from being written into the message buffer when the CPU is reading it.

NOTE

The locking mechanism applies only to RX message buffers that have a code other than INACTIVE (0b) or EMPTY[1] (0100b). TX message buffers cannot be locked.

Consider an example where:

- The second and the fifth message buffers of the array are programmed with the same ID.
- FlexCAN has already received and stored messages into these two message buffers.
- The CPU reads message buffer number 5 while another message with the same ID is arriving.

When the CPU reads the Control and Status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds no free-to-receive message buffers, so it overrides message buffer number 5. This message buffer is locked, so the new message cannot be written to it. The message remains in the RX SMB until the message buffer is unlocked, and only then is it written to the message buffer.

If the message buffer remains locked and another new message with the same ID arrives, the new message overwrites the one in the RX SMB. There is no indication of lost messages in the CODE field of the message buffer or in Error and Status 1 (ESR1).

When the message is moved from the RX SMB to the message buffer, the BUSY bit on the CODE field becomes 1. If the CPU reads the Control and Status word and identifies that the BUSY bit is 1, it must wait until the BUSY bit becomes 0 to access the MB.

NOTE

If the BUSY bit is 1 or the message buffer is empty, reading the Control and Status word does not lock the message buffer.

Inactivation takes precedence over locking. If the CPU inactivates a locked receive message buffer, then its lock status is negated and the message buffer is marked as invalid for the current matching round. Any pending message on the RX SMB is not transferred to the message buffer. A message buffer is unlocked when the CPU reads Free-Running Timer (TIMER) or the Control and Status word of another message buffer.

The lock and unlock mechanisms have the same functionality in Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. If unlocking occurs during a low-power mode, however, the move-in is postponed (see Modes of operation). Move-in takes place only when the module returns to Normal or Freeze mode.

59.3.8 Enhanced RX FIFO

FlexCAN supports an enhanced RX FIFO engine which can store up to 20 CAN FD messages. The region 2000h–204Fh contains the output of the FIFO, which the CPU should read. To enable the enhanced RX FIFO, write 1 to ERFCR[ERFEN]. FlexCAN has two FIFO options, Legacy RX FIFO and Enhanced RX FIFO, but both options cannot be enabled at the same time. See Legacy RX FIFO for additional information.

To configure the enhanced RX FIFO watermark, write a value to ERFCR[ERFWM]. If ERFCR[ERFWM] is configured, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in ERFCR[ERFWM], the module sets ERFSR[ERFWMI]. Optionally, if MCR[DMA] or ERFIER[ERFWMIIE] are enabled, a DMA transfer or an interrupt can be triggered, respectively.

For the enhanced RX FIFO to receive, the CPU must execute the configuration procedure below. If the CPU must change any configurations of the Enhanced RX FIFO, the same procedure must be followed.

Prerequisites

[1] In previous FlexCAN versions, reading the Control and Status word locked the message buffer even when CODE indicates it is EMPTY. This behavior is maintained when the IRMQ bit is 0.

MCR[RFEN] must be 0.

Procedure

Step	Purpose	Programming	Notes
1	Enter Freeze mode.	See Freeze mode.	—
2	If enhanced RX FIFO is not already enabled, enable it.	Write 1 to ERFCR[ERFEN].	—
3	Reset enhanced RX FIFO engine.	Write 1 to ERFSR[ERFCLR].	—
4	If the enhanced RX FIFO error flags are set, clear them.	Write 1 to these flags: • ERFSR[ERFUFW] • ERFSR[ERFOVF] • ERFSR[ERFWMI] • ERFSR[ERFDA]	—
5	Specify the total number of enhanced RX FIFO filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NFE].	—
6	Specify the number of extended ID and standard ID filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NEXIF].	ERFCR[NEXIF] ≤ ERFCR[NFE] + 1.
7	If you are using DMA, enable DMA.	Write 1 to MCR[DMA].	—
8	If you are using DMA, specify the number of words to transfer for each Enhanced RX FIFO data element.	Write the number to ERFCR[DMALW].	—
9	Specify the Enhanced RX FIFO watermark.	Write the number to ERFCR[ERFWM].	If MCR[DMA] = 1, ERFCR[ERFWM] should be 0h.
10	If you are using interrupts, enable the interrupts.	Write 1 to the interrupt enables in Enhanced RX FIFO Interrupt Enable (ERFIER).	—
11	Configure the filter elements.	Write to the ERFFEL*n* registers.	ERFFEL*n* registers are implemented in RAM; you must explicitly initialize them before prior any reception.
12	Exit Freeze mode.	See Freeze mode.	—

There are two types of enhanced RX FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter elements and standard-ID filter elements. Each extended-ID filter element is stored in two ERFFEL*n* registers, and each standard-ID filter element is stored in one ERFFEL*n* register. ERFCR[NFE] defines the total number of Enhanced RX FIFO filter elements.

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. Figure 438 shows how the enhanced RX filter elements are defined. See Enhanced RX FIFO matching process for information about the Enhanced RX FIFO matching process and filter element formats.

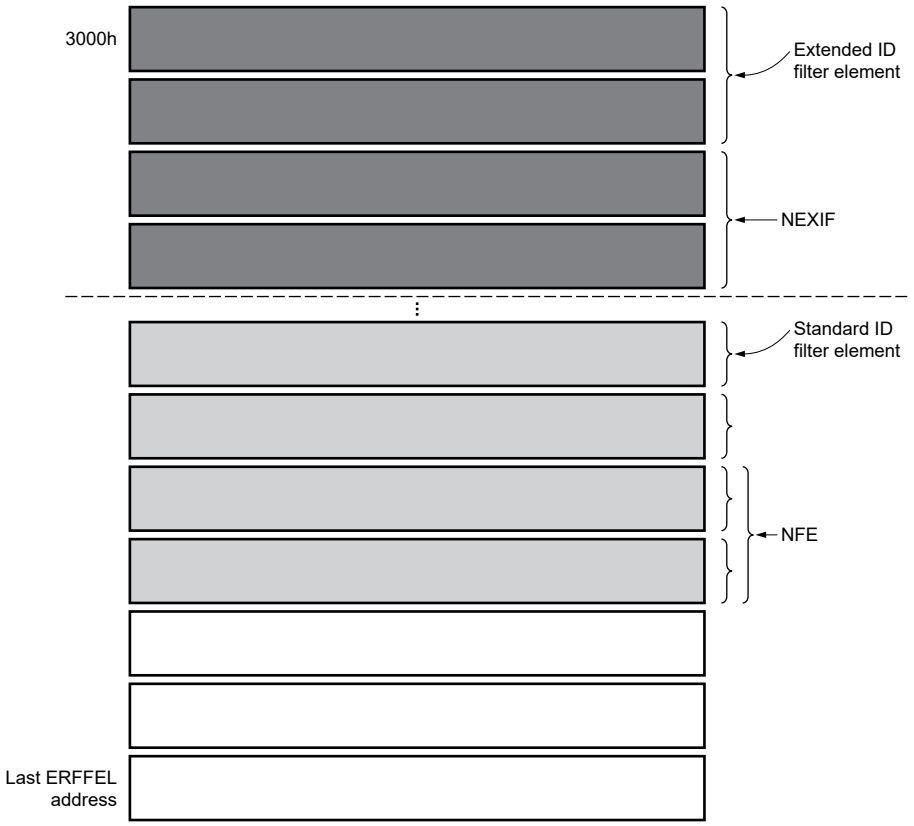

Figure 438. Number of enhanced RX FIFO filter elements

59.3.8.1 Enhanced RX FIFO matching process

When ERFCR[ERFEN] = 1, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, the CAN message content is transferred to the enhanced RX FIFO memory. If multiple filters match the incoming message ID, the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. ERFFEL*n*[FEL][31:30], also called FSCH, determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base-frame format (IDE = 0).
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] = 0) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in Table 936.

Table 936. Standard ID filter element with filter and mask scheme (FSCH = b00)

31	30	29	28	27	26										16	15			12	11	10										0
FSCH = b00		Reserved		RTR filter	STD ID filter											Reserved				RTR mask	STD ID mask										

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. ID ≥ STD ID Filter1.
  3. ID ≤ STD ID Filter2.
  4. (RTR = RTR filter) or (RTR MASK = 0).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in Table 937.

Table 937. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b01		Reserved		RTRfilter	STD ID Filter2		Reserved		RTR mask	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in Table 938.

Table 938. Standard ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. ERFFEL*n*[FSCH] determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] = 0) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b00, the filters and masks are defined as shown in Table 939.

Table 939. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR filter	EXT ID filter	
Reserved		RTR mask	EXT ID mask	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. ID ≥ EXT ID Filter1.
  3. ID ≤ EXT ID Filter2.
  4. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b01, the filters and masks are defined as shown in Table 940.

Table 940. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28																										0
FSCH		RTR filter	EXT ID Filter2																										
Reserved		RTR mask	EXT ID filter 1																										

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

If FSCH = b10, the filters are defined as shown in Table 941.

Table 941. Extended ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28																										0
FSCH		RTR Filter2	EXT ID Filter2																										
Reserved		RTR Filter1	EXT ID filter 1																										

59.3.8.2 Enhanced RX FIFO under DMA operation

You can enable the DMA feature by writing 1 to both ERFCR[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the enhanced FIFO output port at the address range defined in Enhanced RX FIFO structure.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

For proper FIFO engine operation, the CPU should not access the Enhanced FIFO output port address range during DMA operation. Before writing 1 to MCR[DMA], the CPU must service Enhanced RX FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must first clear the ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFWMI], and ERFSR[ERFDA] flags. It must then clear the enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

When there is one frame available to be read from the Enhanced RX FIFO, FlexCAN sets ERFSR[ERFDA]. Upon receiving the request, the DMA controller can read the message in the Enhanced RX FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

Follow these rules for Enhanced RX FIFO DMA operation:

- Because a DMA transfer cannot be changed dynamically, program ERFCR[DMALW] so the enhanced RX FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 969.

Each time the DMA controller reads one message from the FIFO, FlexCAN clears ERFSR[ERFDA]. If there is at least one message stored in the FIFO, FlexCAN sets it again.

Consider an example where the maximum number of bytes in the data field of a CAN frame for a certain application is eight, and high-resolution timestamp is enabled. In that case, the last enhanced RX FIFO address offset can be found in Table 979 and Table 980. Using this address offset, ERFCR[DMALW] can be determined in this way:

- Maximum number of data bytes = 8
- HR_TIME_STAMP enabled
- Last address offset = TS_OFF = 2014h
- DMALW = 5

59.3.8.3 Enhanced RX FIFO clear operation

When ERFCR[ERFEN] is 1, the CPU can clear the Enhanced RX FIFO by writing 1 to ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode; the module blocks the operation in other modes. This operation does not clear ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFDA], or ERFSR[ERFWMI]. The CPU must service all these fields before executing the clear FIFO operation.

59.3.9 Legacy RX FIFO

The Legacy RX FIFO is receive-only. To enable it, write 1 to MCR[RFEN]. To maintain software backward compatibility with previous versions of FlexCAN that did not have the Legacy FIFO feature, the reset value of this field is zero.

CAUTION

Do not enable Legacy RX FIFO when the CAN FD feature is enabled.

The Legacy FIFO is six messages deep. The memory region the Legacy FIFO structure occupies (both message buffers and Legacy FIFO engine) is described in Legacy RX FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames Available in Legacy RX FIFO) is set when at least one frame is available to be read from the Legacy FIFO. If the corresponding mask bit enables it, an interrupt is generated. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and Legacy RX FIFO Information (RXFIR), then clear the interrupt. If there are more messages in the Legacy FIFO, clearing the interrupt:

1. Updates the output of the Legacy FIFO with the next message.
2. Updates RXFIR with the attributes of that message.
3. Reissues the interrupt to the CPU.

Otherwise, the flag remains cleared. The output of the Legacy FIFO is valid only when IFLAG1[BUF5I] is set.

IFLAG1[BUF6I] (Legacy RX FIFO Warning) is set when the Legacy RX FIFO receives a new message that increases the number of unread messages from four to five. This change means that the Legacy RX FIFO is almost full. The flag remains set until the CPU clears it.

IFLAG1[BUF7I] (Legacy RX FIFO Overflow) is set when an incoming message is lost because the Legacy RX FIFO is full. The flag is not set when the Legacy RX FIFO is full and a message buffer captures the message. The flag remains set until the CPU clears it.

Clearing one of the three flags above does not affect the state of the other two.

If an IFLAG flag is set and the corresponding mask bit is 1, an interrupt is generated.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria are specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN]. This table can be configured to one of the following formats (see also Legacy RX FIFO structure):

- Format A: 128 Identifier Acceptance Filters (IDAFs) — extended or standard IDs including IDE and RTR
- Format B: 256 IDAFs — standard IDs or extended 14-bit ID slices including IDE and RTR
- Format C: 512 IDAFs — standard or extended 8-bit ID slices

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy RX FIFO has a corresponding Identifier Acceptance Filter Hit Indicator (IDHIT). The IDHIT can be read in the IDHIT field in the Control and Status word, as shown in the Legacy RX FIFO Structure description. The CPU can also obtain this information by accessing Legacy RX FIFO Information (RXFIR). RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO, and is valid when IFLAG1[BUF5I] is set. RXFIR must be read only before clearing the flag, guaranteeing that the information refers to the correct frame within the Legacy FIFO.

The Individual Mask Registers (RXIMR*n*) individually affect up to 32 elements of the filter table, according to the value of CTRL2[RFFN]. This configuration allows very powerful filtering criteria to be defined. If MCR[IRMQ] is 0, the Legacy RX FIFO filter table is affected by Legacy RX FIFO Global Mask (RXFGMASK).

NOTE

See Table 929 for information about the difference between FD and non-FD regarding this feature.

59.3.9.1 Legacy RX FIFO in DMA Operation

The receive-only Legacy FIFO can support DMA. To enable this feature, write 1 to both MCR[RFEN] and MCR[DMA]. To maintain backward compatibility with previous versions of the module that did not have the DMA feature, the reset value of MCR[DMA] is zero.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port in the 80h–8Ch address range.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] = 1, the CPU must not access the Legacy FIFO output port address range. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. Otherwise, these flags may indicate that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

When at least one frame available to be read from the FIFO, IFLAG1[BUF5I] (Frames available in Legacy RX FIFO) is set. A DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch. This read operation:

- Clears IFLAG1[BUF5I].
- Updates the FIFO output with the next message (if the FIFO is not empty).
- Updates Legacy RX FIFO Information (RXFIR) with the attributes of the new message.

If there are more messages stored in the FIFO, IFLAG1[BUF5I] is reasserted and another DMA request is issued. Otherwise, the flag remains cleared.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy RX FIFO interruption and must not clear the related IFLAG flags. The related IMASK bits are not used to mask the generation of DMA requests.

NOTE

See Table 929 for information about the difference between FD and non-FD regarding this feature.

59.3.9.2 Clear Legacy FIFO

When MCR[RFEN] = 1, you can use the clear Legacy FIFO operation to empty Legacy FIFO contents. When the CPU writes 1 to IFLAG1[BUF0I], the clear FIFO operation occurs. This operation can only be performed in Freeze mode; FlexCAN blocks it in other modes. This operation does not clear the FIFO IFLAG flags; the CPU must service all FIFO IFLAG flags before executing the clear FIFO operation.

When Legacy RX FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I], and the DMA request is canceled.

CAUTION

The clear Legacy FIFO operation does not clear IFLAG flags, except when MCR[DMA] = 1; in this case, only IFLAG1[BUF5I] is cleared.

59.3.10 CAN protocol-related features

59.3.10.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure-detection capability that was in the original CAN FD protocol. This original protocol is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-ISO CAN FD protocol. FlexCAN still supports non-ISO CAN FD, so it can be used during an intermediate phase, for evaluation and development purposes.

It is recommended that you configure FlexCAN with the ISO CAN FD protocol by writing 1 to CTRL2[ISOCANFDEN].

59.3.10.2 CAN FD frames

ISO 11898-1:2015 specifies the Classical Frame format compliant to ISO 11898-1:2003 (2003) and introduces the CAN Flexible Data Rate Frame format (CAN FD). The Classical Frame format allows bit rates up to one Mbit/s and payloads up to eight bytes per frame. The Flexible Data Rate Frame format allows bit rates faster than one Mbit/s and payloads longer than eight bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are additional control bits in the CAN FD frame:

- The Extended Data Length (EDL) bit enables a longer data payload with different data length coding.
- The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in Classical CAN format. When an FD frame is received and matches a message buffer, the RTR bit in the receiving message buffer becomes 0. The RTR bit must be considered in classical frames only.

59.3.10.2.1 CAN FD messages

CAN FD messages may be formatted as long frames where the data field exceeds eight bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching. In this case, the control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of eight bytes at nominal rate. Figure 439 illustrates the message formats for Classical and FD frames with either standard or extended ID.

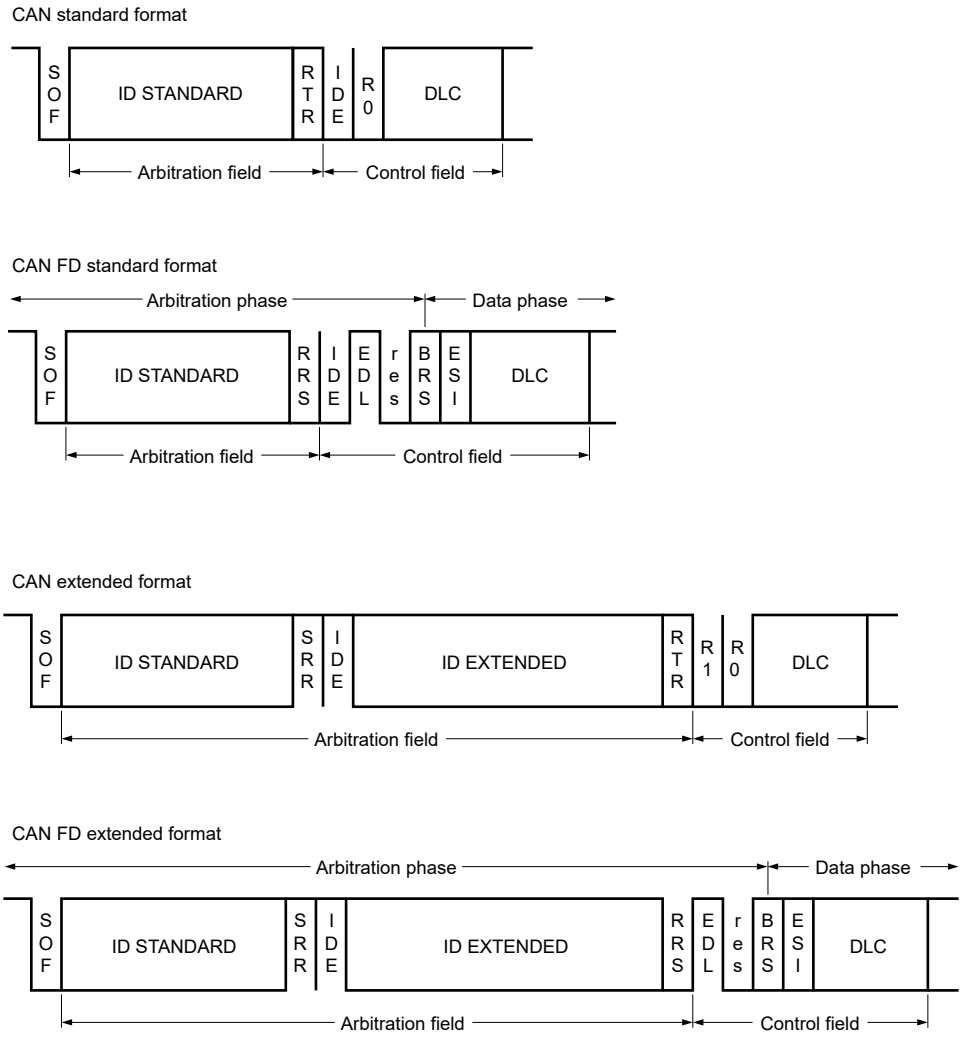

Figure 439. CAN message formats

MCR[FDEN] enables the ability to receive and transmit CAN FD messages. A recessive R0 bit in CAN frames with 11-bit identifiers, or a recessive R1 bit in CAN frames with 29-bit identifiers, is decoded as an EDL bit (not a reserved one). A recessive EDL bit identifies a CAN FD frame, and a dominant EDL bit identifies a Classical CAN frame. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start of Frame (SOF) bit until the Bit Rate Switch (BRS) bit is called the arbitration phase. This part is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, is called the data phase. When this second part is transmitted, a second set of CAN data bit timing configuration values determines the data bit rate. Finally, from the CRC delimiter until the Intermission bits, the transmission returns to nominal bit rate.

59.3.10.2.2 BRS in CAN FD

In CAN FD frames with bit rate switching, the bit timing changes inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by CAN Bit Timing (CBT). (Control 1 (CTRL1) also defines this timing for backward compatibility.) Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by CAN FD Bit Timing (FDCBT).

NOTE

If the time quantum length in nominal bit timing and in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase, and it lasts until the next synchronization event. The length of the time quantum should be the same in nominal and data bit timing. This configuration minimizes the chance of error frames on the CAN bus, and optimizes the clock tolerance in networks that use FD frames.

If BRS = 1 in the selected TX MB, FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching. If FDCTRL[FDRATE] = 0, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written at any time but takes effect only for the next message transmitted or received.

Nominal bit timing is resumed at the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. Figure 440 describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

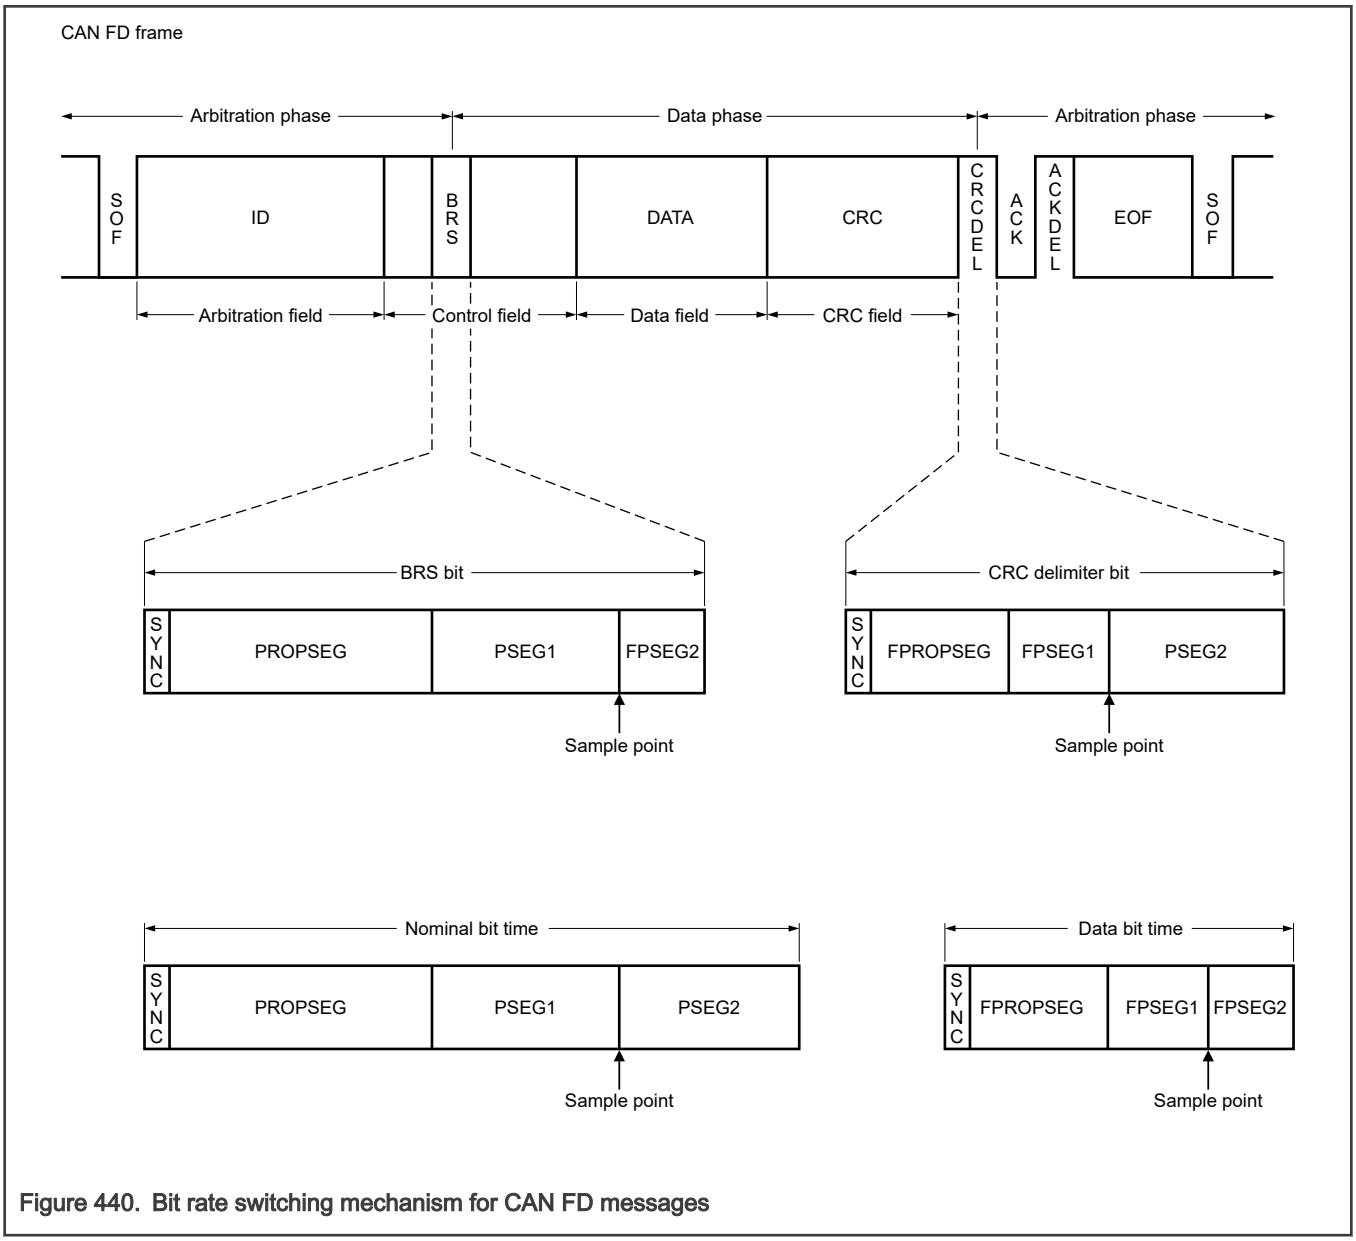

Figure 440. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter. It accepts two recessive bits before the recessive-to-dominant edge that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of the CAN_PE subblock. For example, for a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.

NOTE

The frequency used in this example may not be supported on this chip. It is shown only to demonstrate how the maximum configurable bit rate is calculated.

59.3.10.2.3 ESI in CAN FD

The value of the ESI bit is determined:

- By the error state of the transmitter at the start of the transmission, if the frame is originated in the FlexCAN node,
- Or by the original transmitting node when FlexCAN is acting as a gateway for the message.

If the transmitter is error-passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in Table 942.

Table 942. Written versus transmitted values of ESI field

FlexCAN fault confinement status at start of frame	ESI bit of TX MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

59.3.10.2.4 CRC calculations in CAN FD

Different CAN frame formats have different CRC polynomials. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to 16 bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than 16 bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The values of the EDL bit and the DLC field select the CRC sequence to be transmitted. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, CAN FD CRC (FDCRC) stores the calculated CRC for the transmitted message. This storage is performed with adequate length for the type of message, for CAN FD and non-FD messages. Cyclic Redundancy Check (CRCR) reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method changes for the CRC sequence, so the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence. This insertion occurs even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN receives a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

59.3.10.2.5 CAN FD errors

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters ECR[RXERRCNT] and ECR[TXERRCNT] accumulate the counts of RX and TX errors, respectively, for both FD and non-FD frames indiscriminately. Two extra error counters, ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST], accumulate RX and TX errors occurring in the data phase of CAN FD frames with BRS = 1 only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see Error Counter (ECR)).

These error flags report errors in both CAN FD and non-FD frames:

- ESR1[BIT1ERR]
- ESR1[BIT0ERR]
- ESR1[ACKERR]
- ESR1[CRCERR]
- ESR1[FRMERR]
- ESR1[STFERR]

If CTRL1[ERRMSK] = 1, they also generate the ERRINT interrupt.

These additional error flags indicate the occurrence of errors in the data phase of CAN FD frames with BRS = 1:

- ESR1[BIT1ERR_FAST]
- ESR1[BIT0ERR_FAST]
- ESR1[CRCERR_FAST]
- ESR1[FRMERR_FAST]
- ESR1[STFERR_FAST]

No ACKERR is detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on ECR[RXERRCNT] and ECR[TXERRCNT] only. Information in ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST] may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN detects an error while transmitting or receiving a CAN FD message in the data phase, it immediately switches:

- Back to the arbitration phase, and
- Back to the nominal rate to start an error flag.

59.3.10.2.6 CAN FD synchronization

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize when transmitting in the CAN FD data phase.

59.3.10.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase, when BRS = 1 in the message. This feature enables the use of rates up to 8 Mbit/s.

During the data phase of a CAN FD frame, if the transmitter cannot receive its own latest transmitted bit at the sample point of that bit, it detects a bit error. When bit rate switching is enabled (BRS = 1), the CAN bit time in the data phase can become shorter than the loop delay of the transceiver. This condition impedes the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The transceiver delay compensation (TDC) process defines a secondary sample point where the transmitted bit is correctly compared to the received bit to check for bit errors.

You can enable the TDC mechanism via FDCTRL[TDCEN] or ETDC[ETDCEN]. The TDC mechanism is effective only during the data phase of FD frames with BRS = 1. It has no effect on either non-FD frames or FD frames transmitted at the normal bit rate. When the transmitted message has BRS = 1, TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit. When TDC is active, the real received bit is compared to the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The transmitters using TDC disregard the value of the CRC delimiter bit. A global error at the end of the CRC field causes the receivers to send error frames that the transmitter detects during Acknowledge or End of Frame.

For every transmitted FD frame with BRS = 1, the transition from the recessive EDL bit to the dominant R0 bit triggers the delay measurement (as shown in Figure 441). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF] determines the position of the secondary sample point. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

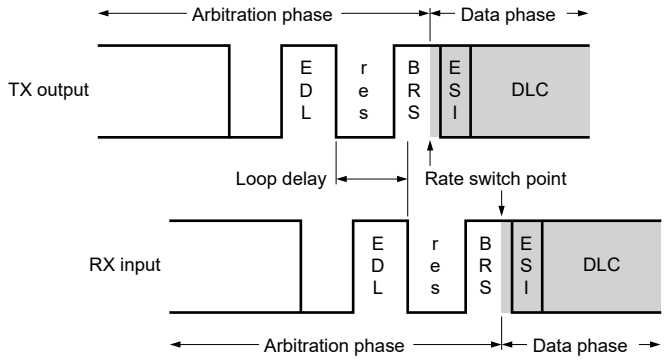

Figure 441. Transceiver loop delay measurement

The measured loop delay is not enough to define the secondary sample point, because it relates to the CAN bit edges. The transceiver delay compensation offset FDCTRL[TDCOFF] or ETDC[ETDCOFF] is used to shift the secondary sample point to an intermediate point inside the bit time, far away from its edges. The value of FDCTRL[TDCOFF] or ETDC[ETDCOFF] cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset must use optimal settings. To ensure that bit sampling is performed in the best region, configure the TDC offset as shown in this equation:

$$Offset = (FPSEG1 + FPROPSEG + 2) \times (FPRESDIV + 1)$$
or
$$Offset = (DTSEG1 + 2) \times (EDPRESDIV + 1), \textit{ if ETDCEN}$$

Equation 14. TDC offset calculation

Figure 442 shows the SSP position when these settings are used.

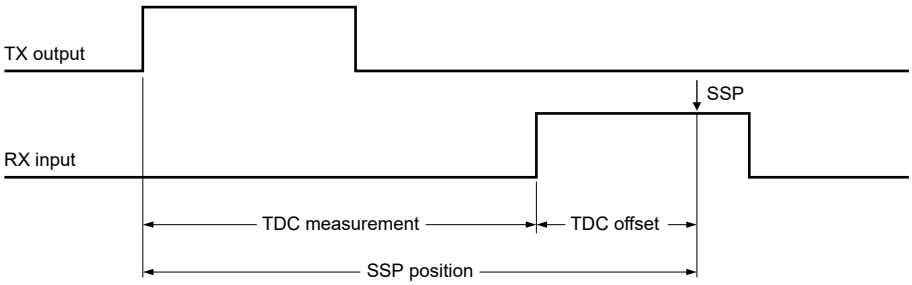

Figure 442. SSP position with optimal values

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are 1, you can write 1 to ETDC[TDMDIS] to disable the transceiver delay measurement. In this case, only ETDC[ETDCOFF] defines the SSP position. Figure 443 shows the secondary sample point position when the transceiver delay measurement is disabled.

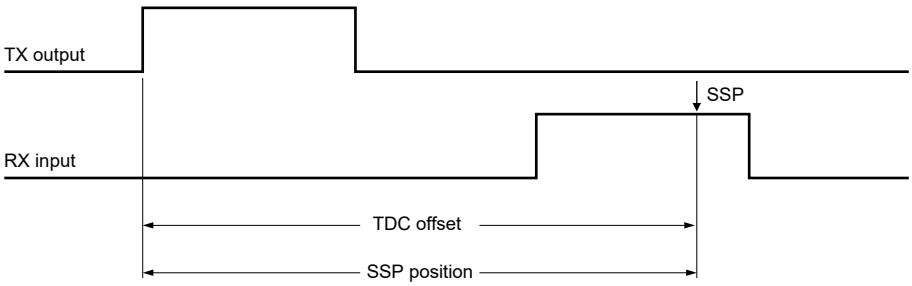

Figure 443. SSP position with TDC measurement disabled by ETDCEN and TDMDIS

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every TX CAN bit:

- The transmitted TX bit value is temporarily stored in a buffer.
- A time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started. This countdown ends with the comparison of the received RX bit (delayed by the external loop delay plus the specified offset) to the stored TX bit.

If a bit error is detected at the secondary sample point, FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, delay compensation is always disabled. During the data phase, the TDC mechanism of FlexCAN can compensate a maximum delay of 3 CAN bit times − 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set. The flag indicates when the TDC mechanism is out of range and is unable to compensate the transceiver loop delay.

59.3.10.4 Remote frames

A remote frame is a special type of frame. You can program a message buffer to be a remote request frame by configuring the message buffer as Transmit with the RTR = 1. After the remote request frame is transmitted successfully, the message buffer becomes a receive message buffer, with the same ID as before.

When FlexCAN receives a remote request frame, the frame can be treated in different ways, depending on remote request storing (CTRL2[RRS]) and RX FIFO Enable (MCR[RFEN]):

- If RRS = 0, the ID of the frame is compared to the IDs of the transmit message buffers with the CODE field 1010b. If a matching ID exists, this message buffer frame is transmitted. If the matching message buffer has the RTR = 1, FlexCAN transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response.

  The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. If a remote request frame is received and matches a message buffer, this message buffer immediately enters the internal arbitration process. However, it is considered a normal TX message buffer, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If CTRL2[RRS] = 1, the ID of the frame is compared to the IDs of the receive message buffers with the CODE field 0100b, 0010b, or 0110b. If a matching ID exists, this message buffer stores the remote frame in the same fashion as a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- If MCR[RFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the Legacy FIFO and presented to the CPU.

  For filtering formats A and B (see Legacy RX FIFO structure), it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted if they match the ID. Remote request frames are considered as normal frames. They generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.
- If ERFCR[ERFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Enhanced RX FIFO filtering criteria. Remote Request Frames are considered normal frames. They generate an Enhanced RX FIFO overflow when a successful reception occurs and the enhanced RX FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. A fixed dominant RRS bit replaces the RTR bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

59.3.10.5 Overload frames

When a dominant bit is detected on the CAN bus in these locations, FlexCAN transmits overload frames:

- The first or second bit of Intermission.
- The seventh bit (last) of End of Frame field (RX frames).
- The eighth bit (last) of Error Frame Delimiter or Overload Frame Delimiter.

59.3.10.6 Message buffer timestamp

The value of the free-running timer is sampled at the beginning of the Identifier field on the CAN bus. This value is stored at the end of move-in in the TIME_STAMP field of a message buffer, providing network behavior regarding time.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously clocks the free-running timer.

When CTRL2[TIMER_SRC] = 0, the FlexCAN bit clock clocks the free-running timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free-running timer is not incremented during Disable, Doze, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See CTRL1[TSYN].

Alternatively, by configuring CTRL2[MBTSBASE], the timestamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter.

59.3.10.7 High-resolution timestamp

The high-resolution timestamp (HR_TIME_STAMP) uses a dedicated timer with a 32-bit counter operating in free-running mode. CTRL2[TSTAMPCAP] enables the high-resolution timestamp. When this field is not zero, the dedicated 32-bit counter value is captured during a valid CAN frame and stored in an HR_TIME_STAMP*n* register.

Each HR_TIME_STAMP*n* corresponds to a specific message buffer. For example, HR_TIME_STAMP0 stores the 32-bit timestamp associated with message buffer 0. HR_TIME_STAMP1 stores the 32-bit timestamp associated with message buffer 1, and so on.

The counter value is captured according to CTRL2[TSTAMPCAP]. For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid. This valid point is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception.

For CAN FD frames, the capture points can be:

- The start of frame

- The point in time a CAN FD frame is considered valid
- The res bit of a CAN FD frame

The 16-bit timestamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE].

59.3.10.8 Protocol timing

Figure 444 shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source field CTRL1[CLKSRC] defines whether the internal clock is connected to the output of a crystal oscillator (oscillator clock) or to the peripheral clock. To guarantee reliable operation, select the clock source when the module is in Disable mode (MCR[MDIS] = 1).

NOTE

To identify the proper clock source, see the clock distribution chapter (module clocks table).

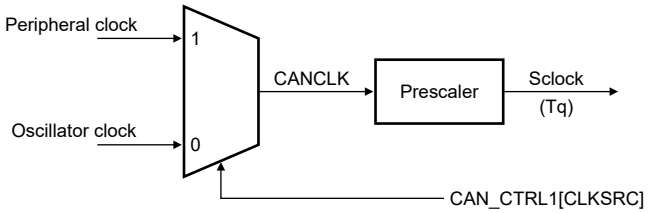

Figure 444. CAN engine clocking scheme

Select the oscillator clock whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

59.3.10.8.1 Bit timing configuration

FlexCAN supports various means to configure bit timing parameters required by the CAN protocol. Control 1 (CTRL1) has various fields to control bit timing parameters:

- CTRL1[PRESDIV]
- CTRL1[PROPSEG]
- CTRL1[PSEG1]
- CTRL1[PSEG2]
- CTRL1[RJW]

CAN Bit Timing (CBT) extends the range of the CAN bit timing variables in CTRL1. Enhanced Data Phase CAN Bit Timing (EDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) = 1.

Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in CBT. Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, you must program the nominal bit timing and data phase serial clock (Sclock) dividers in Enhanced CAN Bit Timing Prescalers (EPRS).

NOTE

When the CAN FD feature is enabled, always write 1 to CBT[BTF] or CTRL2[BTE] and specify the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

CTRL1[PRESDIV], and its extended range CBT[EPRESDIV] (or EPRS[ENPRESDIV]) and FDCBT[FPRESDIV] (or EPRS[EDPRESDIV]) for the data phase bits of CAN FD messages, defines the prescaler value that generates the serial

clock (Sclock). (See Equation 15.) The period of Sclock defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine. It is the smallest time unit for all configuration values.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

Equation 15. Time quantum

The bit rate, which defines the rate the CAN message is received or transmitted, is calculated with the formula:

$$CAN\ bit\ time = (Number\ of\ time\ quanta\ in\ 1\ bit\ time) \times Tq$$

$$Bit\ rate = \frac{1}{CAN\ bit\ time}$$

Equation 16. CAN bit time and baud rate

59.3.10.8.2 Bit time segments

A bit time is subdivided into three segments as shown in Figure 445. See also Figure 446 , Figure 447, and Table 943.

NOTE

For further explanation of the underlying concepts, see ISO 11898-1:2015. See also *CAN Specification Version 2.0, Part A and Part B* for bit timing.

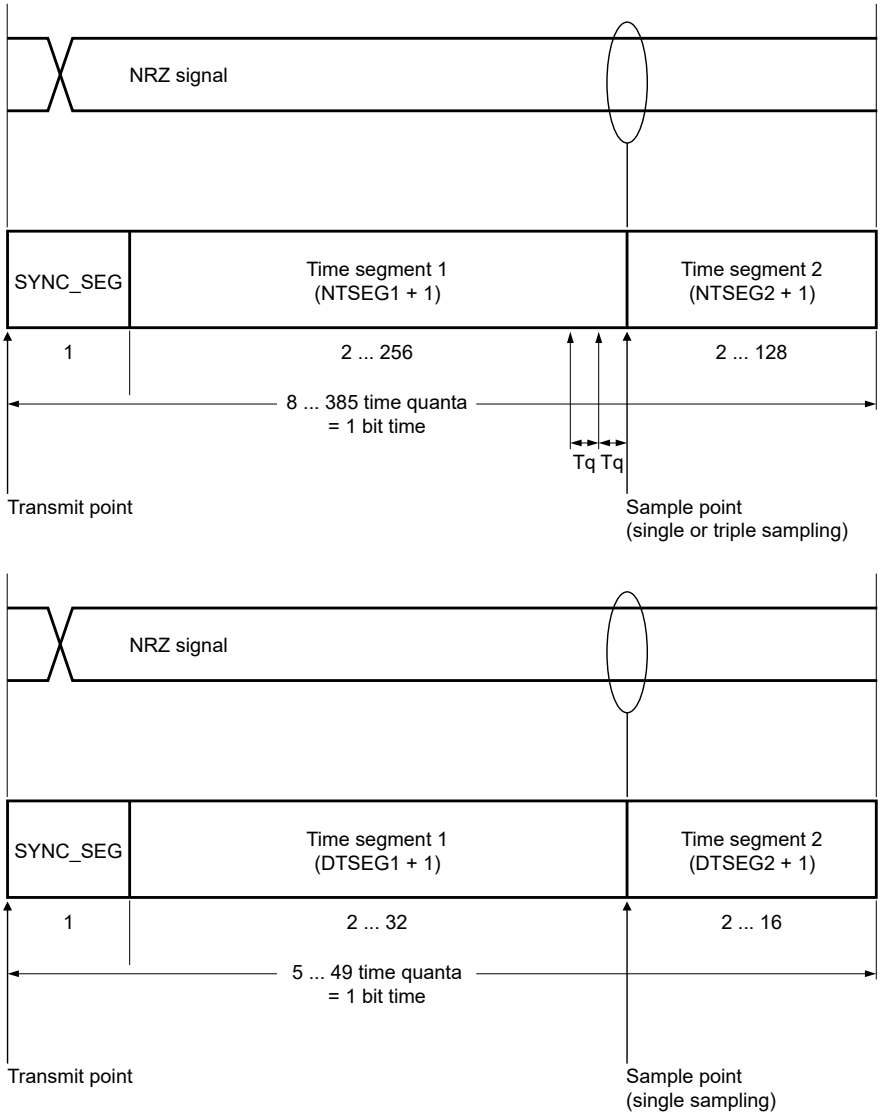

Figure 445. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

The three bit time segments are:

- SYNC_SEG—this segment has a fixed length of one time quantum. Signal edges are expected to occur within this section.
- Time Segment 1—this segment includes the propagation segment and the phase segment 1 of the CAN standard.

  It can be programmed by configuring CTRL1[PROPSEG] and CTRL1[PSEG1] so that the sum (plus 2) is 2–16 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPROPSEG] and CBT[EPSEG1] so that the sum (plus 2) is 2–96 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPROPSEG] and FDCBT[FPSEG1] so that the sum (plus 1) is 2–39 time quanta.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 to 2–256 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG1] must be used for configuring time segment 1 to 2–32 time quanta.
- Time Segment 2—this segment represents the phase segment 2 of the CAN standard.

  It can be programmed by configuring CTRL1[PSEG2] (plus 1) to be 2–8 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPSEG2] so that its value (plus 1) is 2–32 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses

FDCBT[FPSEG2] instead, so that its value (plus 1) is 2–8 time quanta. Time segment 2 cannot be smaller than the Information Processing Time (IPT), which is 2 time quanta in FlexCAN.

If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 to 2–128 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG2] must configure time segment 2 to 2–16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

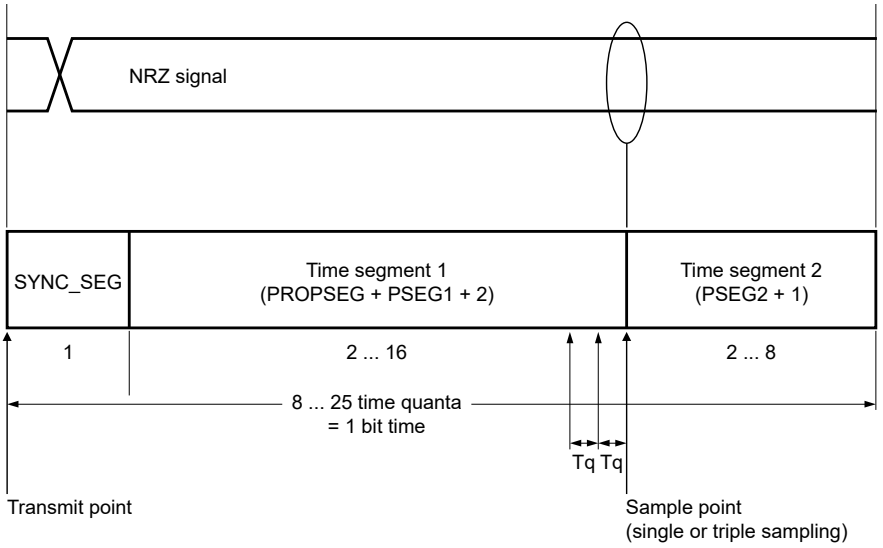

Figure 446. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

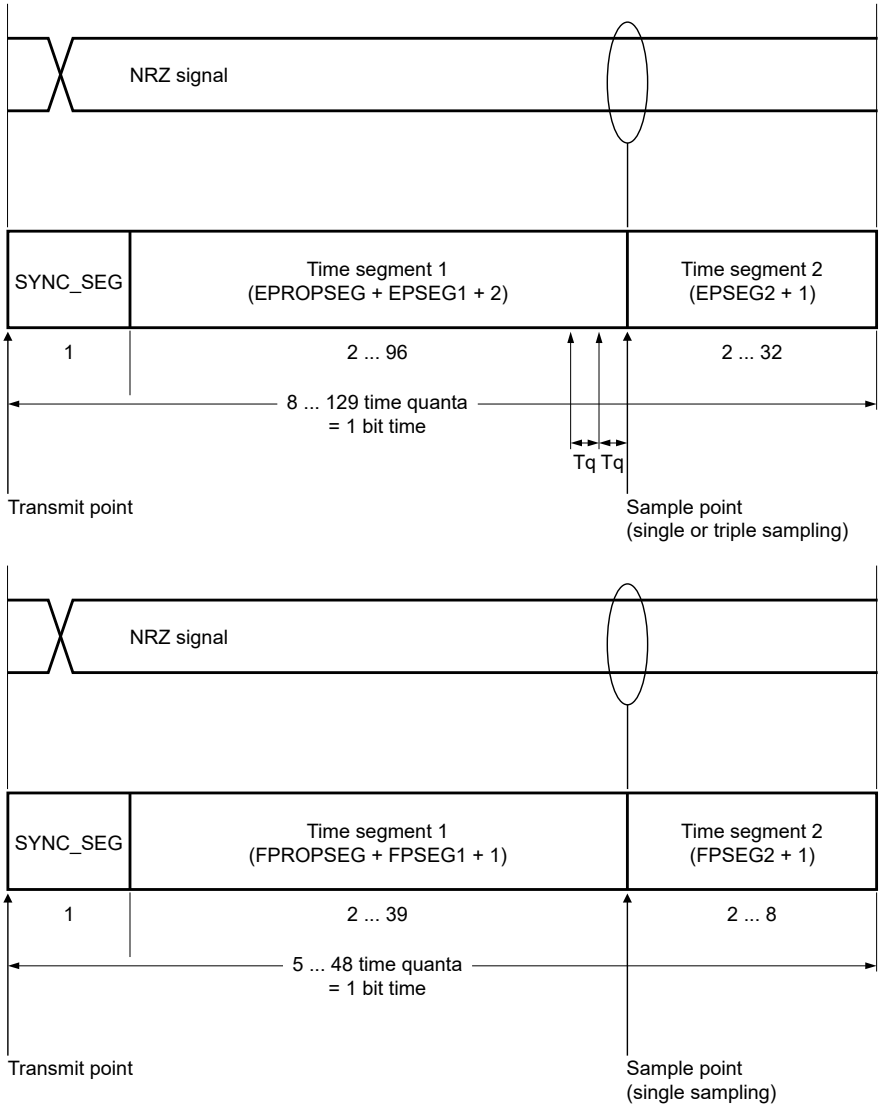

Figure 447. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 943. Time segment syntax

Syntax	Description
SYNC_SEG	Period during which the system expects transitions to occur on the bus
TSEG1	Period corresponding to the sum of PROPSEG and PSEG1
TSEG2	Period corresponding to the PSEG2 value
Transmit point	Point at which a node in Transmit mode transfers a new value to the CAN bus
Sample point	Point at which a node samples the bus. If the option of three samples per bit is selected, this point marks the position of the third sample.

Table 944 gives some examples of the CAN-compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 944. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Resynchronization jump width
5 to 10	2	1 to 2
4 to 11	3	1 to 3
5 to 12	4	1 to 4
6 to 13	5	1 to 4
7 to 14	6	1 to 4
8 to 15	7	1 to 4
9 to 16	8	1 to 4

NOTE

You must ensure the bit time settings comply with the CAN Protocol standard (ISO 11898-1:2015).

59.3.10.8.3 Calculating peripheral clocks

A CAN bit can be used as a measure of duration (for example, estimating the occurrence of a CAN bit event in a message). When a CAN bit is used in this way, the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 17. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

Or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 18. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

Where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 444), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value of CTRL1[PSEG1].
- PSEG2 is the value of CTRL1[PSEG2].
- PROPSEG is the value of CTRL1[PROPSEG].
- PRESDIV is the value in CTRL1[PRESDIV].
- ENPRESDIV is the value of EPRS[ENPRESDIV].
- NTSEG1 is the value of ENCBT[NTSEG1].
- NTSEG2 is the value of ENCBT[NTSEG2].

The formula above is also applicable to the alternative CAN bit timing variables described in:

- CAN Bit Timing (CBT)

- Enhanced Nominal CAN Bit Timing (ENCBT)
- CAN FD Bit Timing (FDCBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

For example, 180 CAN bits = (180 × NumClkBit) peripheral clock periods.

59.3.10.9 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame. These windows are shown in the following figures.

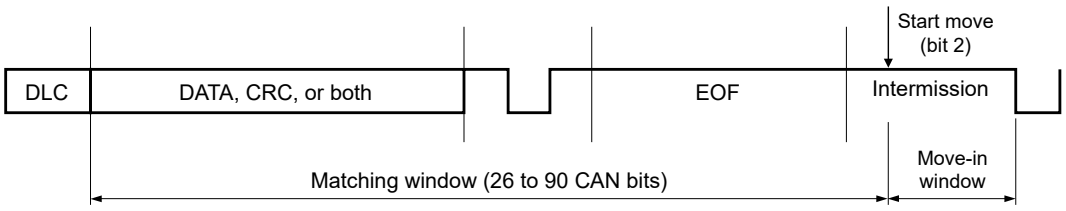

Figure 448. Matching and move-in time windows

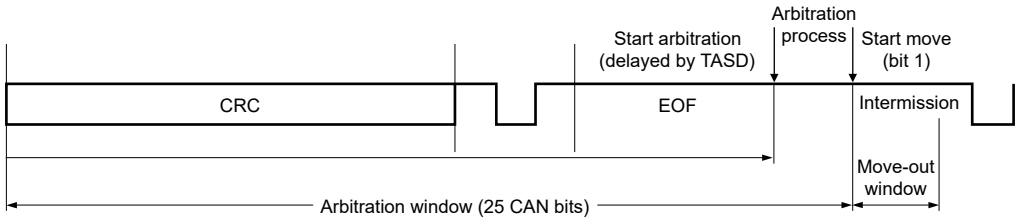

Figure 449. Arbitration and move-out time windows

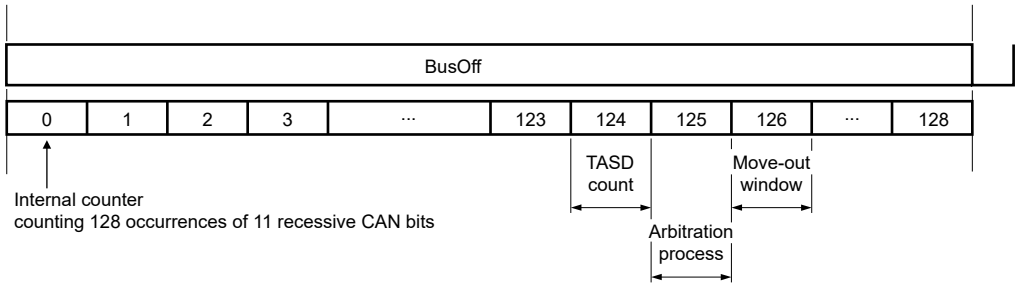

Figure 450. Arbitration at the end of bus off and move-out time windows

NOTE

In these figures, the matching and arbitration timing do not consider delays caused by concurrent memory access due to the CPU or other internal FlexCAN subblocks.

59.3.10.10 TX arbitration start delay

TX Arbitration Start Delay (CTRL2[TASD]) indicates the number of CAN bits that FlexCAN uses to delay the TX arbitration process starting point from the first bit of the CRC field of the current frame. This variable can be written only in Freeze mode; FlexCAN blocks it in other modes.

The ability of the CPU to reconfigure message buffers for transmission after the end of the internal arbitration process impacts transmission performance. In the arbitration process, FlexCAN finds the winner MB for transmission (see Arbitration process). If

the arbitration ends too early (before the first bit of the Intermission field) the CPU may reconfigure some TX message buffers. It is possible that the winning message buffer is no longer the best candidate to be transmitted.

TASD can optimize the transmission performance by defining the arbitration start point, as shown in Figure 451, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers in use by the matching and arbitration processes

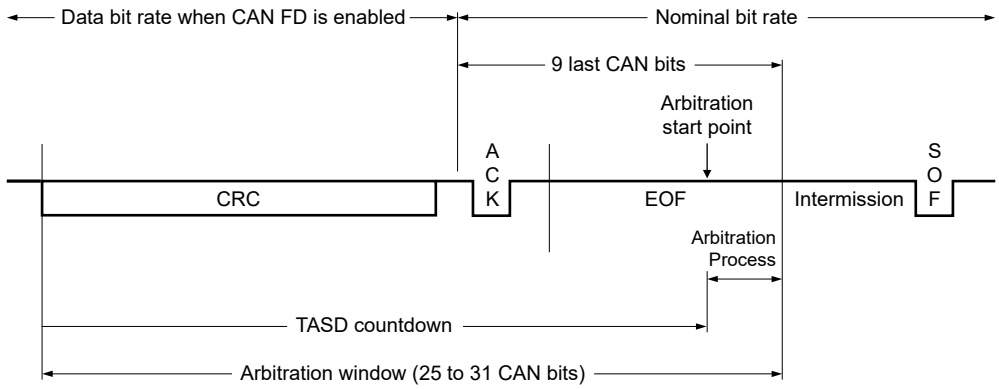

Figure 451. Optimal TX arbitration start point

The duration of an arbitration process, in terms of CAN bits, is:

- Directly proportional to the number of available message buffers
- Directly proportional to the CAN bit rate
- Inversely proportional to the peripheral clock frequency

The optimal arbitration timing occurs when the last message buffer is scanned immediately before the first bit of the Intermission field of a CAN frame. For instance, if the following are true:

- There are few message buffers.
- The peripheral-to-oscillator clock ratio is high.
- The CAN baud rate is low.

Then the arbitration can be placed closer to the end of the frame, adding more delay to its starting point, and vice versa.

If CTRL2[TASD] = 0, the arbitration start is not delayed, and more time is reserved for arbitration. Alternatively, if CTRL2[TASD] is close to 24, the CPU can configure a TX message buffer later, and less time is reserved for arbitration. If too little time is reserved for arbitration, FlexCAN may not be able to find a winner MB in time. The transmitted arbitration winner may not have the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and (MAXMB + 1) ≤ NMB_{END}

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and (MAXMB + 1) > NMB_{END}

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

Equation 19. Optimal value for TASD

Where:

$$NMB_{END} = \frac{(9 \times CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

Equation 20. Variables used in TASD calculation

- MAXMB is the value in MCR[MAXMB].
- NMB_{END} is the number of message buffers that the arbitration process can scan during the last nine CAN bits at the end of a frame. (See Equation 20.)
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].

- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] = 1, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Equation 21. Nominal baud rate when CTRL2[BTE] = 1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

Equation 22. Fast baud rate when CTRL2[BTE] = 1

See also Protocol timing for more details.

59.3.10.10.1 TASD configuration examples

The following tables show the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (for example, peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 945. TASD values in Case 1

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0
64	23	8.0
96	22	8.0

Case 2:

- Clock ratio = 1:1 (for example, peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 946. TASD values in Case 2

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid

Table continues on the next page...

Table 946. TASD values in Case 2 (continued)

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

Case 3:

- Clock ratio = 2:1 (for example, peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 947. TASD values in Case 3

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33
96	20	1.54

59.3.11 Clocks

The following table describes the clock sources for FlexCAN. See the Clock Controller Module (CCM) for clock setting, configuration, and gating information.

Table 948. FlexCAN clocks

Clock name	Description
MODULE_CLK (system_clk)	Peripheral clock
MODULE_CLK_CHI (host_clock)	Control Host Interface (CHI) clock
MODULE_CLK_PE (protocol_engine_clock)	Protocol Engine (PE) clock
MODULE_CLK_PE_NOGATE (protocol_engine_clock_nogate)	Protocol Engine clock (no gating)
MODULE_CLK_S (system_clock_nogate)	Peripheral access clock

59.3.11.1 Clock domains and restrictions

FlexCAN has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When CTRL1[CLKSRC] = 1, synchronous operation occurs because both domains are connected to the peripheral clock. This setting creates a 1:1 ratio between the peripheral and oscillator clocks.

When the two domains are connected to clocks with different frequencies or phases, the frequency relationship between the two clock domains is restricted. In asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When performing matching and arbitration, FlexCAN must scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. To provide sufficient time for the scan, observe the following requirements:

- The peripheral clock frequency cannot be less than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in Table 949.

Table 949. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16
64	0	0	25
96	0	0	37
16	1	0	16
32	1	0	17
64	1	0	30
96	1	0	42
16	0	1	16
32	0	1	19
64	0	1	31
96	0	1	42

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in Table 949 determines the minimum peripheral clock frequency for a given number of message buffers and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit. This number can be defined by adjusting one or more of the bit timing values contained in:

- Control 1 (CTRL1)
- CAN Bit Timing (CBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be eight, so the oscillator clock frequency should be at least eight times the CAN bit rate.

59.3.11.1.1 Clock restrictions for CAN FD

For CAN FD frame format, some constraints must be satisfied. The equation below calculates the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit).

$$NumClkNomBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

$$= \frac{f_{SYS}}{NomBitRate}$$

Equation 23. Number of peripheral clocks per nominal CAN bit

Where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in Control 1 (CTRL1). Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CAN Bit Timing (CBT) or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with BRS = 1 (fast CAN bits) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in Table 950. Having fewer data bytes means having fewer fast CAN bits. It also means that less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 950. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

Equation 24. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process

Where MaxNumOfMb is the maximum number of available message buffers defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in Enhanced RX FIFO Control (ERFCR).

The clock-domain-crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit. This minimum is required for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Equation 25. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

Therefore, the larger of the two values calculated above determines the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit).

$$MinNumClkFastBit = Maximum\ (MinNumClkFastBitA, MinNumClkFastBitB)$$

Equation 26. Minimum number of peripheral clocks per fast CAN bit

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

Equation 27. Maximum achievable baud rate for data phase

These factors affect the maximum data bit rate attainable by FlexCAN in CAN FD mode:

- The peripheral and oscillator clock frequencies
- The maximum number of message buffers
- The expected nominal bit rate

Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the configuration of FlexCAN variables affects the CAN FD bit rate, consider this application example:

- The peripheral clock frequency is set to 50 MHz
- The oscillator clock frequency is set to 40 MHz

1. Considering the nominal bit rate as 1 Mbit/s, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

   $$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

   Equation 28. Calculation example for number of peripheral clocks per nominal CAN bit

2. The number of fast CAN bits (NumOfFastBits) is determined in Table 950. For example, if the minimum payload in FD frames is 8 bytes, there are 85 CAN bits in the data phase.
3. Assuming the maximum number of message buffers is 96, and Enhanced RX FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

Equation 29. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

Equation 30. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

$$MinNumClkFastBit = Maximum\ (\ 5.06, 6.75\ ) = 6.75$$

Equation 31. Calculation example for number of peripheral clocks per fast CAN bit

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667\ Mbps$$

Equation 32. Calculation example for maximum achievable baud rate

Even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbit/s in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbit/s. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

Table 951 shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available message buffers. For some cases, if the number of available message buffers is reduced, FlexCAN can then achieve a data rate up to 8 Mbit/s.

Table 951. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced RX FIFO disabled

Peripheral clock frequency (MHz)	Payload size	Number of available message buffers	Maximum data rate (Mbit/s)
40	8	94	6.667
40	8	114	>5.0
40	12	>117	6.667
40	12	128	5.714
50	12–64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

59.3.12 Reset

You can reset FlexCAN in the following ways:

- Chip-level hard reset, which resets all memory-mapped registers asynchronously.
- Soft reset, in one of two ways:
  - MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. To see which registers soft reset affects, see Table 954.
  - Chip-level soft reset, which has the same effect as MCR[SOFTRST].

Soft reset is synchronous and must follow an internal request-and-acknowledge procedure across clock domains. Therefore, it may take some time to propagate its effects fully. MCR[SOFTRST] remains 1 when soft reset is pending, so software can poll this field to identify when the reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

The clock source should be selected when the module is in Disable mode (see CTRL1[CLKSRC]). After the clock source is selected and the module is enabled (MCR[MDIS] becomes 0), FlexCAN automatically enters Freeze mode. In Freeze mode:

1. FlexCAN is unsynchronized to the CAN bus.
2. MCR[HALT] and MCR[FRZ] become 1.
3. The internal state machines are disabled.
4. MCR[FRZACK] and MCR[NOTRDY] become 1.

The TX pin is in the recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Reset does not affect the message buffers and the RX Individual Mask registers, so they are not automatically initialized.

59.3.13 Interrupts

FlexCAN has many interrupt sources:

- Interrupts due to message buffers
- Interrupts due to interrupts combined via an OR operator from:
  - Message buffers
  - Bus Off
  - Bus Off Done
  - Error
  - Error Fast (errors detected in the data phase of CAN FD format messages with BRS = 1)
  - Wake Up
  - TX Warning
  - RX Warning

If its corresponding IMASK bit is 1, each message buffer can be an interrupt source. There is no distinction between TX and RX interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each buffer has an assigned flag bit in the IFLAG registers. When the corresponding buffer completes a successful transfer, the flag is set. When the CPU writes 1 to it, the flag is cleared (unless another interrupt is generated at the same time).

NOTE

The CPU must clear only the bit causing the current interrupt. For this reason, do not use bit manipulation instructions (BSET) to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt handler.

If the Legacy RX FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to message buffers 0–7 have different meanings.

- Bit 7 of Interrupt Flags 1 (IFLAG1) becomes the Legacy FIFO Overflow flag
- Bit 6 becomes the Legacy FIFO Warning flag

- Bit 5 becomes the Frames Available in Legacy FIFO flag
- Bits 4–0 are unused.

See Interrupt Flags 1 (IFLAG1) for more information.

If both Legacy RX FIFO and DMA are enabled (MCR[RFEN] = 1 and MCR[DMA] = 1), FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of IFLAG1 still indicates Frames Available in Legacy FIFO and generates a DMA request. Bits 7, 6, and 4–0 are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD is enabled.

When multiple message buffer interrupt sources are combined via an OR operator into a single interrupt, the interrupt is generated when any associated message buffer (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which message buffer or FIFO source caused the interrupt.

These interrupt sources generate interrupts like the message buffer interrupt sources, and can be read from Error and Status 1 (ESR1):

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Wake Up
- TX Warning
- RX Warning

The Bus Off, Error, TX Warning, and RX Warning interrupt masks are located in Control 1 (CTRL1); the wake-up interrupt mask is located in Module Configuration (MCR).

59.3.14 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers results in an access error. In Table 954, supervisor registers are registers identified with an S, and registers that are identified with S/U that are in Supervisor Mode
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only, no access error is issued. Write permission to specific positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in an access error.
- Read and write access to RAM-located positions during Low-Power mode results in an access error.
- The RXIMR memory region can be considered as general-purpose memory and available for access via these methods:
  - If you write 0 to MCR[IRMQ], the individual masks (RXIMR) are disabled. In this case, the RXIMR memory region is considered general-purpose memory.
  - If MCR[MAXMB] is programmed with a value smaller than the available number of message buffers, the unused memory space can be used as general-purpose RAM space. Reserved words within RAM cannot be used. For example, suppose the RAM in FlexCAN can support up to 16 message buffers, CTRL2[RFFN] = 0h, and MCR[MAXMB] = 0.
    - In this case, the maximum number of message buffers becomes one.
    - The RAM starts at 0080h, and the space 0080h–008Fh is used by the one message buffer.

- The memory space 0090h–017Fh is available.
- The space 0180h–087Fh is reserved.
- The space 0880h–0883h is used by the one individual mask and the available memory in the mask register space is 0884h–08BFh.
- In the space from 08C0h–09DFh, there are reserved words for internal use which cannot be used as general-purpose RAM.

As a rule, free memory space for general purpose depends only on MCR[MAXMB].

— If MCR[FDEN] = 1, general-purpose memory can be used only outside Freeze mode.

Table 952. Access permissions

1. Access in low power is only possible if RAM_clk and MODULE_CLK are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules in the rows below.
3. Write operation has no effect.
4. If MCR[RFEN] = 1, do not access Enhanced RX FIFO.

59.3.15 Detection and correction of memory errors

To update the parity bits in memory properly, all FlexCAN memory must be initialized before starting its operation. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize these registers:

- RX Message Buffers Global Mask (RXMGMASK)
- Receive 14 Mask (RX14MASK)
- Receive 15 Mask (RX15MASK)
- Legacy RX FIFO Global Mask (RXFGMASK)

MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated with five parity bits that ensure a Hamming distance of 4. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors). Errors in two bits can be detected but not corrected (uncorrectable errors). Errors in more than two bits may not be detected. For uncorrectable errors, the error correction logic does not change the corrupted data. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

When an all-zeroes or an all-ones read occurs, FlexCAN detects an uncorrectable error. See Error Report Syndrome (RERRSYNR).

Memory errors are indicated to the host via status register (Error Status (ERRSR)) and bus transfer errors. Memory errors are reported via these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)
- Error Report Syndrome (RERRSYNR)

MECR[ECCDIS] determines whether the error detection and correction mechanism can be activated. When disabled, updates on indications and reporting registers are stopped. To ensure that memory has consistent parity bits associated with the data, the parity bits are still calculated and written with data in memory write operations.

To avoid accidentally changing the critical error correction configuration, follow this protocol to enable the update of Memory Error Control (MECR):

1. Write 1 to CTRL2[ECRWRE]. (By default, CTRL2[ECRWRE] is 0 and MECR[ECRWRDIS] is 1.)
2. Write 0 to MECR[ECRWRDIS].
3. All writes to Memory Error Control (MECR) must keep MECR[ECRWRDIS] = 0.
4. After configuration is done, lock MECR by writing 1 to MECR[ECRWRDIS] or writing 0 to CTRL2[ECRWRE].

59.3.15.1 Sources of memory access

These major sources (or requestors) can access FlexCAN memory:

- Host (CPU). The largest word accessed is 32-bit.
- FlexCAN internal processes:
  - RX matching
  - TX arbitration
  - Move-in on reception
  - Move-out on transmission

  The largest word accessed is 64-bit.

The source of access determines the way that uncorrectable errors are indicated and reported.

59.3.15.2 Error indication

These flags indicate memory errors:

- ERRSR[HANCEIF]
- ERRSR[FANCEIF]
- ERRSR[CEIF]

Uncorrectable errors detected in memory reads requested by the host are indicated separately from the errors detected in requests by FlexCAN internal processes. When correctable errors are detected, FlexCAN makes no distinction of the source of the access. There are three independent flags for these three cases, and each flag raises an interrupt unless a mask in Memory Error Control (MECR) masks it. If both uncorrectable and correctable errors are found in different bytes in the same read operation, both flags are set.

An uncorrectable error detected in host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If ERRSR[HANCEIF] is not masked, the same uncorrectable error raises a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in Error Status (ERRSR). The overrun flags do not request interrupts. Overrun flags for uncorrectable errors indicate that other errors of the same nature were detected after the current error being treated. Overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated.

The recommended handling sequence for error indication is:

1. Get error report information from report registers.
2. Use this information to take proper measures in the application.
3. Clear the ERRSR[HANCEIF], ERRSR[FANCEIF], and ERRSR[CEIF] flags.
4. If the overrun flag is active:
    a. Alert the application that at least one error could not be managed.
    b. Clear the overrun flag.

FlexCAN internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in two or more 32-bit words, the interrupt and overrun flags are set simultaneously.

59.3.15.3 Error reporting

The error report registers provide detailed information about the address read, raw data, and syndrome read with error. The flags described in Error indication indicate these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)
- Error Report Syndrome (RERRSYNR)

The address, data, and syndrome registers are updated simultaneously with the error flags, according to these rules:

1. If either of the uncorrectable error flags is set, the report registers are not updated. The previous uncorrectable error reporting is preserved.
2. Otherwise, either no error flag is set or only the correctable error flag is set. The report registers are updated according to the new error, or according to the most severe new error, if uncorrectable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32 bits follows the rules described in Error indication and in the description of Error Report Address (RERRAR).

The addresses reported in RERRAR and defined in ERRIAR are not the same as the addresses listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the description of Error Injection Address (ERRIAR).

Addresses reported when reading memory portions organized as FIFOs refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address. Such memory portions include:

- Legacy RX FIFO Structure
- Enhanced RX FIFO Structure
- Legacy RX FIFO Information (RXFIR)

To ensure coherence of error report registers, disable the report update by writing 1 to MECR[RERRDIS] before reading the report registers.

59.3.15.4 Error response

Correctable errors have no consequence to FlexCAN operation because the host or FlexCAN internal processes corrects affected data before its use.

For host-initiated reads, an uncorrectable error may affect the host, but does not affect FlexCAN operation.

Uncorrectable errors detected on memory read operations requested by FlexCAN internal processes may result in incorrect operation depending on the state of MECR[NCEFAFRZ], as follows:

- During reception (either matching or move-in process), when an uncorrectable error occurs:
  - An incorrect destination may be selected to store the incoming frame.
  - A corrupted frame may be stored in the correct destination.
  - Both of these events may occur.

  If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. If MECR[NCEFAFRZ] = 0, FlexCAN continues working, and a corrupted frame is received.
- During arbitration, when an uncorrectable error occurs:
  - A non-highest-priority TX message buffer may be mistakenly selected for transmission.
  - Its data may be corrupted.

  If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the move-out. If MECR[NCEFAFRZ] = 0, FlexCAN proceeds to move-out with a corrupted frame that will be transmitted on the CAN bus.
- During move-out, when an uncorrectable error occurs, a corrupted frame is copied from the selected TX MB that won the arbitration to the TX SMB for transmission. If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the transmission. When MECR[NCEFAFRZ] = 0, the corrupted frame is transferred from the TX SMB to the Protocol Engine (PE) subblock and is transmitted on the CAN bus.
- An uncorrectable error can also be detected beyond move-out, when TX data is read from TX SMB (buffer located in RAM) to be transferred to the PE subblock for transmission. In this case, a frame with corrupted ID or data is transmitted on the CAN bus.

  To prevent the external nodes from successfully receiving the frame, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC delimiter). Also, it transmits an error flag just after CRC delimiter due to self-detecting a Bit1 error and a form error due to the CRC field inversion. When MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode just after the error frame. When MECR[NCEFAFRZ] = 0, FlexCAN may attempt to retransmit the same frame, as long as no other higher-priority TX MB is configured for transmission after.

  If the uncorrectable error persists, FlexCAN eventually reaches the Bus Off state due to consecutive error detections. ECR[TXERRCNT] is updated every time FlexCAN inverts the CRC field, causing errors as described above.

When MECR[NCEFAFRZ] = 1 and FlexCAN enters Freeze mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal mode. MECR[NCEFAFRZ] becoming 1 is the only way to prevent corrupted frames from being transmitted on the CAN bus to the move-out internal process.

The error report registers can provide information to the application for customized management of these situations.

59.3.15.5 Error injection

These error injection registers are used to inject errors in memory reads to force errors and update the indication and reporting registers:

- Error Injection Address (ERRIAR)
- Error Injection Data Pattern (ERRIDPR)
- Error Injection Parity Pattern (ERRIPPR)

The relation between the error injection addresses and the corresponding addresses in the module memory map is shown in Error Injection Address (ERRIAR).

The injection is done by flipping the data and parity bits corresponding to the bits set to 1 in ERRIDPR and ERRIPPR. You can select injection specifically for memory accesses requested by the host or by FlexCAN internal processes.

For accesses larger than 32 bits, MECR[EXTERRIE] extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is possible, but very unlikely, for error injection to correct a bit with error. This correction does not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, you must clear MECR[HAERRIE] and MECR[FAERRIE] when configuring the memory injection registers.

59.4 External signal descriptions

FlexCAN has two I/O signals connected to the external chip pins. These signals are summarized in Table 953 and described in the following subsections.

Table 953. FlexCAN signal descriptions

Signal	Description	I/O
CAN RX	CAN receive pin	Input
CAN TX	CAN transmit pin	Output

59.4.1 CAN RX

This pin is the receive pin from the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

59.4.2 CAN TX

This pin is the transmit pin to the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

59.5 Initialization and application information

59.5.1 FlexCAN initialization sequence

For any configuration change or initialization, you must put FlexCAN into Freeze mode (see Freeze mode). The module must be initialized after every reset. FlexCAN memory must be initialized before switching to functional mode.

The following is a generic initialization sequence applicable to FlexCAN:

1. Initialize Module Configuration (MCR).
    a. Enable the individual filtering per message buffer and reception queue features by writing 1 to MCR[IRMQ].
    b. Enable the warning interrupts by writing 1 to MCR[WRNEN].
    c. If required, disable frame self-reception by writing 1 to MCR[SRXDIS].
    d. Enable the Legacy RX FIFO by writing 1 to MCR[RFEN] or enable the Enhanced RX FIFO by writing 1 to ERFCR[ERFEN].
    e. If Legacy RX FIFO or Enhanced RX FIFO is enabled and DMA is required, write 1 to MCR[DMA].
    f. Enable the abort mechanism by writing 1 to MCR[AEN].

g. Enable the local priority feature by writing 1 to MCR[LPRIOEN].

2. Initialize Control 1 (CTRL1) and CAN FD Bit Timing (FDCBT). Optionally initialize CAN Bit Timing (CBT).
   a. Determine the bit timing parameters: CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW].
   b. Optionally determine the bit timing parameters: CBT[EPROPSEG], CBT[EPSEG1], CBT[EPSEG2], and CBT[ERJW].
   c. Determine the CAN FD bit timing parameters: FDCBT[FPROPSEG], FDCBT[FPSEG1], FDCBT[FPSEG2], and FDCBT[FRJW].
   d. Determine the bit rate by programming CTRL1[PRESDIV] and optionally programming CBT[EPRESDIV].
   e. Determine the CAN FD bit rate by programming FDCBT[FPRESDIV].
   f. Determine the internal arbitration mode by programming CTRL1[LBUF].
3. If Error Code Correction (ECC) is enabled, you must initialize all FlexCAN memory. See Detection and correction of memory errors.
4. Initialize the message buffers. (See Message buffer structure for message buffer details.)
   a. The control and status word of all message buffers must be initialized.
   b. If RX FIFO is enabled, the ID filter table must be initialized.
   c. Other entries in each message buffer should be initialized as required.
5. Initialize Receive Individual Mask (RXIMR0 - RXIMR95).
6. Write 1 to required interrupt mask bits in:
   - IMASK registers (for all message buffer interrupts)
   - Module Configuration (MCR) (for wake-up interrupt)
   - Control 1 (CTRL1) and Control 2 (CTRL2) (for Bus Off and Error interrupts)
7. Write 0 to MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

59.6 Memory map and register definition

This section describes the registers and data structures in FlexCAN. The base address of the module depends on the particular memory map of the chip.

59.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of Table 954.

NOTE

An invalid register access results in a bus error. Invalid accesses include reading a write-only register, writing a read-only register, and accessing an invalid address.

NOTE

To update the parity bits in memory properly, all FlexCAN memory must be initialized before reading registers which are implemented in memory. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK) and Legacy RX FIFO Global Mask (RXFGMASK). MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

Table 954. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration (MCR)	S	Yes	Yes
Control 1 (CTRL1)	S/U	Yes	No
Free-Running Timer (TIMER)	S/U	Yes	Yes
RX Message buffers Global Mask (RXMGMASK)	S/U	No	No
RX Buffer 14 Mask (RX14MASK)	S/U	No	No
RX Buffer 15 Mask (RX15MASK)	S/U	No	No
Error Counter (ECR)	S/U	Yes	Yes
Error and Status 1 (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 (IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 (IFLAG1)	S/U	Yes	Yes
Control 2 (CTRL2)	S/U	Yes	No
Error and Status 2 (ESR2)	S/U	Yes	Yes
Cyclic Redundancy Check (CRCR)	S/U	Yes	Yes
RX FIFO Global Mask (RXFGMASK)	S/U	No	No
RX FIFO Information (RXFIR)	S/U	No	No
CAN Bit Timing (CBT)	S/U	Yes	No
Interrupt Masks 3 (IMASK3)	S/U	Yes	Yes
Interrupt Flags 3 (IFLAG3)	S/U	Yes	Yes
Message buffers	S/U	No	No

Table continues on the next page...

Table 954. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
RX Individual Masks	S/U	No	No
Memory Error Control (MECR)	S/U	Yes	Yes
Error Injection Address (ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern (ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern (ERRIPPR)	S/U	Yes	Yes
Error Report Address (RERRAR)	S/U	Yes	Yes
Error Report Data (RERRDR)	S/U	Yes	Yes
Error Report Syndrome (RERRSYNR)	S/U	Yes	Yes
Error Status (ERRSR)	S/U	Yes	Yes
Enhanced CAN Bit Timing Prescalers (EPRS)	S/U	Yes	No
Enhanced Nominal CAN Bit Timing (ENCBT)	S/U	Yes	No
Enhanced Data Phase CAN bit Timing (EDCBT)	S/U	Yes	No
Enhanced Transceiver Delay Compensation (ETDC)	S/U	Yes	No
CAN FD Control (FDCTRL)	S/U	Yes	No
CAN FD Bit Timing (FDCBT)	S/U	Yes	No
CAN FD CRC (FDCRC)	S/U	Yes	Yes
Enhanced RX FIFO Control (ERFCR)	S/U	Yes	Yes
Enhanced RX FIFO Interrupt Enable (ERFIER)	S/U	Yes	Yes
Enhanced RX FIFO Status (ERFSR)	S/U	Yes	Yes
High-Resolution Timestamp (HR_TIME_STAMP)	S/U	No	No
Enhanced RX FIFO	S/U	No	No
Enhanced RX FIFO Filter Element (ERFFEL)	S/U	No	No

FlexCAN can store CAN messages for transmission and reception using message buffers and RX FIFO structures.

59.6.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–67Fh allocates the ninety-six 128-bit message buffers. The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–204Ch allocates the Enhanced RX FIFO output, and the address range from offset 2050h–263Ch allocates the rest of Enhanced RX FIFO 19 elements. The memory map for the Enhanced RX FIFO is in Enhanced RX FIFO structure.

59.6.2.1 CAN memory map

CAN1 base address: 443A_0000h

CAN2 base address: 425B_0000h

CAN3 base address: 445B_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration (MCR)	32	RW	5980_000Fh

59.6.2.2 Module Configuration (MCR)

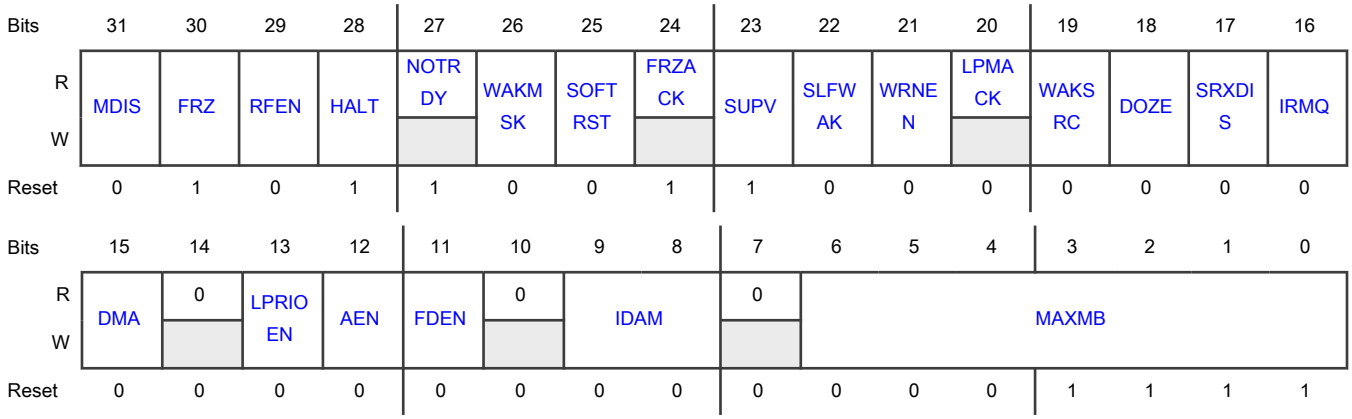
Offset

Register	Offset
MCR	0h

Function

Defines global system configurations, including the module operation modes and the maximum message buffer configuration.

Diagram



Fields

Field	Function
31 MDIS	Module Disable Disables FlexCAN. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Soft reset does not affect this field. 0b - Enable 1b - Disable
30 FRZ	Freeze Enable Specifies FlexCAN behavior when MCR[HALT] = 1 or when Debug mode is requested at chip level. When this field becomes 1, FlexCAN can enter Freeze mode. Writing 0 to this field causes FlexCAN to exit from Freeze mode. The chip writes 1 to this field when a noncorrectable error is detected (MECR[NCEFAFRZ] becomes 1). 0b - Disable 1b - Enable
29 RFEN	Legacy RX FIFO Enable Enables the Legacy RX FIFO feature. When this field is 1, message buffers 0–5 cannot be used for normal reception and transmission. The corresponding memory region (80h–DCh) is used by the FIFO engine and additional message buffers (up to 32, depending on CTRL2[RFFN]). These message buffers are used as Legacy RX FIFO ID filter table elements. This field also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 949. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** When CAN FD operation is enabled (see MCR[FDEN]), you cannot write 1 to this field. **NOTE** This field must not be 1 if ERFCR[ERFEN] = 1. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 HALT	Halt FlexCAN Puts FlexCAN into Freeze mode. The CPU should write 0 to this field after initializing the message buffers and Control 1 (CTRL1) and Control 2 (CTRL2). FlexCAN performs no reception or transmission before this field becomes 0. Freeze mode cannot be entered when FlexCAN is in a low-power mode. The module writes 1 to this field when a noncorrectable error is detected and MECR[NCEFAFRZ] = 1. 0b - No request 1b - Enter Freeze mode, if MCR[FRZ] = 1.
27 NOTRDY	FlexCAN Not Ready Indicates whether FlexCAN is in Disable mode, Doze mode, Stop mode or Freeze mode. When FlexCAN has exited these modes, this field becomes 0. Soft reset does not affect this field. 0b - FlexCAN is in Normal mode, Listen-Only mode, or Loopback mode. 1b - FlexCAN is in Disable mode, Doze mode, Stop mode, or Freeze mode.
26 WAKMSK	Wake-up Interrupt Mask Enables the wake-up interrupt generation under the Self Wake-Up mechanism. 0b - Disabled 1b - Enabled
25 SOFTRST	Soft Reset Resets internal state machines of FlexCAN and some memory-mapped registers. The CPU can write 1 to this field directly. This field also becomes 1 when global soft reset is requested at the chip level. Because soft reset is synchronous and must follow a request-and-acknowledge procedure across clock domains, it may take some time to propagate its effect fully. When reset is pending, this field remains 1; it automatically becomes 0 when reset completes. You can poll this field to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. Transfer the module out of the low-power mode before applying soft reset. Soft reset does not affect this field. **NOTE** This field becomes 0 within 2 CAN bits after assertion of this bit. 0b - No reset 1b - Soft reset affects reset registers
24 FRZACK	Freeze Mode Acknowledge Indicates whether FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore you can poll this field to know when FlexCAN has entered Freeze mode. If the Freeze mode request is negated, this field becomes 0 after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low-power mode, this field becomes 1 only when the low-power mode is exited. See Freeze mode. Soft reset does not affect this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE FRZACK becomes 1 within 178 CAN bits following the Freeze mode request by the CPU. This field becomes 0 within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0b - Not in Freeze mode, prescaler running. 1b - In Freeze mode, prescaler stopped.
23 SUPV	Supervisor Mode Configures FlexCAN to be either in Supervisor or User mode. The registers that this field affects are marked as S/U in the Access type column of Table 954. The affected registers start with Supervisor access allowance only. In User mode, affected registers allow both Supervisor and Unrestricted accesses. In Supervisor mode, affected registers allow only Supervisor access. Unrestricted access behaves as though the access is performed on an unimplemented register location. This field can be written only in Freeze mode; the module blocks it in other modes. 0b - User mode 1b - Supervisor mode
22 SLFWAK	Self Wake-up Enables the Self Wake-up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for a wake-up event (that is, a recessive-to-dominant transition). If a wake-up event is detected during Doze mode, FlexCAN requests to resume its clocks. If enabled to do so, it also generates a wake-up interrupt to the CPU. If a wake-up event is detected during Stop mode, FlexCAN generates, if enabled to do so, a wake-up interrupt to the CPU. The CPU can exit Stop mode globally and FlexCAN can request to resume the clocks. When FlexCAN is in a low-power mode other than Disable mode, this field cannot be written, as the module blocks it. 0b - Disable 1b - Enable
21 WRNEN	Warning Interrupt Enable Enables the generation of the flags ESR1[TWRNINT] and ESR1[RWRNINT]. When this field is 1, TWRNINT and RWRNINT flags are set when the respective error counter transitions from less than 96 to greater than or equal to 96. When this field is 0, the TWRNINT and RWRNINT flags are always zero, independent of the values of the error counters. No warning interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
20	Low-Power Mode Acknowledge

Table continues on the next page...

Table continued from the previous page...

Field	Function
LPMACK	Indicates whether FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission and reception processes have finished. The CPU can poll this field to know when FlexCAN has entered low-power mode. Soft reset does not affect this field. **NOTE** This field becomes 1 within 180 CAN bits after the low-power mode request by the CPU. This field becomes 0 within 2 CAN bits after the low-power mode request removal (see Protocol timing). 0b - Not in a low-power mode 1b - In a low-power mode
19 WAKSRC	Wake-Up Source Determines whether the integrated low-pass filter is applied to the RX input that FlexCAN uses to detect recessive-to-dominant edges on the CAN bus. This filter can protect the RX CAN input from spurious wake-up. This field can be written only in Freeze mode. The module blocks it in other modes. 0b - No filter applied 1b - Filter applied
18 DOZE	Doze Mode Enable Determines whether FlexCAN can enter low-power mode when Doze mode is requested at chip level. This field is automatically reset when FlexCAN wakes from Doze mode upon detecting activity on the CAN bus (self wake-up enabled). 0b - Disable 1b - Enable
17 SRXDIS	Self-Reception Disable Determines whether FlexCAN can receive frames transmitted by itself. If 1, frames transmitted by the module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. This field can be written only in Freeze mode; the module blocks it in other modes. 0b - Enable 1b - Disable
16 IRMQ	Individual RX Masking and Queue Enable Indicates whether RX matching process is based on individual masking and queue, or based on a masking scheme with RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK), and Legacy RX FIFO Global Mask (RXFGMASK). When this field is disabled, for backward compatibility with legacy applications, reading the Control and Status word locks the MB even if it is empty. This field can be written in Freeze mode only. The module blocks it in other modes. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
15 DMA	DMA Enable Enables DMA. The DMA feature can only be used in Legacy RX FIFO or Enhanced RX FIFO, so MCR[RFEN] or ERFCR[ERFEN] must be 1. When DMA and RFEN are 1, IFLAG1[BUF5I] generates the DMA request, and no RX FIFO interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
14 —	Reserved
13 LPRIOEN	Local Priority Enable Enables the local priority feature. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word. However, the actual transmitted ID is 11 bits for standard frames and 29 bits for extended frames. This field can be written only in Freeze mode; the module blocks it in other modes. This bit is provided for backward compatibility with legacy applications. 0b - Disable 1b - Enable
12 AEN	Abort Enable Enables the TX abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** When this field is 1, only use the abort mechanism (see Transmission abort mechanism) to update message buffers configured for transmission. **CAUTION** Writing the abort code into RX message buffers can cause unpredictable results when this field is 1. 0b - Disabled 1b - Enabled
11 FDEN	CAN FD Operation Enable Enables the CAN with flexible data rate (CAN FD) operation. This field can be written in Freeze mode only. FlexCAN can receive and transmit messages in CAN 2.0 format. If this field is enabled, FlexCAN can also receive and transmit messages in CAN FD format. FlexCAN can transmit FD frame format according to ISO 11898-1:2015.

Table continued from the previous page...

Field	Function
	NOTE If the value of this field is 1, the Legacy RX FIFO Enable (MCR[RFEN]) field cannot be 1. 0b - Disable 1b - Enable
10 —	Reserved
9-8 IDAM	ID Acceptance Mode Identifies the format of the Legacy RX FIFO ID filter table elements. This field configures all elements of the table at the same time; they are all the same format. See Legacy RX FIFO structure. This field can be written only in Freeze mode; the module blocks it in other modes. 00b - Format A: One full ID (standard and extended) per ID filter table element. 01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10b - Format C: Four partial 8-bit standard IDs per ID filter table element. 11b - Format D: All frames rejected.
7 —	Reserved
6-0 MAXMB	Number of the Last Message Buffer Defines the number of the last message buffer that takes part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16-MB configuration. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** You must write a value smaller than or equal to the number of available message buffers to this field, as described in FlexCAN memory partition for CAN FD. Additionally, the MAXMB value must consider the region of message buffers occupied by Legacy RX FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit, as described in Table 949.

59.6.2.3 Control 1 (CTRL1)

Offset

Register	Offset
CTRL1	4h

Function

Contains specific FlexCAN control features related to the CAN bus. These features include bit rate, programmable sampling point within an RX bit, Loopback mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW]) can also be configured in CAN Bit Timing (CBT), which extends the range of all these variables. If CBT[BTF] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] become read-only.

If CTRL2[BTE] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are not used by the module. Instead, these fields are read as zero, and a write operation to them has no effect.

NOTE

When the CAN FD feature is enabled, do not use CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] for CAN bit timing. Instead use CBT[EPRESDIV], CBT[ERJW], CBT[EPSEG1], CBT[EPSEG2], and CBT[EPROPSEG].

The CAN bit variables in CTRL1 and in CBT are stored in the same internal register.

Soft reset does not affect the contents of this register.

Diagram

Fields

Field	Function
31-24 PRESDIV	Prescaler Division Factor Determines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (PRESDIV + 1).
23-22 RJW	Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time. One time quantum is equal to one Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 Defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. PhaseBuffer Segment 1 = (PSEG1 + 1) × Time Quanta.
18-16 PSEG2	Phase Segment 2 Defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time Quanta.
15 BOFFMSK	Bus Off Interrupt Mask Provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0b - Interrupt disabled 1b - Interrupt enabled
14 ERRMSK	Error Interrupt Mask Provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Interrupt disabled 1b - Interrupt enabled
13 CLKSRC	CAN Engine Clock Source Selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock or the oscillator clock. When the oscillator clock is selected, the oscillator clock frequency must be lower than the bus clock. The selected clock is fed to the prescaler to generate the serial clock (Sclock). To guarantee reliable operation, this field can be written only in Disable mode. The module blocks it in other modes. See Protocol timing. Ensure the protocol engine clock tolerance according to the CAN Protocol standard (ISO 11898-1:2015). To identify the proper clock source, see the clock distribution chapter (module clocks table). If this field is 0, you can further select the peripheral clock source according to the Clock Root section of CCM chapter. 0b - Peripheral clock 1b - Bus clock
12 LPB	Loopback Mode Configures FlexCAN to operate in Loopback mode. In this mode, FlexCAN performs an internal loopback that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The RX CAN input pin is ignored and the TX CAN output goes to the recessive state (logic

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. It generates an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot become 1, because it would impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and MCR[ETDCEN] must be 0 when this field is 1. 0b - Disabled 1b - Enabled
11 TWRNMSK	TX Warning Interrupt Mask Provides a mask for the TX Warning interrupt associated with the ESR1[TWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled 1b - Enabled
10 RWRNMSK	RX Warning Interrupt Mask Provides a mask for the RX Warning interrupt associated with the ESR1[RWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled 1b - Enabled
9 —	Reserved
8 —	Reserved
7 SMP	CAN Bit Sampling Determines the sampling mode of CAN bits at the RX input. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** For proper operation, to write 1 to this field, you must guarantee a minimum value of two time quanta in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot become 1 when CAN FD is enabled (MCR[FDEN] = 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - One sample is used to determine the bit value. 1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples. A majority rule is used.
6 BOFFREC	Bus Off Recovery Determines how FlexCAN recovers from Bus Off state. If 0, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If 1, automatic recovering from Bus Off is disabled. The module remains in Bus Off state until you write 1 to this field. If this field becomes 0 before 128 sequences of 11 recessive bits are detected on the CAN bus, Bus Off recovery happens as if this field had never become 1. If this field becomes 0 after 128 sequences of 11 recessive bits occurred, FlexCAN resynchronizes to the bus. It waits for 11 recessive bits before joining the bus. After this field becomes 0, it can become 1 again during Bus Off, but it will only be effective the next time the module enters Bus Off. If this field becomes 0 when the module is in Bus Off, writing 1 to this field is not effective for the current Bus Off recovery. **NOTE** See Bus Off in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Enabled 1b - Disabled
5 TSYN	Timer Sync Enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides the means to synchronize multiple FlexCAN stations with a special "SYNC" message (that is, global network time). If MCR[RFEN] = 1 (Legacy RX FIFO enabled), the first available message buffer, according to CTRL2[RFFN], is used for timer synchronization instead of MB0. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
4 LBUF	Lowest Buffer Transmitted First Determines the ordering mechanism for message buffer transmission. When 1, MCR[LPRIOEN] does not affect the priority arbitration. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Buffer with highest priority is transmitted first. 1b - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode Configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in Error Counter (ECR) are frozen, and the module operates in CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it is trying to acknowledge the message.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	FlexCAN acknowledges Listen-Only mode when ESR1[FLTCONF] = 1, indicating the Error Passive state. There can be some delay between the Listen-Only mode request and its acknowledgment. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Listen-Only mode is deactivated. 1b - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment Defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation segment time = (PROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.

59.6.2.4 Free-Running Timer (TIMER)

Offset

Register	Offset
TIMER	8h

Function

Represents a 16-bit free-running counter that the CPU can read and write. The timer starts from 0h after reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously increments the timer. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] = 0, the CAN bit clock increments the timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop and Freeze modes.

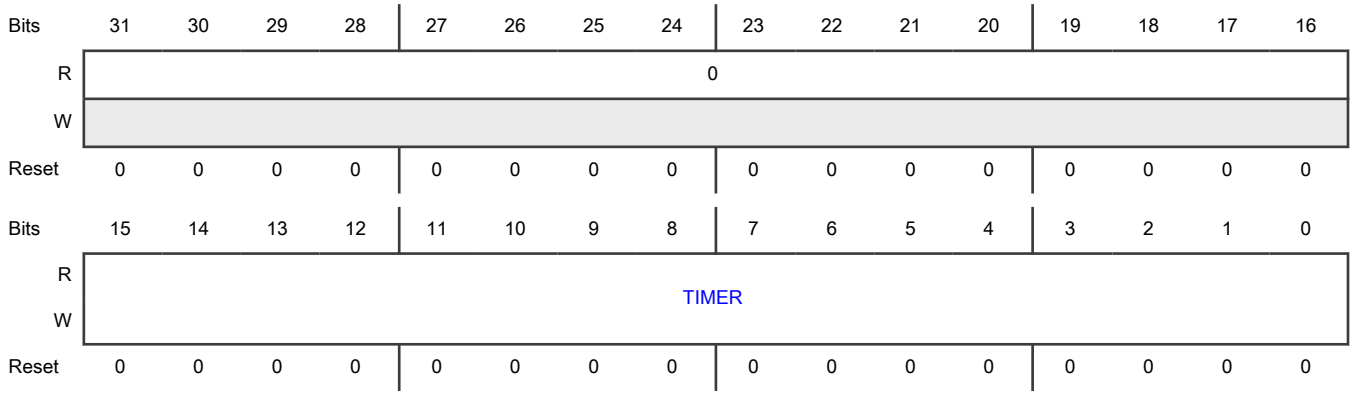
The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the timestamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] = 1, the timer is reset whenever a message is received in the first available message buffer, according to CTRL2[RFFN].

The CPU can write to this register anytime. However, if the write occurs simultaneously with the timer being reset by a reception in the first message buffer, the write value is discarded.

Reading this register affects the message buffer unlocking procedure (see Message buffer lock mechanism).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 TIMER	Timer Value Contains the free-running counter value.

59.6.2.5 RX Message Buffers Global Mask (RXMGMASK)

Offset

Register	Offset
RXMGMASK	10h

Function

Masks the filter bits of all RX message buffers, excluding MB14 and MB15, which have individual mask registers.

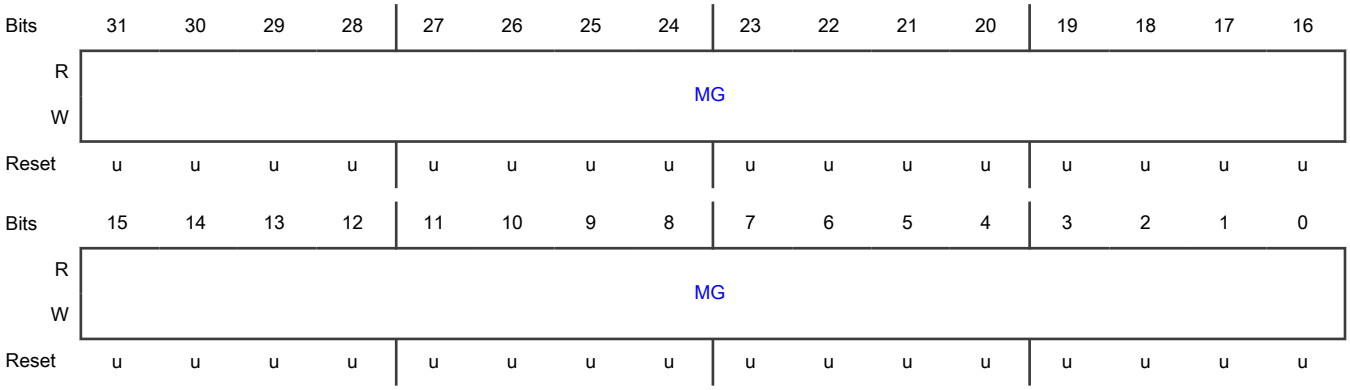
This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is 0, RXMGMASK is always in effect. The bits in RXMGMASK[MG] mask the MB filter bits.
- When MCR[IRMQ] is 1, RXMGMASK has no effect. The bits in RXMGMASK[MG] do not mask the MB filter bits.

This register can only be written in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 MG	Global Mask for RX Message Buffers Masks the message buffer filter bits. The alignment with the ID word of the message buffer is imperfect. The two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the MB. The following table shows which MG bits mask each MB filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Message buffer filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	Note [2]	Note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called RX serial message buffer (RX SMB).
2. If CTRL2[EACEN] is 0, the RTR bit of MB is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is 0, the IDE bit of MB is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."

1b - The corresponding bit in the filter is checked.

59.6.2.6 Receive 14 Mask (RX14MASK)

Offset

Register	Offset
RX14MASK	14h

Function

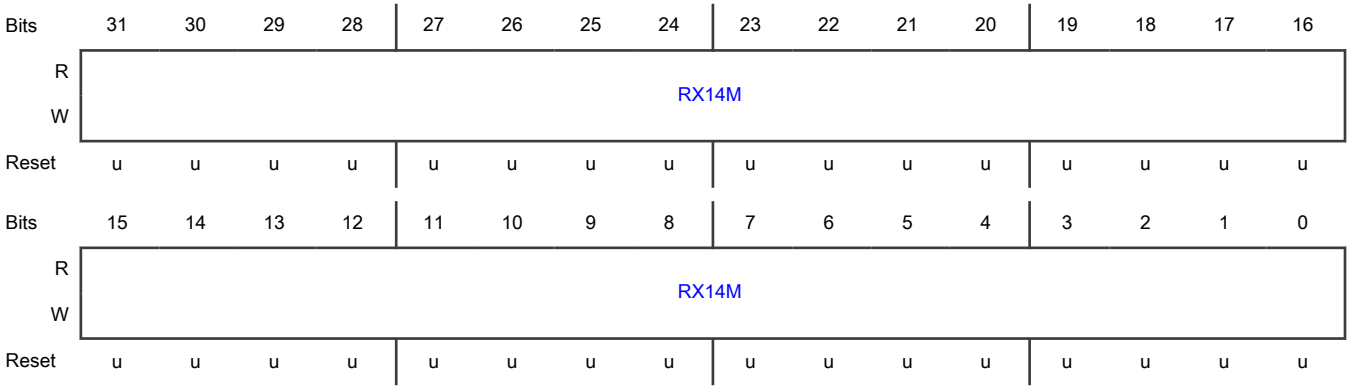
Masks the filter fields of MB14.

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX14MASK has no effect.

This register can only be programmed when the module is in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 RX14M	RX Buffer 14 Mask Bits Masks the corresponding MB14 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of the other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

59.6.2.7 Receive 15 Mask (RX15MASK)

Offset

Register	Offset
RX15MASK	18h

Function

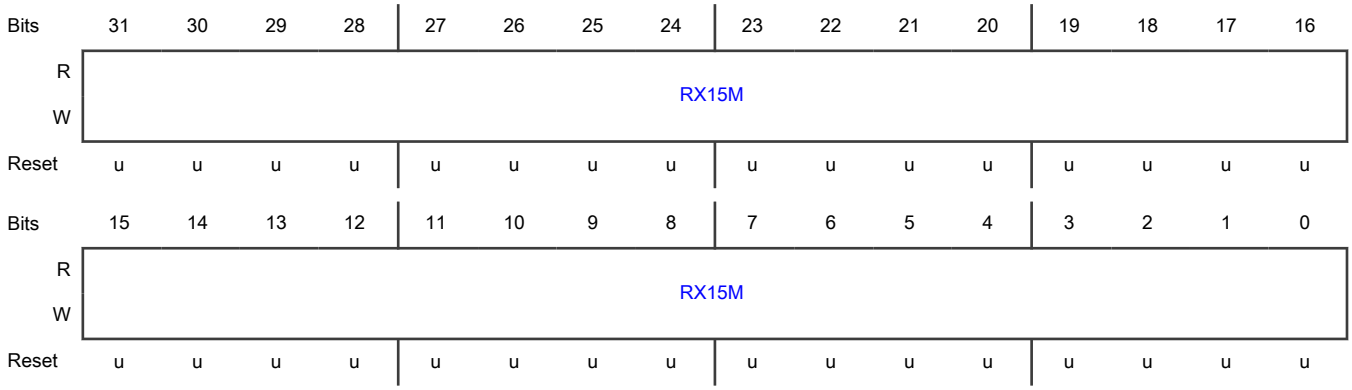
Masks the filter fields of MB15.

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX15MASK has no effect.

This register can be programmed only when the module is in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 RX15M	RX Buffer 15 Mask Bits Masks the corresponding MB15 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

59.6.2.8 Error Counter (ECR)

Offset

Register	Offset
ECR	1Ch

Function

Contains error counters for received and transmitted messages.

TXERRCNT and RXERRCNT consider all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST count only the errors that occur in the data phase of CAN FD frames that have BRS = 1.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. The rules for increasing and decreasing these counters are described in the CAN protocol and are entirely implemented in FlexCAN.

The basic rules for FlexCAN bus state transitions are:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the state of FlexCAN is Error Passive, and TXERRCNT or RXERRCNT decrements to a value less than 128 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off, TXERRCNT is cascaded with another internal counter to count the occurrences of 11 consecutive recessive bits on the bus. TXERRCNT is reset to zero. It counts in a manner where the internal counter

counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to Error Active, and both error counters are reset to zero. Upon any instance of a dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.

- If only one node is operating during system startup, its TXERRCNT increases upon each attempted message transmission, as a result of acknowledge errors (indicated by ESR1[ACKERR]). After the transition to Error Passive state, TXERRCNT no longer increments upon acknowledge errors. The chip never goes into the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to the Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames that have BRS = 1. These counters follow the same increment and decrement rules as TXERRCNT and RXERRCNT. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in the Bus Off state. They are reset when FlexCAN leaves the Bus Off state and resume counting after FlexCAN returns to the Error Active state.

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Function
31-24 RXERRCNT_FAST	Receive Error Counter for Fast Bits Counts errors detected in the data phase of received CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for Fast Bits Counts errors detected in the data phase of transmitted CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Counts all errors detected in received messages. This field is read-only except in Freeze mode, when the CPU can write to it.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 TXERRCNT	Transmit Error Counter Counts all errors detected in transmitted messages. This field is read-only except in Freeze mode, when the CPU can write to it.

59.6.2.9 Error and Status 1 (ESR1)

Offset

Register	Offset
ESR1	20h

Function

Reports various error conditions detected in the reception and transmission of a CAN frame. This register provides status information about the chip, and is the source of some interrupts to the CPU. The reported error conditions are:

NOTE

Reading host can clear these fields.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

One or more error flags may report an error detected in a single CAN frame. To account for more error events occurring in subsequent frames when the CPU does not attempt to read this register, error reporting is cumulative.

Status flags:

- TXWRN
- RXWRN
- IDLE
- TX

- FLTCONF
- RX
- SYNCH

Interrupt flags:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST
- WAKINT
- TWRNINT
- RWRNINT

The CPU should follow this procedure when servicing interrupt requests generated by these flags:

1. Read this register to capture all error condition and status flags. This action clears the respective flags that were set since the last read access.
2. Write 1 to clear the interrupt flag that triggered the interrupt request.
3. Write 1 to clear the ERROVR flag, if it is set.

Starting from all error flags cleared, a first error event sets either ERRINT or ERRINT_FAST (provided the corresponding mask bit is 1). If other error events in subsequent frames occur before the CPU serves the interrupt request, the ERROVR flag is set to indicate that errors from different frames have accumulated.

Table 955. CAN bus status

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	X	X	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Function
31 BIT1ERR_FAST	Fast Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as recessive is received as dominant.
30 BIT0ERR_FAST	Fast Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Fast Cyclic Redundancy Check Error Flag Indicates that the receiver node has detected a CRC error in the CRC field of CAN FD frames that have BRS = 1. This error means that the calculated CRC is different from the received CRC. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
27	Fast Form Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRMERR_FAST	Indicates whether the receiver node has detected a form error in the data phase of CAN FD frames that have BRS = 1. This error means that a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A form error occurred since last read of this register.
26 STFERR_FAST	Fast Stuffing Error Flag Indicates that a stuffing error has been detected in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
25-24 —	Reserved
23 —	Reserved
22 —	Reserved
21 ERROVR	Error Overrun Flag Indicates that an error condition occurred when any error flag is already set. 0b - No overrun 1b - Overrun
20 ERRINT_FAST	Fast Error Interrupt Flag Indicates that at least one error flag detected in the data phase of CAN FD frames that have BRS = 1 (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If CTRL2[ERRMSK_FAST] = 1, an interrupt is generated to the CPU. 0b - No such occurrence. 1b - Error flag set in the data phase of CAN FD frames that have BRS = 1.
19 BOFFDONEINT	Bus Off Done Interrupt Flag Indicates whether ECR[TXERRCNT] has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If CTRL2[BOFFDONEMSK] = 1, an interrupt is generated to the CPU. 0b - No such occurrence 1b - FlexCAN module has completed Bus Off process.
18	CAN Synchronization Status Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
SYNCH	Indicates whether FlexCAN is synchronized to the CAN bus and able to participate in the communication process. FlexCAN sets and clears this flag. See the table in Error and Status 1 (ESR1). 0b - Not synchronized 1b - Synchronized
17 TWRNINT	TX Warning Interrupt Flag Indicates whether TX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the TXWRN flag transitions from 0 to 1, meaning that the TX error counters reached 96. If CTRL1[TWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not generated when in the Bus Off state. This flag is not updated during Freeze mode. 0b - No such occurrence 1b - TX error counter changed from less than 96 to greater than or equal to 96.
16 RWRNINT	RX Warning Interrupt Flag Indicates whether the RX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the RXWRN flag transitions from 0 to 1, meaning that the RX error counters reached 96. If CTRL1[RWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not updated during Freeze mode. 0b - No such occurrence 1b - RX error counter changed from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. **NOTE** A transmitter does not set this flag for an arbitration field or ACK slot. It is not set for a node sending a error passive flag that detects dominant bits. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. After a read operation, the field's value clears to 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error Flag Indicates whether the transmitter node has detected an acknowledge error. This error means that a dominant bit has not been detected during the ACK SLOT. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error Flag Indicates whether the receiver node has detected a cyclic redundancy check (CRC) error either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format. This error means that the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
11 FRMERR	Form Error Flag Indicates whether a form error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This error means that a fixed-form field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
10 STFERR	Stuffing Error Flag Indicates that a stuffing error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
9 TXWRN	TX Error Warning Flag Indicates when repetitive errors occur during message transmission. Only the value of ECR[TXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - TXERRCNT is 96 or greater.

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 RXWRN	RX Error Warning Flag Indicates when repetitive errors occur during message reception. Only the value of ECR[RXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - RXERRCNT is greater than or equal to 96.
7 IDLE	Idle Indicates whether CAN bus is in IDLE state. See Table 955. 0b - Not IDLE 1b - IDLE
6 TX	FlexCAN In Transmission Indicates whether FlexCAN is transmitting a message. See Table 955. 0b - Not transmitting 1b - Transmitting
5-4 FLTCONF	Fault Confinement State Indicates the confinement state of FlexCAN. If CTRL1[LOM] = 1, after a delay that depends on the CAN bit timing, this field indicates Error Passive. The same delay affects the way that this field reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time for coherence to be restored. Soft reset affects this field, but if CTRL1[LOM] = 1, its reset value lasts for only one CAN bit. After that time, this field reports Error Passive. 00b - Error Active 01b - Error Passive 1xb - Bus Off
3 RX	FlexCAN in Reception Flag Indicates whether FlexCAN is receiving a message. See the table in Error and Status 1 (ESR1). 0b - Not receiving 1b - Receiving
2 BOFFINT	Bus Off Interrupt Flag Indicates whether FlexCAN has entered Bus Off state. If CTRL1[BOFFMSK]) = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - FlexCAN module entered Bus Off state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 ERRINT	Error Interrupt Flag Indicates that at least one of the error flags (ESR1[BIT1ERR], ESR1[BIT0ERR], ESR1[ACKERR], ESR1[CRCERR], ESR1[FRMERR], or ESR1[STFERR]) is set. If the corresponding mask CTRL1[ERRMSK] = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - Indicates setting of any error flag in the Error and Status register.
0 WAKINT	Wake-up Interrupt Flag Generates an interrupt to the CPU when a recessive-to-dominant transition is detected on the CAN bus and MCR[WAKMSK] = 1. This field applies when FlexCAN is in low-power mode during Self Wake-up: • Doze mode • Stop mode When MCR[SLFWAK] = 0, this flag is masked. The CPU must clear this flag before disabling the field. Otherwise, it is set when MCR[SLFWAK] becomes 1 again. Writing 0 has no effect. 0b - No such occurrence. 1b - Indicates that a recessive-to-dominant transition was received on the CAN bus.

59.6.2.10 Interrupt Masks 2 (IMASK2)

Offset

Register	Offset
IMASK2	24h

Function

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB63–MB32. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 2 (IFLAG2) flag is set.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BUF63TO32M															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BUF63TO32M															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 BUF63TO32M	Buffer MBi Mask Masks the corresponding FlexCAN message buffer interrupt for MB63–MB32. **NOTE** If the corresponding Interrupt Flags 2 (IFLAG2) flag is set, writing 1 or 0 to a field in IMASK2 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

59.6.2.11 Interrupt Masks 1 (IMASK1)

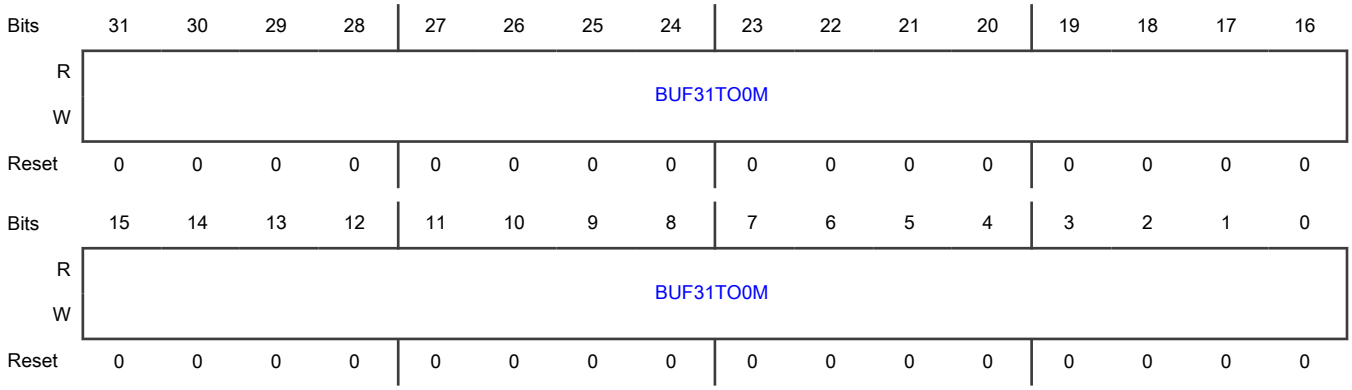
Offset

Register	Offset
IMASK1	28h

Function

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB31–MB0. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 1 (IFLAG1) flag is set.

Diagram



Fields

Field	Function
31-0 BUF31TO0M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB31–MB0. **NOTE** If the corresponding Interrupt Flags 1 (IFLAG1) flag is set, writing 1 or 0 to a field in IMASK1 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

59.6.2.12 Interrupt Flags 2 (IFLAG2)

Offset

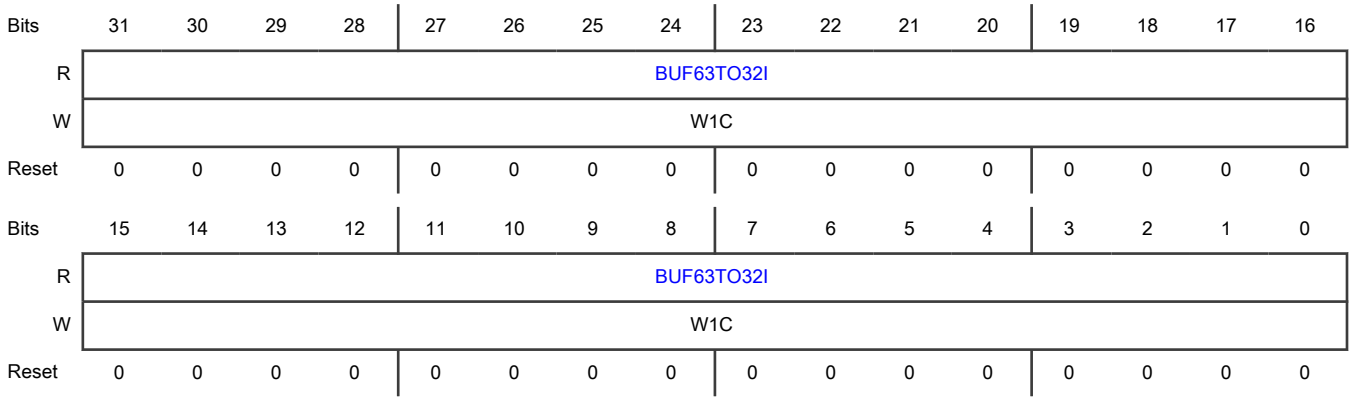
Register	Offset
IFLAG2	2Ch

Function

Contains the flags for the 32 message buffer interrupts for MB63–MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective flag in this register. If the corresponding Interrupt Masks 2 (IMASK2) bit is set, an interrupt is generated.

Before updating MCR[MAXMB], the CPU must service the IFLAG2 flags whose MB value is greater than the MAXMB to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

Diagram



Fields

Field	Function
31-0 BUF63TO32I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB63–MB32. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

59.6.2.13 Interrupt Flags 1 (IFLAG1)

Offset

Register	Offset
IFLAG1	30h

Function

Contains the flags for the 32 message buffer interrupts for MB31–MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding Interrupt Masks 1 (IMASK1) bit is set, an interrupt is generated. There is an exception when DMA for Legacy RX FIFO is enabled, as described below.

The BUF7I–BUF5I flags also represent Legacy FIFO interrupts when the Legacy RX FIFO is enabled. When MCR[RFEN] is 1 and MCR[DMA] is 0, the function of the eight least significant interrupt flags changes:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO.
- BUF4I–BUF1I fields are reserved.
- BUF0I empties the Legacy FIFO.

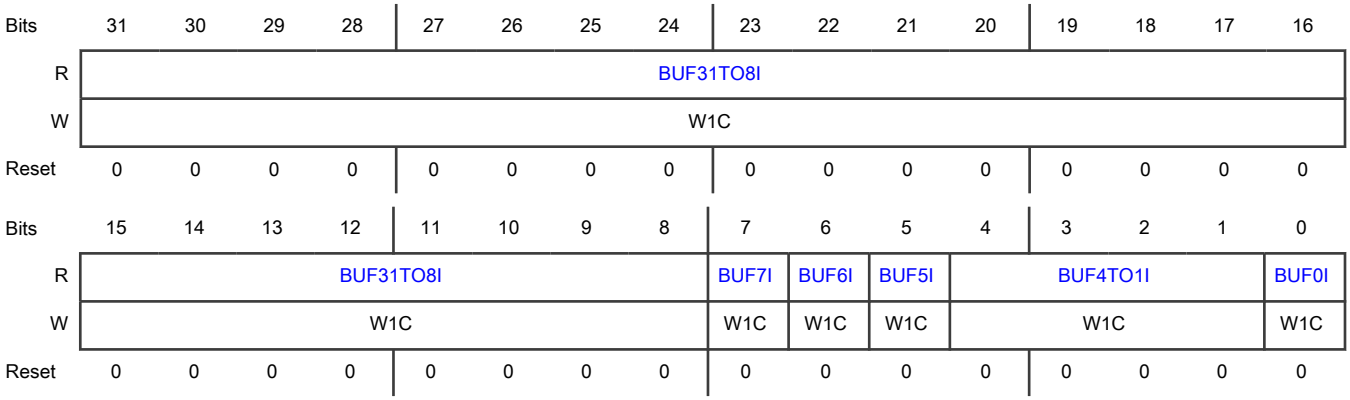
Before writing 1 to MCR[RFEN], the CPU must service the IFLAG flags set in the Legacy RX FIFO region; see Legacy RX FIFO. Otherwise, these IFLAG flags mistakenly show the related message buffers now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is 0, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy RX FIFO filters beyond MB7. For example, when RFFN is 8h, Legacy RX FIFO filters occupy the MB23–MB0 range, and related IFLAG flags must be cleared.

When MCR[RFEN] and MCR[DMA] are 1 (DMA feature for Legacy RX FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) changes to support DMA operation. BUF7I, BUF6I, and BUF4I–BUF1I are not used.

BUF5I indicates the operating condition of the Legacy FIFO, and BUF0I empties the Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but it does generate a DMA request. IMASK1 bits in the Legacy RX FIFO region are not considered when bit MCR[DMA] = 1. In addition, the CPU must not clear the BUF5I flag when DMA is enabled. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. When MCR[DMA] is 0, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] = 1.

Before updating MCR[MAXMB], the CPU must service the IFLAG1 flags whose MB value is greater than the MCR[MAXMB] to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

Diagram



Fields

Field	Function
31-8 BUF31TO8I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB31–MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt or Legacy RX FIFO Overflow Flags the interrupt for MB7 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO overflow. In this case, the flag indicates that a message was lost because the Legacy RX FIFO is full. When the Legacy RX FIFO is full and a message buffer captures the message, this flag is not set. 0b - No occurrence of MB7 completing transmission or reception, or no FIFO overflow. 1b - MB7 completed transmission or reception, or FIFO overflow.
6 BUF6I	Buffer MB6 Interrupt or Legacy RX FIFO Warning Flags the interrupt for MB6 when MCR[RFEN] = 0 (Legacy RX FIFO disabled).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO warning. In this case, the flag indicates when the number of unread messages within the Legacy RX FIFO is increased to five from four due to the reception of a new message. In other words, the Legacy RX FIFO is almost full. If this flag is cleared when there are more than four unread messages, it does not set again until the number of unread messages in the Legacy RX FIFO decreases to four or fewer. 0b - No occurrence of MB6 completing transmission or reception, or FIFO not almost full. 1b - MB6 completed transmission or reception, or FIFO almost full.
5 BUF5I	Buffer MB5 Interrupt or Frames available in Legacy RX FIFO Flags the interrupt for MB5 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, the BUF5I flag represents frames available in Legacy RX FIFO. In this case, the flag indicates that at least one frame is available to be read from the Legacy RX FIFO. When MCR[DMA] = 1, this flag generates a DMA request. The CPU must not clear this field by writing 1 to BUF5I. 0b - No occurrence of completed transmission or reception, or no frames available 1b - MB5 completed transmission or reception, or frames available
4-1 BUF4TO1I	Buffer MBi Interrupt or Reserved Flags the interrupts for MB4–MB1 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears these flags. When MCR[RFEN] = 1, the BUF4TO1I flags are reserved. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
0 BUF0I	Buffer MB0 Interrupt or Clear Legacy FIFO bit Flags the interrupt for MB0 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). If MCR[RFEN] = 1, this field is used to trigger the clear Legacy FIFO operation. This operation empties the Legacy FIFO contents. Before performing this operation, the CPU must service all Legacy FIFO-related IFLAG flags. When MCR[DMA] = 1, this operation also clears the BUF5I flag, aborting the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 to BUF0I. This operation is only allowed in Freeze mode; the module blocks it in other conditions.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - MB0 has no occurrence of successfully completed transmission or reception. 1b - MB0 has successfully completed transmission or reception.

59.6.2.14 Control 2 (CTRL2)

Offset

Register	Offset
CTRL2	34h

Function

Complements Control 1 (CTRL1), providing control bits for memory write-access in Freeze mode. This register extends Legacy FIFO filter quantity, and adjusts the operation of internal FlexCAN processes such as matching and arbitration.

Soft reset does not affect the contents of this register.

Table 956 shows how the value of CTRL2[RFFN] determines the Legacy RX FIFO filter structure.

Table 956. Possible Legacy RX FIFO filter structures

RFFN[3:0]	Number of Legacy RX FIFO filter elements	Message buffers occupied by Legacy RX FIFO and ID filter table	Remaining available message buffers	Legacy RX FIFO ID filter table elements affected by RX individual masks	Legacy RX FIFO ID filter table elements affected by Legacy RX FIFO global mask

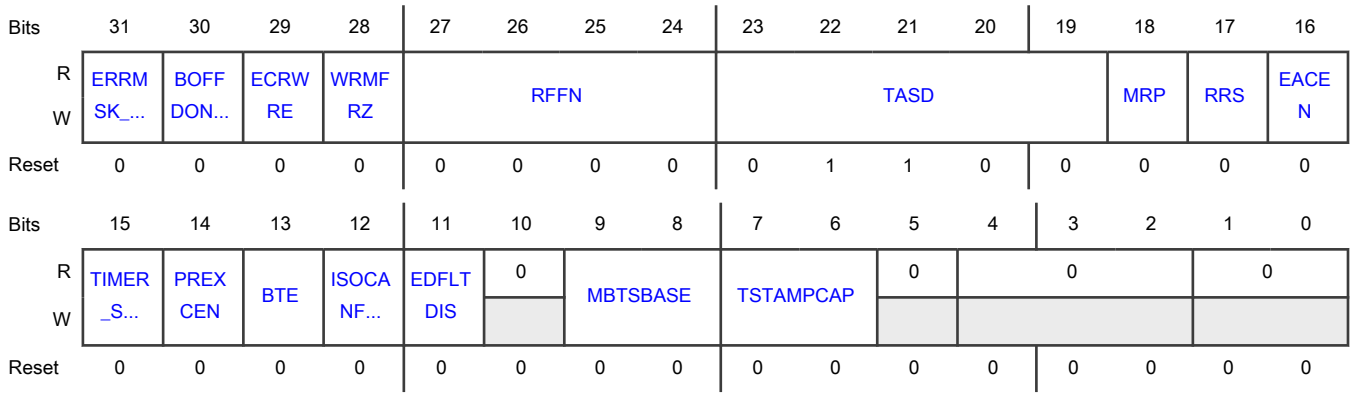
Diagram



Fields

Field	Function
31 ERRMSK_FAST	Error Interrupt Mask for Errors Detected in the Data Phase of Fast CAN FD Frames Enables the ESR1[ERRINT_FAST] interrupt. 0b - Disable 1b - Enable
30 BOFFDONEMSK	Bus Off Done Interrupt Mask Enables the Bus Off Done interrupt, ESR1[BOFFDONEINT]. 0b - Disable 1b - Enable
29 ECRWRE	Error Correction Configuration Register Write Enable Enables updates for Memory Error Control (MECR). If the protocol described in Detection and correction of memory errors is not followed, this field is automatically 0. 0b - Disable 1b - Enable
28 WRMFRZ	Write Access to Memory in Freeze Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables unrestricted write access to FlexCAN memory in Freeze mode. When this field is 0, write access restrictions are maintained. This field can only be written in Freeze mode, and has no effect out of Freeze mode. **NOTE** Do not write 1 to MCR[RFEN] during FlexCAN memory initialization. 0b - Disable 1b - Enable
27-24 RFFN	Number of Legacy Receive FIFO Filters Defines the number of Receive Legacy FIFO filters, as shown in Table 956. The chip determines the maximum selectable number of filters. Do not program this field with values that cause the number of message buffers occupied by Legacy RX FIFO and Legacy RX FIFO ID Filter to exceed MCR[MAXMB]. MCR[MAXMB] defines the number of message buffers present. This field can only be written in Freeze mode; the module blocks it in other modes. Each group of eight filters occupies a memory space equivalent to two message buffers. The more filters are implemented, the fewer message buffers are available. The Legacy RX FIFO occupies the memory space originally reserved for MB5–MB0. This field should be programmed with a value corresponding to a number of filters less than the number of available memory words. The number of available words can be calculated as follows: (SETUP_MB - 6) × 4 Where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining message buffers available is: (SETUP_MB - 8) - (RFFN × 2) If the number of Legacy RX FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. **NOTE** • The number of the last remaining available message buffers is the smaller of (NUMBER_OF_MB - 1) and MCR[MAXMB]. • If RX Individual Mask registers are not enabled, the Legacy RX FIFO Global Mask affects all Legacy RX FIFO filters.
23-19 TASD	Transmission Arbitration Start Delay Indicates by how many CAN bits the transmission arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See TX arbitration start delay for details. This field can be written only in Freeze mode; the module blocks it in other modes.
18 MRP	Message Buffers Reception Priority Sets the priority for the matching process. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Matching starts from Legacy RX FIFO or Enhanced RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on Legacy RX FIFO or Enhanced RX FIFO.
17 RRS	Remote Request Storing Determines what the module does with a remote request. The remote request frame is submitted to a matching process. If this field is 1, the frame is stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame is generated. If this field is 0, an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID. You can only write to this field in Freeze mode. The module blocks it in other modes. 0b - Generated 1b - Stored
16 EACEN	Entire Frame Arbitration Field Comparison Enable for RX Message Buffers Controls the comparison of IDE and RTR fields within RX message buffer filters with their corresponding bits in the incoming frame by the matching process. If enabled, the IDE and RTR fields of the RX message buffer are compared to their corresponding bits within the incoming frame (mask bits apply). If disabled, the IDE field of the RX message buffer filter is always compared and RTR is never compared despite mask bits. This field does not affect matching for Legacy RX FIFO or Enhanced RX FIFO. You can only write to this field in Freeze mode; the module blocks it in other modes. 0b - Disable 1b - Enable
15 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the free-running timer counter. If CAN bit clock is selected, it defines the baud rate on the CAN bus. If External time tick is selected, the period can be adjusted to match the baud rate on the CAN bus. It can also be adjusted to a different value as required. See the chip-specific section for details about the external time tick. You can only write to this field in Freeze mode. 0b - CAN bit clock 1b - External time tick
14 PREXCEN	Protocol Exception Enable Enables the protocol exception feature. You can only write to this field in Freeze mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE See Protocol exception event in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Disabled 1b - Enabled
13 BTE	Bit Timing Expansion Enable Enables the use of Enhanced CAN Bit Timing Prescalers (EPRS), Enhanced Data Phase CAN Bit Timing (EDCBT), and Enhanced Nominal CAN Bit Timing (ENCBT) to configure the CAN bit timing segments, instead of using the bit timing fields of CAN Bit Timing (CBT), CAN FD Bit Timing (FDCBT), and Control 1 (CTRL1). If this field is 1: • CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are read as zero. A write operation to these fields has no effect. • CBT[EPRESDIV], CBT[ERJW], CBT[EPROPSEG], CBT[EPSEG1], and CBT[EPSEG2], and the corresponding fields in CAN FD Bit Timing (FDCBT), are read as zero. A write operation to these fields has no effect. • ETDC[ETDCOFF], ETDC[ETDCEN], ETDC[ETDCFAIL], and ETDC[ETDCVAL] are used by FlexCAN instead of FDCTRL[TDCOFF], FDCTRL[TDCEN], FDCTRL[TDCFAIL], and FDCTRL[TDCVAL]. These fields are read as zero, and a write operation to them has no effect. • ETDC[TDMDIS] can be used to disable transceiver delay measurement. 0b - Disable 1b - Enable
12 ISOCANFDEN	ISO CAN FD Enable Enables the CAN FD protocol according to ISO specification (ISO 11898-1:2015) (see CAN FD ISO compliance). When disabled, FlexCAN operates using the non-ISO CAN FD protocol. You can only write to this field in Freeze mode. **NOTE** FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1:2015). 0b - Disable 1b - Enable
11 EDFLTDIS	Edge Filter Disable Disables the edge filter used during the Bus Integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus states are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of 11 consecutive recessive bits is restarted. The edge filter prevents dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You can only write to this field in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Enabled 1b - Disabled
10 —	Reserved
9-8 MBTSBASE	Message Buffer Timestamp Base Selects the timebase used for capturing the 16-bit TIME_STAMP field of the message buffer register. This field can be written in Freeze Mode only. 00b - TIMER 01b - Lower 16 bits of high-resolution timer 10b - Upper 16 bits of high-resolution timer 11b - Reserved
7-6 TSTAMPCAP	Timestamp Capture Point Configures the point in time when a 32-bit timebase is captured during a CAN frame. This base is stored in the high-resolution timestamp register (HR_TIME_STAMP). For classical CAN frames, capture points can be the start-of-frame bit or the point when CAN frame is considered valid. This point is the seventh bit of the end-of-frame for transmission and the sixth bit of the end-of-frame for reception. For CAN FD frames, the high-resolution timestamp can be captured at the start of frame, when a CAN FD frame is considered valid, or the res bit. You can only write to this field in Freeze mode. 00b - Disabled 01b - End of the CAN frame 10b - Start of the CAN frame 11b - Start of frame for classical CAN frames; res bit for CAN FD frames
5 —	Reserved
4-2 —	Reserved
1-0 —	Reserved

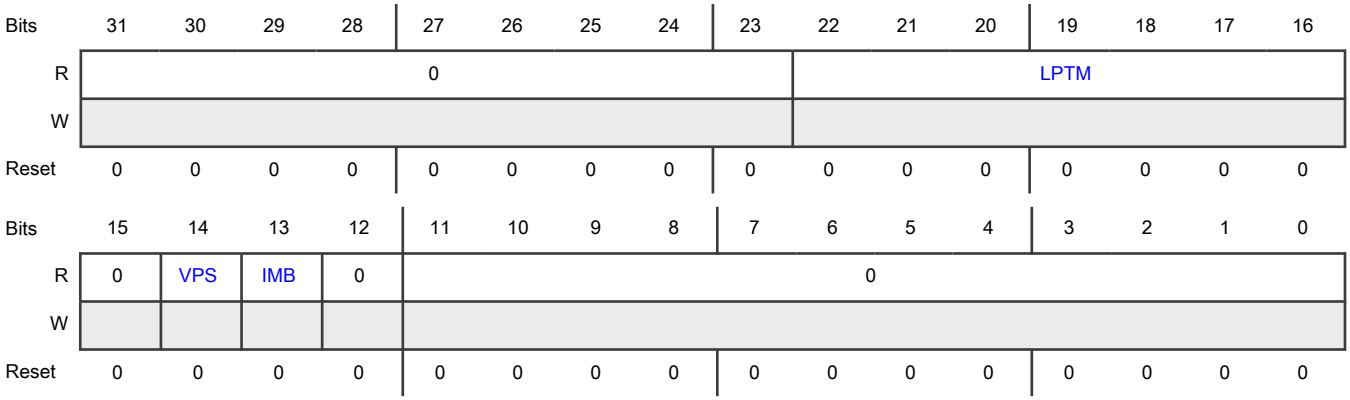
59.6.2.15 Error and Status 2 (ESR2)

Offset

Register	Offset
ESR2	38h

Function
Reports general status information.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 LPTM	Lowest Priority TX Message Buffer Indicates the lowest number inactive message buffer when ESR2[VPS] = 1 (see ESR2[IMB]). If no message buffer is inactive, the message buffer indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] = 0, the message buffer indicated is the one with the greatest arbitration value (see Highest-priority message buffer first). If CTRL1[LBUF] = 1, the message buffer indicated is the active TX message buffer with the highest number. If a TX message buffer is being transmitted, it is not considered in the LPTM calculation. If ESR2[IMB] is not 0 and a frame is transmitted successfully, the value of LPTM is updated with its message buffer number.
15 —	Reserved
14 VPS	Valid Priority Status Indicates whether the contents of ESR2[IMB] and ESR2[LPTM] are valid. It becomes 1 upon every complete TX arbitration process, unless the CPU writes to the Control and Status word of a message buffer already scanned. In other words, it is behind the TX Arbitration Pointer, during the TX arbitration process. If there is

Table continues on the next page...

Table continued from the previous page...

Field	Function
	no inactive message buffer and only one TX message buffer that is being transmitted, this field remains 0. This field becomes 0 upon the start of every TX arbitration process or upon a write to the Control and Status word of any message buffer. **NOTE** No CPU write to the Control and Status of a message buffer that the abort mechanism blocks affects this field. When MCR[AEN] = 1, the abort code write to the Control and Status of an MB being transmitted (pending abort) is blocked. Any write attempt to a TX MB with its IFLAG flag set is also blocked. 0b - Invalid 1b - Valid
13 IMB	Inactive Message Buffer Indicates whether any message buffer is inactive (CODE field is either 1000b or 0b) when ESR2[VPS] = 1. This field becomes 1 when: • A lowest-priority TX message buffer (ESR2[LPTM]) is found and it is inactive during arbitration. • This field is not 1, and a frame is transmitted successfully. This field always becomes 0 at the start of arbitration (see Arbitration process). If a message buffer is successfully transmitted and this field is 0 (no inactive message buffer), ESR2[VPS] and this field both become 1. The index related to the MB transmitted is loaded into ESR2[LPTM]. In this case, the value of ESR2[LPTM] is the number of the first inactive message buffer. 0b - Message buffer indicated by ESR2[LPTM] is not inactive. 1b - At least one message buffer is inactive.
12 —	Reserved
11-0 —	Reserved

59.6.2.16 Cyclic Redundancy Check (CRCR)

Offset

Register	Offset
CRCR	44h

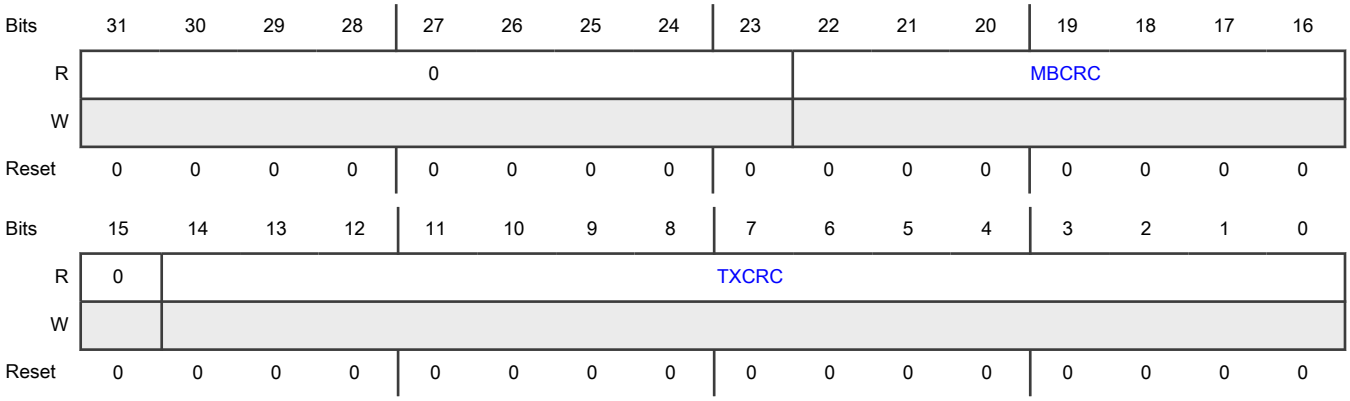
Function

Provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low-order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, you must use the CAN FD CRC (FDCRC). This register is updated at the same time that the TX interrupt flag is set.

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 MBCRC	CRC Message Buffer Indicates the number of the message buffer corresponding to the value in CRCR[TXCRC].
15 —	Reserved
14-0 TXCRC	Transmitted CRC value Indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in CAN FD CRC (FDCRC).

59.6.2.17 Legacy RX FIFO Global Mask (RXFGMASK)

Offset

Register	Offset
RXFGMASK	48h

Function

Masks the Legacy RX FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN], when Legacy RX FIFO is enabled.

This register is located in RAM.

You can only write to this register in Freeze mode; the module blocks it in other modes.

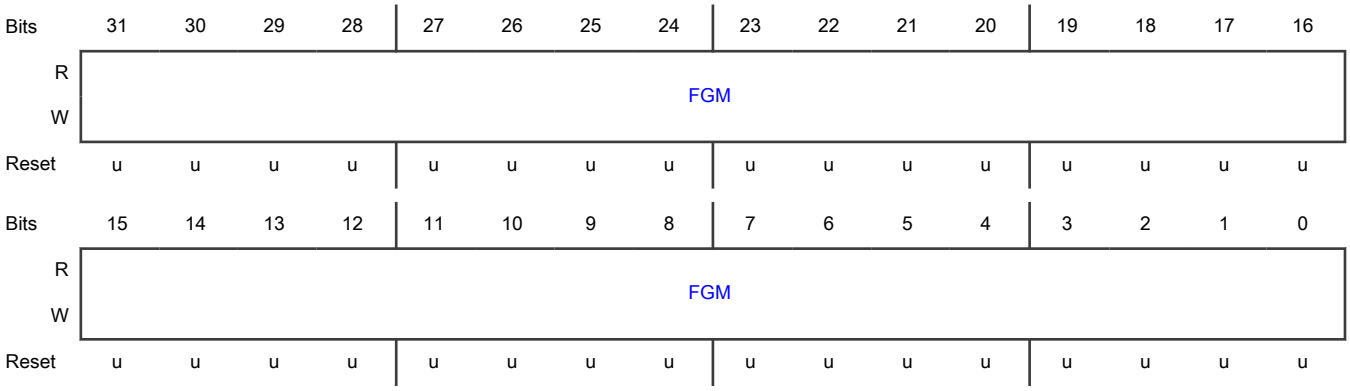
The following table shows how the FGM bits correspond to each IDAF field.

Table 957. Correspondence of Legacy RX FIFO global mask bits to IDF fields

Legacy RX FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the 14 most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.

Diagram



Fields

Field	Function
31-0 FGM	Legacy RX FIFO Global Mask Bits Masks the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

59.6.2.18 Legacy RX FIFO Information (RXFIR)

Offset

Register	Offset
RXFIR	4Ch

Function

Provides information about Legacy RX FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. FlexCAN writes to the Legacy RXFIR FIFO when a new message is moved into the Legacy RX FIFO. Also, its output is updated whenever the output of the Legacy RX FIFO is updated with the next message. See Legacy RX FIFO for instructions on reading this register.

NOTE

RXFIR can be written only during memory initialization, due to the error code correction (ECC) feature. In every other case, this register is read-only.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0								IDHIT							
W																
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator Indicates which Identifier Acceptance filter that the received message hit in the output of the Legacy RX FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is set.

59.6.2.19 CAN Bit Timing (CBT)

Offset

Register	Offset
CBT	50h

Function

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1). EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] respectively.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

CBT[BTF] selects the use of the timing variables defined in this register.

When the CAN FD feature is enabled (MCR[FDEN] = 1), always write 1 to CBT[BTF].

Soft reset does not affect the contents of this register.

NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] = 1, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 are read as zero. A write operation to them has no effect.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BTF	EPRESDIV											ERJW			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	EPROPSEG				EPSEG1				EPSEG2							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 BTF	Bit Timing Format Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW. These fields replace the CAN bit timing variables defined in Control 1 (CTRL1). This field can be written in Freeze mode only. 0b - Disable 1b - Enable
30-21 EPRESDIV	Extended Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (EPRESDIV + 1)
20-16 ERJW	Extended Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time when CBT[BTF] = 1. Otherwise, it has no effect. It extends the CTRL1[RJW] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = ERJW + 1. One Time Quantum = one Sclock period.
15-10 EPROPSEG	Extended Propagation Segment Defines the length of the propagation segment in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 Defines the length of phase segment 1 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 Defines the length of phase segment 2 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

59.6.2.20 Interrupt Masks 3 (IMASK3)

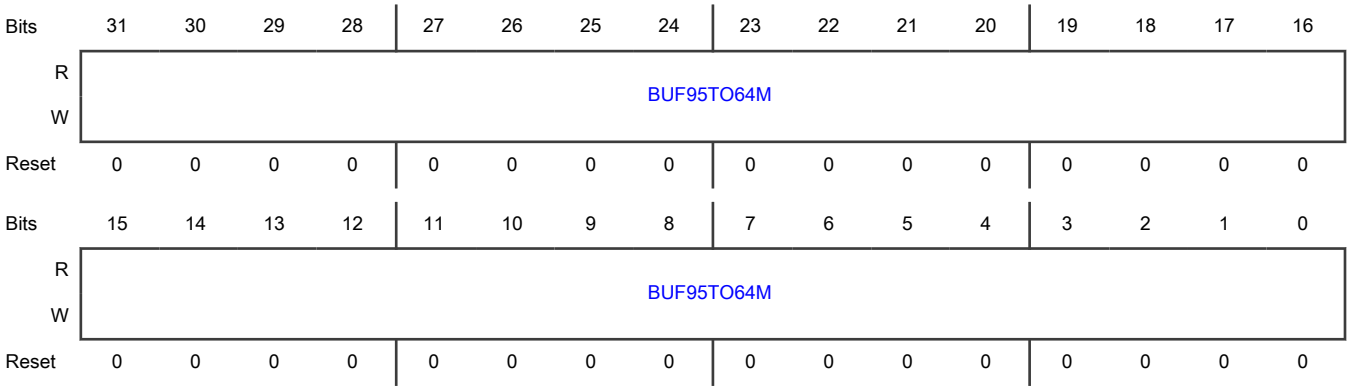
Offset

Register	Offset
IMASK3	6Ch

Function

Enables or disables any number of the 32 message buffer interrupts for MB95–MB64. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding IFLAG3 flag is set.

Diagram



Fields

Field	Function
31-0 BUF95TO64M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB95–MB64. When CAN FD is enabled, the MB range is defined in accordance with FDCTRL[MBDSRn]. **NOTE** If the corresponding IFLAG3 flag is set, writing 1 or 0 to a field in IMASK3 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

59.6.2.21 Interrupt Flags 3 (IFLAG3)

Offset

Register	Offset
IFLAG3	74h

Function

Defines the flags for the 32 message buffer interrupts for MB95–MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG3 flag. If the corresponding IMASK3 bit is 1, an interrupt is generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], the CPU must service the IFLAG3 flags whose MB value is greater than the MAXMB to be updated. Otherwise, they remain set and are inconsistent with the number of message buffers available.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BUF95TO64

R	BUF95TO64															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 BUF95TO64	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB95–MB64.When CAN FD is enabled, the MB range is defined in accordance with FDCTRL[MBDSRn]. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

59.6.2.22 Receive Individual Mask (RXIMR0 - RXIMR95)

Offset

For n = 0 to 95:

Register	Offset
RXIMRn	880h + (n × 4h)

Function

Stores the acceptance masks for ID filtering in RX message buffers and the Legacy RX FIFO.

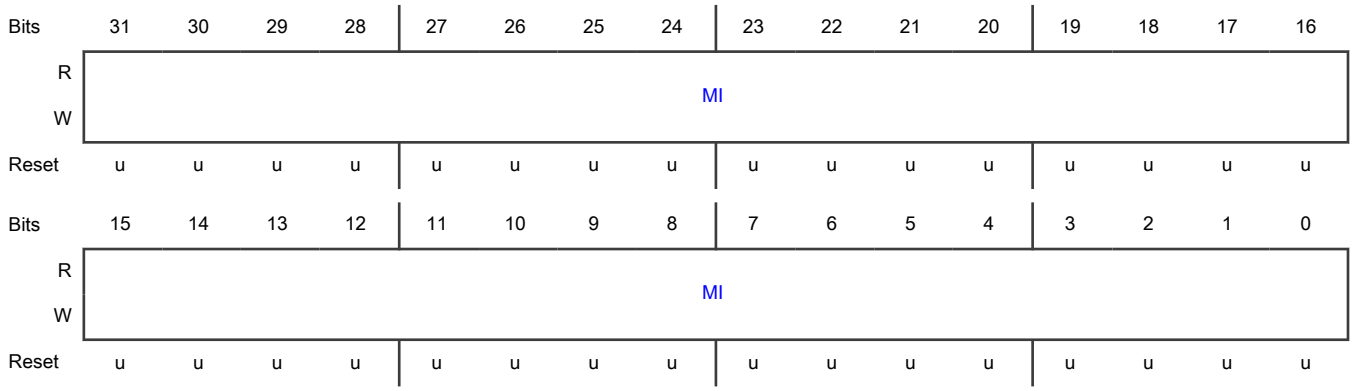
When the Legacy RX FIFO is disabled (MCR[RFEN] = 0), an individual mask is provided for each available RX message buffer on a one-to-one correspondence. When the Legacy RX FIFO is enabled (MCR[RFEN] = 1), an individual mask is provided for each Legacy RX FIFO ID filter table element on a one-to-one correspondence. This correspondence depends on the setting of CTRL2[RFFN] (see Legacy RX FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0. RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

The CPU can only access the RXIMR registers when the module is in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general-purpose memory. See Bus interface for more information.

Diagram



Fields

Field	Function
31-0 MI	Individual Mask Bits Masks the corresponding bit in both the message buffer filter and Legacy RX FIFO ID filter table element in distinct ways. For message buffer filters, see RX Message Buffers Global Mask (RXMGMASK). For Legacy RX FIFO ID filter table elements, see Legacy RX FIFO Global Mask (RXFGMASK). 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

59.6.2.23 Memory Error Control (MECR)

Offset

Register	Offset
MECR	AE0h

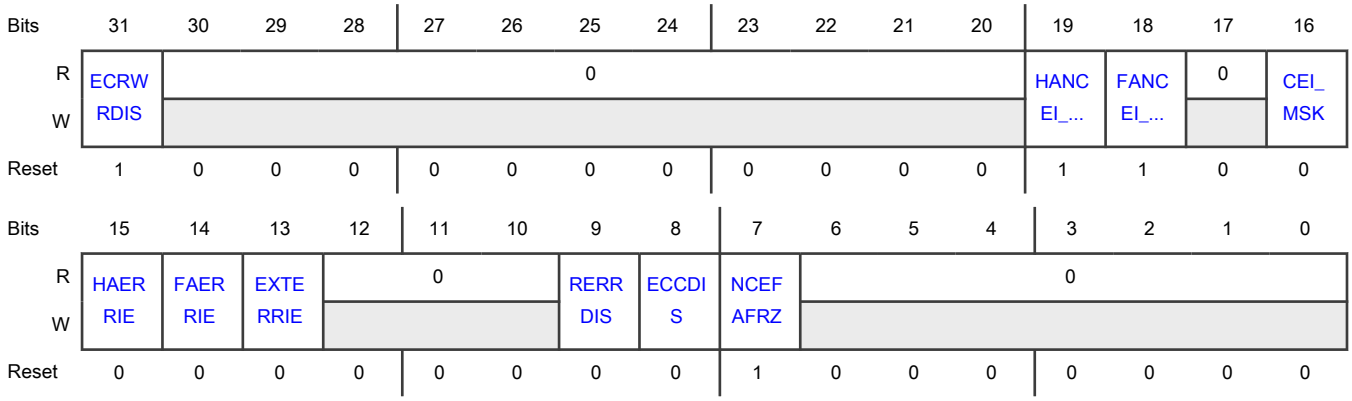
Function

Contains control bits for memory error detection and correction (ECC).

NOTE

When CTRL2[ECRWRE] = 0, writes to this register are blocked, except for MECR[ECRWRDIS].

Diagram



Fields

Field	Function
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This field automatically becomes 1 (disabled) when CTRL2[ECRWRE] is 1. The protocol described in Detection and correction of memory errors must be followed. 0b - Enable 1b - Disable
30-20 —	Reserved
19 HANCEI_MSK	Host Access with Noncorrectable Errors Interrupt Mask Enables the interrupt for noncorrectable errors detected in memory reads issued by the host (CPU). 0b - Disable 1b - Enable
18 FANCEI_MSK	FlexCAN Access with Noncorrectable Errors Interrupt Mask Enables the interrupt for noncorrectable errors detected in memory reads issued by FlexCAN internal processes. 0b - Disable 1b - Enable
17 —	Reserved
16 CEI_MSK	Correctable Errors Interrupt Mask Enables the interrupt for correctable errors detected in memory reads issued by the host or FlexCAN internal processes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0b - Disable 1b - Enable
14 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by FlexCAN internal processes. 0b - Disable 1b - Enable
13 EXTERRIE	Extended Error Injection Enable Extends the error injection on 32-bit memory accesses to the complementary 32-bit word. This feature uses the same 32-bit error injection data and parity words used for 64-bit memory accesses performed by internal FlexCAN processes. See Error Injection Data Pattern (ERRIDPR) and Error Injection Parity Pattern (ERRIPPR). 0b - Disable. Apply error injection only to the 32-bit word. 1b - Enable. Apply error injection to the 64-bit word.
12-10 —	Reserved
9 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. **NOTE** When reading the report registers, this field must be 1 to ensure coherence on the consecutive register reads. 0b - Enable 1b - Disable
8 ECCDIS	Error Correction Disable Completely disables the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and the generation of bus transfer errors. The parity bits continue to be calculated and written into memory on write transactions. 0b - Enable 1b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 NCEFAFRZ	Noncorrectable Errors in FlexCAN Access Put Chip in Freeze Mode Determines whether to put FlexCAN into Freeze mode when a noncorrectable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents FlexCAN internal processes from treating corrupted data as valid. See Freeze mode for more information. 0b - Normal operation 1b - Freeze mode
6-0 —	Reserved

59.6.2.24 Error Injection Address (ERRIAR)

Offset

Register	Offset
ERRIAR	AE4h

Function

Contains the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM. Where pairs of values are provided, the first is the address for MCR[FDEN] = 0, the second is for MCR[FDEN] = 1.

Table 958. Error injection address for classical CAN format

RAM contents	Injection address	Memory map
FlexCAN registers	Not mapped	—
Message buffers	0000h	0080h
RXIMRs	600h	0880h
RXFIR_0	780h	0A80h
RXFIR_1	784h	0A84h
RXFIR_2	788h	0A88h
RXFIR_3	78Ch	0A8Ch
RXFIR_4	790h	0A90h
RXFIR_5	794h	0A94h
Reserved	—	0A98h
RXMGMASK	7A0h	0AA0h
RXFGMASK	7A4h	0AA4h

Table continues on the next page...

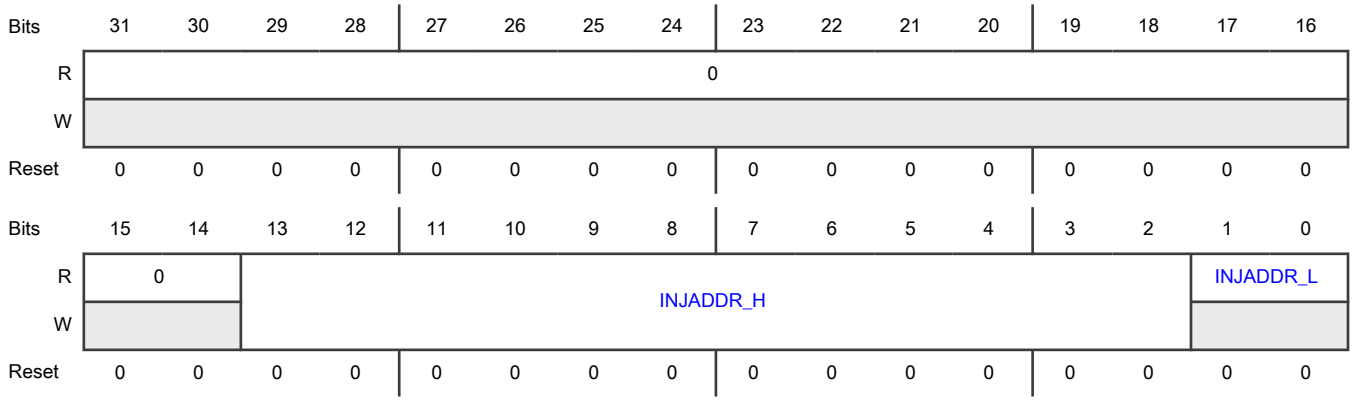
Table 958. Error injection address for classical CAN format (continued)

RAM contents	Injection address	Memory map
RX14MASK	7A8h	0AA8h
RX15MASK	7ACh	0AACh
Tx_SMB	7B0h	0AB0h / 0F28h
Rx_SMB0	7C0h / 7F8h	0AC0h / 0F70h
Rx_SMB1	7D0h / 840h	0AD0h / 0FB8h
Rx_SMB0_TIME_STAMP	888h	0C20h
Rx_SMB1_TIME_STAMP	88Ch	0C24h
HR_TIME_STAMP	890h	0C30h
Enhanced RX FIFO	A10h	2000h
ERFFEL	1050h	3000h

NOTE

For RXFIR, Enhanced RX FIFO, and HR_TIME_STAMP addresses, you must inject ECC errors in host access only.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-2 INJADDR_H	Error Injection Address High Defines the 12 most significant bits of the physical RAM address where error is to be injected (see table above).
1-0	Error Injection Address Low

Table continues on the next page...

Table continued from the previous page...

Field	Function
INJADDR_L	Defines the two least significant bits of the physical RAM address where error is to be injected. These bits ensure that the address is on a 32-bit boundary.

59.6.2.25 Error Injection Data Pattern (ERRIDPR)

Offset

Register	Offset
ERRIDPR	AE8h

Function

Contains the error pattern to be injected in the data word read from memory.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	DFLIP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 DFLIP	Data Flip Pattern Contains the flip pattern. Bits set to 1 in the flip pattern cause the corresponding data bit in the word read from memory to invert.

59.6.2.26 Error Injection Parity Pattern (ERRIPPR)

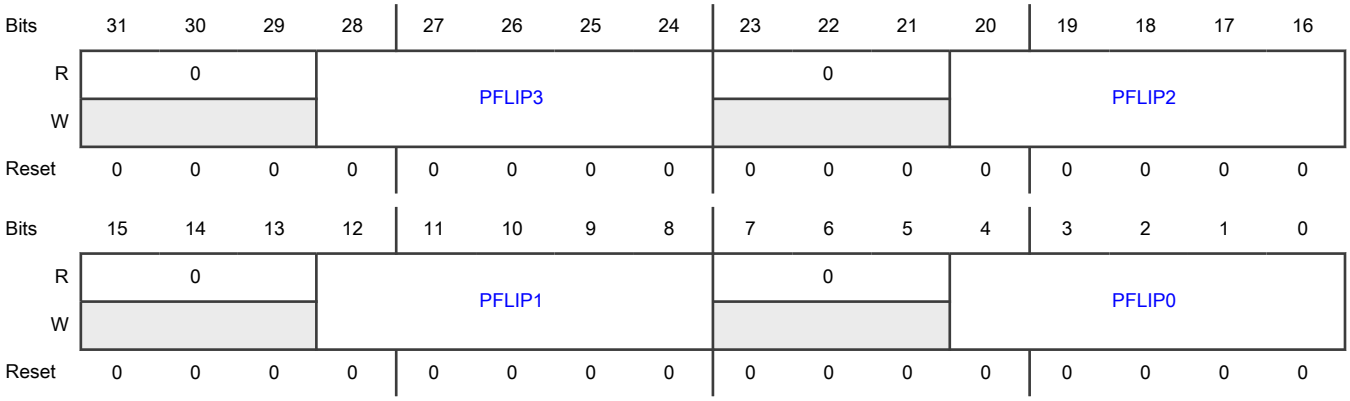
Offset

Register	Offset
ERRIPPR	AECh

Function

Contains the error pattern to be injected in parity bits read from memory with the data word. Bits set to 1 in the flip pattern cause the corresponding parity bit in the word read from memory to invert.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 PFLIP3	Parity Flip Pattern for Byte 3 (Most Significant) Contains the error injection pattern for Byte 3.
23-21 —	Reserved
20-16 PFLIP2	Parity Flip Pattern for Byte 2 Contains the error injection pattern for Byte 2.
15-13 —	Reserved
12-8 PFLIP1	Parity Flip Pattern for Byte 1 Contains the error injection pattern for Byte 1.
7-5 —	Reserved
4-0 PFLIP0	Parity Flip Pattern for Byte 0 (Least Significant) Contains the error injection pattern for Byte 0.

59.6.2.27 Error Report Address (RERRAR)

Offset

Register	Offset
RERRAR	AF0h

Function

Reports the address used for an access operation in which an error (correctable or noncorrectable) was detected. Also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] nonzero) are reported with the address aligned, and data is reported in Error Report Data (RERRDR) shifted accordingly. When errors are detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word where the error was detected is reported. For errors detected in more than one 32-bit word, only the least significant address is reported.

Table 959. Source of memory access

SAID[2:0]	Error during...
0	Move-out FlexCAN access
1	Move-in
2	TX arbitration
3	RX matching
4	Move-out host access
5–7	Reserved

23-19 —	Reserved
18-16 SAID	SAID SAID[2] — Identification of the requester of the memory read request: • 0 = Requested by FlexCAN internal processes • 1 = Requested by host (CPU) SAID[1] — Details of FlexCAN operation: • 0 = Move • 1 = Scanning SAID[0] — Operation that requested the memory read: • 0 = Transmission • 1 = Reception For more information, see Table 959.
15-14 —	Reserved
13-0 ERRADDR	Address Where Error Detected See description of Error Injection Address (ERRIAR).

59.6.2.28 Error Report Data (RERRDR)

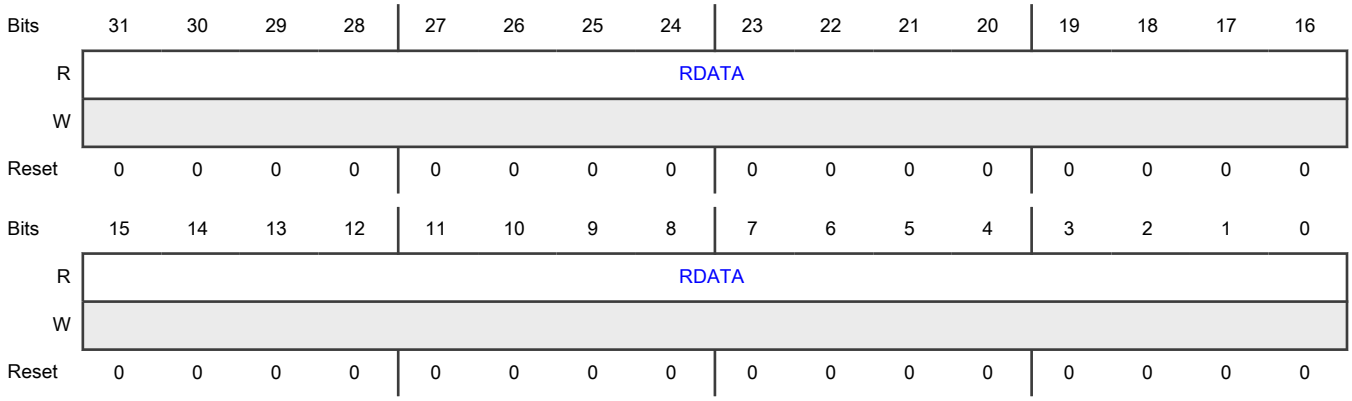
Offset

Register	Offset
RERRDR	AF4h

Function

Reports the raw data (unmodified by the correction performed by ECC logic) read from memory with error. The value reported does not represent the transient values of the BUSY bit (see Table 965) when reading a message buffer.

Diagram



Fields

Field	Function
31-0 RDATA	Raw Data Word Read from Memory with Error

59.6.2.29 Error Report Syndrome (RERRSYNR)

Offset

Register	Offset
RERRSYNR	AF8h

Function

Contains the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYND*n* field indicates the type of error and which bit in byte (*n*) the error affects. SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.

Table 960. Syndrome definition

SYND*n* (hex)	Type	Bit affected
00	—	None (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7

Table continues on the next page...

Table 960. Syndrome definition (continued)

SYND*n* (hex)	Type	Bit affected
10	Code	4
13	Data	2
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
06	—	All-zeroes noncorrectable error
1F	—	All-ones noncorrectable error
All others	—	Noncorrectable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, including the non-read ones. Errors detected in non-read bytes are indicated (see Error indication) and reported (see Error reporting).

Diagram

Fields

Field	Function
31-20 —	Reserved
19 HANCEIF	Host Access with Noncorrectable Error Interrupt Flag Indicates that a noncorrectable error was detected in a memory read initiated by host. A bus transfer error is asserted for that access. If MECR[HANCEI_MSK] = 1, the interrupt is 1. 0b - No errors detected 1b - Error detected
18 FANCEIF	FlexCAN Access with Noncorrectable Error Interrupt Flag Indicates that a noncorrectable error was detected in a memory read initiated by FlexCAN internal processes. If MECR[FANCEI_MSK] = 1, the interrupt is 1. 0b - No errors detected 1b - Error detected
17 —	Reserved
16 CEIF	Correctable Error Interrupt Flag Indicates that a correctable error was detected in a memory read. If MECR[CEI_MSK] = 1, the interrupt is 1. 0b - No errors detected 1b - Error detected
15-4 —	Reserved
3	Host Access With Noncorrectable Error Interrupt Overrun Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
HANCEIOF	Indicates that a noncorrectable error was detected in a memory read initiated by host when ERRSR[HANCEIF] was set. No interrupt is associated with this flag. See Error indication. 0b - No errors detected 1b - Error detected
2 FANCEIOF	FlexCAN Access with Noncorrectable Error Interrupt Overrun Flag Indicates that a noncorrectable error was detected in a memory read initiated by FlexCAN internal processes when ERRSR[FANCEIF] was set. No interrupt is associated with this flag. See Error indication. 0b - No errors detected 1b - Error detected
1 —	Reserved
0 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory read when ERRSR[CEIF] was set. No interrupt is associated with this flag. See Error indication. 0b - No errors detected 1b - Error detected

59.6.2.31 Enhanced CAN Bit Timing Prescalers (EPRS)

Offset

Register	Offset
EPRS	BF0h

Function

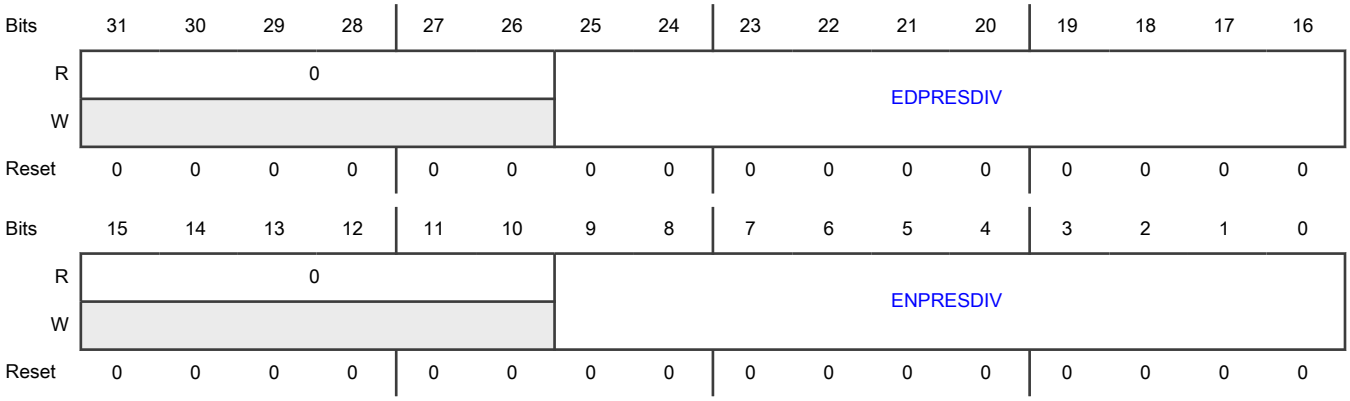
Defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] = 1.

Used by the module only if CTRL2[BTE] = 1; otherwise a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode; the module blocks it in other modes.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency in the data phase of a CAN FD message when CTRL2[BTE] = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency ÷ (EDPRESDIV + 1) **NOTE** To minimize errors when processing FD frames, use the same value for this field and for EPRS[ENPRESDIV]. See the first note in CAN FD frames for details.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency when CTRL2[BTE] = 1. Otherwise, it reads as 0 and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency ÷ (ENPRESDIV + 1)

59.6.2.32 Enhanced Nominal CAN Bit Timing (ENCBT)

Offset

Register	Offset
ENCBT	BF4h

Function

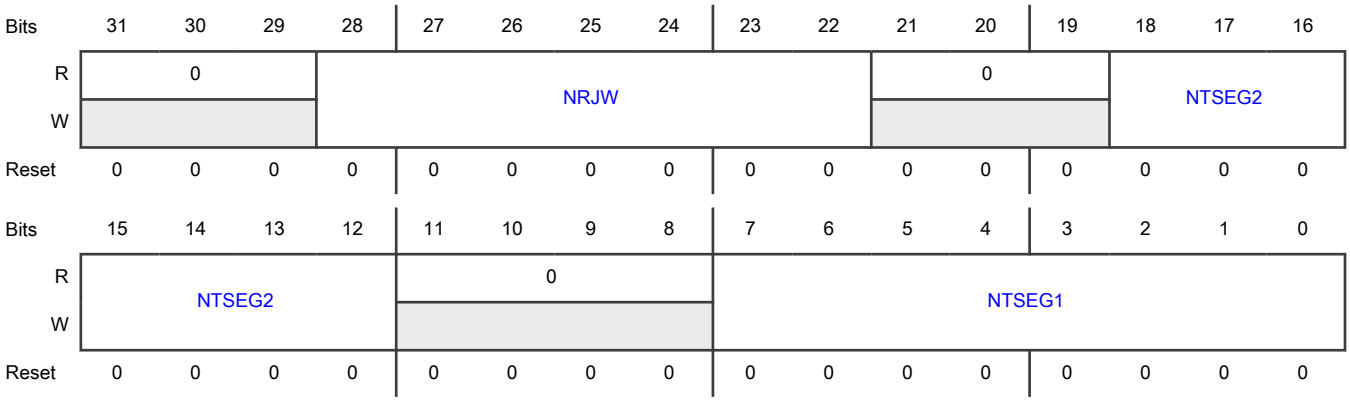
Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1) and CAN Bit Timing (CBT), to get higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-22 NRJW	Nominal Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. One time quantum = one Sclock period Nominal Resync Jump Width = NRJW + 1
21-19 —	Reserved
18-12 NTSEG2	Nominal Time Segment 2 Defines the length of Time Segment 2 in the nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 2 = (NTSEG2 + 1) × Time Quanta One time quantum = one Sclock period
11-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 NTSEG1	Nominal Time Segment 1 Defines the length of Time Segment 1 in the bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 1 = (NTSEG1 + 1) × Time Quanta One time quantum = one Sclock period

59.6.2.33 Enhanced Data Phase CAN Bit Timing (EDCBT)

Offset

Register	Offset
EDCBT	BF8h

Function

Provides an alternative way to store the data phase CAN bit timing variables described in CAN FD Bit Timing (FDCBT) to achieve higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1; otherwise a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

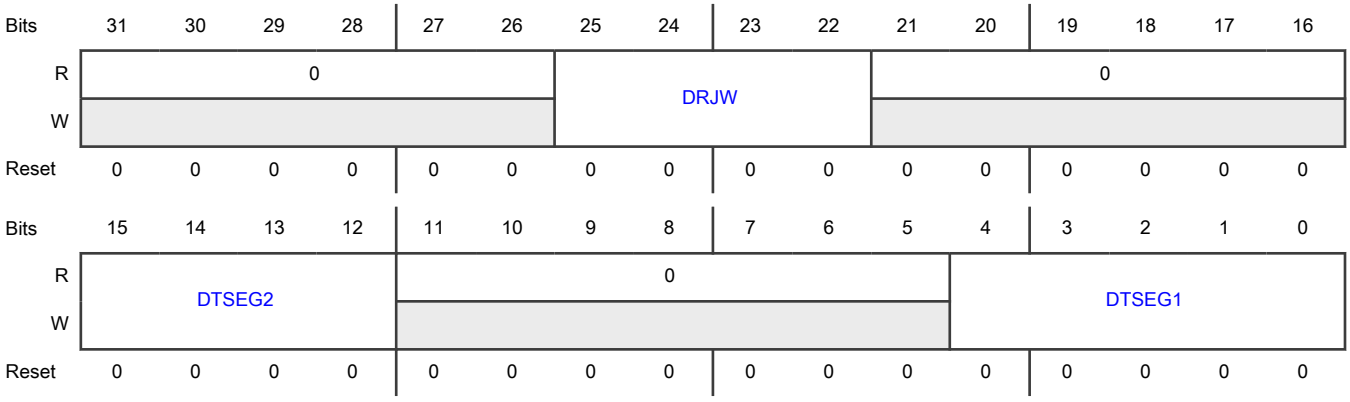
NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

DTSEG1 must be at least two time quanta.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-22 DRJW	Data Phase Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Resync Jump Width = DRJW + 1.
21-16 —	Reserved
15-12 DTSEG2	Data Phase Time Segment 2 Defines the length of time segment 2 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 2 = (DTSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.
11-5 —	Reserved
4-0 DTSEG1	Data Phase Segment 1 Defines the length of time segment 1 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 1 = (NTSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.

59.6.2.34 Enhanced Transceiver Delay Compensation (ETDC)

Offset

Register	Offset
ETDC	BFCh

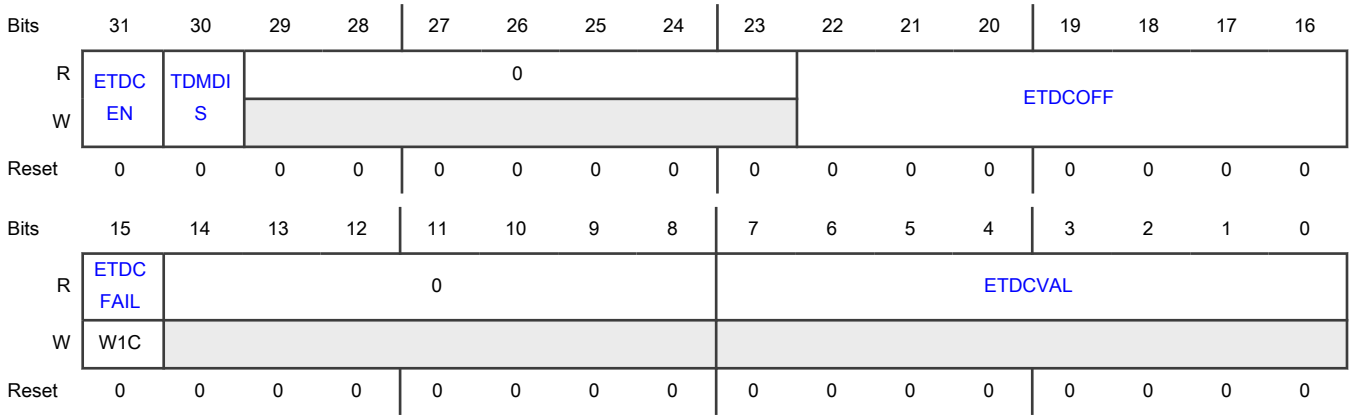
Function

Contains extended versions of FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

NOTE

See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31 ETDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. **NOTE** See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled. See CTRL1[LPB]. 0b - Disable 1b - Enable
30 TDMDIS	Transceiver Delay Measurement Disable Disables the transceiver delay measurement. When the TDC measurement is disabled, only ETDC[ETDCOFF] determines the secondary sample point position. If TCD measurement is enabled, the sum of the transceiver delay measurement plus the enhanced TDC offset determines the secondary sample point position. Soft reset does not affect this field. **NOTE** This bit can be enabled only if CTRL2[BTE] = 1. 0b - Enable 1b - Disable
29-23 —	Reserved
22-16	Enhanced Transceiver Delay Compensation Offset

Table continues on the next page...

Table continued from the previous page...

Field	Function
ETDCOFF	Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details on how the loop delay measurement is performed. This field can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details). It must be smaller than the CAN bit duration in the data bit rate for proper operation. Do not write 0 to this field. **NOTE** If CTRL2[BTE] becomes 1 after a chip-level hard reset, this field is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail Indicates whether the transceiver delay compensation (TDC) mechanism is out of range. In this case, it is unable to compensate the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. (See Transceiver delay compensation.) This field becomes 0 the first time FlexCAN detects the out of range condition. 0b - In range 1b - Out of range
14-8 —	Reserved
7-0 ETDCVAL	Enhanced Transceiver Delay Compensation Value Contains ETDC[ETDCOFF] added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS = 1. The module only updates this field when ETDC[ETDCEN] = 1. Soft reset affects this field. **NOTE** If ETDC[TDMDIS] = 1, this field stores ETDC[ETDCOFF] only.

59.6.2.35 CAN FD Control (FDCTRL)

Offset

Register	Offset
FDCTRL	C00h

Function

Contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in Table 961.

When an 8-byte payload is selected:

- Block R0 allocates MB0–MB31.
- Block R1 allocates MB32–MB63.
- Block R2 allocates MB64–MB95.

When a payload larger than eight bytes is selected, the maximum number of message buffers in a block is limited as described below.

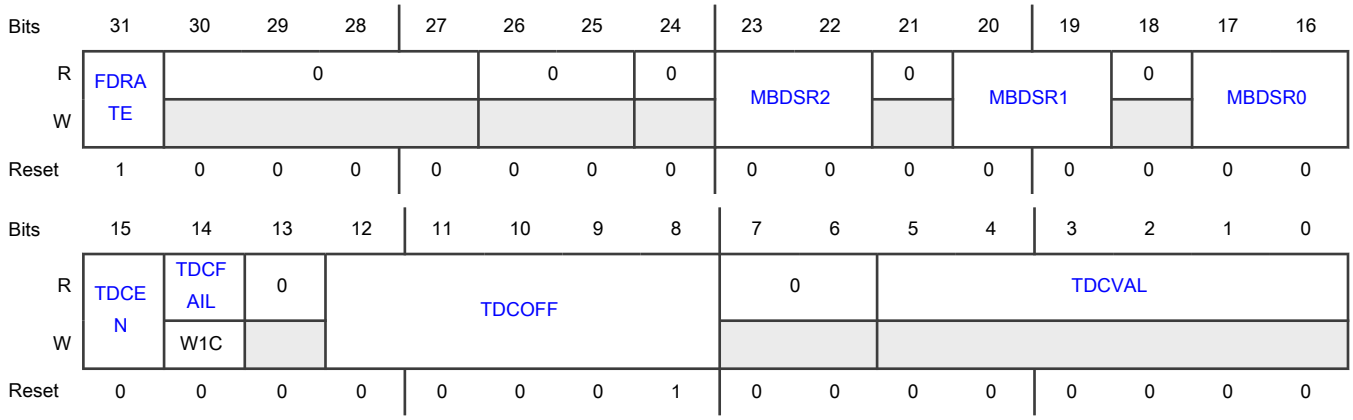
Table 961. Number of message buffers

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

One memory block fits exactly 32 message buffers with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last message buffer in a block and the beginning of the next block. This empty memory corresponds to less than one message buffer, and must not be used.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31 FDRATE	Bit Rate Switch Enable Enables the effect of the Bit Rate Switch (BRS bit) during the data phase of TX messages. When 1, if BRS = 1 in the TX message buffer, frames are transmitted with bit rate switching. When 0, frames are transmitted at a nominal rate, and the BRS bit in the TX MB has no effect. The CPU can write to this field at any time. However, its effect becomes active only under one of these conditions: • The CAN bus is in the Wait for Bus Idle state. • The CAN bus is in the Bus Idle state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The CAN bus is in the Bus Off state. • The current frame under reception or transmission reaches the interframe space. By writing 0 to FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted at nominal bit rate. This transmission occurs regardless of the value in the BRS bit of the TX message buffers. 0b - Disable 1b - Enable
30-27 —	Reserved
26-25 —	Reserved
24 —	Reserved
23-22 MBDSR2	Message Buffer Data Size for Region 2 Selects the data size per message buffer for region R2 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00b - 8 bytes 01b - 16 bytes 10b - 32 bytes 11b - 64 bytes
21 —	Reserved
20-19 MBDSR1	Message Buffer Data Size for Region 1 Selects the data size per message buffer for region R1 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00b - 8 bytes 01b - 16 bytes 10b - 32 bytes 11b - 64 bytes
18 —	Reserved
17-16	Message Buffer Data Size for Region 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
MBDSR0	Selects the data size per message buffer for region R0 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00b - 8 bytes 01b - 16 bytes 10b - 32 bytes 11b - 64 bytes
15 TDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. TDC must be disabled when Loopback mode is enabled (see CTRL1[LPB]). **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - Disable 1b - Enable
14 TDCFAIL	Transceiver Delay Compensation Fail Indicates whether the Transceiver Delay Compensation (TDC) mechanism is out of range. In this case, the mechanism cannot compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). The first time that FlexCAN detects the out-of-range condition, this field becomes 1. **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - In range 1b - Out of range
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details about loop delay measurement. This field can be written in Freeze mode only. Its value can be defined in Protocol Engine Clock periods (CANCLK, see Protocol timing for more details). The value must be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** If CTRL2[BTE] = 1, TDCOFF is read as 0 and a write operation has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Do not write 0 to this field.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value Contains the value of the transceiver loop delay measured from the transmitted EDL-to-R0 transition edge to the respective received one added to FDCTRL[TDCOFF]. This value is an integer multiple of the Protocol Engine Clock period (CANCLK). If CTRL2[BTE] = 1, this field is read as 0. See Protocol timing for details on the loop delay measurement.

59.6.2.36 CAN FD Bit Timing (FDCBT)

Offset

Register	Offset
FDCBT	C04h

Function

Stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] = 1, compatible with the CAN FD specification. Fields in this register define:

- The time quantum duration
- The number of time quanta per CAN bit
- The sample point position for the data bit rate portion of a CAN FD message with BRS = 1

Soft reset does not affect the contents of this register.

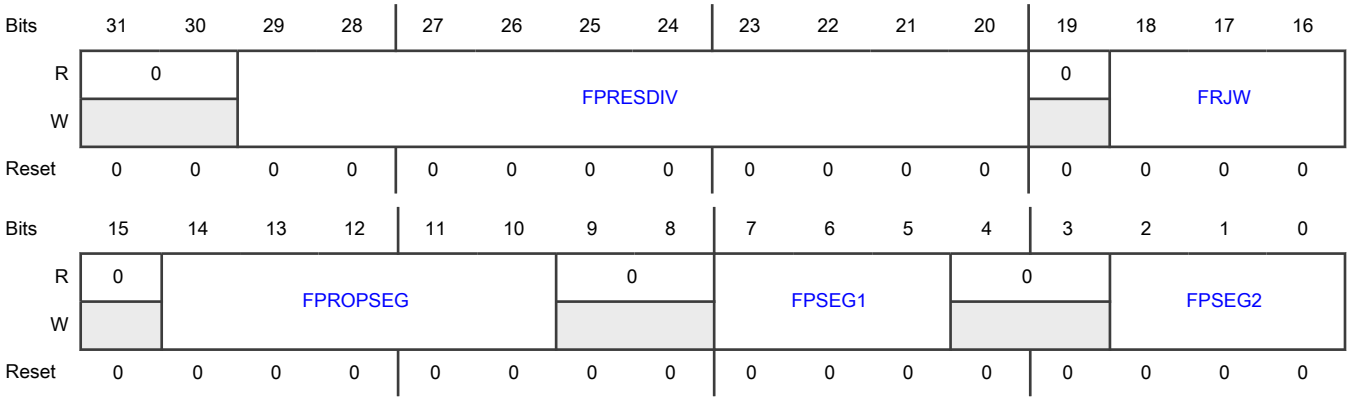
The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] = 1, this register is read as zero and a write operation has no effect.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with BRS = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for this field and for CTRL1[PRESDIV] or CBT[EPRESDIV]. See the first note in CAN FD frames for details.
19 —	Reserved
18-16 FRJW	Fast Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = FSJW + 1. One Time Quantum = one Sclock period.
15 —	Reserved
14-10 FPROPSEG	Fast Propagation Segment

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = FPROPSEG × Time Quanta. One Time Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 Defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 Defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

59.6.2.37 CAN FD CRC (FDCRC)

Offset

Register	Offset
FDCRC	C08h

Function

Provides information about the cyclic redundancy check (CRC) of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats.

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to 16 bytes.
- The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than 16 bytes.

Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time that the TX Interrupt flag is set.

$$CRC\_15 = C599h: \ (x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1)$$

$$CRC\_17 = 3685Bh: \ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x^1 + 1)$$

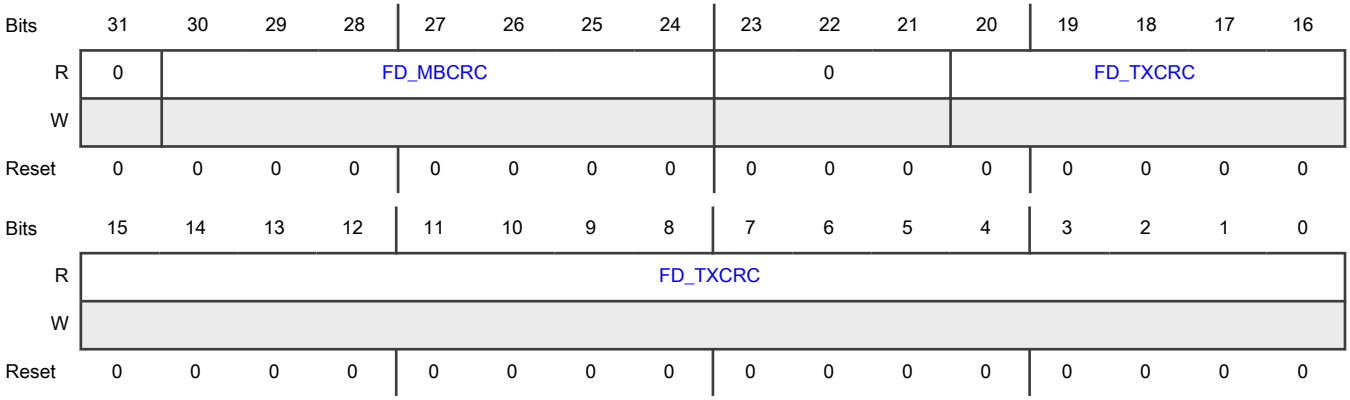
$$CRC\_21 = 302899h: \ (x^{21} + x^{20} + x^{13} + x^{11} + x^7 + x^4 + x^3 + 1)$$

Equation 33. CRC polynomial used on CAN frame

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31 —	Reserved
30-24 FD_MBCRC	CRC Message Buffer Number for FD_TXCRC Indicates the number of the message buffer corresponding to the value in FDCRC[FD_TXCRC], for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21 —	Reserved
20-0 FD_TXCRC	Extended Transmitted CRC value Contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeroes, respectively. For CRC_15, this field has the same content as Cyclic Redundancy Check (CRCR).

59.6.2.38 Enhanced RX FIFO Control (ERFCR)

Offset

Register	Offset
ERFCR	C0Ch

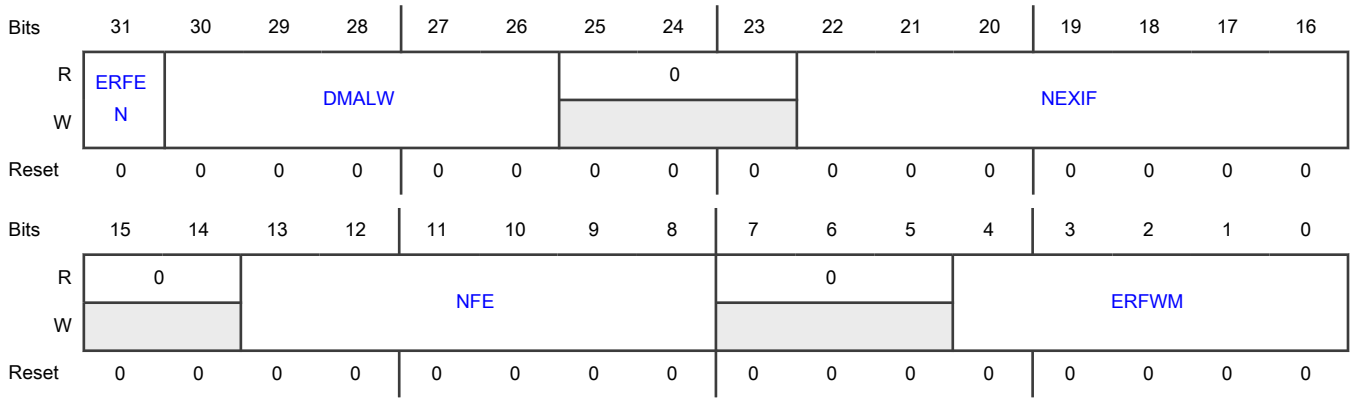
Function

Defines the Enhanced RX FIFO configuration.

This register can be written only in Freeze mode.

Soft reset does not affect any of the contents of this register.

Diagram



Fields

Field	Function
31 ERFEN	Enhanced RX FIFO enable Enables the Enhanced RX FIFO. **NOTE** If MCR[RFEN] = 1, do not write 1 to this field. 0b - Disable 1b - Enable
30-26 DMALW	DMA Last Word Defines the last DMA address for each Enhanced RX FIFO element. This table shows the number of elements and the last address for each Enhanced RX FIFO element according to the value of DMALW.

Table continued from the previous page...

Field	Function
	<table><tr><th>DMALW</th><th>Number of 32-bit words transferred</th><th>Last FIFO address</th></tr><tr><td>0</td><td>1</td><td>2000h</td></tr><tr><td>1</td><td>2</td><td>2004h</td></tr><tr><td>2</td><td>3</td><td>2008h</td></tr><tr><td>3</td><td>4</td><td>200Ch</td></tr><tr><td>4</td><td>5</td><td>2010h</td></tr><tr><td>5</td><td>6</td><td>2014h</td></tr><tr><td>6</td><td>7</td><td>2018h</td></tr><tr><td>7</td><td>8</td><td>201Ch</td></tr><tr><td>8</td><td>9</td><td>2020h</td></tr><tr><td>9</td><td>10</td><td>2024h</td></tr><tr><td>10</td><td>11</td><td>2028h</td></tr><tr><td>11</td><td>12</td><td>202Ch</td></tr><tr><td>12</td><td>13</td><td>2030h</td></tr><tr><td>13</td><td>14</td><td>2034h</td></tr><tr><td>14</td><td>15</td><td>2038h</td></tr><tr><td>15</td><td>16</td><td>203Ch</td></tr><tr><td>16</td><td>17</td><td>2040h</td></tr><tr><td>17</td><td>18</td><td>2044h</td></tr><tr><td>18</td><td>19</td><td>2048h</td></tr><tr><td>19</td><td>20</td><td>204Ch</td></tr></table> **NOTE** Undefined DMALW values in the table are reserved and must not be used.
25-23 —	Reserved
22-16 NEXIF	Number of Extended ID Filter Elements Defines the number of extended ID filter elements used during the Enhanced RX FIFO matching process. The value of this field must be less than or equal to NFE + 1. The number of standard ID filter elements is 2 × (NFE - NEXIF + 1).

Field	Function
	This table shows the number of extended ID filters and standard ID filters available for Enhanced RX FIFO if all filter elements are used.

NEXIF	NFE	Number of Extended ID filter elements	Number of Standard ID filter elements

Fields

Field	Function
31 ERFUFW	Enhanced RX FIFO Underflow Flag Indicates whether an underflow condition occurred in the enhanced RX FIFO. If ERFIER[ERFUFWIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Underflow
30 ERFOVF	Enhanced RX FIFO Overflow Flag Indicates whether an overflow condition occurred in the Enhanced RX FIFO. If ERFIER[ERFOVFIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Overflow
29 ERFWMI	Enhanced RX FIFO Watermark Indication Flag Indicates whether the number of messages available in the Enhanced RX FIFO is greater than the watermark defined in ERFCR[ERFWM]. If ERFIER[ERFWMIIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Number of messages in FIFO is greater than the watermark
28 ERFDA	Enhanced RX FIFO Data Available Flag Indicates whether there is at least one message stored in the ERX FIFO. If ERFIER[ERFDAIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - At least one message stored in Enhanced RX FIFO

Table continues on the next page...

Table continued from the previous page...

Field	Function
27 ERFCLR	Enhanced RX FIFO Clear Writing one to this field during Freeze mode clears Enhanced RX FIFO content. Writing to this field outside Freeze mode, or writing 0 to this field, has no effect. 0b - No effect 1b - Clear enhanced RX FIFO content
26-18 —	Reserved
17 ERFE	Enhanced RX FIFO Empty Flag Indicates whether Enhanced RX FIFO is empty. 0b - Not empty 1b - Empty
16 ERFF	Enhanced RX FIFO Full Flag Indicates whether enhanced RX FIFO is full. 0b - Not full 1b - Full
15 —	Reserved
14-6 —	Reserved
5-0 ERFEL	Enhanced RX FIFO Elements Indicates the number of CAN messages stored in the Enhanced RX FIFO.

59.6.2.41 High-Resolution Timestamp (HR_TIME_STAMP0 - HR_TIME_STAMP95)

Offset

For n = 0 to 95:

Register	Offset
HR_TIME_STAMPn	C30h + (n × 4h)

Function

Stores a copy of a 32-bit timer at the start or end of a CAN frame.

HR_TIME_STAMP0 stores the 32-bit timestamp associated with MB0, HR_TIME_STAMP1 stores the 32-bit timestamp associated with MB1, and so on.

Reset does not affect these registers.

NOTE

Do not write to these registers outside Freeze mode.

Table 962. High-Resolution Timestamp register operation

TSTAMPCAP	Captured timebase	Capture point
b00	None	None
b01	32 bits of high-resolution on-chip timer	Seventh bit of the end-of-frame field for transmission and sixth bit of the end-of-frame field for reception.
b10	32 bits of high-resolution on-chip timer	Start of frame
b11	32 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TS															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

R W	TS															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
31-0 TS	High-Resolution Timestamp Captures the copy of the timestamp of corresponding message buffer. This field always captures a 32-bit timer value.

59.6.2.42 Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127)

Offset

For n = 0 to 127:

Register	Offset
ERFFELn	3000h + (n × 4h)

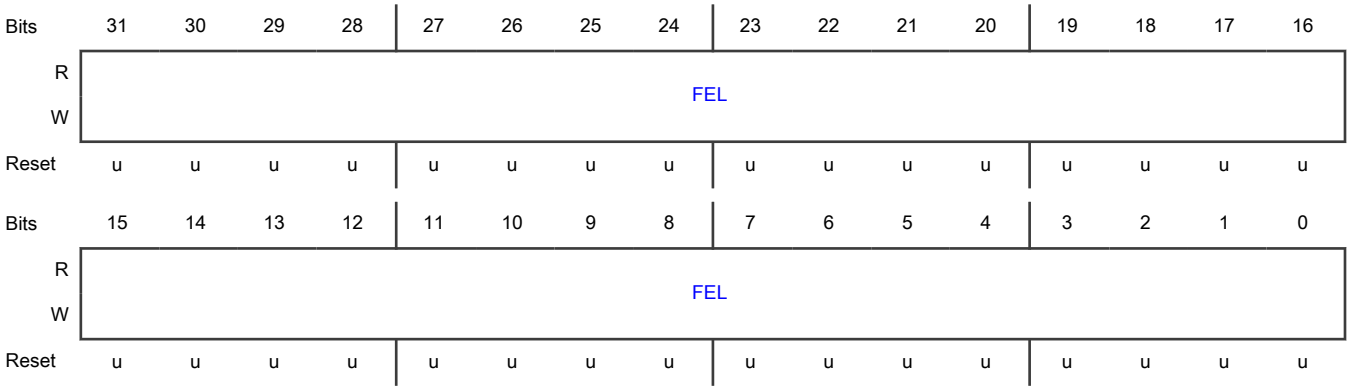
Function

Stores the filter elements of the Enhanced RX FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

ERFFEL registers can be written only in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

Diagram



Fields

Field	Function
31-0 FEL	Filter Element Bits Stores filter elements. Each filter element is used during the match process. If the matching criteria are met, a message is stored in the Enhanced RX FIFO.

59.6.3 Message buffer structure

The message buffer structure used by FlexCAN is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–67Fh is used by the message buffers. When CAN FD is enabled, the exact address for each message buffer depends on the size of its payload. See FlexCAN memory partition for CAN FD.

Table 963. Message buffer structure example with 64-byte payload

	31	30	29	28	27 24	23	22	21	20	19 18 17 16	15 8	7 0

Table 964. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between CAN format and CAN FD format frames. EDL must not be 1 for message buffers configured to RANSWER with code field 1010b (see Table 965).
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive.
CODE	Message Buffer Code	Can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 965 and Table 966. See Functional description.

Table 965. Message buffer code for RX buffers

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	—	Message buffer does not participate in the matching process.
0100b: EMPTY. Message buffer is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after Move-in), CODE is automatically updated to FULL.

Table continues on the next page...

Table 965. Message buffer code for RX buffers (continued)

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0010b: FULL. Message buffer is full.	FULL	Yes	FULL	—	The act of reading the Control and Status word followed by unlocking the message buffer (SRV) does not make CODE return to EMPTY. It remains FULL. If a new frame is moved to the message buffer after the message buffer is serviced, the code remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the message buffer is FULL and a new frame is moved to this message buffer before the CPU services it, CODE is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0110b: OVERRUN. Message buffer is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If CODE indicates OVERRUN and the CPU has serviced the message buffer, when a new frame is moved to the message buffer, CODE returns to FULL.
		No	OVERRUN	—	If CODE already indicates OVERRUN, and another new frame must be moved, the message buffer is overwritten again, and CODE remains OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4]. A frame was configured to recognize a Remote	RANSWER	—	TANSWER (1110b)	0	A Remote Answer was configured to recognize a Remote Request

Table continues on the next page...

Table 965. Message buffer code for RX buffers (continued)

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
Request frame and transmit a Response frame in return.[5]					frame received. After that, a message buffer is set to transmit a response frame. CODE is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] = 0, transmit a response frame when a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0] = 1: BUSY. FlexCAN is updating the contents of the message buffer. The CPU must not access the message buffer.	BUSY[6]	—	FULL	—	Indicates that the message buffer is being updated. It automatically becomes 0 and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced message buffer. Message buffer was read and unlocked by reading TIMER or other message buffer.
2. A frame is considered a successful reception after the frame is moved to a message buffer (move-in process). See Move-in.
3. Remote Request Stored field. See Control 2 (CTRL2).
4. Code 1010b is not considered TX and a message buffer with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, with EDL = 1.
6. For TX message buffers, the BUSY bit should be ignored upon read, except when MCR[AEN] = 1. If this field is 1, the corresponding message buffer does not participate in the matching process.

Table 966. Message buffer code for TX buffers

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
1000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	Message buffer does not participate in arbitration process.
1001b: ABORT. Message buffer is aborted.	ABORT	—	—	Message buffer does not participate in arbitration process.
1100b: DATA. Message buffer is a TX data frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the message

Table continues on the next page...

Table 966. Message buffer code for TX buffers (continued)

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
				buffer automatically returns to the INACTIVE state.
1100b: REMOTE. Message buffer is a Transmit Remote Request frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the message buffer automatically becomes an RX Empty message buffer with the same ID.
1110b: TANSWER. Message buffer is a Transmit Response frame from an incoming Remote Request frame.	TANSWER	—	RANSWER	This intermediate code is automatically written to the message buffer by the CHI as a result of a match to a Remote Request frame. The Remote Response frame is transmitted unconditionally once, then the code automatically returns to RANSWER (1010b). The CPU can also write this code with the same effect. The Remote Response frame can be a data frame or another remote request frame, depending on the value of RTR. See Matching process and Arbitration process for details.

Table 967. RX and TX message buffer field descriptions

Mnemonic	Field	Description
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Write 1 to SRR for transmission (TX Buffers). SRR is stored with the value received on the CAN bus for RX receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss. 1: Recessive value is compulsory for transmission in extended format frames. 0: Dominant is not a valid value for transmission in extended format frames.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 1: Frame format is extended 0: Frame format is standard

Table continues on the next page...

Table 967. RX and TX message buffer field descriptions (continued)

Mnemonic	Field	Description
RTR	Remote Transmission Request	Affects the behavior of remote frames and is part of the reception filter. See Table 965, Table 966, and CTRL2[RRS]. If FlexCAN transmits this field as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If this field is transmitted as 0 (dominant) and it is received as 1 (recessive), FlexCAN treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission. 1: If message buffer is TX, indicates that the current message buffer may have a Remote Request frame to be transmitted. If the message buffer is RX, incoming remote request frames may be stored. 0: Indicates that the current message buffer has a Data frame to be transmitted. In an RX message buffer, it may be considered in matching processes. **NOTE** When configuring CAN FD frames, this field must be 0.
DLC	Data Length Code	Indicates the length (in bytes) of the RX or TX data, which is located in offset 8h–Fh of the message buffer space (see Table 963). In reception, this field is written by FlexCAN, copied from the DLC field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 969).
TIMESTAMP	Free-Running Counter Timestamp	Provides a copy of the Free-Running Timer, captured for TX and RX frames when the beginning of the Identifier field appears on the CAN bus. See Table 968 for Timestamp operation.
PRIO	Local priority	Used only when MCR[LPRIOEN] = 1, and only makes sense for transmit message buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.
ID	Frame Identifier	In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the message buffers. For RX frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC, as shown in Table 969.

Table 968. Timestamp operation

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured timebase	Capture point
b00	bxx	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
b00	bxx	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
bxx	b00	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
bxx	b00	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
b01	b01	x	Lower 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b01	b10	x	Upper 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b10	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame
b10	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame
b11	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format
b11	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

14	DATA BYTE 0–47
15	DATA BYTE 0–63

59.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, FlexCAN RAM can be partitioned into blocks of 512 bytes each. Each block can accommodate a number of message buffers depending on the configuration provided by FDCTRL[MBDSR*n*] as shown in Table 970.

Table 970. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control field in FDCTRL	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0 = 00, 32 MBs with 8-byte payload MBDSR0 = 01, 21 MBs with 16-byte payload MBDSR0 = 10, 12 MBs with 32-byte payload MBDSR0 = 11, 7 MBs with 64-byte payload
1	32 to 63	MBDSR1	MBDSR1 = 00, 32 MBs with 8-byte payload MBDSR1 = 01, 21 MBs with 16-byte payload MBDSR1 = 10, 12 MBs with 32-byte payload MBDSR1 = 11, 7 MBs with 64-byte payload
2	64 to 95	MBDSR2	MBDSR2 = 00, 32 MBs with 8-byte payload MBDSR2 = 01, 21 MBs with 16-byte payload MBDSR2 = 10, 12 MBs with 32-byte payload MBDSR2 = 11, 7 MBs with 64-byte payload

Payload sizes of 16, 32, or 64 bytes may be configured in some or all of RAM blocks. In those cases, the total number of MBs and their respective number order may differ from the default configuration of 8 bytes. Consider an example where:

- Block0 is configured to an 8-byte payload
- Block1 is configured to a 16-byte payload
- Block2 is configured to 32-byte payload

In this case, Table 971 indicates how the message buffers are arranged in RAM.

Table 971. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0] = 00, 8-byte payload	32	0 to 31
1	FDCTRL[MBDSR1] = 01, 16-byte payload	21	32 to 52
2	FDCTRL[MBDSR2] = 10, 32-byte payload	12	53 to 64

59.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

59.6.6 Legacy RX FIFO structure

When MCR[RFEN] = 1, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy RX FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the value of CTRL2[RFFN], contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy RX FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy RX FIFO data structure.

Table 976. Legacy RX FIFO structure

	31 28	24 23	22	21	20	19 18 17 16	15 8	7 0
80h	IDHIT		SRR	IDE	RTR	DLC	TIMESTAMP	
84h		ID standard				ID extended		
88h	Data byte 0		Data byte 1				Data byte 2	Data byte 3
8Ch	Data byte 4		Data byte 5				Data byte 6	Data byte 7
90h–DCh	Reserved							
E0h	ID filter table element 0							
E4h	ID filter table element 1							
E8h–2D4h	ID filter table elements 2 to 125							
2D8h	ID filter table element 126							
2DCh	ID filter table element 127							
		= Unimplemented or reserved						

Each ID filter table element occupies an entire 32-bit word. One, two, or four Identifier Acceptance Filters (IDAF) can compound each element, depending on MCR[IDAM]. The following tables show the IDAF indexing.

Table 977 shows the three different formats of the ID table elements. All elements of the table must have the same format. See Legacy RX FIFO for more information.

Table 977. ID table structure

Format	31	30	29 24	23 16	15	14	13 8	7 1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)						
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 296–)		RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)		
C	RXIDC_0 (std and ext = 31–24)		RXIDC_1 (std and ext = 23–16)		RXIDC_2 (std and ext = 15–8)		RXIDC_3 (std and ext = 7–0)		
		= Unimplemented or Reserved							

Table 978. Field descriptions

Mnemonic	Field	Description
RTR	Remote Frame	Specifies whether remote frames are accepted into the Legacy FIFO if they match the target ID. 1: Remote frames can be accepted and data frames are rejected.

Table continues on the next page...

Table 978. Field descriptions (continued)

Mnemonic	Field	Description
		0: Remote frames are rejected and data frames can be accepted.
IDE	Extended Frame	Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID. 1: Extended frames can be accepted and standard frames are rejected. 0: Extended frames are rejected and standard frames can be accepted.
RXIDA	RX Frame Identifier (Format A)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.
RXIDB_0, RXIDB_1	RX Frame Identifier (Format B)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.
RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3	RX Frame Identifier (Format C)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which identifier acceptance filter the received message in the output of the Legacy RX FIFO hit. See Legacy RX FIFO for more information.

59.6.7 Enhanced RX FIFO structure

When ERFCR[ERFEN] = 1, the Enhanced RX FIFO is enabled. The region 2000h–204Ch contains the output of the Enhanced RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read.

Table 979. Enhanced RX FIFO structure

	31	30	29	28 … 24	23	22	21	20	19	18	17	16	15 … 8	7	6 … 0

Table 981. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between classical CAN format and CAN FD format frames. 0: Classical CAN frame format 1: CAN FD frame format

Table continues on the next page...

Table 981. Field descriptions (continued)

Mnemonic	Field	Description
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame. 0: Bit rate is not switched in a CAN FD frame. 1: Bit rate is switched in a CAN FD frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive. This field is meaningful only if EDL = 1. 0: Error-active 1: Error-passive
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 0: Standard 1: Extended
RTR	Remote Frame	Identifies whether the current frame is a data frame or a remote request. 0: Data frame 1: Remote request
DLC	Data Length Code	Defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. See Table 969 for more details.
LEGACY TIMESTAMP	16-bit Timestamp	Provides a copy of the Free-Running Timer, captured during the CAN frame. See Table 968 for details about legacy timestamp operation.
ID	Frame Identifier	In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be stored in the data field.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127) the received message in the output of the Enhanced RX FIFO hit. For each filter region, standard-ID filter space, and extended-ID filter space, there is an independent index starting from zero. Table 982 shows how FlexCAN writes IDHIT according to each filter element.
HR TIMESTAMP	High-resolution Timestamp	32-bit timebase captured during the CAN frame. When CTRL2[TSTAMPCAP] is not zero, a 32-bit timebase is captured from a dedicated on-chip timer which operates in free-running mode. See CTRL2[TSTAMPCAP] for details about capture point configuration of the high-resolution timestamp.

Table 982. IDHIT for Enhanced RX FIFO

Enhanced RX FIFO filter element - ERFFEL	IDHIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m-1)	m-1	Extended-ID
ERFFEL(m)	0	Standard-ID
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n-m+1)	2x(n-m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist. If NEXIF > NFE, only extended-ID filter elements exist.

60.2 Overview

FLEXIO is a highly configurable module providing a wide range of functionality, including:

- Emulation of various serial or parallel communication protocols
- Flexible 16-bit timers with support for various trigger, reset, enable, and disable conditions
- Programmable logic blocks which allow the implementation of digital logic functions on-chip and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from the CPU

60.2.1 Block diagram

The following diagram provides a high-level overview of the FLEXIO timers and shifters configuration.

FLEXIO uses shifters, timers, and external triggers to shift data into or out of the FLEXIO. As shown in the block diagram, timers control the timing of this data shift. You can configure the timers to use generic timer functions, external triggers, or various other conditions to determine the control.

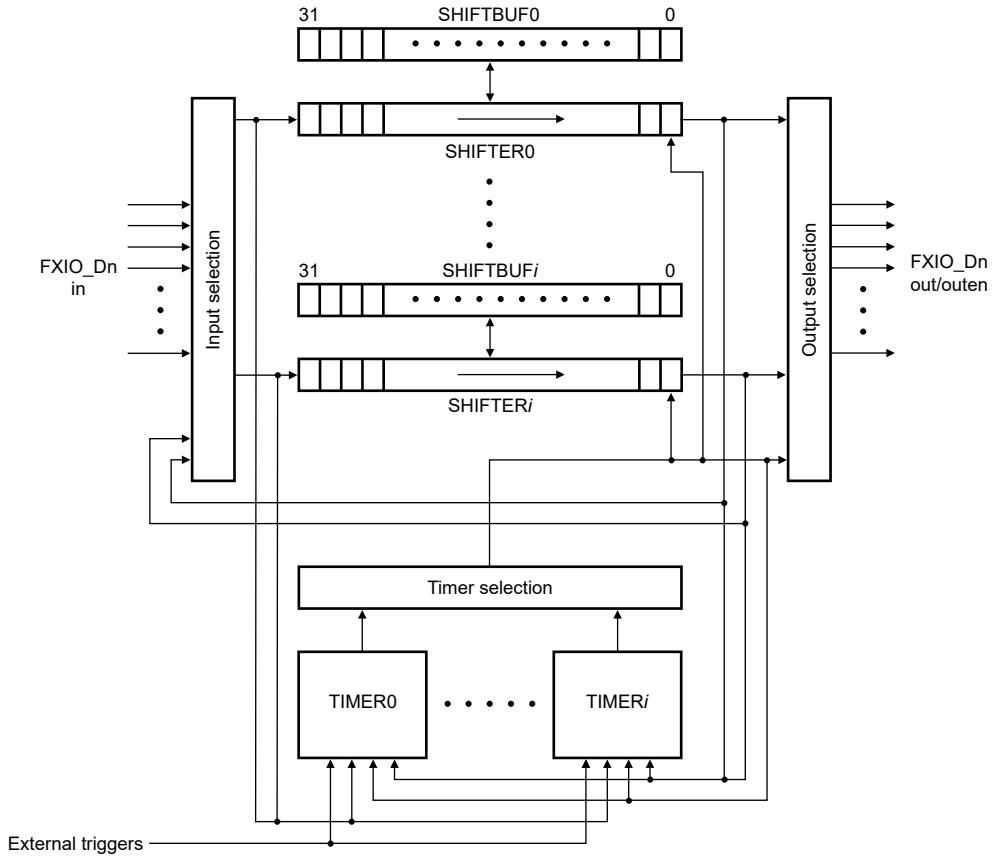

Figure 452. FLEXIO block diagram

60.2.2 Features

FLEXIO includes the following features:

- Array of 32-bit shift registers with transmit, receive, data match, logic, and state modes
  - Double-buffered shifter operation for continuous data transfer
  - Shifter concatenation to support large transfer sizes
  - Automatic start and stop bit generation
  - 1, 2, 4, 8, 16, or 32 multi-bit shift widths for parallel interface support
  - Interrupt, DMA, or polled transmit and receive operation
- Highly flexible 16-bit timers with support for various internal or external trigger, reset, enable, and disable conditions
  - Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during Stop mode
  - Programmable logic mode for integrating external digital logic functions on-chip, or combining pin, shifter, or timer functions to generate complex outputs
  - Programmable state machine for offloading basic system control functions from CPU, with support for up to eight states, eight outputs, and three selectable inputs per state
- Integrated general-purpose input/output registers and pin rising or falling edge interrupts to simplify software support
- Support for a wide range of protocols, including but not limited to:

— UART

— I2C

— SPI

— I2S

— Camera IF

— Motorola 68K or Intel 8080 bus

— PWM or waveform generation

— Input-capture (pulse edge interval measurement), such as SENT

60.3 Functional description

60.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FLEXIO. The timing of shift, load, and store events is controlled by the timer assigned to the shifter via the SHIFTCTL[TIMSEL] register. Shifters are designed to support either DMA, interrupt, or polled operation. The following diagram provides a detailed view of the shifter microarchitecture.

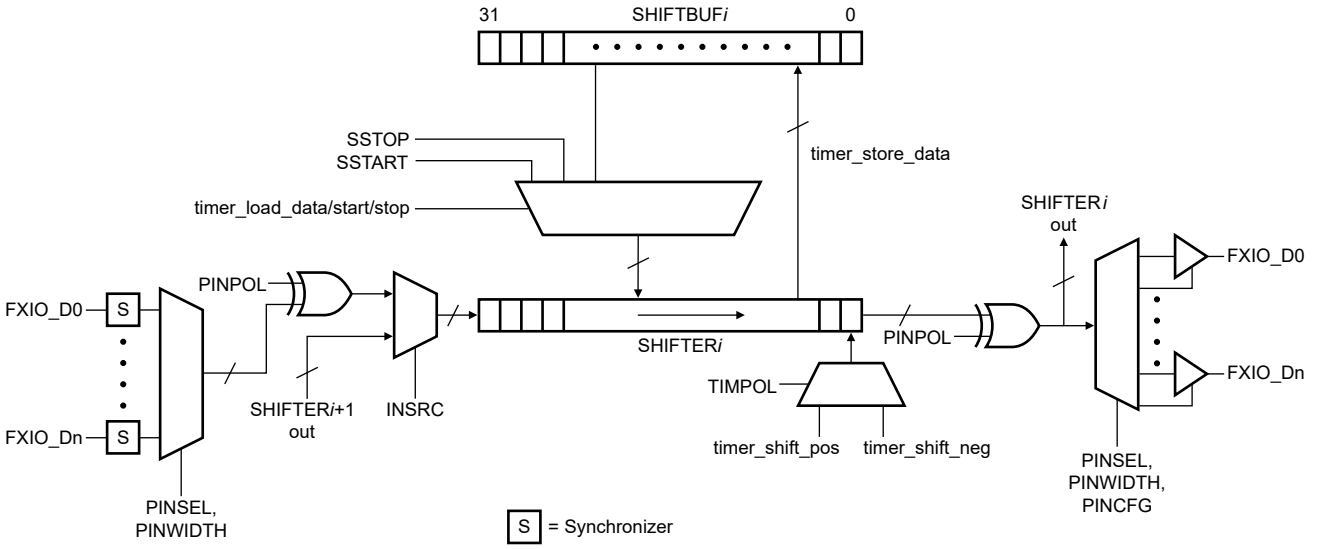

Figure 453. Shifter microarchitecture

60.3.1.1 Transmit mode

In Transmit mode (SHIFTCTL[SMOD]=Transmit), the shifter loads data from the SHIFTBUF register and shifts data out when a load event is signaled by the assigned timer. An optional start and stop bit can be automatically loaded before or after SHIFTBUF data by configuring either the SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] registers in the shifter and timer.

NOTE

If a stop bit is enabled, the shifter immediately loads a stop bit when it is initially configured for Transmit mode.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has either been loaded from the SHIFTBUF register into the shifter or when the shifter is initially configured for Transmit mode. To clear the flag, write a logic 1 or write new data to the SHIFTBUF register. In Transmit mode, write any value to the SHIFTBUF register to clear the corresponding Shifter Status Flag. The flag is cleared regardless of what is writing or the state of the DMA or interrupt enables. See the SSF register description for information on how the flag is set and cleared for each mode.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). Clear the flag by writing logic 1.

60.3.1.2 Receive mode

When a store event is signaled by the assigned timer in Receive mode (SHIFTCTL[SMOD]=Receive), the shifter shifts data in and stores data in the SHIFTBUF register. You can check for a start and stop bit before or after the shifter data is sampled by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART] or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] registers in the shifter and timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has been stored in the SHIFTBUF register from the shifter. To clear the flag, write a logic 1 or read the data from the SHIFTBUF register. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is in Receive mode. The flag is cleared regardless of what is reading or the state of the DMA or interrupt enables. See the SSF register description for information on how the flag is set or cleared for each mode.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set either when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start or stop bit check. Write logic 1 to clear the flag.

60.3.1.3 Match Store mode

In Match Store mode (SHIFTCTL[SMOD]=Match Store), the shifter shifts data in, checks for a match result, and stores matched data into the SHIFTBUF register when a store event is signaled by the assigned timer. By configuring either the SHIFTCFG[SSTART], TIMCFG[TSTART], and SHIFTCFG[SSTOP], or TIMCFG[TSTOP] registers in the shifter and timer, you can check for a start and stop bit before or after the shifter data is sampled. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and the matched data is stored in the SHIFTBUF register from the shifter. To clear the flag, read the matched data from the SHIFTBUF register or write a logic 1 to the flag. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is configured in Match Store mode. The flag is cleared regardless of what is reading or the state of the DMA or interrupt enables. See the SSF register description for information on how the flag is set or cleared for each mode.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start or stop bit check. Write logic 1 to clear the flag.

60.3.1.4 Match Continuous mode

In Match Continuous mode (SHIFTCTL[SMOD]=Match Continuous), the shifter shifts data in and continuously checks for a match result whenever a shift event is signaled by the assigned timer. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as there is no longer a match between the shifter data and the SHIFTBUF register. **The flag cannot be cleared by reading the SHIFTBUF register.**

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. To clear the flag, write logic 1 or perform a read from the SHIFTBUF register.

60.3.1.5 State mode

State mode enables you to implement any state machine with up to eight states, eight outputs, and three selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which can remain in a low-power mode.

In State mode (SHIFTCTL[SMOD]=State) when the shifter has been selected by the current state pointer (SHIFTSTATE[STATE]), use the SHIFTBUF register to drive the output and compute the next state values. The following diagram provides a detailed view of shifter microarchitecture when configured for State mode.

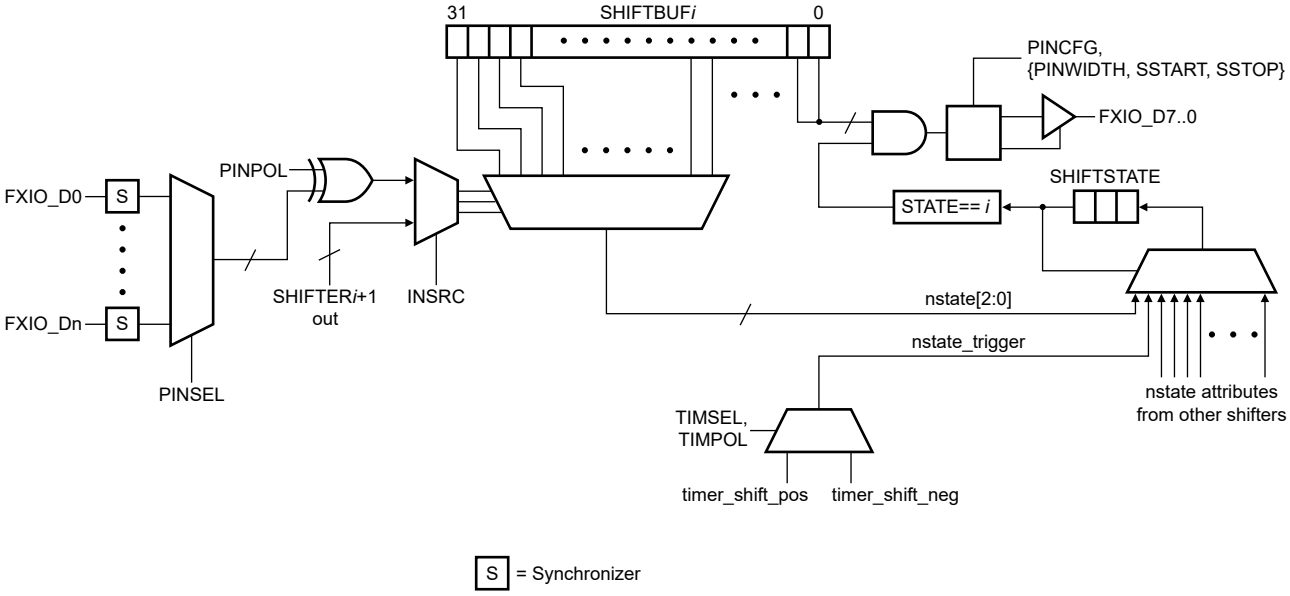

Figure 454. State microarchitecture

When a specific shifter (Shifter *n*) is selected by the current state pointer, output pins FXIO_D[7:0] are driven by SHIFTBUFn[31:24] the configuration set by SHIFTCTLi[PINCFG]. Set SHIFTCFGi{PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} to disable the output drive on pins FXIO_D[7:0] for state machine applications which require less than eight output pins.

Use the three input pins selected by SHIFTCTLi[PINSEL] and SHIFTBUFn[23:0] to compute the next state value.

NOTE

Each state can use a different set of three input pins.

The following table shows how the next state value is computed when the current state pointer is pointing to Shifter *n*.

Table 984. Next State computation for SHIFTSTATE[STATE]=*n*

FXIO_D[PINSEL+2]	FXIO_D[PINSEL+1]	FXIO_D[PINSEL]	Next State value
0	0	0	SHIFTBUFn[2:0]
0	0	1	SHIFTBUFn[5:3]
0	1	0	SHIFTBUFn[8:6]
0	1	1	SHIFTBUFn[11:9]
...	...	...	...
1	1	1	SHIFTBUFn[23:21]

NOTE

Other shifters and timers can be configured to drive the input pins of a given state, allowing you to create complex combinations of shifters and timers as needed. For example, the output of a shifter configured for Logic mode can be used to drive a state machine input.

The next state transition is triggered using the timer output selected by SHIFTCTLi[TIMSEL], with polarity controlled by SHIFTCTLi[TIMPOL].

NOTE

Each state can use a different timer to trigger each next state transition, allowing various internal or external trigger sources and clocking configurations to be used. See Timer section for more details.

The current state pointer defaults to Shifter 0 at reset; however, you can write to select a different shifter for the initial state. If the current state pointer selects a shifter which is not configured for State mode, then outputs are not driven and a next state transition is never triggered.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when the shifter is selected by the current state pointer. The flag is cleared when the current state pointer is updated to a different shifter.

60.3.1.6 Logic mode

Logic mode enables you to implement a small amount of programmable digital logic within a FLEXIO shifter.

In Logic mode (SHIFTCTL[SMOD]=Logic), use the SHIFTBUF register to implement a 5-input, 32-bit programmable logic lookup table. The following diagram provides a detailed view of shifter microarchitecture when configured for Logic mode.

Use SHIFTBUF*n* to configure the lookup table for the four pin inputs. You can also use SHIFTER*n* to configure a feedback or delayed pin source as the fifth input to the lookup table.

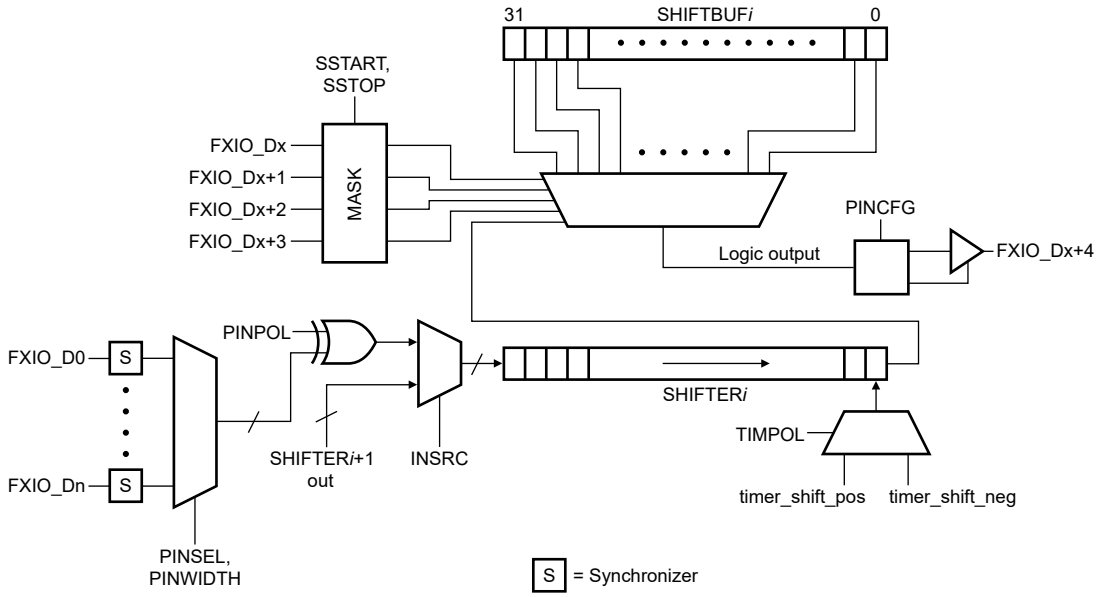

Figure 455. Logic microarchitecture

The lookup table is driven using four pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]), plus one input from the internal shifter. It can be configured to drive an output pin using the SHIFTCTL[PINCFG] field. Pin inputs and outputs are fixed for each logic lookup table and are not selectable. The following table lists the logic output value selected by the lookup table for shifter *n*.

Table 985. Logic lookup table for Shifter *n*

SHIFTER*n*[0]	FXIO_D[x+3][1]	FXIO_D[x+2]	FXIO_D[x+1]	FXIO_D[x]	Logic Output to FXIO_D[x+4]
0	0	0	0	0	SHIFTBUF*n*[0]
0	0	0	0	1	SHIFTBUF*n*[1]

Table continues on the next page...

Table 985. Logic lookup table for Shifter *n* (continued)

0	0	0	1	0	SHIFTBUF*n*[2]
0	0	0	1	1	SHIFTBUF*n*[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUF*n*[31]

1. for Shifter *n*=0...3, x=*n*

   for Shifter *n*=4...7, x=*n*+4

To minimize output glitches, use SHIFTCFG[SSTOP] and SHIFTCFG[SSTART] to mask unused input pins. When set, {SSTOP[1:0] and SSTART[1:0]} mask FXIO_D[x+3]...FXIO_D[x] inputs respectively so that any transitions on these pins do not cause the logic output to glitch.

NOTE

Other shifters and timers can be configured to drive the input pins of a given lookup table, allowing you to concatenate lookup tables or create complex combinations of shifters and timers as needed.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTERi[0]). For example, when configured for a 1-bit shift (PWIDTH=0), the internal shifter introduces a 32-shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the lookup table. When configured for a 32-bit shift (PWIDTH=16...31), the internal shifter introduces a 1-shift clock delay to its input.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic lookup table has a value of 1 after being synchronized to the FLEXIO clock. The flag clears when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a timer if needed.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic lookup table is asserted. Clear the flag by writing it with logic 1.

The Logic mode input pins, including pins driven by other shifters and timers, are synchronized to the FLEXIO functional clock before they are input to the programmable logic lookup table.

60.3.2 Timer operation

The FLEXIO 16-bit timers control the loading, shifting, and storing of the shift registers. The counters load the contents of the compare register and decrement down to zero on the FLEXIO clock. The counters can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to:

- Enable in response to a trigger, pin, or shifter condition,
- Decrement always or only on a trigger or pin edge,
- Reset in response to a trigger or pin condition, or
- Disable on a trigger or pin condition or on a timer compare.

Timers can optionally include a start condition and a stop condition.

Although each timer operates independently, a timer can be configured to enable or disable at the same time as the previous timer (for example, Timer 1 can enable or disable at the same time as Timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input, or an external trigger input. The trigger configuration is separate from the pin configuration which can be configured for input, output data, or output enable. See the chip-specific FLEXIO information for details on the external trigger connections.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD).

60.3.2.1 Timer 8-bit Baud Counter mode

In 8-bit Baud Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the baud rate of the shift clock and the upper 8 bits are used to configure the number of shift clock edges in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits decrement when the lower 8 bits equal zero and decrement.

NOTE

A timer reset event in 8-bit Baud Counter mode only resets the lower 8-bit counter. The upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output. The timer output toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8 bits equal zero and decrement. The timer status flag is set on a timer compare event.

60.3.2.2 Timer 8-bit High PWM mode

In 8-bit High PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output high period and the upper 8 bits are used to configure the timer output low period. The lower 8 bits decrement when the output is high. When the lower 8 bits equal zero and decrement, the timer output is cleared and the lower 8 bits are reloaded from the compare register. The upper 8 bits decrement when the output is low. When the upper 8 bits equal zero and decrement, the timer output is set and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits equal zero and decrements. The timer status flag is set on a timer compare event.

60.3.2.3 Timer 16-bit Counter mode

In 16-bit Counter mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

60.3.2.4 Timer 16-bit Counter Disable mode

In 16-bit Counter Disable mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

60.3.2.5 Timer 8-bit Word Counter mode

In 8-bit Word Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the number of shift clock edges in each word and the upper 8 bits are used to configure the number of words in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits only decrement when the lower 8 bits equal zero and decrement.

A timer compare event occurs when the lower 8 bits equal zero and decrement. The timer status flag is set when the upper 8 bits equal zero and decrement.

60.3.2.6 Timer 8-bit Low PWM mode

In 8-bit Low PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output low period and the upper 8 bits are used to configure the timer output high period. The lower 8 bits decrement when the output is low. When the lower 8 bits equal zero and decrement, the timer output is set and the lower 8 bits are reloaded from the compare

register. The upper 8 bits decrement when the output is high. When the upper 8 bits equal zero and decrement, the timer output is cleared and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits equal zero and decrements. The timer status flag is set on a timer compare event.

60.3.2.7 Timer Enable and Start bit

The following events occur when TIMOD is configured for the desired mode and the condition configured by the timer enable (TIMENA) is detected. When ONETIM is set, the timer status flag must be clear to generate a timer enable event, otherwise the timer enable event is blocked. You can use this to enforce software intervention after each timer iteration.

- Timer counter loads the current value of the compare register and starts decrementing as configured by TIMDEC.
- Timer output may update to its initial state depending on the TIMOUT configuration. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

If the timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT=1), a shifter that is configured to shift on falling edge and load on the first shift will not load correctly.

60.3.2.8 Timer decrement and reset

The timer generates the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC != 10 or 11) or equal to the decrement clock (when TIMDEC = 10 or 11). When TIMDEC is configured to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a timer is configured to decrement on the FLEXIO functional clock divided by 16 or 256 (when TIMDEC = 100 or 101), then a common prescaler that is shared by all timers is used to generate the two divide ratios. This prescaler is reset when all timers are either idle or configured not to use the prescaler (TIMDEC != 100 or 101).

When the timer is configured to reset as determined by the TIMRST field, then the timer counter loads the current value of the compare register again. The timer output and timer shift clock can be configured to update on timer reset, as configured by TIMOUT. If the time output toggles as a result of the timer reset, this can result in a timer shift clock edge. In 8-bit Baud Counter mode this will also decrement the upper 8-bits of the counter.

In general, when the timer counter decrements to zero, a timer compare event is triggered. The timer compare event causes the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the timer mode, the timer status flag may also be set.

60.3.2.9 Timer Disable and Stop bit

When the timer is configured to add a stop bit on each compare, the following additional events occur:

- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.
- The timer counter reloads the current value of the Compare Register on the first rising edge of the shifter clock after the compare.

When the timer is configured to insert a stop bit on each compare, transmit shifters must be configured to load on the first shift.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur:

- Timer counter reloads the current value of the Compare Register and starts decrementing as configured by TIMDEC.
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock would otherwise generate one.

- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit. The timer output does not generate shift events during the stop bit.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When ONETIM is set, the timer status flag must be clear before the next timer enable condition is detected. When the timer is in the stop state condition, receive shift registers with stop bit enabled will store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge. If there is no configured edge between the timer disable and the next rising edge of the shift clock, then the final store and verify do not occur.

60.3.3 Pin operation

The pin configuration for each timer and shifter can be configured to use any FLEXIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable, or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion causes logic zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter can be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

60.3.3.1 Parallel interface

You can configure shifters to use multiple FLEXIO pins in parallel using the SHIFTCFG[PWIDTH] field. PWIDTH is used to configure the following settings of a shifter:

1. Number of bits shifted per shift clock.
2. Number of pins driven by the shifter per shift clock. (Only on shifters supporting parallel transmit. That is, SHIFTER0 and SHIFTER4.)
3. Number of pins sampled by the shifter per shift clock. (Only on shifters supporting parallel receive. That is, SHIFTER3 and SHIFTER7.)

When configured for parallel shift, either 4, 8, 16 or 32 bits can be shifted on every shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG[INSRC]=1), the least significant 4, 8, 16 or 32 bits from the adjacent shifter are sampled on each shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), you can configure the shifter to sample multiple pins (SHIFTCFG[INSRC]=0), with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant bits are masked with 0. For example, if PINSEL=7 and PWIDTH=6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), you can configure the shifter to drive multiple pins using SHIFTCTL[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant pins are not driven. For example, if PINSEL=7 and PWIDTH=6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each shift clock.

60.3.3.2 Pin synchronization

When you configure a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FLEXIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FLEXIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FLEXIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

NOTE

FLEXIO pins are also connected internally. Configuring a FLEXIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timers to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FLEXIO clock and therefore incurs a 1 cycle latency.

When using a pin input as a timer trigger, timer clock, or shifter data input, the following synchronization delays occur:

1. 0.5 to 1.5 FLEXIO clock cycles for external pin
2. 1 FLEXIO clock cycle for an internally driven pin

See Application information for timing considerations such as output valid time and input setup time for specific applications (SPI Controller, SPI Target, I2C Controller, I2S Controller, and I2S Target).

60.3.3.3 Pin override

You can change the state of any FLEXIO pin at any time with software. The pin output enable register configures any pin as an output and drives that pin with the value in the Pin Output Data register.

Alias registers for the Pin Output Enable and Data registers also exist. Writing a logic one to an alias register updates the corresponding register bits in both the Pin Output Enable Register and the Pin Output Data Register as follows.

- Pin Output Disable Register clears Output Enable Register and clear Output Data Register.
- Pin Output Clear Register sets Output Enable Register and clear Output Data Register.
- Pin Output Set Register sets Output Enable Register and set Output Data Register.
- Pin Output Toggle Register sets Output Enable Register and toggle Output Data Register.

60.3.3.4 Pin interrupt

You can read the state of any FLEXIO pin at any time with software. Software can also configure any pin to set a status flag when either a rising or falling edge is detected on that pin. The pin status flag can also be configured to generate an interrupt.

60.3.4 Low power modes

The FLEXIO remains functional during low power modes, provided the Doze Enable field (CTRL[DOZEN]) is clear and the FLEXIO functional clock remains enabled.

The exception to this is in LLS mode. In this case, the Doze Enable (CTRL[DOZEN]) field is ignored and the FLEXIO waits for all timers to complete any pending operation before acknowledging LLS mode entry.

60.3.5 Debug mode

FLEXIO remains functional in Debug mode, provided the Debug Enable field (CTRL[DBGE]) is set.

60.3.6 Clocking

Table 986. FLEXIO clocks

Clock	Description
Functional clock	The FLEXIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FLEXIO functional clock must be enabled before accessing any FLEXIO registers. Provided the FLEXIO functional clock is at least equal to the bus clock, the CTRL[FASTACC] field can be set to support fast register accesses.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers.

60.3.7 Reset

Table 987. FLEXIO resets

Reset	Description
Chip reset	The logic and registers for FLEXIO are reset to their default state on chip reset.
Software reset	The FLEXIO implements a software reset field in its Control Register. CTRL[SWRST] resets all logic and registers to their default state, except for the CTRL itself.

60.3.8 Interrupts and DMA requests

The following table shows the status flags that generate the FLEXIO interrupt and DMA requests.

Table 988. FLEXIO interrupts and DMA requests

Flag	Description	Interrupt	DMA request	Low power wakeup
SSF	Shifter Status Flag	Y	Y	Y
SEF	Shifter Error Flag	Y	N	Y
TSF	Timer Status Flag	Y	Y	Y
PSF	Pin Status Flag	Y	N	Y
ETSF	External Trigger Status Flag	Y	N	Y

60.3.9 Peripheral triggers

The connection between the FLEXIO peripheral triggers and other peripherals is device-specific.

Output triggers

Each FLEXIO timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

Input trigger

FLEXIO supports multiple external trigger inputs that can be used to trigger one or more FLEXIO timers. If a rising edge is detected on an external trigger when FLEXIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FLEXIO functional clock and must assert for at least two cycles of the FLEXIO functional clock to be sampled correctly.

60.4 External signals

Table 989. External signals

Signal	Description	Direction
FXIO_D*n* (*n*=0...31)	Bidirectional FLEXIO shifter and timer pin	Input or output

60.5 Initialization

To initialize FLEXIO registers:

1. Enable FLEXIO by writing CTRL[FLEXEN]=1
2. Configure shift registers for the given application; it is recommended to write Shifter Configuration N (SHIFTCFG0 - SHIFTCFG7) before the corresponding Shifter Control N (SHIFTCTL0 - SHIFTCTL7)
3. Configure timer registers for the given application; it is recommended to write Timer Compare N (TIMCMP0 - TIMCMP7) and Timer Configuration N (TIMCFG0 - TIMCFG7) before the corresponding Timer Control N (TIMCTL0 - TIMCTL7)
4. Enable interrupts and/or DMA requests as appropriate for the given application
5. Write transmit data to initiate a transfer (depending on the given application)

60.6 Application information

This section provides examples for a variety of FLEXIO module applications. See FLEXIO register descriptions for further details.

60.6.1 UART transmit

UART transmit can be supported using one timer, one shifter, and one pin (two pins, if supporting CTS). The start and stop bit insertion is handled automatically, and multiple transfers are supported using DMA controller. The timer status flag is used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention. Before transmitting a break or idle character, the SSTART and SSTOP fields must be altered to transmit the required state, and the data to transmit must equal FFh or 00h. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). When performing byte writes to SHIFTBUF*n* (or SHIFTBUFBIS for transmitting MSB first), the rest of the register remains unaltered. This allows an address mark bit or additional stop bit to remain undisturbed.

NOTE

FLEXIO does not support automatic insertion of parity bits.

Table 990. UART transmit configuration

Register	Value	Comments
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open-drain by setting PINPOL=1h and PINCFG=1h.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1.

Table continues on the next page...

Table 990. UART transmit configuration (continued)

Register	Value	Comments
		Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG*n*	0000_2222h	Configure start bit, stop bit, enable on trigger asserted and disable on compare. Can support CTS by configuring TIMEN=3h.
TIMCTL*n*	01C0_0001h	Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Supports CTS by configuring PINSEL=1h (for Pin 1) and PINPOL=1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports MSB first transfer by writing to the SHIFTBUFBBS[7:0] register instead.

The following table shows an alternative configuration that supports slower baud rates. This configuration requires two timers.

Table 991. UART transmit configuration for slow baud rate

Register	Value	Comments
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Invert output data by setting PINPOL. Support open-drain by setting PINPOL=1h and PINCFG=1h.
TIMCMP*n*	0000_000Fh	Configure for 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG*n*	0030_2622h	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.
TIMCTL*n*	0740_0003h	Configure 16-bit counter using Timer 1 output as internal trigger source.
TIMCMP(*n*+1)	0000_0001h	Configure baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:0] = (baud rate divider / 2) - 1.
TIMCFG(*n*+1)	0000_1200h	Configure enable on trigger asserted and disable on Timer 0 disable. Can support CTS by configuring TIMEN=3h.

Table continues on the next page...

Table 991. UART transmit configuration for slow baud rate (continued)

Register	Value	Comments
TIMCTL(*n*+1)	01C0_0003h	Configure 16-bit counter using Shifter 0 status flag as inverted internal trigger source. Support CTS by configuring PINSEL=1h (for Pin 1) and PINPOL=1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Support MSB first transfer by writing to SHIFTBUFBBS[7:0] instead.

60.6.2 UART receive

UART receive can be supported using one timer, one shifter, and one pin (two timers and two pins, if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FLEXIO; data is sampled only once in the middle of each bit. You can use a timer to implement a glitch filter on the incoming data and a different timer to detect an idle line of programmable length. Break characters cause the error flag to set and the shifter buffer register will return 00h.

NOTE

FLEXIO does not support automatic verification of parity bits.

Table 992. UART receiver configuration

Register	Value	Comments
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG*n*	0204_2422h	Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=2h and TIMRST=4h.
TIMCTL*n*	0000_0081h	Configure dual 8-bit counter using inverted Pin 0 input.
SHIFTBUF*n*	Data to receive	Received data can be read from SHIFTBUFBYS[7:0]. Use the Shifter Status Flag to indicate when data can

Table continues on the next page...

Table 992. UART receiver configuration (continued)

Register	Value	Comments
		be read using interrupt or DMA request. Supports MSB first transfer by reading from the SHIFTBUFBIS[7:0] register instead.

The UART receiver with RTS configuration uses a second timer to generate the RTS output. The RTS asserts when the start bit is detected and negates when the data is read from the shifter buffer register. If no start bit is detected while the RTS is asserted, the received data is ignored.

Table 993. UART receiver with RTS configuration

Register	Value	Comments
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Invert input data by setting PINPOL.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG*n*	0204_2522h	Configure start bit, stop bit, enable on pin posedge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT=2h and TIMRST=4h.
TIMCTL*n*	02C0_0081h	Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input.
TIMCMP(*n*+1)	0000_FFFFh	Never compare.
TIMCFG(*n*+1)	0030_6100h	Enable on Timer *n* enable and disable on trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(*n*+1)	0143_0003h	Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag.
SHIFTBUF*n*	Data to receive	Received data can be read from SHIFTBUFBYS[7:0]. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports MSB first transfer by reading from the SHIFTBUFBIS[7:0] register instead.

60.6.3 SPI Controller

SPI Controller mode can be supported using two timers, two shifters, and four pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of one clock cycle between the target select negating and before the next transfer. To initiate each transfer, write to the transmit buffer by either core or DMA.

NOTE

Due to synchronization delays, the setup time for the serial input data is 1.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 994. SPI Controller (CPHA=0) configuration

Register	Value	Comments
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using Timer 0 on negedge of clock with output data on Pin 0.
SHIFTCFG(*n*+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n*+1)	0000_0101h	Configure receive using Timer 0 on posedge of clock with input data on Pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0.
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock.
TIMCMP(*n*+1)	0000_FFFFh	Never compare.
TIMCFG(*n*+1)	0000_1100h	Enable when Timer 0 is enabled and disable when Timer 0 is disabled.
TIMCTL(*n*+1)	0003_0383h	Configure 16-bit counter (never compare) using inverted Pin 3 output (as target select).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports MSB first transfer by writing to the SHIFTBUFBIS register instead.

Table continues on the next page...

Table 994. SPI Controller (CPHA=0) configuration (continued)

Register	Value	Comments
SHIFTBUF(*n*+1)	Data to receive	Received data can be read from SHIFTBUF. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports MSB first transfer by reading from the SHIFTBUFBIS register instead.

Table 995. SPI Controller (CPHA=1) configuration

Register	Value	Comments
SHIFTCFG*n*	0000_0021h	Start bit loads data on first shift.
SHIFTCTL*n*	0003_0002h	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0.
SHIFTCFG(*n*+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n*+1)	0080_0101h	Configure receive using Timer 0 on negedge of clock with input data on Pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0.
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock. Set TIMDIS=3 to keep target select asserted for as long as there is data in the transmit buffer.
TIMCMP(*n*+1)	0000_FFFFh	Never compare.
TIMCFG(*n*+1)	0000_1100h	Enable when Timer 0 is enabled and disable when Timer 0 is disabled.
TIMCTL(*n*+1)	0003_0383h	Configure 16-bit counter (never compare) using inverted Pin 3 output (as target select).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

Table continues on the next page...

Table 995. SPI Controller (CPHA=1) configuration (continued)

Register	Value	Comments
		Supports MSB first transfer by writing to the SHIFTBUFBIS register instead.
SHIFTBUF(*n*+1)	Data to receive	Received data can be read from SHIFTBUF. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports MSB first transfer by reading from SHIFTBUFBIS register instead.

60.6.4 SPI Target

SPI Target mode can be supported using one timer, two shifters, and four pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The transmit data must be written to the transmit buffer register before the external target select asserts, otherwise the shifter error flag is set.

NOTE

Due to synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

Table 996. SPI Target (CPHA=0) configuration

Register	Value	Comments
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using Timer 0 on falling edge of shift clock with output data on Pin 0.
SHIFTCFG(*n*+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n*+1)	0000_0101h	Configure receive using Timer 0 on rising edge of shift clock with input data on Pin 1.
TIMCMP*n*	0000_003Fh	Configure 32-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG*n*	0120_0600h	Configure enable on trigger rising edge. Initial clock state is logic 0 and decrements on pin input.
TIMCTL*n*	06C0_0203h	Configure 16-bit counter using Pin 2 input (shift clock), with Pin 3 input (target select) as the inverted trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

Table continues on the next page...

Register	Value	Comments
SHIFTCFG*n*	0000_0001h	Shifter configured to load on first shift and stop bit disabled.
SHIFTCTL*n*	0003_0002h	Configure transmit using Timer 0 on rising edge of shift clock with output data on Pin 0.
SHIFTCFG(*n*+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n*+1)	0080_0101h	Configure receive using Timer 0 on falling edge of shift clock with input data on Pin 1.
TIMCMP*n*	0000_003Fh	Configure 32-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG*n*	0120_6602h	Configure start bit, enable on trigger rising edge, disable on trigger falling edge. Initial clock state is logic 0 and decrements on pin input.
TIMCTL*n*	06C0_0203h	Configure 16-bit counter using Pin 2 input (shift clock), with Pin 3 input (target select) as the inverted trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports MSB first transfer by writing to the SHIFTBUFBIS register instead.
SHIFTBUF(*n*+1)	Data to receive	Received data can be read from SHIFTBUF. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports MSB first transfer by reading from SHIFTBUFBIS register instead.

60.6.5 I2C Controller

I2C Controller mode can be supported using two timers, two shifters, and two pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word when receiving the transmitter must transmit FFh to 3-state the output. FLEXIO inserts a stop bit after every word to generate and verify the ACK or NACK. FLEXIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START or STOP), so the compare register must be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin is equal to output. However, this increases both the clock high and clock low periods by at least 1 FLEXIO clock cycle each. The second timer uses the SCL input pin to control the transmit and receive shift registers. This enforces an SDA data hold time by an extra 2 FLEXIO clock cycles.

Both the transmit and receive shifters must be serviced for each word in the transfer. The transmit shifter must transmit FFh when receiving and the receive shifter returns the data present on the SDA pin. The transmit shifter loads one additional word on the last falling edge of SCL pin. If generating a STOP condition or a repeated START condition, this word must be 00h or FFh, respectively. During the last word of a controller-receiver transfer, you must set the transmit SSTOP bit to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but you are responsible for generating the STOP or repeated START condition. If a NACK is detected during controller-transmit, the interrupt routine must immediately write 00h (if generating STOP) or FFh (if generating repeated START) to the transmit shifter register. You must wait for the next rising edge on SCL before disabling both timers. The transmit shifter should be disabled after waiting the setup delay for a repeated START or STOP condition.

NOTE

Due to synchronization delays, the data valid time for the transmit output is two FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

To guarantee SDA hold time, the I2C controller data valid is delayed two cycles because the clock output is passed through a synchronizer before clocking the transmit or receive shifter. Because the SCL output is synchronous with FLEXIO clock, the synchronization delay is one cycle, and then one cycle to generate the output.

Table 998. I2C Controller configuration

Register	Value	Comments
SHIFTCFG*n*	0000_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTL*n*	0101_0082h	Configure transmit using Timer 1 on rising edge of clock with inverted output enable (open-drain output) on Pin 0.
SHIFTCFG(*n*+1)	0000_0020h	Start bit disabled and stop bit enabled (logic 0) for ACK or NACK detection.
SHIFTCTL(*n*+1)	0180_0001h	Configure receive using Timer 1 on falling edge of clock with input data on Pin 0.
TIMCMP*n*	0000_2501h	Configure 2 word transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of words x 18) + 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG*n*	0102_2222h	Configure start bit, stop bit, enable on trigger high, disable on compare, reset

Register	Value	Comments
		if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTL*n*	01C1_0101h	Configure dual 8-bit counter using Pin 1 output enable (SCL open-drain), with Shifter 0 flag as the inverted trigger.
TIMCMP(*n*+1)	0000_000Fh	Configure 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(*n*+1)	0020_1112h	Enable when Timer 0 is enabled, disable when Timer 0 is disabled. Enable start bit and stop bit at end of each word and decrement on pin input.
TIMCTL(*n*+1)	01C0_0183h	Configure 16-bit counter using inverted Pin 1 input (SCL).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0]. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(*n*+1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0]. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

60.6.6 I2S Controller

I2S Controller mode can be supported using two timers, two shifters, and four pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FLEXIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers are supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FLEXIO clock frequency. The initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure that the frame sync is generated one clock cycle before the first output data.

NOTE

Due to synchronization delays, the setup time for the receiver input is 1.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 999. I2S controller configuration

Register	Value	Comments
SHIFTCFG*n*	0000_0001h	Load transmit data on first shift and stop bit disabled.

Table continues on the next page...

Table 999. I2S controller configuration (continued)

Register	Value	Comments
SHIFTCTL*n*	0003_0002h	Configure transmit using Timer 0 on rising edge of clock with output data on Pin 0.
SHIFTCFG(*n*+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n*+1)	0080_0101h	Configure receive using Timer 0 on falling edge of clock with input data on Pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG*n*	0000_0202h	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTL*n*	01C3_0281h	Configure dual 8-bit counter using inverted Pin 2 output (bit clock), with Shifter 0 flag as the inverted trigger. Clear PINPOL to invert the polarity of the output shift clock.
TIMCMP(*n*+1)	0000_007Fh	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:0] = (number of bits x baud rate divider) - 1.
TIMCFG(*n*+1)	0000_0100h	Enable when Timer 0 is enabled and never disable.
TIMCTL(*n*+1)	0003_0383h	Configure 16-bit counter using inverted Pin 3 output (as frame sync). Clear PINPOL to invert the polarity of the output frame sync
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUFBIS. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(*n*+1)	Data to receive	Received data can be read from SHIFTBUFBIS. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports LSB first transfer by reading from SHIFTBUF register instead.

60.6.7 I2S Target

I2S Target mode can be supported using three timers, two shifters, and four pins. For single transmit and single receive, other combinations of transmit and receive are possible.

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Due to synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

The output valid time of I2S Target is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization, plus 1 cycle to output the data.

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until the rising edge of bit clock (when the frame sync is normally sampled). Timer 0 detects rising edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects falling edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 1000. I2S Target configuration

Register	Value	Comments
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0103_0002h	Configure transmit using Timer 1 on rising edge of shift clock with output data on Pin 0.
SHIFTCFG(*n*+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n*+1)	0180_0101h	Configure receive using Timer 1 on falling edge of shift clock with input data on Pin 1.
TIMCMP*n*	0000_007Fh	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] = (number of bits x 4) - 1.
TIMCFG*n*	0020_2500h	Configure enable on pin rising edge (inverted bit clock) with trigger high (Timer 2) and disable on compare. Initial clock state is logic 1 and decrements on pin input (bit clock).
TIMCTL*n*	0B40_0203h	Configure 16-bit counter using Pin 2 input (bit clock), with Timer 2 output as the trigger.
TIMCMP(*n*+1)	0000_003Fh	Configure 32-bit transfers. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(*n*+1)	0020_2500h	Configure enable on pin (bit clock) rising edge with trigger (Timer 0) high and disable on compare. Initial clock state is logic 1 and decrement on pin input (bit clock).

Table continues on the next page...

Table 1000. I2S Target configuration (continued)

Register	Value	Comments
TIMCTL(*n*+1)	0340_0283h	Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 0 output as the trigger.
TIMCMP(*n*+2)	0000_0000h	Compare on zero (first edge).
TIMCFG(*n*+2)	0020_6400h	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock). Initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(*n*+2)	04C0_0383h	Configure 16-bit counter using inverted Pin3 input (frame sync), with Pin 2 inverted input (bit clock) as the trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUFBIS. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(*n*+1)	Data to receive	Received data can be read from SHIFTBUFBIS. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports LSB first transfer by reading from SHIFTBUF register instead.

60.6.8 SENT receiver

SENT receiver can be supported by using one timer and one pin. The timer is configured as Input-Capture mode, and captures the counter value at falling edge of the pin input. After the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value always indicates the period between previous falling edge and current falling edge. The CPU interrupt or DMA trigger can be configured at each capture of the counter. The entire SENT frame decoding with the latest tick width adjustment is performed by CPU software.

Table 1001. SENT receiver configuration

Register	Value	Comments
TIMCMPn	-	Stores counter value at the falling edge of the pin.
TIMCFGn	0x0000_6000	Timer is always enabled. Timer is disabled on trigger falling edge, decrement counter on FLEXIO clock.
TIMCTLn	0xnn40_0007	Single 16-bit input capture mode. Timer pin input and output are selected by PINSEL. Timer pin output disabled, internal trigger selected, select pin nn as trigger.

60.6.9 Camera interface

Camera interface can be supported using one timer, one or more shifters, and multiple pins. Multiple transfers can be supported using DMA controller.

The example below describes the FLEXIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF, and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer. You can use a bigger or smaller buffer depending on system DMA performance and FLEXIO resource usage by other applications.

NOTE

You can use additional timers to track the number of pixels per row and number of rows per frame, or HREF or VSYNC can be assigned as GPIO interrupts for software tracking.

Table 1002. Camera interface configuration for 8-bit CMOS sensor

Register	Value	Comments
SHIFTCFG*n*...*n*+2[1]	0007_0100h	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFG*n*+3	0007_0000h	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTL*n*...*n*+3	0080_0001h	Configure receive using Timer 0 on negedge of clock.
TIMCMP*n*	0000_001Fh	Configure 16-pixel (8 bits/pixel x 16 pixels = 128-bits) transfer. Set TIMCMP[15:0] = (number of pixels x 2) - 1.
TIMCFG*n*	0120_6600h	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge. Initial Shift clock state is logic 0 and decrement on PCLK input.
TIMCTL*n*	12C0_0803h	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUF*n*...*n*+3	Data to receive	Received data can be read from SHIFTBUF*n*...*n*+3. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

1. *n*=0 or 4

60.6.10 Motorola 68K and Intel 8080 bus interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. With GPIO, FLEXIO can drive these interfaces using one Timer and one Shifter. Additional Shifters can be used to support large transfers via the DMA controller.

The table below provides an example of how to drive a 16-bit 68K or 8080 bus. For an 8080 bus, two GPIOs are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 1003. Motorola 68K and Intel 8080 write configuration

Register	Value	Comments
SHIFTCFG0...0	000F_0100h	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0003_0002h	Configure transmit using Timer 0 on posedge of clock with data output to FXIO_D[15:0].
SHIFTCTL1...0	0000_0002h	Configure transmit using Timer 0 on posedge of clock.
TIMCMP0	0000_0101h (1-beat) 0000_1F01h (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0000_2200h	Configure enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	01C3_1001h (Motorola 68K, 1-beat) 1DC3_1001h (Motorola 68K, 16-beats) 01C3_1081h (Intel 8080, 1-beat) 1DC3_1081h (Intel 8080, 16-beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with Shifter 0 (1-beat) or Shifter 0 (16-beats) flag as the inverted trigger.
SHIFTBUF0...0	Data to transmit	Transmit data can be written to SHIFTBUF0 (1-beat) or SHIFTBUF0...0(16-beats) to initiate a transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

Table 1004. Motorola 68K 8080 read configuration

Register	Value	Comments
SHIFTCFG0...3	000F_0100h	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCFG0	000F_0000h	Configure 16-bit parallel shift in from pin.
SHIFTCTL0...0	0080_0001h	Configure receive using Timer 0 on negedge of clock with data input from FXIO_D[15:0].
TIMCMP0	0000_0101h (1-beat) 0000_1F01h (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.

Table continues on the next page...

Table 1004. Motorola 68K 8080 read configuration (continued)

Register	Value	Comments
TIMCFG0	0000_2220h	Configure stop_bit. Enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	1DC3_1001h (Motorola 68K, 1 beat) 01C3_1001h (Motorola 68K, 16 beats) 1DC3_1181h (Intel 8080, 1 beat) 01C3_1181h (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with Shifter 0 flag (1-beat) or Shifter 0 flag (16-beats) as the inverted trigger.
SHIFTBUF0...0	Data received	Received data can be read from SHIFTBUF0 (1-beat) or SHIFTBUF0...0 (16-beats). Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K or 8080 bus target begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow must be used:

1. Configure FLEXIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]
4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FLEXIO with desired read or write configuration (1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to and from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

60.6.11 Low-power state machine

The table below shows an example of a hypothetical state machine in order to illustrate the flexibility allowed in Shifter State mode.

In this example, FLEXIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted. This assumes that the comparator is connected to external trigger 15. See the chip-specific FLEXIO information for actual FLEXIO trigger mappings. Throughout this operation, the CPU can be kept in a STOP or VLPS mode by clearing the CTRL[DOZEN] field and ensuring the FLEXIO_CLK is enabled. The state diagram below shows the states and transitions implemented by this example.

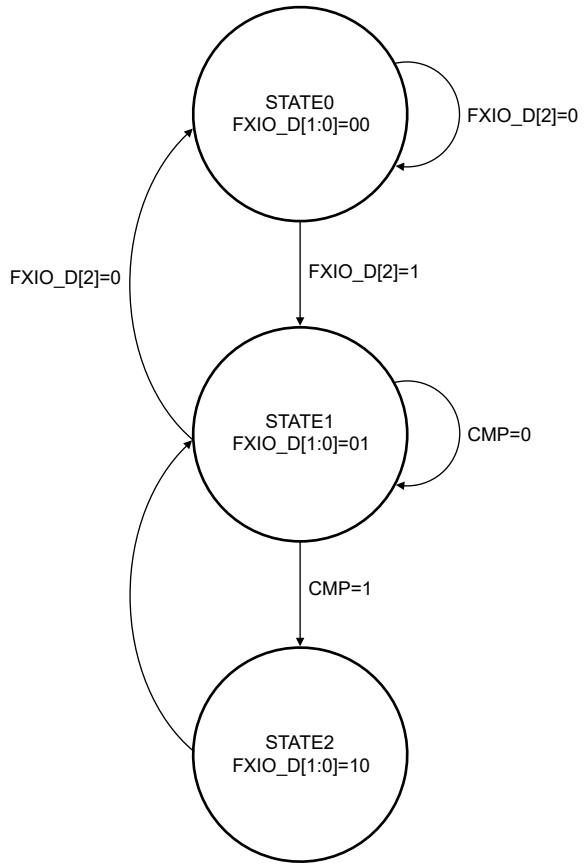

Figure 456. State diagram

Table 1005. State machine configuration

Register	Value	Comments
SHIFTCFG0...2	0000_0003h	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer 0 output low to trigger next state.
SHIFTBUF0	0020_8208h	State0: Drive FXIO_D[1:0]=00, transition to State0 if FXIO_D[2]=0, State1 if FXIO_D[2]=1.
SHIFTCTL1	0000_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer 0 output high to trigger next state.
SHIFTBUF1	0140_8408h	State1: Drive FXIO_D[1:0]=01, transition to State0 if FXIO_D[2]=0, State1 if CMP=0, State2 if CMP=1 (FXIO_D[3]=1)

Table continues on the next page...

Table 1005. State machine configuration (continued)

Register	Value	Comments
SHIFTCTL2	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer 0 output low to trigger next state.
SHIFTBUF2	0224_9249h	State2: Drive FXIO_D[1:0]=10, transition to State1 when Timer 0 output low
TIMCMP0	0000_FFFFh	Configure baud rate of divide by 131072 of the FLEXIO clock. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0000_0000h	Configure timer always enabled.
TIMCTL0	0000_0003h	Configure single 16-bit counter.
TIMCFG1	0010_7600h	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0F03_0303h	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

60.6.12 Keypad interface

The keypad interface can support a 3 × 4 keypad matrix using three timers and three shifters, although a larger matrix can be supported using additional shifters. The configuration is designed for four columns configured as active low open-drain pins and three rows configured as input pins with pull-up resistors enabled.

One shifter is configured in logic mode to assert its output when any of the row inputs are low, indicating a key is pressed. Use a timer to filter the shifter output to ensure that the key is pressed for a minimum amount of time before performing the column scan.

A different shifter is configured for parallel transmit. Use this shifter to scan each column when a keypress is detected. When not scanning, the shifter output is configured to assert all active low open-drain column outputs to detect any keypress. Use a dedicated timer to control the transmit shifter.

The last shifter is configured for parallel receive. Use this shifter to capture the result of the column scanning for software to decode which key (or keys) was pressed. This configuration captures the state of both row and column pins for each scan, although the row state can also be deduced by the shift order. Use a dedicated timer to control the receive shifter, which shifts at half the frequency of the transmit shifter.

When the result of the key scan is available in the receive shifter register, FLEXIO continues to monitor the row inputs and can trigger multiple scans from the one keypress. To support debouncing, you can decide how many consecutive scans should be considered a single keypress.

NOTE

Because the pins used in Logic mode are fixed per shifter and the shifters that support parallel shifts are limited, this configuration is restricted in what pins and shifters it can use. Increasing the matrix beyond four-row inputs requires multiple shifters in logic mode. Increasing beyond four-column outputs requires concatenating transmit shifters to create a larger shift register.

Table 1006. Keypad interface configuration

Register	Value	Comments
SHIFTCFG0	0003_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1), configured for 4-bit shift.
SHIFTCTL0	0101_0402h	Configure transmit using Timer 1 on rising edge of clock generating open-drain output on Pins[7:4] (column outputs).
SHIFTBUF0	0804_0201h	Static data containing the column scan pattern, each column is scanned one-hot with dead time in between.
SHIFTCFG1	0000_0020h	In logic mode, mask input 3.
SHIFTCTL1	0000_0007h	Configure logic mode.
SHIFTBUF1	07FF_07FFh	Static data configuring logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0007_0000h	Configured for 8-bit shift.
SHIFTCTL3	0280_0001h	Configure receive using Timer 2 on falling edge of clock with input data on Pins [7:0] (both rows and columns, Pin 0 is don't care).
TIMCMP0	0000_00ffh	Configures pre-scanning glitch filter to 256 FLEXIO clock cycles. For different filter cycles, set TIMCMP[15:0] = (filter cycles) - 1.
TIMCFG0	0103_6600h	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0540_0003h	Configure 16-bit counter using Shifter 1 flag (logic state) as trigger.
TIMCMP1	0000_0F3Fh	Configure 8 shifts (twice for each column) at column scan rate of divide by 128. For different scan frequency, set TIMCMP[7:0] = (scan divider / 2) - 1.
TIMCFG1	0020_2622h	Enable on trigger rising edge, disable on compare. Start and stop bits are enabled.
TIMCTL1	0340_0001h	Configure dual 8-bit counter using Timer 0 output as the trigger.
TIMCMP2	0000_0801h	Configure 4 shifts at half the frequency of Timer 1 trigger.
TIMCFG2	0110_2100h	Enable on Timer 1 enable, disable on compare, decrement on trigger input

Table continues on the next page...

60.7.1.2 Version ID (VERID)

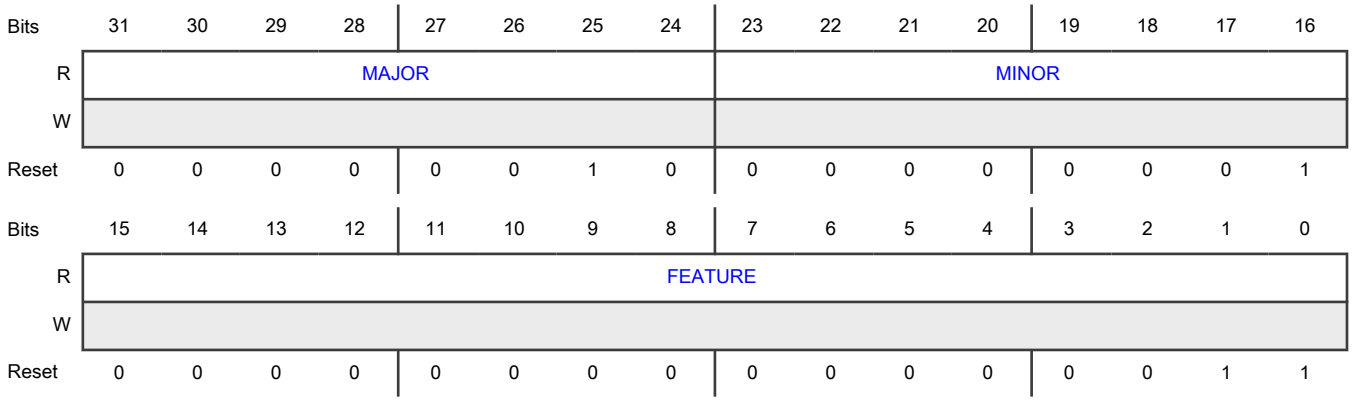
Offset

Register	Offset
VERID	0h

Function

Contains the version of the FLEXIO.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number This read-only field returns the major version number for the module specification.
23-16 MINOR	Minor Version Number This read-only field returns the minor version number for the module specification.
15-0 FEATURE	Feature Specification Number This read-only field returns the feature set number. 0000_0000_0000_0000b - Standard features implemented.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000_0000_0000_0001b - Supports state, logic, and parallel modes. 0000_0000_0000_0010b - Supports pin control registers. 0000_0000_0000_0011b - Supports state, logic, and parallel modes, plus pin control registers.

60.7.1.3 Parameter (PARAM)

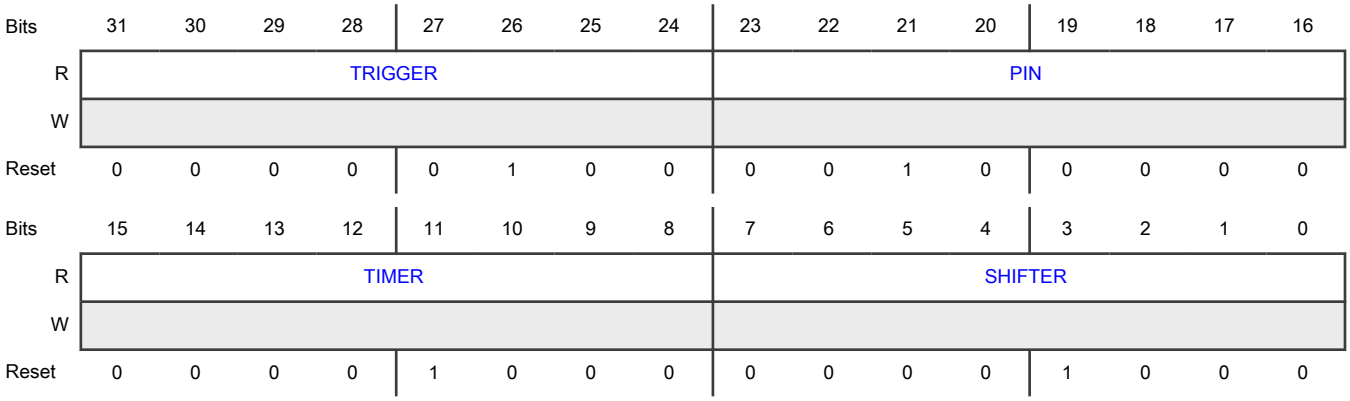
Offset

Register	Offset
PARAM	4h

Function

Contains the number of shifters, timers, pins, and triggers.

Diagram



Fields

Field	Function
31-24 TRIGGER	Trigger Number Number of external triggers implemented.
23-16 PIN	Pin Number Number of pins implemented.
15-8 TIMER	Timer Number Number of timers implemented.
7-0 SHIFTER	Shifter Number Number of shifters implemented.

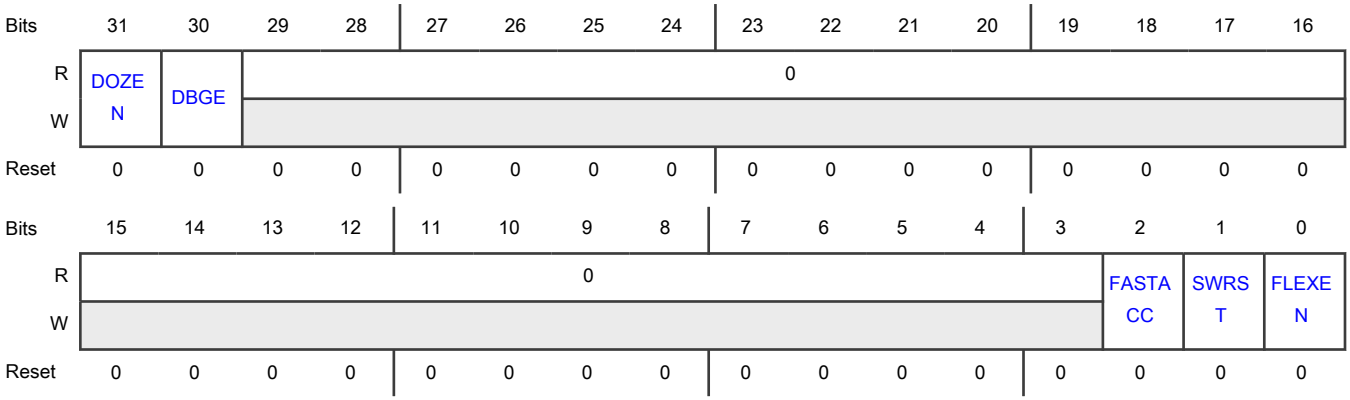
60.7.1.4 FLEXIO Control (CTRL)

Offset

Register	Offset
CTRL	8h

Function
Controls various aspects of FLEXIO operation.

Diagram



Fields

Field	Function
31 DOZEN	Doze Enable Disables FLEXIO operation in Doze modes. 0b - FLEXIO enabled in Doze modes. 1b - FLEXIO disabled in Doze modes.
30 DBGE	Debug Enable Enables FLEXIO operation in Debug mode. 0b - FLEXIO is disabled in Debug modes. 1b - FLEXIO is enabled in Debug modes.
29-3 —	Reserved
2 FASTACC	Fast Access Enables fast register accesses to FLEXIO registers, but requires the FLEXIO functional clock to be at least equal to the frequency of the bus clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Configures for normal register accesses to FLEXIO 1b - Configures for fast register accesses to FLEXIO
1 SWRST	Software Reset The FLEXIO Control Register is not affected by the software reset. All other logic in the FLEXIO is affected by the software reset and all other register accesses are ignored until this field is cleared. This field remains set until cleared by software, and the reset has cleared in the FLEXIO clock domain. 0b - Software reset is disabled 1b - Software reset is enabled. All FLEXIO registers except the Control Register are reset.
0 FLEXEN	FLEXIO Enable Enables or disables the FLEXIO. 0b - FLEXIO module is disabled. 1b - FLEXIO module is enabled.

60.7.1.5 Pin State (PIN)

Offset

Register	Offset
PIN	Ch

Function

Reports status of the Pin Data Input.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PDI

R	PDI															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PDI	Pin Data Input Returns the input data on each of the FLEXIO pins.

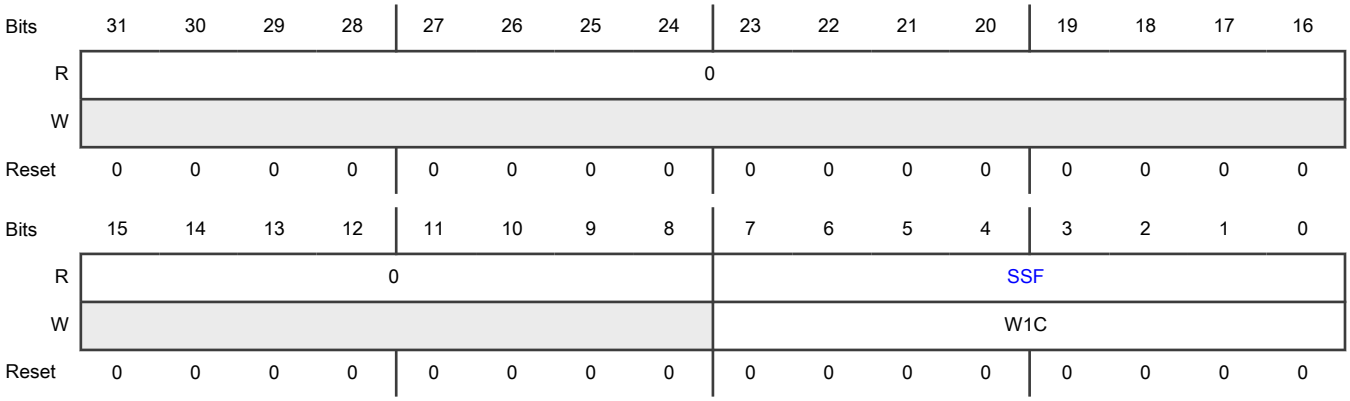
60.7.1.6 Shifter Status (SHIFTSTAT)

Offset

Register	Offset
SHIFTSTAT	10h

Function
Contains Shifter Status Flags.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSF	Shifter Status Flag The shifter status flag is updated when one of the following events occurs: • For SMOD=Receive, the status flag is set when SHIFTBUF has been loaded with data from the shifter (SHIFTBUF is full). The status flag is cleared when SHIFTBUF register is read. • For SMOD=Transmit, the status flag is set when SHIFTBUF data has been transferred to the shifter (SHIFTBUF is empty) or when initially configured for SMOD=Transmit. The status flag is cleared when the SHIFTBUF register is written.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• For SMOD=Match Store, the status flag is set when a match has occurred between SHIFTBUF and the shifter. The status flag is cleared when the SHIFTBUF register is read. • For SMOD=Match Continuous, returns the current match result between the SHIFTBUF and shifter. The status flag cannot be cleared by reading SHIFTBUF. • For SMOD=State, the status flag for a shifter sets when it is selected by the current state pointer. • For SMOD=Logic, returns the current value of the programmable logic block output. The status flag can also be cleared by writing a logic one to the flag for all modes except Match Continuous/ State /Logic. 0b - Status flag is clear. 1b - Status flag is set.

60.7.1.7 Shifter Error (SHIFTERR)

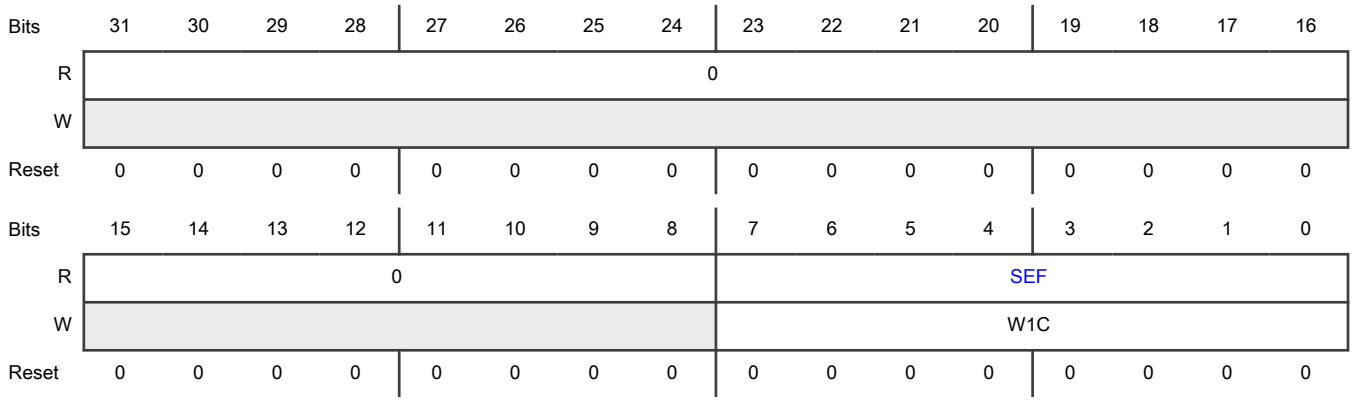
Offset

Register	Offset
SHIFTERR	14h

Function

Reports Shifter Error Flags.

Diagram



Fields

Field	Function
31-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 SEF	Shifter Error Flags The shifter error flag is set when one of the following events occurs: • For SMOD=Receive, this indicates that either the shifter was ready to store new data into SHIFTBUF before the previous data was read from SHIFTBUF (SHIFTBUF overrun), or it indicates that the received start or stop bit does not match the expected value. • For SMOD=Transmit, indicates that the shifter was ready to load new data from SHIFTBUF before new data had been written into SHIFTBUF (SHIFTBUF underrun). • For SMOD=Match Store, indicates that a match event occurred before the previous match data was read from SHIFTBUF (SHIFTBUF overrun). • For SMOD=Match Continuous, the error flag is set when a match has occurred between SHIFTBUF and the shifter. • For SMOD=Logic, the error flag is set when the output of the programmable logic block has asserted. Clear this field by writing logic one to the flag. For SMOD=Match Continuous, it can also be cleared when the SHIFTBUF register is read. 0b - Shifter Error Flag is clear. 1b - Shifter Error Flag is set.

60.7.1.8 Timer Status (TIMSTAT)

Offset

Register	Offset
TIMSTAT	18h

Function

Reports Timer Status Flags.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								TSF							
W									W1C							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 TSF	Timer Status Flags The timer status flag sets depending on the timer mode, and can be cleared by writing logic one to the flag. In 8-bit baud counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit high PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 16-bit counter mode, the timer status flag is set when the 16-bit counter equals zero and decrements. In 16-bit counter disable mode, the timer status flag is set when a timer disable event is detected. In 8-bit word counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit low PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 16-bit input capture mode, the timer status flag is set when a timer disable event is detected and the timer status flag is clear. In this mode, the timer compare register should only be read when the timer status flag is set. 0b - Timer Status Flag is clear. 1b - Timer Status Flag is set.

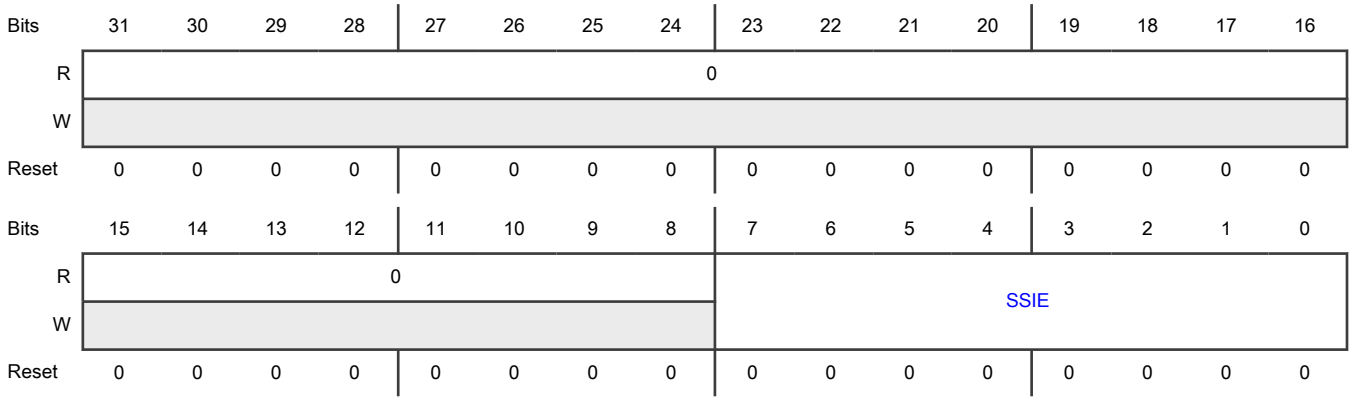
60.7.1.9 Shifter Status Interrupt Enable (SHIFTSIEN)

Offset

Register	Offset
SHIFTSIEN	20h

Function
Contains enables for Shifter Status Interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSIE	Shifter Status Interrupt Enable Enables interrupt generation when corresponding SSF is set. 0b - Shifter Status Flag interrupt disabled. 1b - Shifter Status Flag interrupt enabled.

60.7.1.10 Shifter Error Interrupt Enable (SHIFTEIEN)

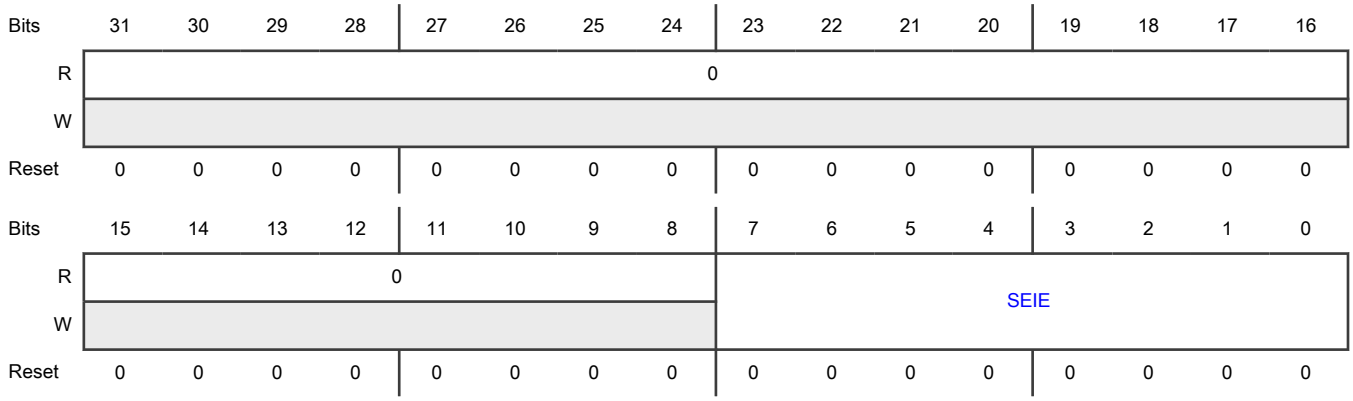
Offset

Register	Offset
SHIFTEIEN	24h

Function

Contains enables for Shifter Error Interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEIE	Shifter Error Interrupt Enable Enables interrupt generation when corresponding SEF is set. 0b - Shifter Error Flag interrupt disabled. 1b - Shifter Error Flag interrupt enabled.

60.7.1.11 Timer Interrupt Enable (TIMIEN)

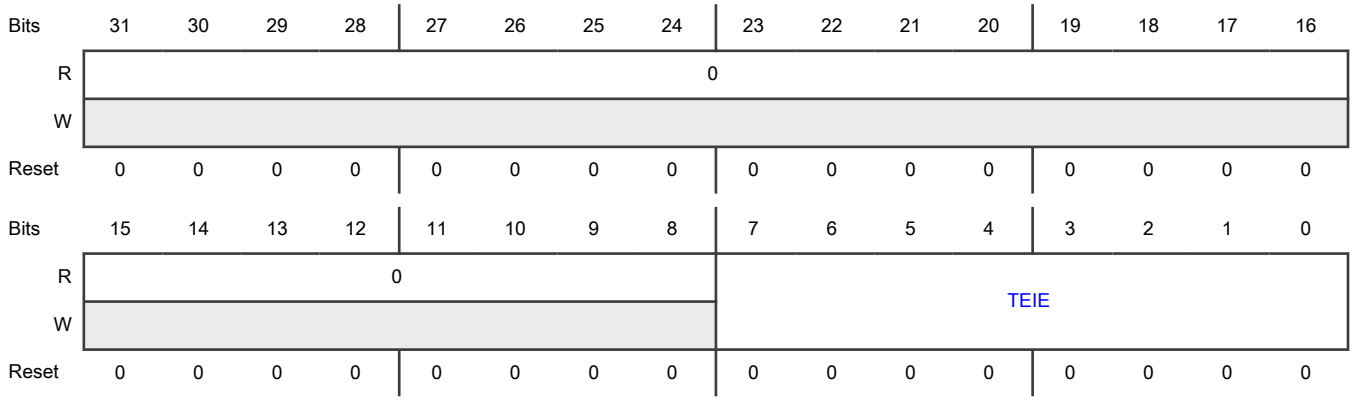
Offset

Register	Offset
TIMIEN	28h

Function

Contains enables for Timer Status Interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TEIE	Timer Status Interrupt Enable Enables interrupt generation when corresponding TSF is set. 0b - Timer Status Flag interrupt is disabled. 1b - Timer Status Flag interrupt is enabled.

60.7.1.12 Shifter Status DMA Enable (SHIFTSDEN)

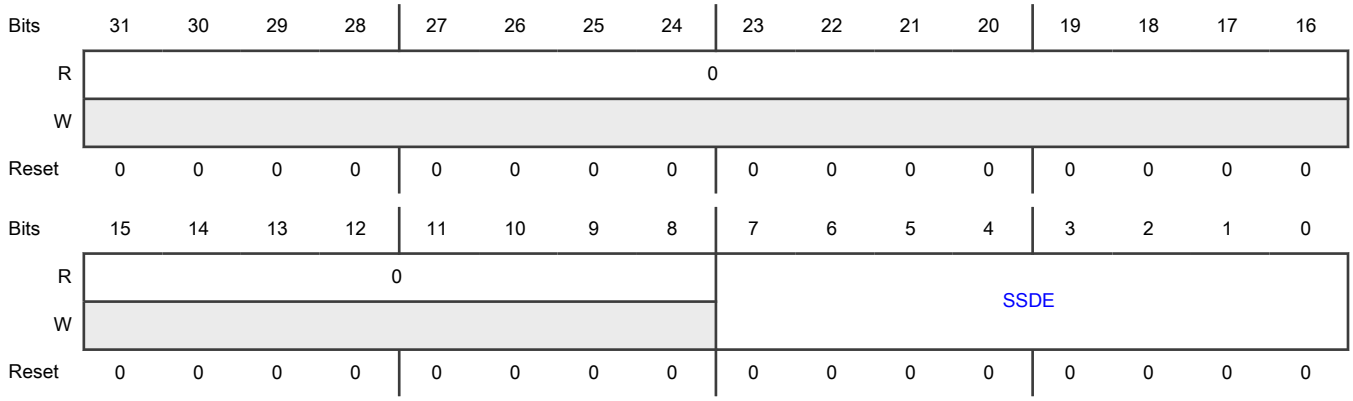
Offset

Register	Offset
SHIFTSDEN	30h

Function

Contains enables for Shifter DMA requests.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSDE	Shifter Status DMA Enable Enables DMA request generation when corresponding SSF is set. 0b - Shifter Status Flag DMA request is disabled. 1b - Shifter Status Flag DMA request is enabled.

60.7.1.13 Timer Status DMA Enable (TIMERSDEN)

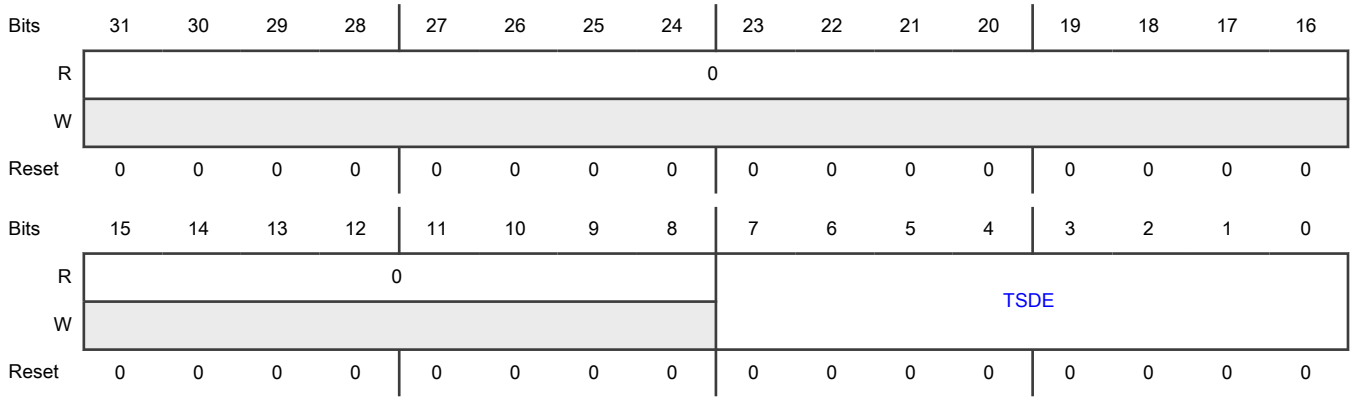
Offset

Register	Offset
TIMERSDEN	38h

Function

Contains enables for DMA requests when Timer Status Flag is set.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TSDE	Timer Status DMA Enable Enables DMA request generation when corresponding TSF is set. When the Timer Status DMA request is enabled, reading or writing a Timer Compare Register clears the corresponding Timer Status Register. The DMA must therefore read or write the Timer Compare Register as part of the DMA transfer, otherwise the DMA request remains asserted. 0b - Timer Status Flag DMA request is disabled. 1b - Timer Status Flag DMA request is enabled.

60.7.1.14 Shifter State (SHIFTSTATE)

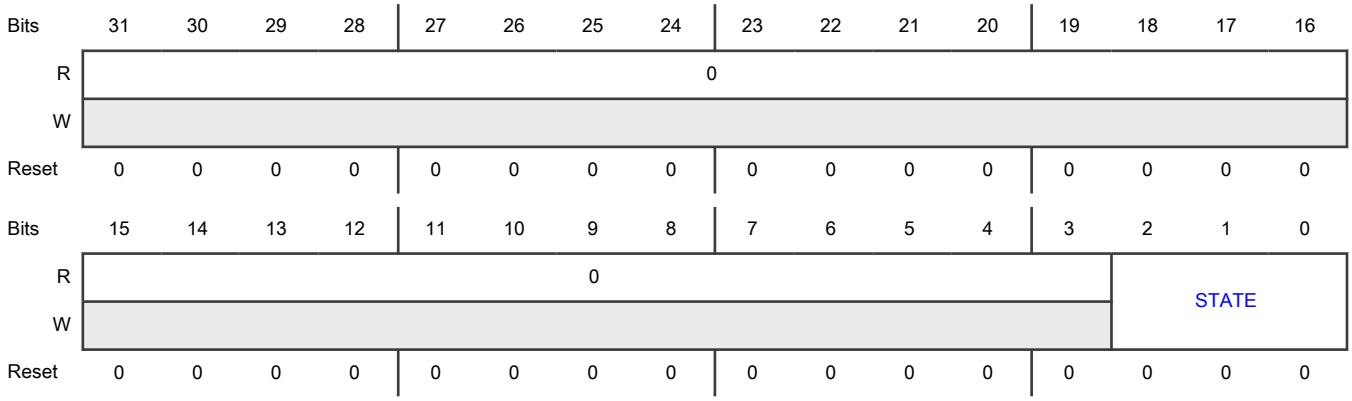
Offset

Register	Offset
SHIFTSTATE	40h

Function

Contains the pointer to track the current shifter.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 STATE	Current State Pointer The current state field maintains a pointer to track the current shifter (configured for State mode) enabled to drive outputs and compute the next state. Reading this register when the state pointer is updating can result in the incorrect state returned. This field is writable and the value written overrides the current state.

60.7.1.15 Trigger Status (TRGSTAT)

Offset

Register	Offset
TRGSTAT	48h

Function

Contains External Trigger Status Flags.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												ETSF			
W													W1C			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-4 —	Reserved
3-0 ETSF	External Trigger Status Flags The external trigger status flag is set when a rising edge is detected on the corresponding external trigger input. 0b - External Trigger Status Flag is clear 1b - External Trigger Status Flag is set

60.7.1.16 External Trigger Interrupt Enable (TRIGIEN)

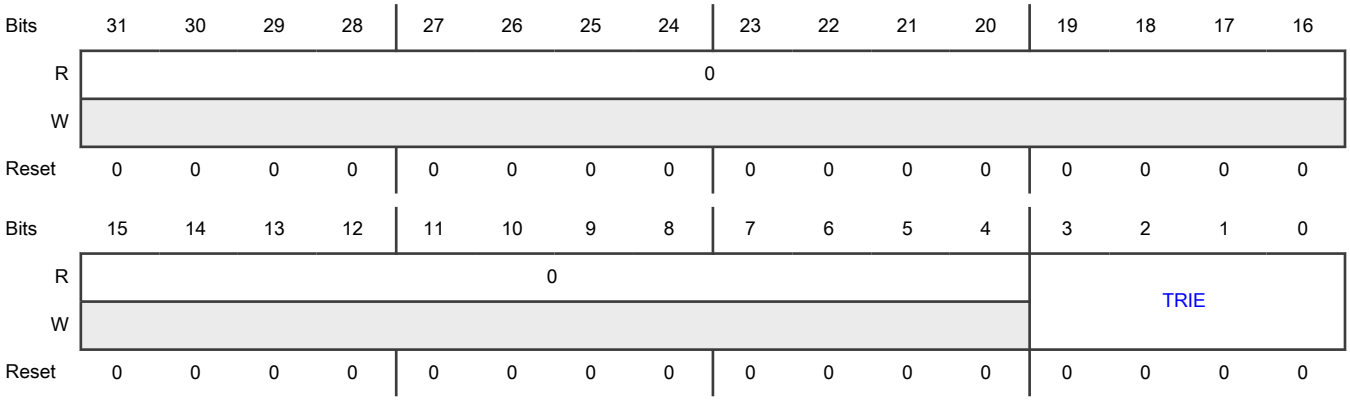
Offset

Register	Offset
TRIGIEN	4Ch

Function

Contains enables for External Trigger Interrupts.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TRIE	External Trigger Interrupt Enable Enables interrupt generation when corresponding ETSF is set. 0b - External Trigger Status Flag interrupt is disabled. 1b - External Trigger Status Flag interrupt is enabled.

60.7.1.17 Pin Status (PINSTAT)

Offset

Register	Offset
PINSTAT	50h

Function

Contains Pin Status Flags.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PSF															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PSIE	Pin Status Interrupt Enable Enables interrupt generation when corresponding PSF is set. 0b - Pin Status Flag interrupt is disabled. 1b - Pin Status Flag interrupt is enabled.

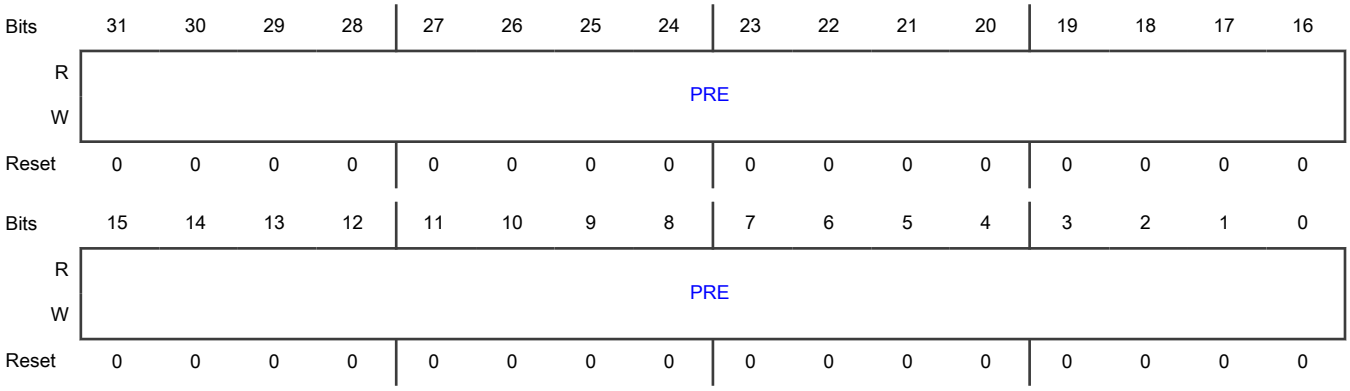
60.7.1.19 Pin Rising Edge Enable (PINREN)

Offset

Register	Offset
PINREN	58h

Function
Contains enables for Pin Status Flag on rising edge.

Diagram



Fields

Field	Function
31-0 PRE	Pin Rising Edge When set, the pin status flag is set whenever a rising edge is detected on the pin. 0b - Pin Status Flag does not set when a pin rising edge is detected. 1b - Pin Status Flag does set when a pin rising edge is detected.

60.7.1.20 Pin Falling Edge Enable (PINFEN)

Offset

Register	Offset
PINFEN	5Ch

Function
Contains enables for Pin Status Flag on falling edge.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	OUTE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OUTE	Output Enable Enables direct output on the corresponding pin. 0b - Pin is controlled by timer/shifter configuration. 1b - Pin is an output and driven with value of PINOUTD register.

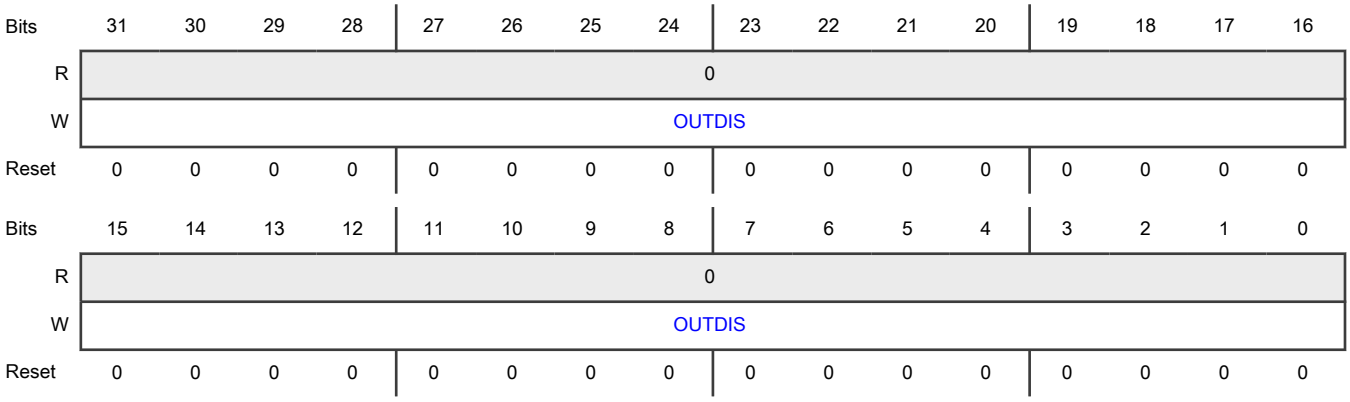
60.7.1.23 Pin Output Disable (PINOUTDIS)

Offset

Register	Offset
PINOUTDIS	68h

Function
Contains disables for pin output.

Diagram



Fields

Field	Function
31-0 OUTDIS	Output Disable Configures corresponding pins to disable direct output. 0b - No effect. 1b - Corresponding PINOUTD and PINOUTE bits are cleared.

60.7.1.24 Pin Output Clear (PINOUTCLR)

Offset

Register	Offset
PINOUTCLR	6Ch

Function
Clears pin output.

Diagram

Fields

Field	Function
31-0 OUTTOG	Output Toggle Configures corresponding pins to toggle. 0b - No effect. 1b - Corresponding PINOUTD is inverted and PINOUTE is set.

60.7.1.27 Shifter Control N (SHIFTCTL0 - SHIFTCTL7)

Offset

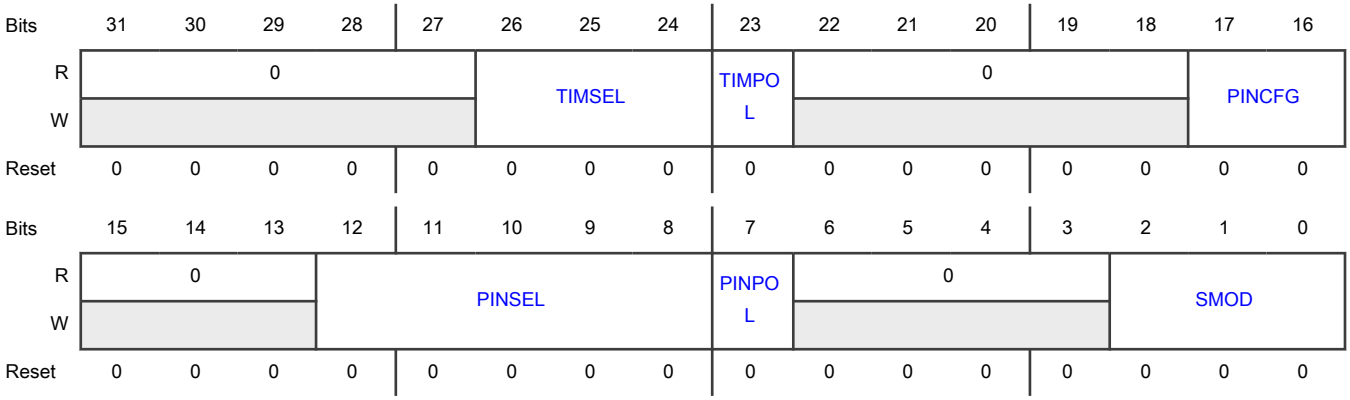
For n = 0 to 7:

Register	Offset
SHIFTCTLn	80h + (n × 4h)

Function

Controls Shift Register N.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 TIMSEL	Timer Select Selects which timer is used for controlling the logic or shift register and generating the shift clock. TIMSEL=i selects TIMERi.
23	Timer Polarity

Table continues on the next page...

Table continued from the previous page...

Field	Function
TIMPOL	Determines the shift occurs on the positive edge or negative edge of the shift clock. 0b - Shift on posedge of shift clock 1b - Shift on negedge of shift clock
22-18 —	Reserved
17-16 PINCFG	Shifter Pin Configuration For pins configured as an output (PINCFG=11b), this field takes effect when the register is written. **NOTE** When initially configuring PINCFG=11b, FLEXIO may briefly drive the pin low. To avoid this, you can configure PINCFG=10b along with the rest of the control register and then perform a subsequent write to set PINCFG=11b. Likewise, when changing PINCFG=11b to PINCFG=00b software should perform an initial write to set PINCFG=10b and then perform a subsequent write to update the rest of the control register with PINCFG=00b. 00b - Shifter pin output disabled 01b - Shifter pin open-drain or bidirectional output enable 10b - Shifter pin bidirectional output data 11b - Shifter pin output
15-13 —	Reserved
12-8 PINSEL	Shifter Pin Select Selects which pin is used by the Shifter input or output. PINSEL=i selects the FXIO_Di pin. For pins configured as an output (PINCFG=11b), this field takes effect when the register is written.
7 PINPOL	Shifter Pin Polarity For pins configured as an output (PINCFG=11b), this field takes effect when the register is written. 0b - Pin is active high 1b - Pin is active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the shifter. 000b - Disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	001b - Receive mode. Captures the current shifter content into the SHIFTBUF on expiration of the timer. 010b - Transmit mode. Load SHIFTBUF contents into the shifter on expiration of the timer. 011b - Reserved. 100b - Match Store mode. Shifter data is compared to SHIFTBUF content on expiration of the timer. 101b - Match Continuous mode. Shifter data is continuously compared to SHIFTBUF contents. 110b - State mode. SHIFTBUF contents are used for storing programmable state attributes. 111b - Logic mode. SHIFTBUF contents are used for implementing programmable logic lookup table.

60.7.1.28 Shifter Configuration N (SHIFTCFG0 - SHIFTCFG7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTCFGn	100h + (n × 4h)

Function

Contains configuration bit fields for Shifter Register N.

Diagram

Field	Function
—	
20-16 PWIDTH	Parallel Width For all shifters, this field configures the number of bits to be shifted on each shift clock as follows: • 1-bit shift for PWIDTH=0 • 2-bit shift for PWIDTH=1 • 4-bit shift for PWIDTH=2...3 • 8-bit shift for PWIDTH=4...7 • 16-bit shift for PWIDTH=8...15 • 32-bit shift for PWIDTH=16...31 For shifters which support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this field, together with SHIFTCTL[PINSEL], also selects the pins to be driven or sampled on each shift clock: • FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL] Shifters which do not support parallel transmit or parallel receive only support parallel shift when INSRC=1. For SMOD=State, use this field to disable state outputs. See State mode for more details.
15-13 —	Reserved
12 SSIZE	Shifter Size Configures the size of the Shift Registers. A 24-bit shift register shifts data only into bits [23:0] and does not update bits [31:24] during shift operations. When shift register is configured for a 24-bit shift, configuring PWIDTH=8..15 performs a 12-bit shift, and PWIDTH=16..31 performs a 24-bit shift. 0b - Shift register is 32-bit. 1b - Shift register is 24-bit.
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match shift register is configured to both shift and store on the same cycle. 0b - Shift register stores the pre-shift register state. 1b - Shift register stores the post-shift register state.
8 INSRC	Input Source Selects the input source for the shifter. Configuring INSRC=1 is not supported for the last shifter.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Pin 1b - Shifter N+1 Output
7 —	Reserved
6 —	Reserved
5-4 SSTOP	Shifter Stop bit For SMOD=Transmit, this field allows automatic stop bit insertion if the selected timer has also enabled a stop bit. For SMOD=Receive or Match Store, this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00b - Stop bit disabled for transmitter/receiver/match store 01b - Stop bit disabled for transmitter/receiver/match store. When timer is in stop condition, receiver/match store stores receive data on the configured shift edge. 10b - Transmitter outputs stop bit value 0 on store. If stop bit is not 0, receiver/match store sets error flag. When timer is in stop condition, receiver/match stores also store receive data on the configured shift edge. 11b - Transmitter outputs stop bit value 1 on store. If stop bit is not 1, receiver/match store sets error flag. When timer is in stop condition, receiver/match store also stores receive data on the configured shift edge.
3-2 —	Reserved
1-0 SSTART	Shifter Start Bit For SMOD=Transmit, this field allows automatic start bit insertion if the selected timer has also enabled a start bit. For SMOD=Receive or Match Store, this field allows automatic start bit checking if the selected timer has also enabled a start bit. For SMOD=State, this field is used to disable state outputs. See State mode for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See Logic mode for more detail. 00b - Start bit disabled for transmitter/receiver/match store. Transmitter loads data on enable. 01b - Start bit disabled for transmitter/receiver/match store. Transmitter loads data on first shift. 10b - Transmitter outputs start bit value 0 before loading data on first shift. If start bit is not 0, receiver/match store sets error flag.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Transmitter outputs start bit value 1 before loading data on first shift. If start bit is not 1, receiver/match store sets error flag.

60.7.1.29 Shifter Buffer N (SHIFTBUF0 - SHIFTBUF7)

Offset

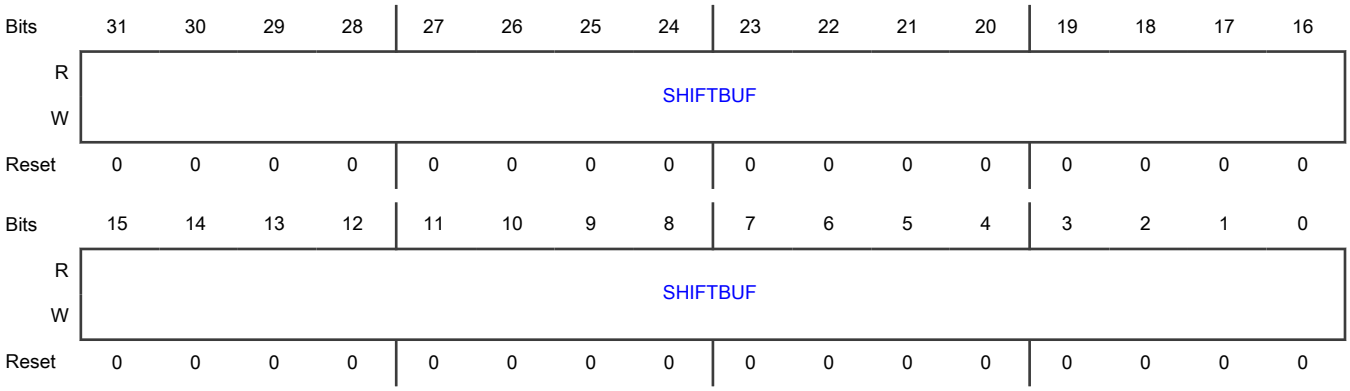
For n = 0 to 7:

Register	Offset
SHIFTBUFn	200h + (n × 4h)

Function

Contains Shift Buffer data.

Diagram



Fields

Field	Function
31-0 SHIFTBUF	Shift Buffer Shift buffer data is used for various functions depending on the SHIFTCTL0[SMOD] setting: For SMOD=Receive, shifter data is transferred into SHIFTBUF at the expiration of timer. Only read the SHIFTBUF register when the corresponding shifter status flag is set, indicating new shifter data is available. For SMOD=Transmit, SHIFTBUF data is transferred into the shifter before the timer begins. For SMOD=Match Store, SHIFTBUF[31:16] contains the data to be matched with the shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). The match is checked when the timer expires. Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. Only read the SHIFTBUF register when the corresponding shifter status flag is set, indicating new shifter data is available.

Table continues on the next page...

Field	Function
	For SMOD=Match Continuous, SHIFTBUF[31:16] contains the data to be matched with the shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). For SMOD=Logic, SHIFTBUF[31:0] is used to implement a 5-input, 32-bit programmable logic look-up table. See Logic mode for more details. For SMOD=State, use SHIFTBUF[31:24] to drive the output value when this shifter is selected by the current state pointer and use SHIFTBUF[23:0] to configure the value of the next state transition. See State mode for more detail.

60.7.1.30 Shifter Buffer N Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBISn	280h + (n × 4h)

Function

Contains SHIFTBUF register content, but contents are bit-swapped.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SHIFTBUFBIS

R W	SHIFTBUFBIS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUFBIS	Shift Buffer Alias to SHIFTBUF register, but reads or writes to this register are bit-swapped. Reads return SHIFTBUF[0:31].

60.7.1.31 Shifter Buffer N Byte Swapped (SHIFTBUFBYS0 - SHIFTBUFBYS7)

Offset

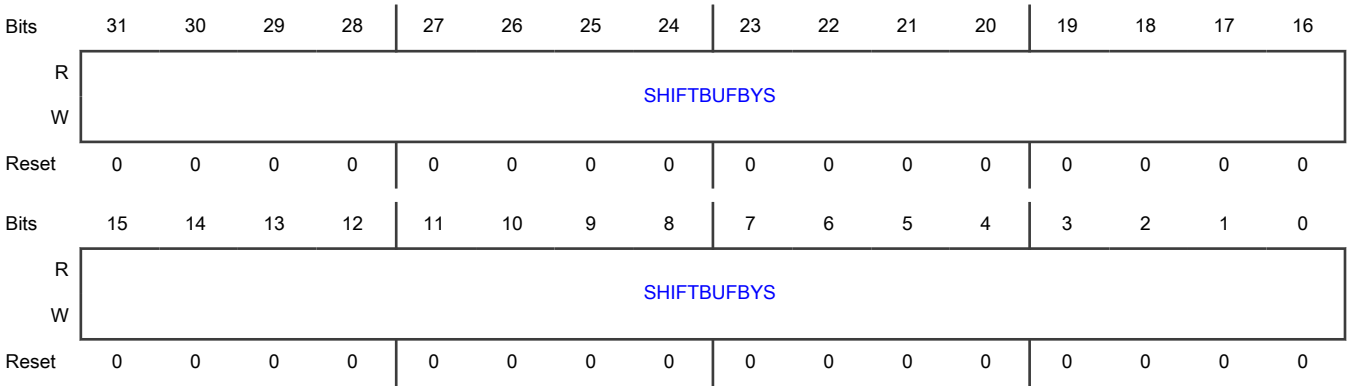
For n = 0 to 7:

Register	Offset
SHIFTBUFBYSn	300h + (n × 4h)

Function

Contains SHIFTBUF register content, but contents are byte-swapped.

Diagram



Fields

Field	Function
31-0 SHIFTBUFBYS	Shift Buffer Alias to SHIFTBUF register, but reads or writes to this register are byte-swapped. Reads return {SHIFTBUF[7:0], SHIFTBUF[15:8], SHIFTBUF[23:16], SHIFTBUF[31:24]}.

60.7.1.32 Shifter Buffer N Bit Byte Swapped (SHIFTBUFBBS0 - SHIFTBUFBBS7)

Offset

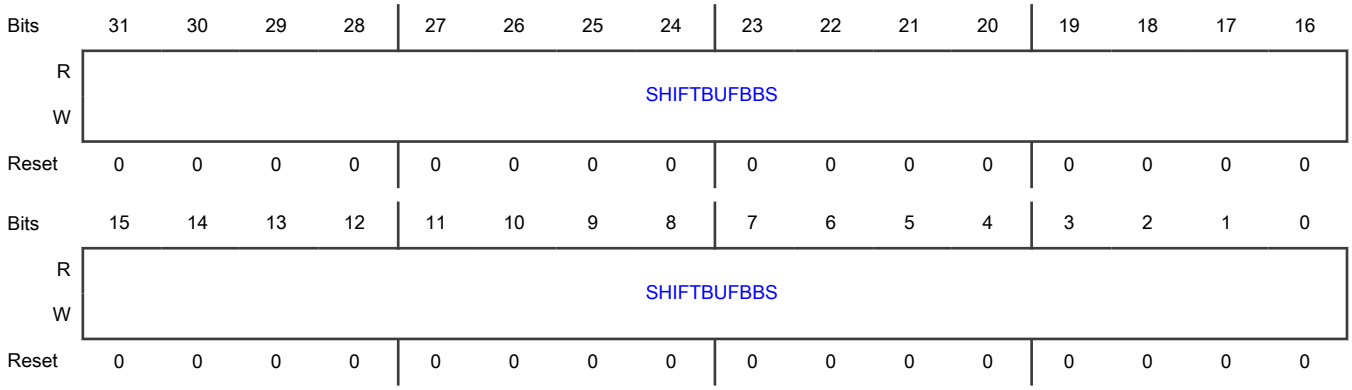
For n = 0 to 7:

Register	Offset
SHIFTBUFBBSn	380h + (n × 4h)

Function

Contains SHIFTBUF register data, but is bit-swapped within each byte.

Diagram



Fields

Field	Function
31-0 SHIFTBUFBBS	Shift Buffer Alias to SHIFTBUF register, except reads or writes to this register are bit-swapped within each byte. Reads return {SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7]}.

60.7.1.33 Timer Control N (TIMCTL0 - TIMCTL7)

Offset

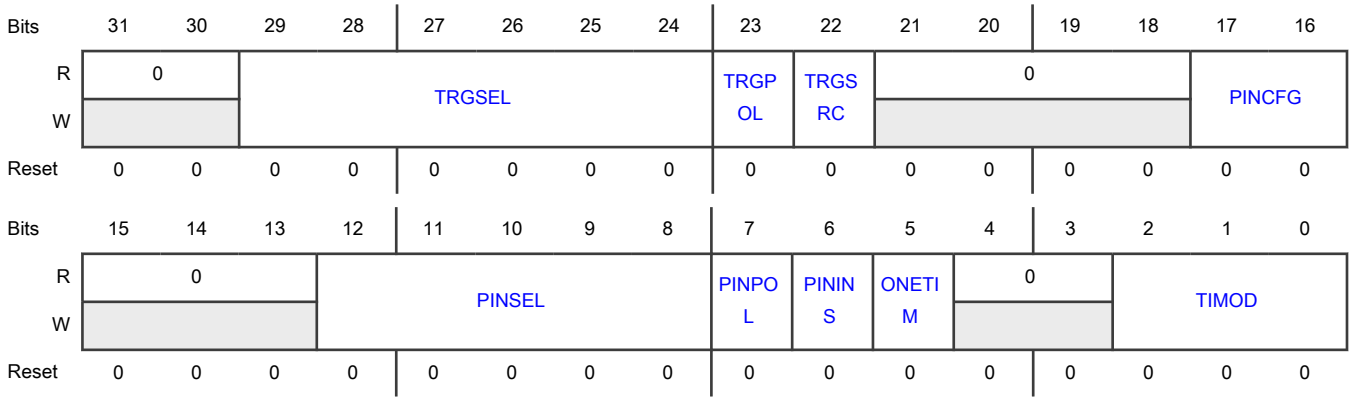
For n = 0 to 7:

Register	Offset
TIMCTLn	400h + (n × 4h)

Function

Controls various settings for Timer N.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 TRGSEL	Trigger Select The valid values for TRGSEL depend on the FLEXIO_PARAM register: • When TRGSRC = 1, the valid values for N depend on the PIN, TIMER, and SHIFTER fields in the FLEXIO_PARAM register. • When TRGSRC = 0, the valid values for N depend on the TRIGGER field in FLEXIO_PARAM register. See the chip-specific FLEXIO information for external trigger selection. **NOTE** For a pin, N=0 to 31. For a shifter, N=0 to 7. For a timer, N=0 to 7. When TRGSRC = 0 the trigger selection is configured as follows: • N - External trigger N input When TRGSRC = 1, the internal trigger can be configured to select an input pin as follows: • 2*N - Pin N input When TRGSRC = 1, the internal trigger can be configured to select a shifter or timer signal as follows: • 4*N+1 - Shifter N status flag • 4*N+3 - Timer N trigger output The expanded internal trigger selection (TRGSRC = 1) is as follows: • 0000 = Pin 0 • 0001 = Shifter 0 Flag • 0010 = Pin 1 • 0011 = Timer 0 Trigger • 0100 = Pin 2 • 0101 = Shifter 1 Flag • 0110 = Pin 3 • 0111 = Timer 1 Trigger • ... • This continues up to the Pin 31, Shifter 7, and Timer 7.
23 TRGPOL	Trigger Polarity Determines if the trigger is active high or active low. 0b - Trigger active high 1b - Trigger active low
22	Trigger Source

Table continues on the next page...

Table continued from the previous page...

Field	Function
TRGSRC	Determines if the trigger source is external or internal. 0b - External trigger selected 1b - Internal trigger selected
21-18 —	Reserved
17-16 PINCFG	Timer Pin Configuration Configures the direction of the timer pin. For pins configured as an output (PINCFG=11b), this field takes effect when the register is written. **NOTE** When initially configuring PINCFG=11b, FLEXIO may briefly drive the pin low. To avoid this, configure PINCFG=10b along with the rest of the control register and then perform a subsequent write to set PINCFG=11b. Likewise, when changing PINCFG=11b to PINCFG=00b software should perform an initial write to set PINCFG=10b and then perform a subsequent write to update the rest of the control register with PINCFG=00b. 00b - Timer pin output disabled 01b - Timer pin open-drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output
15-13 —	Reserved
12-8 PINSEL	Timer Pin Select Selects which pin is used by the timer input or output. PINSEL=i selects the FXIO_Di pin. For pins configured as an output (PINCFG=11b), this field takes effect when the register is written.
7 PINPOL	Timer Pin Polarity For pins configured as an output (PINCFG=11b), this field takes effect when the register is written. 0b - Pin is active high 1b - Pin is active low
6 PININS	Timer Pin Input Select When set, the timer input pin is a different pin from the timer output pin. PINSEL must select an even-numbered pin when this field is set, meaning the output pin is even-numbered and input pin is odd-numbered. 0b - Timer pin input and output are selected by PINSEL. 1b - Timer pin input is selected by PINSEL+1. Timer pin output remains selected by PINSEL.

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 ONETIM	Timer One Time Operation Use this field to configure the timer to perform a single enable/disable iteration. Clear the timer status flag for the timer to be enabled again. 0b - The timer enable event is generated as normal. 1b - The timer enable event is blocked unless timer status flag is clear.
4-3 —	Reserved
2-0 TIMOD	Timer Mode In 8-bit baud counter mode, the lower 8 bits of the counter and compare register are used to configure the baud rate of the timer shift clock. The upper 8 bits are used to configure the shifter bit count. In 8-bit PWM high mode, the lower 8 bits of the counter and compare register are used to configure the high period of the timer shift clock. The upper 8 bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit counter mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 16-bit counter disable mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 8-bit word counter mode, the lower 8 bits of the counter and compare register are used to configure the shifter bit count. The upper 8 bits are used to configure the shifter word count. In 8-bit PWM low mode, the lower 8 bits of the counter and compare register are used to configure the low period of the timer shift clock. The upper 8 bits are used to configure the high period of the timer shift clock. Use another timer or external signal to configure the shifter bit count. In 16-bit input capture mode, the inverted value of the 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMDIS). This also sets the timer status flag. The timer counter is immediately restarted from FFFFh 000b - Timer disabled. 001b - Dual 8-bit counters baud mode. 010b - Dual 8-bit counters PWM high mode. 011b - Single 16-bit counter mode. 100b - Single 16-bit counter disable mode. 101b - Dual 8-bit counters word mode. 110b - Dual 8-bit counters PWM low mode. 111b - Single 16-bit input capture mode.

60.7.1.34 Timer Configuration N (TIMCFG0 - TIMCFG7)

Offset

For n = 0 to 7:

Register	Offset
TIMCFGn	480h + (n × 4h)

Function

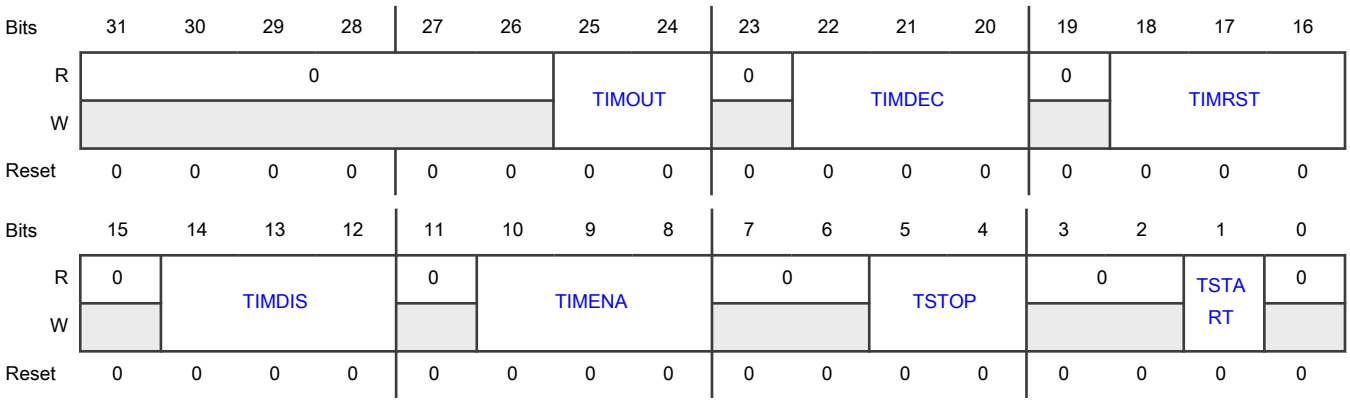
Controls various aspects of Timer Configuration.

The options to enable or disable the timer using the Timer N-1 enable or disable are reserved when N is evenly divisible by 4 (Timer 0, for example).

NOTE

The pin and trigger level/edges specified below refer to the signal state after being modified by the PINPOL or TRGPOL setting in the TIMCTL register. For example, "Trigger low" means that a trigger is actually at logic level 1 if the TRGPOL is set to 1 (active low).

Diagram



Fields

Field	Function
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the timer output and whether it is affected by the timer reset. 00b - Timer output is logic one when enabled and is not affected by timer reset 01b - Timer output is logic zero when enabled and is not affected by timer reset 10b - Timer output is logic one when enabled and on timer reset 11b - Timer output is logic zero when enabled and on timer reset
23 —	Reserved
22-20	Timer Decrement

Table continues on the next page...

Table continued from the previous page...

Field	Function
TIMDEC	Configures the source of the timer decrement and the source of the shift clock. 000b - Decrement counter on FLEXIO clock. Shift clock equals timer output. 001b - Decrement counter on trigger input (both edges). Shift clock equals timer output. 010b - Decrement counter on pin input (both edges). Shift clock equals pin input. 011b - Decrement counter on trigger input (both edges). Shift clock equals trigger input. 100b - Decrement counter on FLEXIO clock divided by 16. Shift clock equals timer output. 101b - Decrement counter on FLEXIO clock divided by 256. Shift clock equals timer output. 110b - Decrement counter on pin input (rising edge). Shift clock equals pin input. 111b - Decrement counter on trigger input (rising edge). Shift clock equals trigger input.
19 —	Reserved
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8-bits that configure the baud rate. In all other modes, the timer reset resets the full 16-bits of the counter. 000b - Timer never reset 001b - Timer reset on timer output high. 010b - Timer reset on timer pin equal to timer output 011b - Timer reset on timer trigger equal to timer output 100b - Timer reset on timer pin rising edge 101b - Reserved 110b - Timer reset on trigger rising edge 111b - Timer reset on trigger rising or falling edge
15 —	Reserved
14-12 TIMDIS	Timer Disable Configures the condition that causes the timer to be disabled and stop decrementing. 000b - Timer never disabled 001b - Timer disabled on Timer N-1 disable 010b - Timer disabled on timer compare (upper 8-bits match and decrement) 011b - Timer disabled on timer compare (upper 8-bits match and decrement) and trigger low 100b - Timer disabled on pin rising or falling edge

Table continues on the next page...

Table continued from the previous page...

Field	Function
	101b - Timer disabled on pin rising or falling edge provided trigger is high 110b - Timer disabled on trigger falling edge 111b - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the timer to be enabled and start decrementing. 000b - Timer always enabled 001b - Timer enabled on Timer N-1 enable 010b - Timer enabled on Trigger high 011b - Timer enabled on Trigger high and Pin high 100b - Timer enabled on Pin rising edge 101b - Timer enabled on Pin rising edge and Trigger high 110b - Timer enabled on Trigger rising edge 111b - Timer enabled on Trigger rising or falling edge
7-6 —	Reserved
5-4 TSTOP	Timer Stop Bit The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00b - Stop bit disabled 01b - Stop bit is enabled on timer compare 10b - Stop bit is enabled on timer disable 11b - Stop bit is enabled on timer compare and timer disable
3-2 —	Reserved
1 TSTART	Timer Start Bit When start bit is enabled, configured shifters output the contents of the start bit when the timer is enabled. The timer counter reloads from the compare register on the first rising edge of the shift clock. 0b - Start bit disabled 1b - Start bit enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 —	Reserved

60.7.1.35 Timer Compare N (TIMCMP0 - TIMCMP7)

Offset

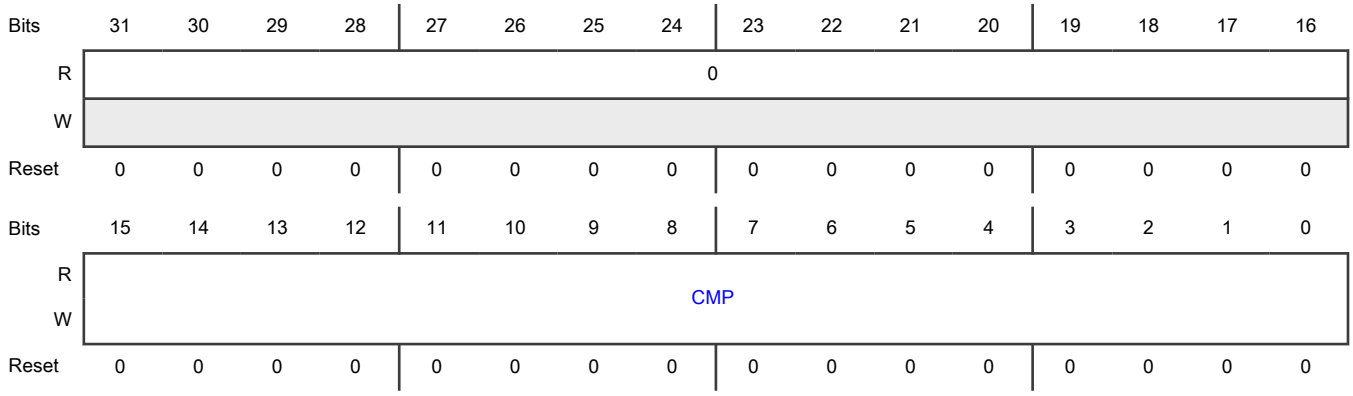
For n = 0 to 7:

Register	Offset
TIMCMPn	500h + (n × 4h)

Function

Contains the Timer Compare Value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CMP	Timer Compare Value The timer compare value is loaded into the timer counter when the timer is first enabled, when the timer is reset, and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8 bits configure the baud rate divider equal to (CMP[7:0] + 1) * 2. The upper 8 bits configure the number of bits in each word equal to (CMP[15:8] + 1) / 2.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In 8-bit PWM high mode, the lower 8 bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 8-bit word counter mode, the lower 8 bits configure the number of bits in each word equal to (CMP[7:0] + 1) / 2. The upper 8 bits configure the number of words to transfer equal to (CMP[15:8] + 1) / 2. In 8-bit PWM low mode, the lower 8 bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the high period of the output to (CMP[15:8] + 1). In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. Only read the timer compare register when the timer status flag is set.

60.7.1.36 Shifter Buffer N Nibble Byte Swapped (SHIFTBUFNBS0 - SHIFTBUFNBS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFNBSn	680h + (n × 4h)

Function

Contains SHIFTBUF register content, but contents are nibble-swapped within each byte.

Diagram

61.2 Overview

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O). The figure below shows the KPP block diagram. The KPP provides interface for the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

61.2.1 Block diagram

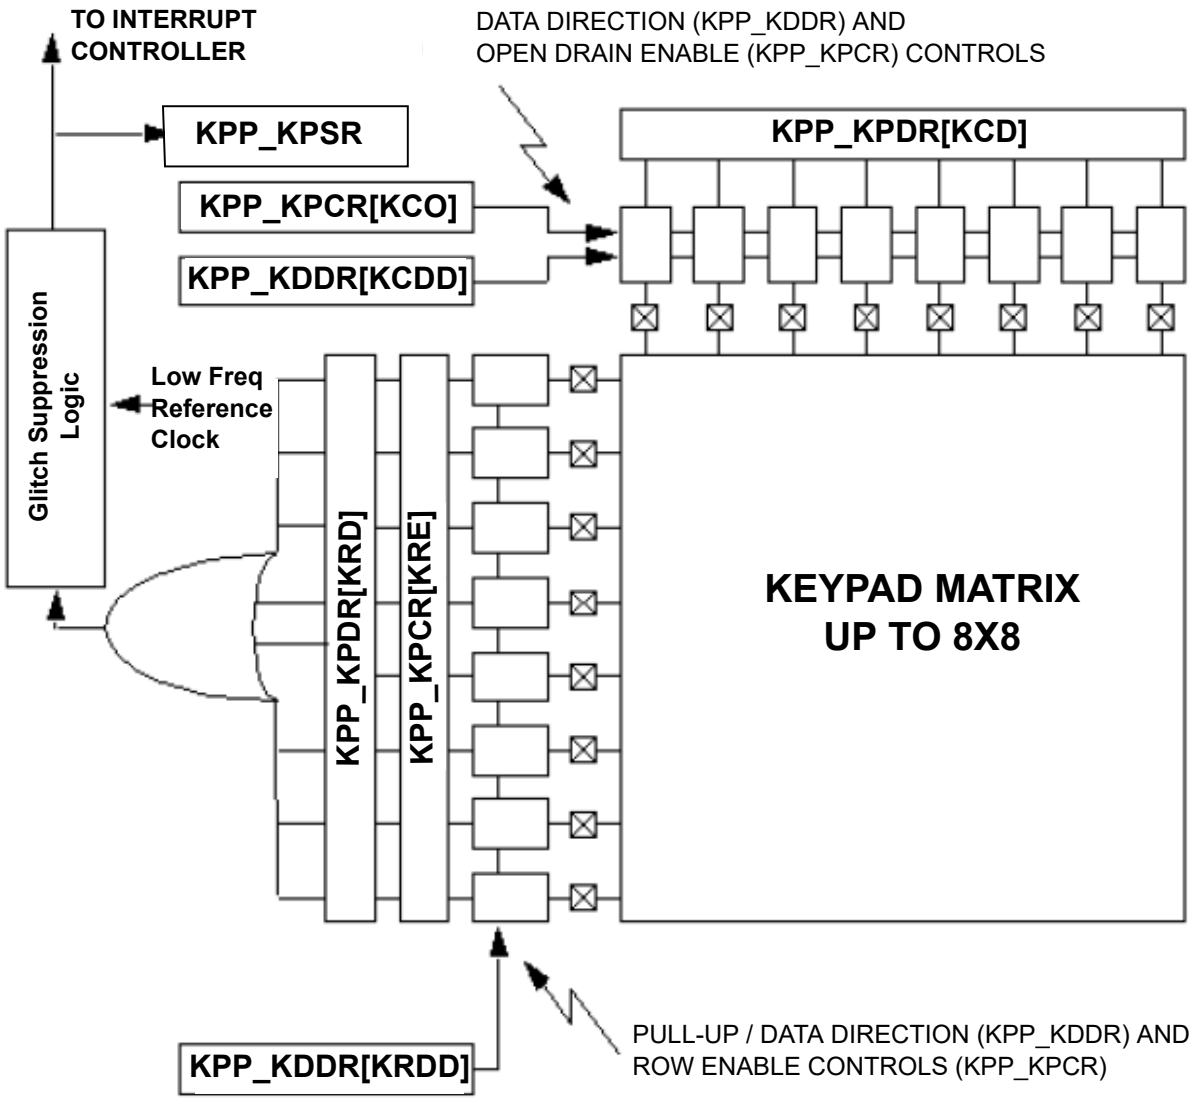

Figure 457. KPP Peripheral Block Diagram

61.2.2 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection
- Long key-press detection
- Standby key-press detection

- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

61.3 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes provided that a low frequency reference clock (ipg_clk_32k) is on. The KPP may generate an ARM platform interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

61.3.1 Modes and Operations

This block supports the following modes:

- Run Mode-This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Mode-The keypad can detect any key press even in low power modes (when there is no MCU clock).

61.3.2 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

61.3.3 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

61.3.4 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those from the previous pass. When several consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next software layer.

The KPP may be used to control the debounce period, but it must be defined in software by the user’s application. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

61.3.5 Keypad Standby

There is no need for the ARM platform to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the ARM platform can attend to other tasks or revert to a low power standby mode. The KPP can interrupt the ARM platform if any key is pressed.

Upon receiving a keypad interrupt, the ARM platform should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

61.3.6 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the ARM platform. The circuit is a 4-state synchronizer clocked from a low frequency reference clock (ipg_clk_32k) source. This clock must continue to run in any low power mode where the keypad is a wake-up source, as the ARM platform interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods in duration of a low frequency reference clock. Noise filtering of the duration between three to four clock periods cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See the figure below.

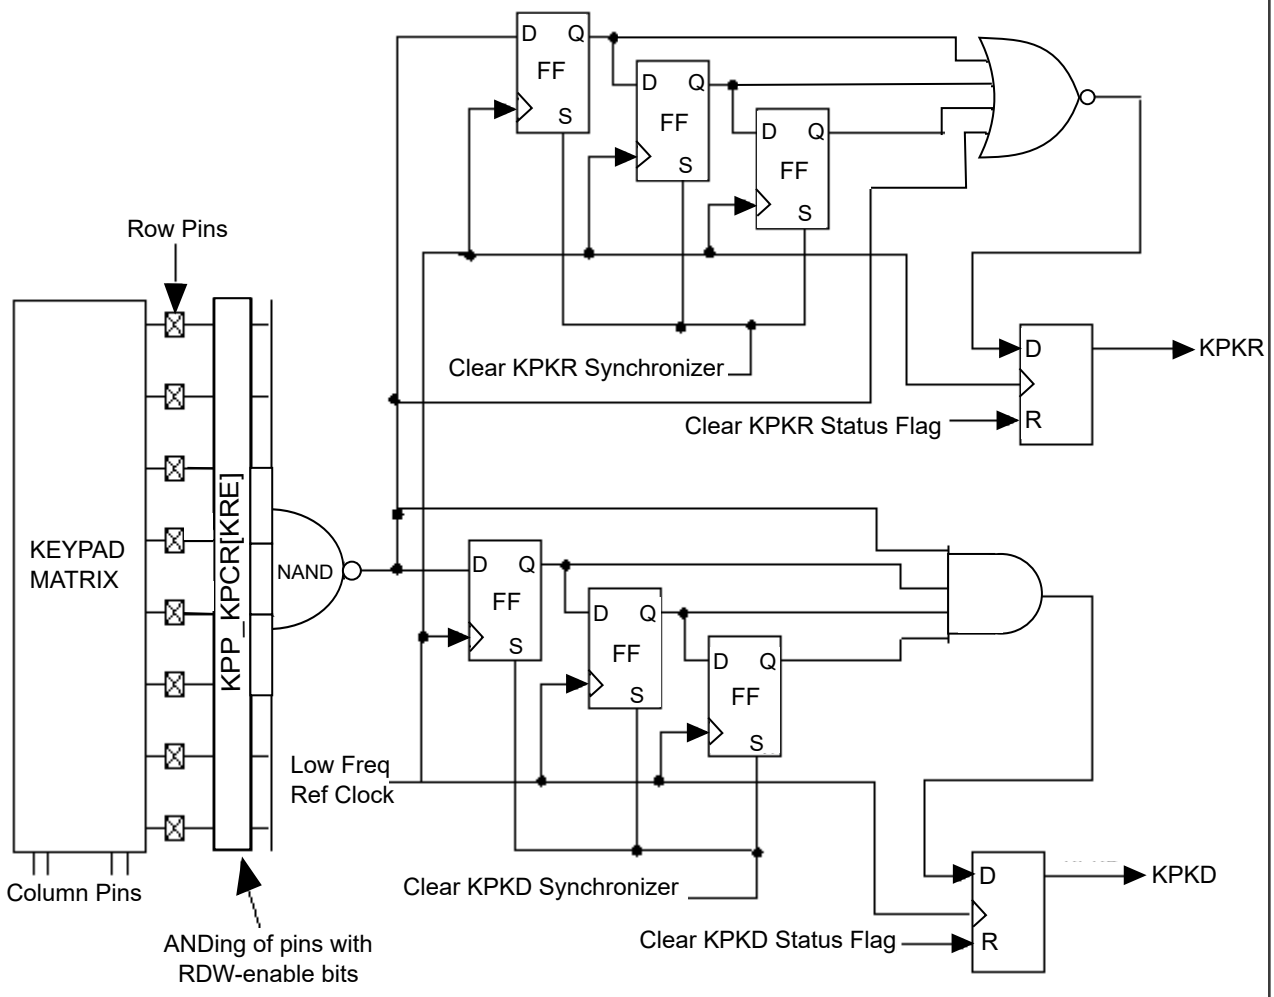

Figure 458. Keypad Synchronizer Functional Diagram

61.3.7 Multiple Key Closures

Using the key press and key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly (See Initialization/Application Information for more information).

The following figures illustrate the interface of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed keys can be detected. Similarly, when keys present on same column line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

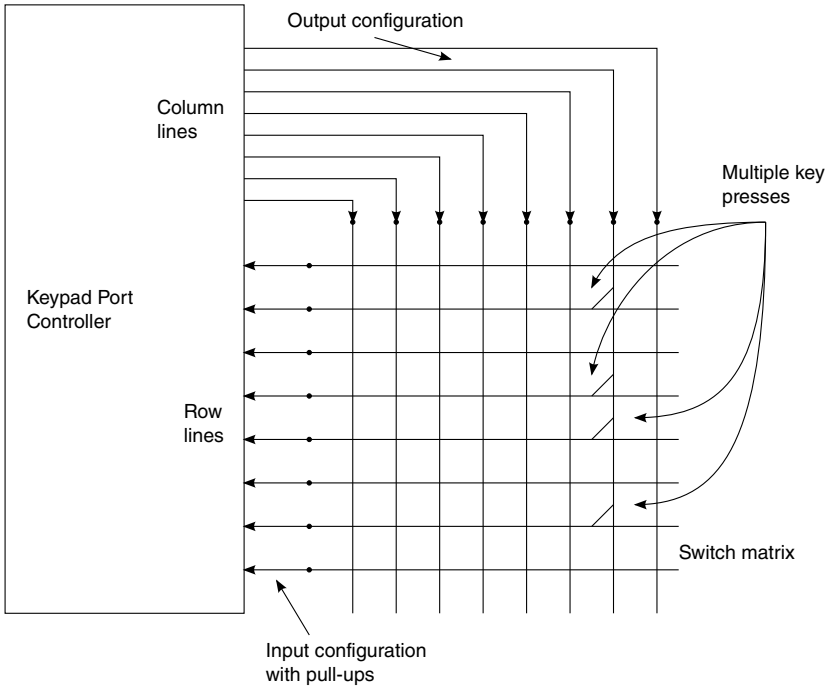

Figure 459. Multiple Key Presses on Same Column Line (Simplified View)

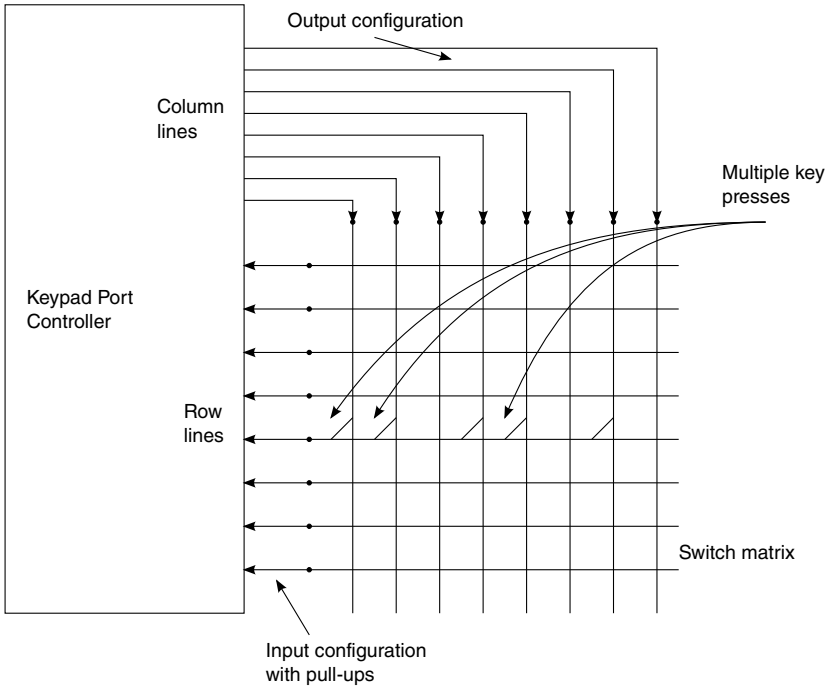

Figure 460. Multiple Key Presses on Same Row Line (Simplified View)

NOTE

An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

61.3.7.1 Ghost Key Problem and Correction

The KPP detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of "ghost" key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix.

As seen in Figure 461, three keys pressed simultaneously can cause a short between the column currently "scanned" by the software and another column. Depending on the location of the third key pressed, a "ghost" key press may be detected.

However, this can be corrected by using a keypad matrix that provides "ghost" key protection. Such a matrix implements a one-way "diode" at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see Figure 462).

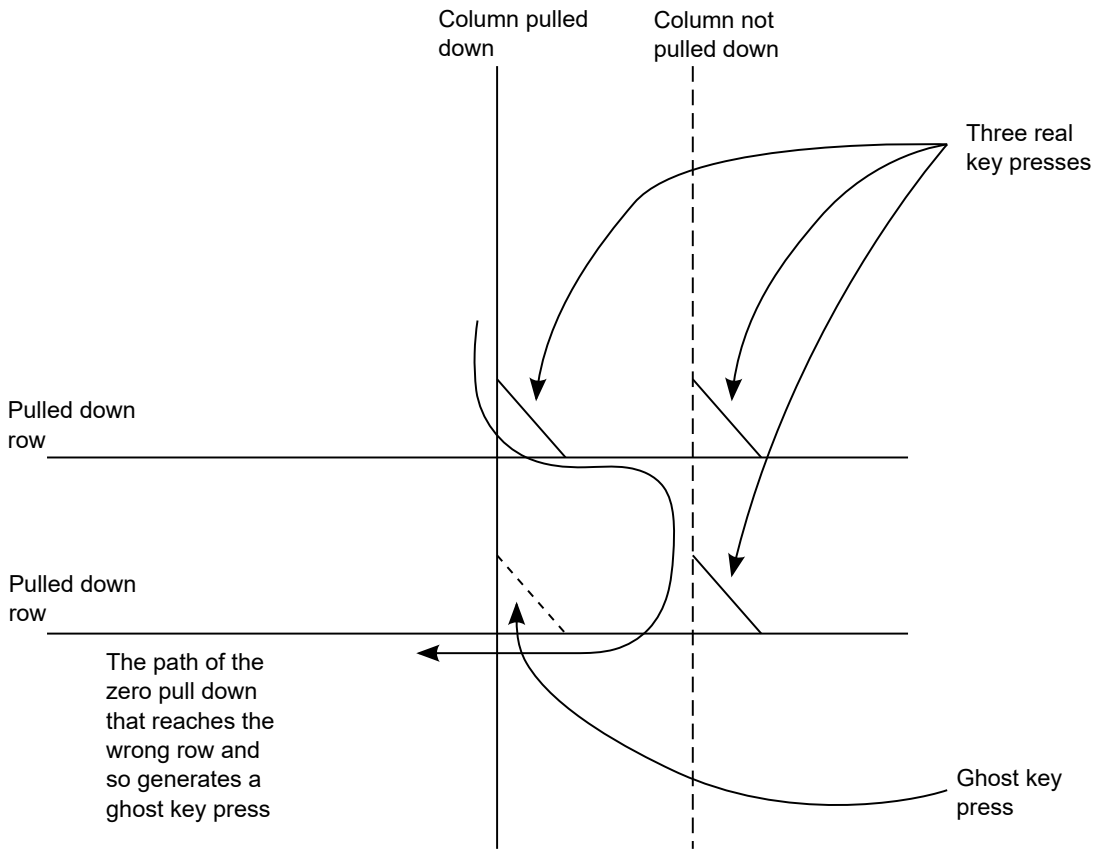

Figure 461. Decoding Wrong Three- Key-Presses

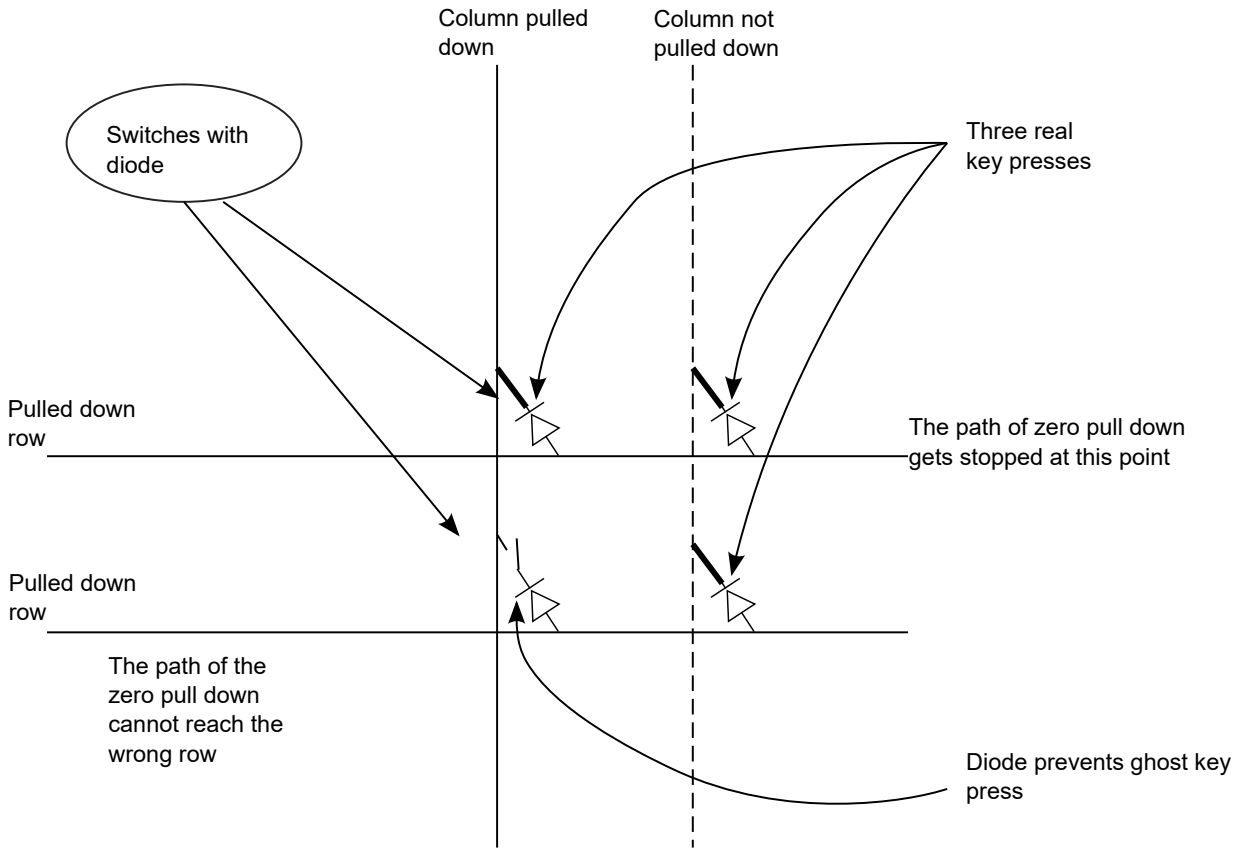

Figure 462. Matrix with "Ghost" Key Protections

61.3.8 3-Point Contact Keys Support

The KPP supports interfacing to a matrix consisting of 3-point contact keys. As shown in Figure 463, two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic).

The keypad lines should be configured as input and a pull-up should to be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

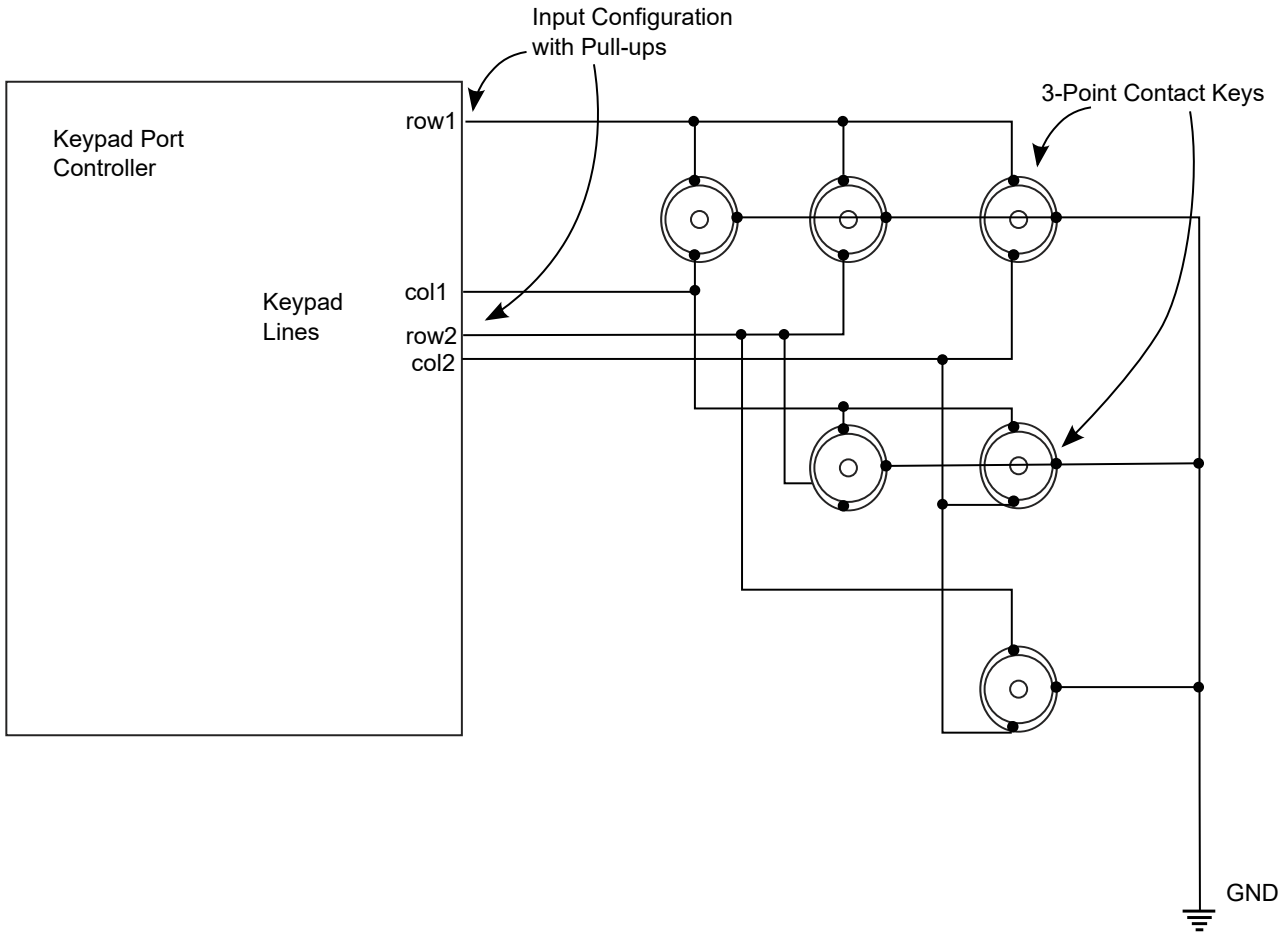

Figure 463. KPP Interface with 3-point Contact Key Matrix (Simplified View)

61.3.9 Clocks

The table found here describes the clock sources for KPP. Please see clock control block for clock setting, configuration and gating information.

Table 1008. KPP Clocks

Clock name	Description
ipg_clk_32k	Low-frequency reference clock (32 kHz)
ipg_clk_s	Peripheral access clock

61.4 External Signals

There are several pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide. Please see IOMUX Controller for KPP pin mux assignments.

See the table below for the list of external signals.

Table 1009. KPP External Signals

Name	Direction	Function	Reset State	Pull-Up
KEY_COL[7:0]	IO	Column input or output pin, from chip	0	Active[1]
KEY_ROW[7:0]	IO	Row input or output pin, from chip	1	Active[1]

1. The corresponding pads are required to be pull-up enabled.

61.4.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a "0" to the appropriate bits in the KPP_KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KPP_KDDR[KRDD] have internal pull-ups, which are enabled when the pin is used as an input.

61.4.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KPP_KDDR to a "1". Additionally, the 8 most significant bits (15-8) can be designated as open drain outputs by writing a "1" to the appropriate bits in the KPP_KPCR. The lower 8 bits (7-0) are always in "totem pole" style, driven when configured as outputs. See the table below.

Table 1010. Keypad Port Column Modes

KPP_KDDR (15:8)	KPP_KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

NOTE

Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a "1" during the scan routine. With this configuration, delay between the scanning of two subsequent columns is reduced. Totem pole mode is to be used temporarily on the column pins to discharge the lines only, but should be switched to open-drain mode for normal operation.

61.4.3 Generation of Transfer Error Signal on Peripheral Bus

If there is an access to an address which is not implemented, then the KPP asserts a transfer error signal on Peripheral Bus.

61.5 Initialization/Application Information

61.5.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPP_KPCR[KRE]).
2. Write 0s to KPP_KPDR[KCD].
3. Configure the keypad columns as open-drain (KPP_KPCR[KCO]).
4. Configure columns as output (KPP_KDDR[KCDD]) and rows as input (KPP_KDDR[KRDD]).

5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

61.5.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPP_KPDR[KCD], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).
4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2-6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a "1"; set the KPKR synchronizer chain by writing a "1" to the KPP_KRSS register; and clear the KPKD synchronizer chain by writing a "1" to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

61.5.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP is that the block is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

61.6 Memory Map and Register Definition

61.6.1 KPP register descriptions

The KPP contains four registers.

61.6.1.1 KPP memory map

KPP base address: 42A0_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Keypad Control Register (KPCR)	16	RW	0000h
2h	Keypad Status Register (KPSR)	16	RW	0002h
4h	Keypad Data Direction Register (KDDR)	16	RW	0000h
6h	Keypad Data Register (KPDR)	16	RW	0000h

61.6.1.2 Keypad Control Register (KPCR)

Offset

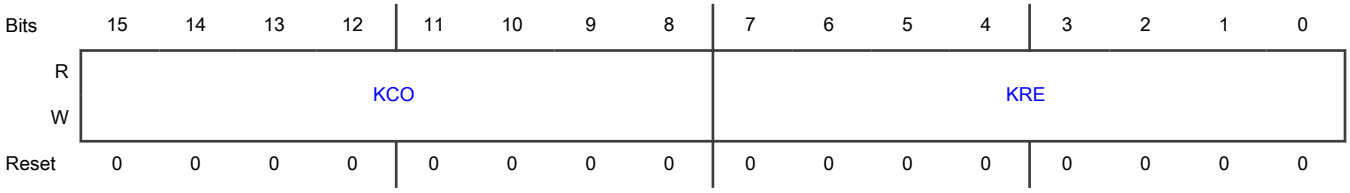
Register	Offset
KPCR	0h

Function

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPP_KPCR register is byte- or half-word-addressable.

Diagram



Fields

Field	Function
15-8 KCO	KCO Keypad Column Strobe Open-Drain Enable. Setting a column open-drain enable bit (KCO7-KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input. **NOTE** Configuration of external port control logic (for example, IOMUX) should be done properly so that the KPP controls an open-drain enable of the pin. 0000_0000b - Column strobe output is totem pole drive. 0000_0001b - Column strobe output is open drain.
7-0 KRE	KRE Keypad Row Enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a "0" to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set. 0000_0000b - Row is not included in the keypad key press detect. 0000_0001b - Row is included in the keypad key press detect.

61.6.1.3 Keypad Status Register (KPSR)

Offset

Register	Offset
KPSR	2h

Function

The Keypad Status Register reflects the state of the key press detect circuit. The KPP_KPSR register is byte- or half-word-addressable.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						KRIE	KDIE	0				0	0	KPKR	KPKD
W													KRSS	KDSC	W1C	W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Fields

Field	Function
15-10 —	- Reserved
9 KRIE	KRIE Keypad Release Interrupt Enable. The software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0b - No interrupt request is generated when KPKR is set. 1b - An interrupt request is generated when KPKR is set.
8 KDIE	KDIE Keypad Key Depress Interrupt Enable. Software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0b - No interrupt request is generated when KPKD is set. 1b - An interrupt request is generated when KPKD is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-4 —	- Reserved, should be cleared
3 KRSS	KRSS Key Release Synchronizer Set. Self-clear bit. The Key release synchronizer is set by writing a logic one into this bit. Reads return a value of "0". 0b - No effect 1b - Set bits which sets keypad release synchronizer chain
2 KDSC	KDSC Key Depress Synchronizer Clear. Self-clear bit. The Key depress synchronizer is cleared by writing a logic "1" into this bit. Reads return a value of "0". 0b - No effect 1b - Set bits that clear the keypad depress synchronizer chain
1 KPKR	KPKR Keypad Key Release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents. Reset value of register is "0" as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become "1". 0b - No key release detected 1b - All keys have been released
0 KPKD	KPKD Keypad Key Depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the low frequency reference clock (ipg_clk_32k) elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents. 0b - No key presses detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - A key has been depressed

61.6.1.4 Keypad Data Direction Register (KDDR)

Offset

Register	Offset
KDDR	4h

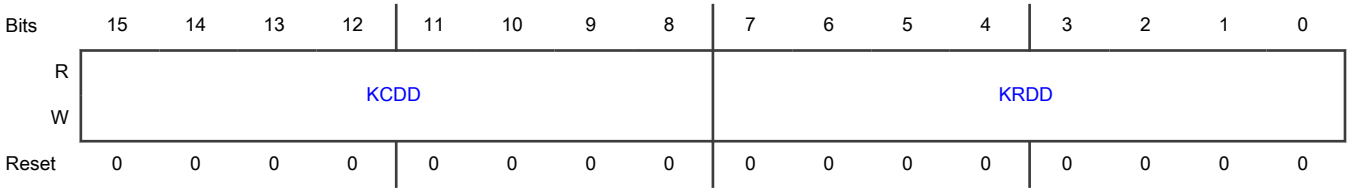
Function

The bits in the KPP_KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KPP_KDDR register is byte- or half-word addressable.

NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in KRDD is cleared.

Diagram



Fields

Field	Function
15-8 KCDD	KCDD Keypad Column Data Direction Register. Setting a bit configures the corresponding COL*n* pin as an output (where *n* = 7 through 0). 0000_0000b - COLn pin is configured as an input. 0000_0001b - COLn pin is configured as an output.
7-0 KRDD	KRDD Keypad Row Data Direction. Setting a bit configures the corresponding ROW*n* pin as an output (where *n* = 7 through 0).

Table continues on the next page...

Table continued from the previous page...

	0000_0000b - ROWn pin configured as an input. 0000_0001b - ROWn pin configured as an output.

61.6.1.5 Keypad Data Register (KPDR)

Offset

Register	Offset
KPDR	6h

Function

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPP_KPDR register is byte- or half-word addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

62.2 Overview

LPI2C supports an efficient interface to an I2C bus as a controller and target:

- Implements logic support for Standard, Fast, Fast+, HS-mode (target only) and Ultra-Fast modes of operation
- Uses little CPU overhead, with DMA offloading of FIFO register accesses
- Continues operating in Stop modes if an appropriate clock is available

LPI2C also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low-bandwidth communications.

The Inter-Integrated Circuit (I^2C) serial bus is multi-controller, multi-target, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

NOTE

Terminology in this chapter has been updated to align with I²C-bus specification, Rev. 7.0, as shown in Table 1012.

Table 1012. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

62.2.1 Block diagram

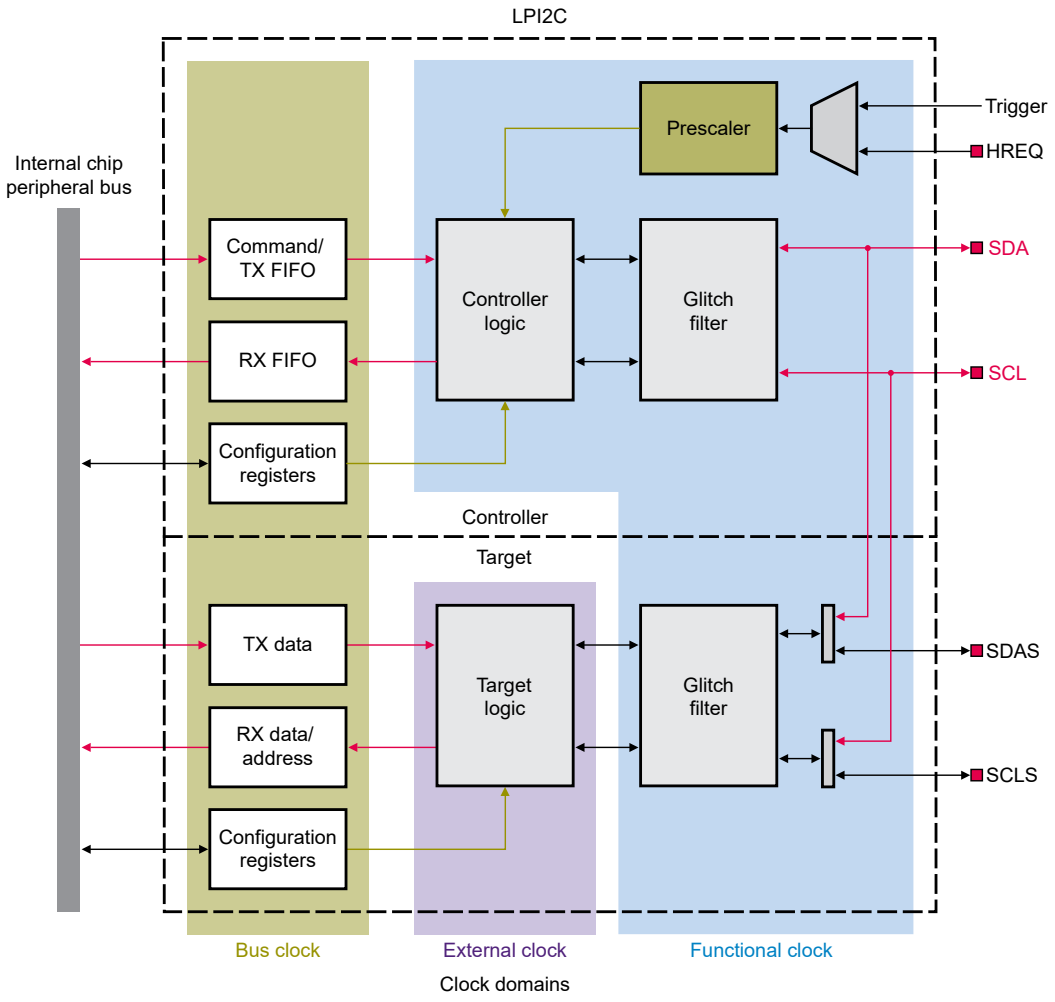

Figure 464. Block diagram

62.2.2 Features

LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes
- HS mode in target mode
- Multicontroller, including synchronization and arbitration, means that any number of controller nodes can be present. Also, controller and target roles can be changed between messages (after a Stop signal is sent).

- Clock stretching. Used on the SCL line, as an I2C flow control mechanism.
- Arbitration for when the system has more than one controller. When used on the SDA line, ensures that there is only one I2C transmitter at a time.
- General call, seven-bit addressing, and ten-bit addressing
- Software reset, Start byte, and device ID (also require software support)

The LPI2C controller supports:

- Command and transmit FIFO of 8 words (8-bit transmit data + 3-bit command)
- Receive FIFO of 8 words (8-bit receive data).
- Command FIFO waiting for an I2C idle bus before initiating a transfer
- Initiation of repeated Start and Stop conditions and one or more controller-receiver transfers by command FIFO
- Stop condition generation from command FIFO, or automatic generation of Stop condition when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Interrupt generation on data match and unwanted data rejection, via flexible receive data match
- Flags and optional interrupt signals at repeated Start condition, Stop condition, loss of arbitration, unexpected NACK, and command word errors
- Configurable bus idle timeout and pin-stuck-low timeout

The LPI2C target supports:

- Separate I2C target registers to minimize software overhead because of controller or target switching
- 7-bit or 10-bit addressing, address range, SMBus alert, and general call address.
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK or NACK field
- Configurable clock stretching, to avoid transmit-FIFO-underrun and receive-FIFO-overrun errors
- Flags and optional interrupt at end of packet, Stop condition, or bit error detection

62.3 Functional description

62.3.1 Controller mode

The LPI2C controller logic operates independently from the target logic to perform all controller-mode transfers on the I2C bus.

62.3.1.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- Start or repeated Start condition with address byte, expecting ACK or NACK.
- Transmit data. This operation is the default for zero-extended-byte writes to the transmit FIFO.
- Receive 1-256 bytes of data. You can configure this operation to discard received data and not to store it in the receive FIFO.
- Stop condition. You can configure this operation to send a Stop condition when the transmit FIFO is empty.

Multiple transmit and receive commands can be inserted between the Start and Stop conditions. To comply with the I2C specification, transmit and receive commands must not be interleaved. The receive data command and the receive data and

discard commands can be interleaved. This interleaving ensures that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C controller automatically transmits a NACK on the last byte of a receive data command. It transmits the NACK unless the next command in the FIFO is also a receive data command. If the transmit FIFO is empty when a receive data command completes, a NACK is also automatically transmitted.

The LPI2C controller supports 10-bit addressing via a (repeated) Start condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the controller transmit data.

A Start or repeated Start condition expecting a NACK (for example, HS mode controller code) must be followed by a Stop or (repeated) Start condition.

62.3.1.2 Controller operations

When LPI2C is enabled, it monitors the I2C bus to detect when the I2C is idle (MSR[BBF]). If either SCL or SDA are low, the I2C bus is no longer considered idle. The bus becomes idle if a Stop condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the bus is idle, if the transmit FIFO is not empty and the host request is asserted or disabled, the LPI2C controller initiates a transfer on the bus. This transfer involves the following steps:

1. Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
2. Transmit a Start condition and address byte using the timing configuration in Controller Clock Configuration 0 (MCCR0). If an HS mode transfer is configured, the timing configuration from Controller Clock Configuration 1 (MCCR1) is used instead.
3. Perform controller transmit or controller receive transfers, as configured by the transmit FIFO.
4. Transmit NACK on the last byte of a controller receive transfer. This action is performed unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
5. Transmit a repeated Start or Stop condition as configured by the transmit FIFO or MCFGR1[AUTOSTOP]. A repeated Start can change which timing configuration register is used.

When MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. It also relaxes some restrictions on the order of FIFO commands. For example, it allows a Stop command when it is idle to generate a Start condition, followed by one SCL clock pulse, and then a Stop condition.

When the LPI2C controller is disabled, LPI2C continues emptying the transmit FIFO until a Stop condition is transmitted. (The controller could be disabled due to MCR[MEN] being 0, or automatically due to mode entry.) However, LPI2C no longer stalls the I2C bus by waiting for the transmit or receive FIFO. After the transmit FIFO is empty, LPI2C generates a Stop condition automatically.

The LPI2C controller can stall the I2C bus under certain conditions. This stalling results in SCL pulled low continuously on the first bit of a byte, until these conditions change:

- The LPI2C controller is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is 0. The LPI2C controller continues to stall the bus until the transmit FIFO is loaded with more data.
- The LPI2C controller is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full. The LPI2C controller continues to stall the I2C bus until the receive FIFO is emptied.

The LPI2C controller aborts the existing transfer when MCFGR0[ABORT] becomes 1. This action causes the LPI2C controller to complete the existing word and then transmit a Stop condition. If the receive FIFO is full when the receive operation is aborted, the last received data is discarded. A new transfer does not start while MCFGR0[ABORT] is 1.

62.3.1.3 Receive FIFO and data matching

The receive FIFO stores receive data during controller-receiver transfers. You can configure the LPI2C controller to discard received data instead of storing it in the receive FIFO. This option is configured via the command word in the transmit FIFO.

Received data supports a receive data match function that can match received data against one of two bytes, or against a masked data byte. You can configure the data match function to compare only the first one or two data words received since the last

(repeated) Start condition. Received data that is already discarded due to the command word cannot cause a data match. It delays the match on the first data word received until after the discarded data is received.

You can configure the receiver match function to discard all received data until a data match is detected, using MCFGR0[RDMO]. Following a data match, write 0 to MCFGR0[RDMO] before writing 0 to MSR[DMF] to allow all subsequent data to be received.

62.3.1.4 Timing parameters

The LPI2C controller can configure the following timing parameters. Parameters are configured separately for HS mode (Controller Clock Configuration 1 (MCCR1)) and other modes (Controller Clock Configuration 0 (MCCR0)). This separation allows the HS mode controller code to be sent using regular timing parameters. Then it allows a switch to HS mode timing (following a repeated Start) until the next STOP condition.

Configure the LPI2C controller timing parameters, measured in LPI2C functional clock cycles, as shown in Table 1013. You must configure these parameters to meet the I2C timing specification for the required mode.

Table 1013. Timing parameters

I2C specification timing parameter	I2C specification timing symbol	LPI2C timing parameter (in LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) × (2 ^ PRESCALE)
Hold time (repeated) Start condition	tHD:STA	(SETHOLD +1) × (2 ^ PRESCALE)
Low period of the SCL clock	tLOW	(CLKLO + 1) × (2 ^ PRESCALE)
High period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) × (2 ^ PRESCALE)
Setup time for a repeated Start condition or Stop condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) × (2 ^ PRESCALE)
Data hold time	tHD:DAT	(DATAVD + 1) × (2 ^ PRESCALE)
Data setup time	tSU:DAT	(SDA_LATENCY + 1) × (2 ^ PRESCALE)
Bus free time between a Stop and Start condition	tBUF	(CLKLO + 1 + SDA_LATENCY) × (2 ^ PRESCALE)
Data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) × (2 ^ PRESCALE)

Table 1014 defines the latency parameters. These parameters assume that the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading, and the external pullup resistor sizing. A larger risetime increases the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 1014. Synchronization latency

Timing parameter	Timing definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) ÷ (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) ÷ (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected Start or Stop conditions on the I2C bus. These restrictions also avoid unexpected Start or Stop conditions detected by the LPI2C controller. The timing restrictions can be summarized as "SDA cannot change when SCL is high outside a transmitted (repeated) Start or Stop condition."

Table 1015. LPI2C timing parameter restrictions

Timing parameter	Minimum	Maximum	Comment
CLKLO	03h	—	CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	01h	—	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	02h	—	SETHOLD × (2 ^ PRESCALE) > SDA_LATENCY
DATAVD	01h	CLKLO – SDA_LATENCY – 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	00h	[CLKLO × (2 ^ PRESCALE)] – 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)
FILTSDA	FILTSCL	[CLKLO × (2 ^ PRESCALE)] – 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO + SETHOLD + 2) × 2	—	Must also be greater than (CLKHI + 1)

See the UM10204, *I2C-bus specification and user manual*.

See Application information for example LPI2C timing configurations.

62.3.1.5 Error conditions

The LPI2C controller monitors errors while it is active. The following conditions generate an error flag and block a new Start condition from being sent, until the flag is cleared by software:

- A Start or Stop condition is detected and is not generated by the LPI2C controller (MSR[ALF] becomes 1).
- Transmitting data on SDA and different values are received (MSR[ALF] becomes 1). LPI2C controller stops driving SDA immediately, but continues to drive SCL for the remainder of the byte.
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- Transmit FIFO is requesting to transmit or receive data without a Start condition (MSR[FEF] becomes 1). This restriction is ignored when MCFGR0[RELAX] is 1.
- SCL (or SDA if MCFGR1[TIMECFG] is 1) is low for (MCFGR2[TIMELOW] × 256) prescaler cycles without a pin transition (MSR[PLTF] becomes 1).

You must respond to MSR[PLTF] to terminate the existing command. You can terminate the command cleanly by writing 0 to MCR[MEN], or you can terminate it abruptly by writing 1 to MCR[RST].

You can use MCFGR0[RELAX] to attempt to recover a target with SDA stuck low. If MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. Initiating a Start command with address FFh, then the Stop condition, should generate sufficient SCL clock edges to cause the target to release SDA.

You can use MCFGR2[BUSIDLE] to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE + 1) prescaler cycles. The bus is considered idle when the LPI2C controller is first enabled. When BUSIDLE is configured greater than zero, then SCL or SDA must be high for (BUSIDLE + 1) prescaler cycles before the I2C bus is considered idle.

62.3.1.6 DMA support

For efficient DMA transfers to the transmit and command FIFO, two alias regions support incrementing 8-bit, 16-bit, or 32-bit write accesses to that FIFO.

- Controller Transmit Command Burst (MTCBR0 - MTCBR127) is a 512-byte region that supports pushing CMD and DATA into the transmit FIFO.
- Transmit Data Burst (MTDBR0 - MTDBR255) is a 1024-byte region that supports pushing zero extended DATA into the transmit FIFO.

The two regions are contiguous. A DMA transfer can start in the MTCBR region to initialize the transfer including START condition with address. The same transfer can complete in the MTDBR region with the data to transmit without changing the transfer size.

The transmit FIFO prevents writes that overflow the FIFO, but this prevention does not signal an error. Do not perform 32-bit writes to the MTDBR unless there are four empty slots in the transmit FIFO. Do not perform 16-bit writes to the MTDBR unless there are two empty slots in the transmit FIFO.

62.3.1.7 Pin configuration

Configuration	Description
Open-drain support	The LPI2C controller defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
HS mode support	Support for HS mode depends on the specific device. This mode requires the SCL pin to support the current source pullup required in the I2C specification.
Ultra-Fast mode support	The LPI2C controller supports the output-only push-pull function required for I2C Ultra-Fast mode using the SDA and SCL pins. Support for Ultra-Fast mode also requires MCFGR1[IGNACK] to be 1.
Push-pull two-wire support	A push-pull two-wire configuration is available to the LPI2C controller. If LPI2C is the only controller and all I2C pins on the bus are at the same voltage, this configuration may support a partial HS mode. A partial HS mode, not a full HS mode, because this configuration actively drives high rather than enabling a current service pull-up. This configuration sets the SCL pin as push-pull for every clock except the ninth clock pulse, to allow HS-mode-compatible targets to perform clock stretching. In this mode, the SDA pin is tristated for controller-receive data bits and controller-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, configure the pin for open-drain operation, as part of the device-specific configuration.
Push-pull four-wire support	The push-pull four-wire configuration separates the SCL input data and output data into separate pins. It also separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This configuration simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this four-wire configuration, the LPI2C controller logic and LPI2C target logic cannot connect to separate I2C buses.

62.3.2 Target mode

To perform all target mode transfers on the I2C bus, the LPI2C target logic operates independently from the LPI2C controller logic.

62.3.2.1 Address matching

You can configure the LPI2C target:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address.

- To match a range of addresses in either 7-bit or 10-bit addressing modes.
- To match the general call address and generate appropriate flags.
- To match the SMBus alert address and generate appropriate flags.
- To detect the HS mode controller code address, and to disable the digital filters and output valid delay time until the next Stop condition is detected.

After a valid address is matched, the LPI2C target automatically performs target-transmit or target-receive transfers until:

- A NACK is detected (unless SCFGR1[IGNACK] becomes 1).
- A bit error is detected (the LPI2C target is driving SDA, but a different value is sampled).
- A (repeated) Start or Stop condition is detected.

When SCFGR1[RXALL] is 1, the LPI2C target receives all addresses and data on the I2C bus. Unless the address is matched, it never drives the SDA pin. Configure the LPI2C target to match only on 7-bit address mode when this feature is enabled. Software can support 10-bit address mode. This option is intended for debugging the contents of an I2C transfer between another controller and target. Likewise, SCFGR1[SDCFG] and SCFGR1[RSCFG] configure the Stop or repeated Start flags to assert on all Stop or repeated Start conditions, even when there is no address match.

62.3.2.2 Transmit and receive data

Target Transmit Data (STDR) and Target Receive Data (SRDR) are double-buffered and only update during a target-transmit and target-receive transfer, respectively.

You can configure the target address that was received to be read from SRDR (for example, when using DMA to transfer data) or from Target Address Status (SASR).

You can configure STDR to request data only after a target-transmit transfer is detected. You can also configure it to request new data whenever STDR is empty.

Write to STDR only when SSR[TDF] is set.

Read SRDR only when SSR[RDF] is set, or when SSR[AVF] is set and SCFGR1[RXCFG] = 1.

Read SASR only when SSR[AVF] is set.

62.3.2.3 Read request

The LPI2C target generates a read request when the I2C bus is idle and you write 1 to SCFGR0[RDREQ]. This occurrence causes the LPI2C target to pull the SDA pin low until either the first SCL falling edge or SCFGR0[RDREQ] becomes 0. Following the next Stop condition or a software timeout, you can proceed as follows:

- If the LPI2C target is accessed at the correct address, the read request is acknowledged, and you must write 0 to SCFGR0[RDREQ].
- If SCFGR0[RDACK] is 1, the read request is acknowledged by a Start followed by one SCL pulse followed by a STOP condition. You must write 0 to SCFGR0[RDREQ].
- If neither of the first two cases occurred, the read request is not acknowledged. You must write 0 and then 1 to SCFGR0[RDREQ] after an appropriate delay, provided the I2C bus is idle.
- If a software timeout occurs, the read request is not acknowledged, and you should write 0 to SCFGR0[RDREQ]. Another request can be generated after an appropriate delay.

Writing to SCFGR0[RDREQ] when the I2C bus is busy results in a logic 0 being written. Write 1 to SCFGR0[RDREQ], then confirm that the register is written to correctly. If the register does not update correctly, the I2C bus is no longer idle and the read request must be attempted later.

62.3.2.4 Clock stretching

The LPI2C target supports many configurable options for clock stretching. You can configure these conditions to perform clock stretching:

- SSR[AVF] is set during the ninth clock pulse of the address byte.
- SSR[TDF] is set during the ninth clock pulse of a target-transmit transfer.
- SSR[RDF] is set during the ninth clock pulse of a target-receive transfer.
- SSR[TAF] is set during the eighth clock pulse of an address byte or a target-receive transfer. In HS mode, this option is disabled.
- Clock stretching can be extended for a number of cycles equal to the value of SCFGR2[CLKHOLD] cycles. This stretching allows additional setup time to sample the SDA pin externally. In HS mode, this option is disabled.

When clock stretching is enabled, clock stretching extends for one peripheral bus clock cycle after SDA updates, unless extended by the SCFGR2[CLKHOLD] configuration.

62.3.2.5 Timing parameters

The LPI2C target can configure the following timing parameters:

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

These parameters are disabled when SCR[FILTEN] is 0, when SCR[FILTDZ] is 1 in Doze mode, and when LPI2C target detects HS mode. When disabled, the LPI2C target is clocked directly from the I2C bus. In this case, the target may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

The LPI2C target places the following restrictions on the timing parameters:

- You must configure SCFGR2[FILTSDA] to be greater than or equal to SCFGR2[FILTSCL] (unless compensating for board level skew between SDA and SCL).
- You must configure SCFGR2[DATAVD] to be less than the minimum SCL low period.

62.3.2.6 Error conditions

The LPI2C target can flag the following error conditions:

- SSR[BEF] is set when the LPI2C target is driving SDA but it samples a different value than what is expected.
- SSR[FEF] is set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on a receive data overrun.
- SSR[FEF] is also set due to an address overrun, but only when SCFGR1[RXCFG] is 1. To eliminate the possibility of overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on an address overrun regardless of the value of SCFGR1[RXCFG].

The LPI2C target does not implement a timeout due to SCL or SDA being stuck low. If this detection is required, use the LPI2C controller logic so you can reset the LPI2C target when this condition is detected.

62.3.3 Low-power modes

LPI2C remains functional during low-power modes, if MCR[DOZEN] = 0 and LPI2C uses an external or internal clock source that remains enabled. LPI2C can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPI2C to be disabled in low-power modes when MCR[DOZEN] = 1. In this case, LPI2C waits for the current transfer to complete any pending operation.

NOTE

See the chip-specific information for low-power modes available on your chip.

62.3.4 Debug mode

Table 1016. Debug mode

Mode	LPI2C operation
Debug	If MCR[DBGEN] = 1, can continue operating in Debug mode.

62.3.5 Peripheral triggers

The connection of the LPI2C peripheral triggers to other peripherals depends upon the specific device being used.

Table 1017. LPI2C triggers

Trigger	Description
Controller output trigger	Generates an output trigger that can be connected to other peripherals on the device. The controller output trigger asserts on either a repeated Start or a Stop condition. The trigger remains asserted for one cycle of the LPI2C functional clock divided by MCFGR1[PRESCALE].
Target output trigger	Generates an output trigger that can be connected to other peripherals on the device. The target output trigger asserts on either a repeated Start or a Stop condition that occurs after a target address match. The target output trigger remains asserted until the next target SCL pin negation.
Input trigger	To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized. To be detected, the input trigger must assert for at least two cycles of the LPI2C functional clock divided by the value of MCFGR1[PRESCALE]. When LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.

62.3.6 Clocking

Table 1018. LPI2C clocks

Clock	Description
LPI2C functional clock	The LPI2C functional clock is asynchronous to the bus clock. It can remain enabled in low-power modes to support I2C bus transfers by the LPI2C controller. The functional clock is also used by the LPI2C target to support digital filter and data hold time configurations. The LPI2C controller divides the functional clock by a prescaler (MCFGR1[PRESCALE]) and the resulting frequency must be at least eight times faster than the I2C bus bandwidth.
External clock	The LPI2C target logic is clocked directly from the external pins. These pins are SCL and SDA, or SCLS and SDAS if the controller and target are implemented on separate pins). This clocking allows the LPI2C target to remain operational, even when the LPI2C functional clock is disabled. **NOTE** If the LPI2C functional clock is disabled, the LPI2C target digital filter must be disabled. This condition can affect compliance with some timing parameters of the I2C specification, such as data hold time.

Table continues on the next page...

Table 1018. LPI2C clocks (continued)

Clock	Description
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C controller and target registers.

For chip-specific clocking information, see the Clocking chapter.

62.3.7 Reset

Table 1019. LPI2C resets

Reset	Description
Chip reset	The logic and registers for the LPI2C controller and target are reset to their default states after a chip reset.
Software reset	The LPI2C controller implements a software reset field in its control register. MCR[RST] resets all controller logic and registers to their default states, except for Controller Control (MCR) itself. The LPI2C target implements a software reset field in its control register. SCR[RST] resets all target logic and registers to their default states, except for Target Control (SCR) itself.
FIFO reset	The LPI2C controller implements write-only control fields that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. The LPI2C target implements write-only control fields that reset the transmit data register (SCR[RTF]) and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

62.3.8 Interrupts and DMA requests

Depending on the configuration, interrupts and DMA requests can be combined:

- LPI2C controller and target interrupts
- LPI2C controller and target transmit DMA requests
- LPI2C controller and target receive DMA requests

62.3.8.1 Controller mode

Table 1020 lists the Controller mode sources that can generate LPI2C controller interrupts and LPI2C controller transmit and receive DMA requests.

Table 1020. Controller interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (MSR[TDF])	Data can be written to transmit FIFO, as configured by MFCR[TXWATER].	Y	TX	Y
Receive Data Flag (MSR[RDF])	Data can be read from the receive FIFO, as configured by MFCR[RXWATER].	Y	RX	Y

Table continues on the next page...

Table 1020. Controller interrupts and DMA requests (continued)

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
End Packet Flag (MSR[EPF])	Controller has transmitted a repeated Start or Stop condition.	Y	N	Y
Stop Detect Flag (MSR[SDF])	Controller has transmitted a Stop condition (and the LPI2C controller is idle, if MCFGR1[STOPCFG] = 1) .	Y	N	Y
NACK Detect Flag (MSR[NDF])	During an address byte, the controller expects an ACK but detects a NACK. During an address byte, the controller expects a NACK but detects an ACK. During a controller-transmitter data byte, the controller detects a NACK.	Y	N	Y
Arbitration Lost Flag (MSR[ALF])	The controller lost arbitration due to a Start or Stop condition detected at the wrong time, or the controller was transmitting data but received data different from the data that was transmitted.	Y	N	Y
FIFO Error Flag (MSR[FEF])	The controller expects a Start condition in the command FIFO, but the next entry in the command FIFO is not a Start condition.	Y	N	Y
Pin Low Timeout Flag (MSR[PLTF])	Pin low timeout is enabled and SCL (or SDA, if configured) is low for longer than the configured timeout.	Y	N	Y
Data Match Flag (MSR[DMF])	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry.	Y	N	Y
Start Detect Flag (MSR[STF])	A Start condition is detected on the I2C bus (and the LPI2C controller is idle, if MCFGR1[STARTCFG] = 1).	Y	N	Y
Controller Busy Flag (MSR[MBF])	LPI2C controller is busy transmitting or receiving data.	N	N	N
Bus Busy Flag (MSR[BBF])	LPI2C controller is enabled and activity is detected on the I2C bus, but no Stop condition is detected and no bus idle timeout (if enabled) occurred.	N	N	N

62.3.8.2 Target mode

Table 1021 lists the target mode sources that can generate LPI2C target interrupts and LPI2C target transmit and receive DMA requests.

Table 1021. Target interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (SSR[TDF])	Data can be written to Target Transmit Data (STDR).	Y	TX	Y
Receive Data Flag (SSR[RDF])	Data can be read from Target Receive Data (SRDR).	Y	RX	Y
Address Valid Flag (SSR[AVF])	Address can be read from Target Address Status (SASR).	Y	RX	Y
Transmit ACK Flag (SSR[TAF])	ACK or NACK can be written to Target Transmit ACK (STAR).	Y	N	Y
Repeated Start Flag (SSR[RSF])	Target has detected an address match followed by a repeated Start condition.	Y	RX	Y
Stop Detect Flag (SSR[SDF])	Target has detected an address match followed by a Stop condition.	Y	RX	Y
Bit Error Flag (SSR[BEF])	Target was transmitting data, but received data is different from what was transmitted.	Y	N	Y
FIFO Error Flag (SSR[FEF])	This flag is set by: • Transmit data underrun • Receive data overrun • Address status overrun when SCFGR1[RXCFG] = 1 This flag can only be set when clock stretching is disabled.	Y	N	Y
Address Match 0 Flag (SSR[AM0F])	Target detected an address match SAMR[ADDR0].	Y	N	N
Address Match 1 Flag (SSR[AM1F])	Target detected an address match with SAMR[ADDR1] or using an address range.	Y	N	N
General Call Flag (SSR[GCF])	Target detected an address match with the general call address.	Y	N	N
SMBus Alert Response Flag (SSR[SARF])	Target detected an address match with the SMBus alert address.	Y	N	N
Target Busy Flag (SSR[SBF])	LPI2C target is busy receiving an address byte or is transmitting or receiving data.	N	N	N
Bus Busy Flag (SSR[BBF])	LPI2C target is enabled and a Start condition is detected on I2C bus, but no Stop condition detected.	N	N	N

62.3.8.3 End-of-packet DMA transfer

End-of-packet functionality serves serial interfaces where the transfer size may not be known in advance and the data is pushed by an external device. Examples include UART receive, I2C Target mode, and SPI Target mode. End-of-packet processing

is intended to ensure that data does not become stranded in either the receive FIFO or DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and DMA controller.

The condition that signals the end of packet differs for each serial interface but is processed by the serial peripheral and DMA in the same way. For example:

- UART end of packet is signaled by an idle line condition.
- I2C end of packet is signaled by Stop or repeated Start condition.
- SPI end of packet is signaled by PCS negation.

When the serial peripheral is configured to signal an end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO regardless of the watermark configuration. For larger watermark configurations, this behavior ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO starts a new packet, data is not pulled from the receive FIFO. Also, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO does not start a new packet, the DMA transfers data as normal.

Because the DMA may transfer multiple words per request, the end-of-packet condition persists until the DMA minor loop finishes and no additional data is pulled from the FIFO. The status flag that triggered the end-of-packet condition is cleared when the minor loop completes after the end of packet is signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of packet into system memory. It also saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking, and scatter-gather. The final destination address can be saved to system memory or is available in the destination address register.

Because the DMA terminates the major loop, the receive FIFO is not serviced until the DMA is reconfigured. You can perform this reconfiguration through software or hardware (for example, channel linking or scatter-gather). Minimize this delay to avoid receiver FIFO overrun. Automatic DMA end-of-packet processing is not recommended when there are only a few words transferred between end-of-packet conditions. In this case, the DMA spends more time processing the end of packet than transferring the data. For example, to avoid an excessive number of idle conditions, increase the UART idle line length as needed.

62.4 External signals

Table 1022. External signals

Signal	Name	Two-wire scheme	Four-wire scheme	Direction
SCL	LPI2C clock line	SCL	In Four-Wire mode, this pin is the SCL input pin.	Input or output
SDA	LPI2C data line	SDA	In Four-Wire mode, this pin is the SDA input pin.	Input or output
SCLS	Secondary I2C clock line	Not used	In Four-Wire mode, this pin is the SCLS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SCL pin.	Input or output
SDAS	Secondary I2C data line	Not used	In Four-Wire mode, this pin is the SDAS output pin. If LPI2C controller/target are	Input

Table continues on the next page...

Table 1022. External signals (continued)

Signal	Name	Two-wire scheme	Four-wire scheme	Direction
			configured to use separate pins, then this pin is the LPI2C target SDA pin.	or output
HREQ	Host request	When configured for controller (input), if host request is asserted and the I2C bus is idle, it initiates a transfer. When configured for target (output), it asserts while valid data is present in Target Transmit Data (STDR). HREQ is an additional pin separate from the two-wire or four-wire scheme.		Input or output

Figure 465 shows the two-signal connection.

Figure 466 shows a possible four-signal connection.

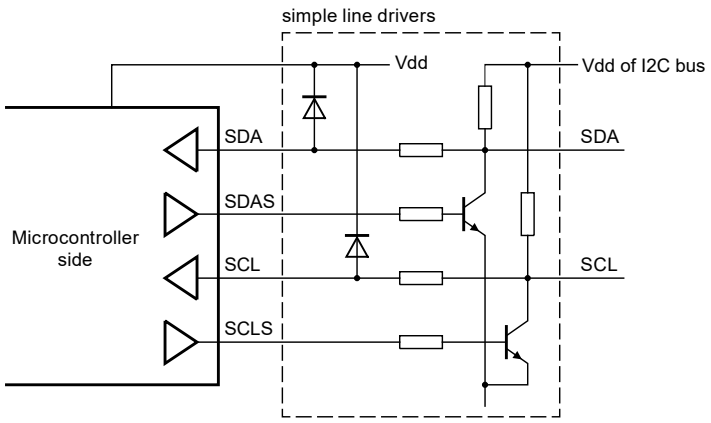

Figure 466. I²C four-wire serial bus

62.5 Initialization

To initialize the LPI2C controller:

1. Configure Controller Configuration 0 (MCFGR0)–Controller Configuration 3 (MCFGR3) as required by the application.

2. Configure Controller Clock Configuration 0 (MCCR0) and Controller Clock Configuration 1 (MCCR1) to satisfy the timing requirements of the I2C mode supported by the application.
3. Enable controller interrupts and DMA requests as required by the application.
4. Enable the LPI2C controller by writing 1 to MCR[MEN].

To initialize the LPI2C target:

1. Configure Target Address Match (SAMR) with the I2C address of the target location on the I2C bus.
2. Configure Target Configuration 0 (SCFGR0) and Target Configuration 1 (SCFGR1) as required by the application.
3. Configure Target Configuration 2 (SCFGR2) to satisfy the timing requirements of the I2C mode supported by the application.
4. Enable target interrupts and DMA requests as required by the application.
5. Enable the LPI2C target by writing 1 to SCR[SEN].

62.6 Application information

Configure the I2C timing parameters to meet the requirements of the I2C specification. This configuration depends on the supported mode and LPI2C functional clock frequency. When switching between two modes using different clock configuration registers (for example, Fast mode and HS mode), MCFGR1[PRESCALE] must remain constant between the modes.

Table 1023. Example timing configurations

I2C mode	Clock frequency	Baud rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Standard	8 MHz	100 kbit/s	0h	0h/0h	24h	28h	24h	02h
Standard	48 MHz	100 kbit/s	2h	1h/1h	37h	3Fh	37h	03h
Standard	60 MHz	100 kbit/s	2h	1h/1h	45h	50h	44h	04h
Fast	8 MHz	400 kbit/s	0h	0h/0h	04h	0Bh	05h	02h
Fast+	8 MHz	1 Mbit/s	0h	0h/0h	02h	03h	01h	01h
Fast	48 MHz	400 kbit/s	0h	1h/1h	1Dh	3Eh	35h	0Fh
Fast	48 MHz	400 kbit/s	2h	1h/1h	07h	11h	0Bh	03h
Fast+	48 MHz	1 Mbit/s	2h	1h/1h	03h	06h	04h	04h
HS	48 MHz	3.2 Mbit/s	0h	0h/0h	07h	08h	03h	01h
Fast	60 MHz	400 kbit/s	1h	2h/2h	11h	28h	1Fh	08h
Fast+	60 MHz	1 Mbit/s	1h	2h/2h	07h	0Fh	0Bh	01h
HS	60 MHz	3.33 Mbit/s	1h	0h/0h	04h	04h	02h	01h

62.7 Memory map and registers

62.7.1 LPI2C register descriptions

Writing to a read-only register or reading from a write-only register can cause bus errors. This module does not check whether programmed values in the registers are correct; you must ensure that valid programmed values are written to the registers.

62.7.1.1 LPI2C memory map

LPI2C1 base address: 4434_0000h

62.7.1.2 Version ID (VERID)

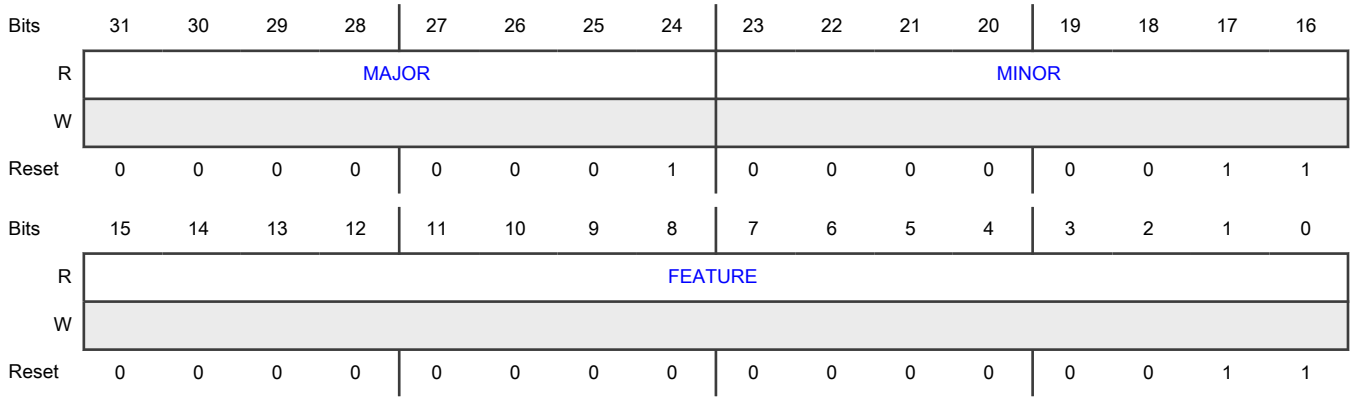
Offset

Register	Offset
VERID	0h

Function

Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module design specification.
23-16	Minor Version Number

Table continues on the next page...

Table continued from the previous page...

Field	Function
MINOR	Returns the minor version number for the module design specification.
15-0 FEATURE	Feature Specification Number Returns the feature set number. 0000_0000_0000_0010b - Controller only, with standard feature set 0000_0000_0000_0011b - Controller and target, with standard feature set

62.7.1.3 Parameter (PARAM)

Offset

Register	Offset
PARAM	4h

Function

Contains parameter values implemented in the module.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 —	Reserved
15-12 —	Reserved
11-8	Controller Receive FIFO Size

Table continues on the next page...

Table continued from the previous page...

Field	Function
MRXFIFO	Configures the number of words in the controller receive FIFO to $2^{MRXFIFO}$.
7-4 —	Reserved
3-0 MTXFIFO	Controller Transmit FIFO Size Configures the number of words in the controller transmit FIFO to $2^{MTXFIFO}$.

62.7.1.4 Controller Control (MCR)

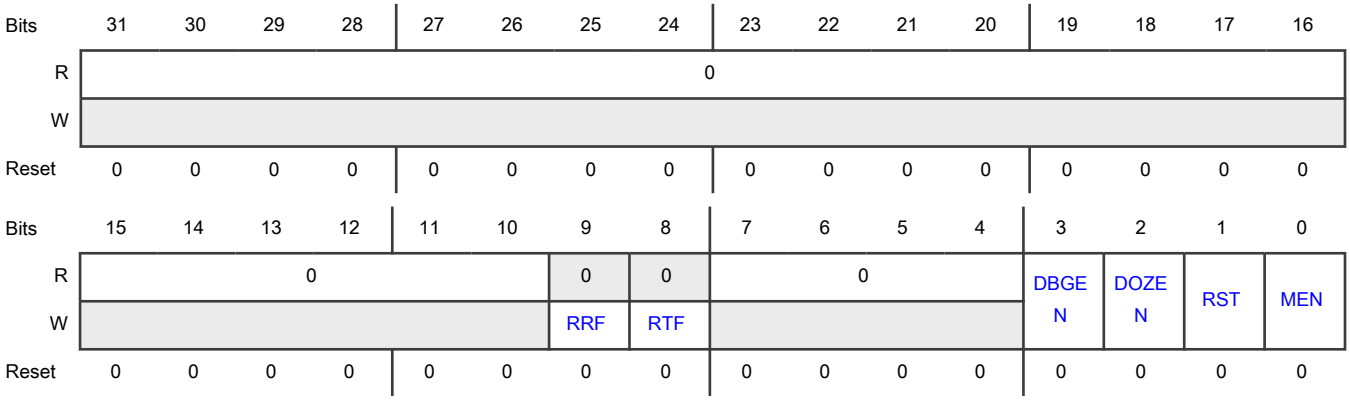
Offset

Register	Offset
MCR	10h

Function

Contains resets, debug enable, and other controller control settings.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Resets the receive FIFO.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Reset receive FIFO
8 RTF	Reset Transmit FIFO Resets the transmit FIFO. 0b - No effect 1b - Reset transmit FIFO
7-4 —	Reserved
3 DBGEN	Debug Enable Enables the controller in Debug mode. 0b - Disable 1b - Enable
2 DOZEN	Doze Mode Enable Enables the controller in Doze mode. 0b - Enable 1b - Disable
1 RST	Software Reset Resets all internal controller logic and registers except Controller Control (MCR). This field remains 1 (enabled) until you write 0 to it. The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0b - No effect 1b - Reset
0 MEN	Controller Enable Enables the controller logic. 0b - Disable 1b - Enable

62.7.1.5 Controller Status (MSR)

Offset

Register	Offset
MSR	14h

Function

Contains status flags for transmit and receive data, for start and stop conditions, and for bus and controller busy or idle status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Specifies whether the I2C bus is busy. 0b - Idle 1b - Busy
24 MBF	Controller Busy Flag Specifies whether the I2C controller is busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 STF	Start Flag Specifies whether a Start condition is detected on the bus when the bus is idle. When MCFGR1[STARTCFG] is 0, this field becomes 1 only if the LPI2C controller is also idle. When MCFGR1[STARTCFG] is 1, STF becomes 1 for any Start condition when the I2C bus is idle. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Start condition not detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Start condition detected When writing 0b - No effect 1b - Clear the flag
14 DMF	Data Match Flag Indicates whether the received data matches MDMR[MATCH0] or MDMR[MATCH1] (as configured by MCFGR1[MATCFG]). Received data discarded due to MTDR[CMD] does not cause this flag to set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Matching data not received 1b - Matching data received When writing 0b - No effect 1b - Clear the flag
13 PLTF	Pin Low Timeout Flag Indicates whether pin low timeout has occurred. Sets when the SCL or SDA input is low for more than the number of PINLOW cycles defined by MCFGR3[PINLOW], even when the LPI2C controller is idle. You must resolve the pin low condition via software. PLTF cannot be cleared as long as the pin low timeout continues. Before LPI2C can initiate a Start condition, you must clear this flag. See MCFGR1[TIMECFG] for the SCL and/or SDA timeout settings. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Pin low timeout did not occur 1b - Pin low timeout occurred When writing 0b - No effect 1b - Clear the flag
12 FEF	FIFO Error Flag Detects the LPI2C controller's attempt to send or receive data without first generating a (repeated) Start condition. This error can occur when the transmit FIFO underflows when MCFGR1[AUTOSTOP] = 1. When this flag is set, the LPI2C controller sends a Stop condition (if busy). The controller does not initiate a new Start condition until the flag is cleared.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
11 ALF	Arbitration Lost Flag Indicates whether arbitration is lost. Either of these conditions sets this flag: • The LPI2C controller transmits a logic 1 and detects a logic 0 on the I2C bus. • The LPI2C controller detects a Start or Stop condition when the LPI2C controller is transmitting data. When ALF is set, the LPI2C controller releases the I2C bus (goes idle), and the LPI2C controller does not initiate a new Start condition until the ALF is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Controller did not lose arbitration 1b - Controller lost arbitration When writing 0b - No effect 1b - Clear the flag
10 NDF	NACK Detect Flag Indicates whether an unexpected NACK has been detected. This flag is set when the LPI2C controller detects a NACK it was not expecting when transmitting an address or data. When set, the controller does not initiate a new Start condition until this flag is cleared. If a NACK is expected for a given address (as configured by the command word), this flag is set if a NACK is not generated. When this flag is set, the LPI2C controller automatically transmits a Stop condition if MCFGR1[AUTOSTOP] = 1, or if the transmit FIFO is not empty. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No unexpected NACK detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Unexpected NACK detected When writing 0b - No effect 1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C controller has generated a Stop condition. When MCFGR1[STOPCFG] = 0, this flag is set for any Stop condition. When MCFGR1[STOPCFG] = 1, this flag is set only when the LPI2C controller is also idle (transmit FIFO is empty). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop condition generated 1b - Stop condition generated When writing 0b - No effect 1b - Clear the flag
8 EPF	End Packet Flag Indicates whether the LPI2C controller has generated a repeated Start condition or a Stop condition. When the controller first generates a Start condition, this flag is not set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop or repeated Start generated 1b - Stop or repeated Start generated When writing 0b - No effect 1b - Clear the flag
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates whether the receive data is ready. This flag is set when the number of words in the receive FIFO is greater than MFCR[RXWATER]. 0b - Receive data not ready

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Receive data ready
0 TDF	Transmit Data Flag Indicates whether transmit data is requested. This flag is set when the number of words in the transmit FIFO is equal or less than MFCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data requested

62.7.1.6 Controller Interrupt Enable (MIER)

Offset

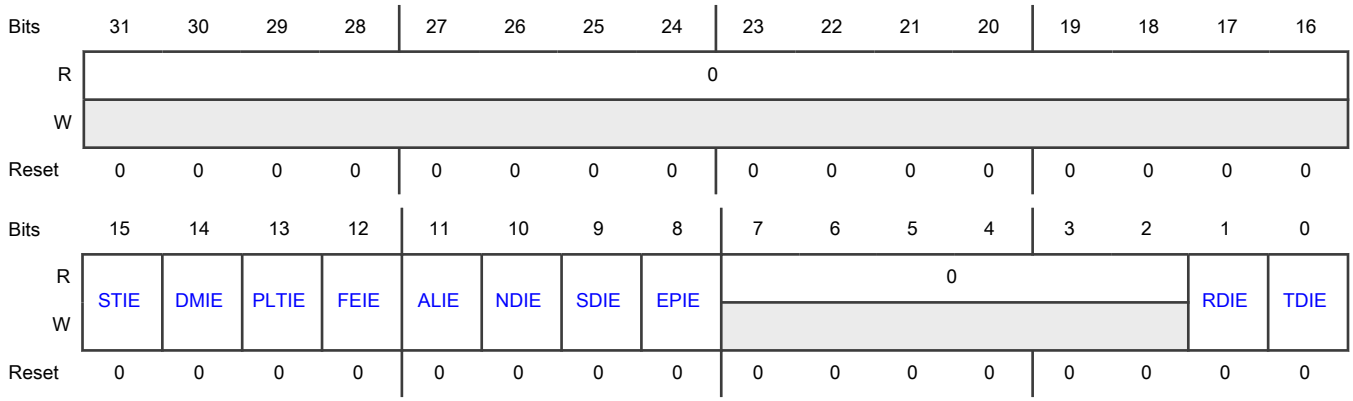
Register	Offset
MIER	18h

Function

Contains enables for:

- Transmit and receive data interrupts
- Start, Stop, and NACK detection interrupts
- DMA interrupts

Diagram



Fields

Field	Function
31-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 STIE	Start Interrupt Enable Enables interrupt for Start condition. 0b - Disable 1b - Enable
14 DMIE	Data Match Interrupt Enable Enables interrupt for data match. 0b - Disable 1b - Enable
13 PLTIE	Pin Low Timeout Interrupt Enable Enables interrupt for pin-low timeout. 0b - Disable 1b - Enable
12 FEIE	FIFO Error Interrupt Enable Enables interrupt for FIFO error. 0b - Disable 1b - Enable
11 ALIE	Arbitration Lost Interrupt Enable Enables interrupt for arbitration lost. 0b - Disable 1b - Enable
10 NDIE	NACK Detect Interrupt Enable Enables interrupt for NACK detection. 0b - Disable 1b - Enable
9 SDIE	Stop Detect Interrupt Enable Enables interrupt for Stop detection. 0b - Disable 1b - Enable
8 EPIE	End Packet Interrupt Enable Enables interrupt for end packet. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable Enables interrupt for receive data. 0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable Enables interrupt for transmit data. 0b - Disable 1b - Enable

62.7.1.7 Controller DMA Enable (MDER)

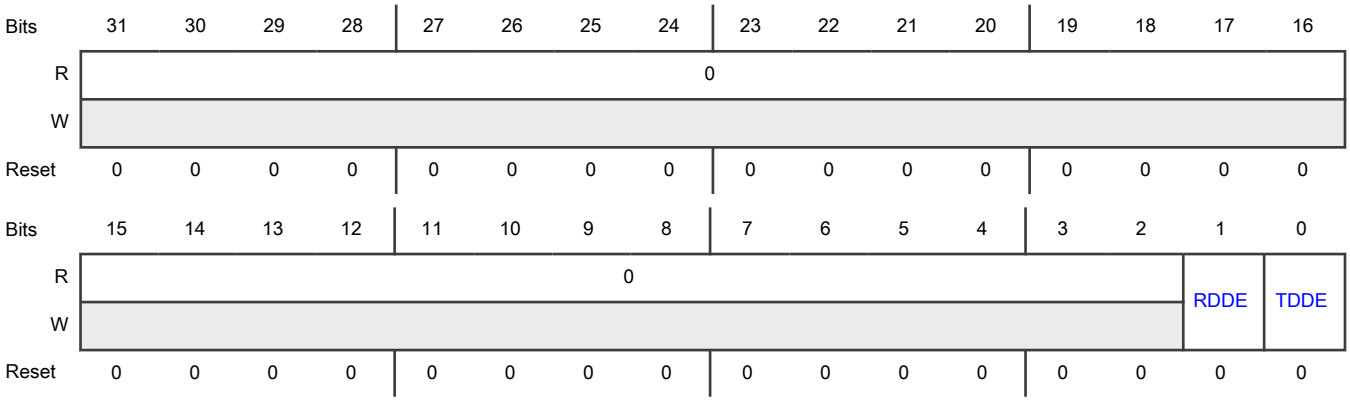
Offset

Register	Offset
MDER	1Ch

Function

Contains DMA transmit, request, and receive enables.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDDE	Receive Data DMA Enable Enables DMA receive data. 0b - Disable 1b - Enable
0 TDDE	Transmit Data DMA Enable Enables DMA transmit data. 0b - Disable 1b - Enable

62.7.1.8 Controller Configuration 0 (MCFGR0)

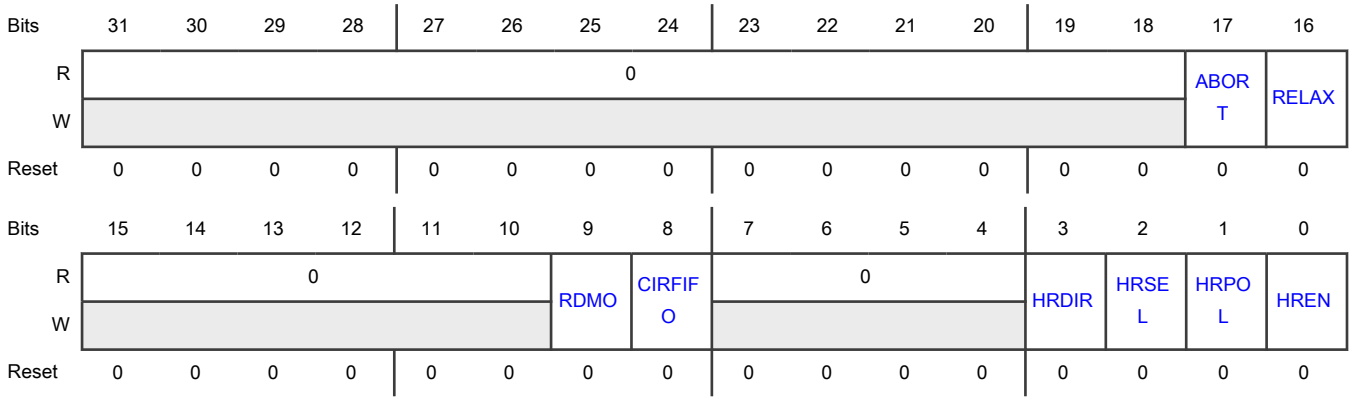
Offset

Register	Offset
MCFGR0	20h

Function

Contains host settings and other receive and transfer settings.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 ABORT	Abort Transfer Determines whether the LPI2C controller completes the existing byte and then sends a Stop condition. A new transfer does not start while this field is 1. 0b - Normal transfer 1b - Abort existing transfer and do not start a new one
16 RELAX	Relaxed Mode Specifies the type of transfer. If this field is 1, the LPI2C controller relaxes several transfer restrictions. Transfers start when the bus is busy and FIFO commands are not checked for errors. You can use this mode to attempt recovery of a stuck I2C target by toggling the SCL pin. 0b - Normal transfer 1b - Relaxed transfer
15-10 —	Reserved
9 RDMO	Receive Data Match Only Determines whether all received data that does not set MSR[DMF] is discarded. After MSR[DMF] is set, the RDMO configuration is ignored. When disabling RDMO, write 0 to this field before writing 0 to MSR[DMF] to ensure that no receive data is lost. 0b - Received data is stored in the receive FIFO 1b - Received data is discarded unless MSR[DMF] is set
8 CIRFIFO	Circular FIFO Enable Enables the transmit FIFO read pointer to be saved to a temporary register. The transmit FIFO empties as normal. After the LPI2C controller is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This setting causes the contents of the transmit FIFO to be cycled through repeatedly. If MCFGR1[AUTOSTOP] is 1, then a Stop condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0b - Disable 1b - Enable
7-4 —	Reserved
3 HRDIR	Host Request Direction Configures the direction of the HREQ pin. When this field is 1, the LPI2C target drives the HREQ output pin and the pin becomes 1 when there is data in the target transmit data register. For proper operation when this field is 1, write 1 to SCFGR1[TXCFG].

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
NOTE
This field is not supported in every instance. The following table includes only supported registers.
<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>LPI2C1</td><td>MCFGR0</td><td>—</td></tr>

</td></tr>
</table>

Table continued from the previous page...

Field	Function
	<table><tr><th>Instance</th><th>Field value and description</th></tr><tr><td>LPI2C6</td><td>0b - Reserved 1b - Host request input is input trigger</td></tr></table>
1 HRPOL	Host Request Polarity Configures the polarity of the host request input. When host request is enabled, this field must not change. HRPOL sets the polarity for both the HREQ pin and the input trigger. • When HRPOL=0, the polarity is configured for active low, so host request is asserted if the HREQ pin or input trigger are logic 0. • When HRPOL=1, the polarity is configured for active high, so host request is asserted if the HREQ pin or input trigger are logic 1. 0b - Active low 1b - Active high
0 HREN	Host Request Enable Enables host request. When enabled, the LPI2C controller only initiates a Start condition if the host request input is asserted and the bus is idle. A repeated Start condition is not affected by the host request. 0b - Disable 1b - Enable

62.7.1.9 Controller Configuration 1 (MCFGR1)

Offset

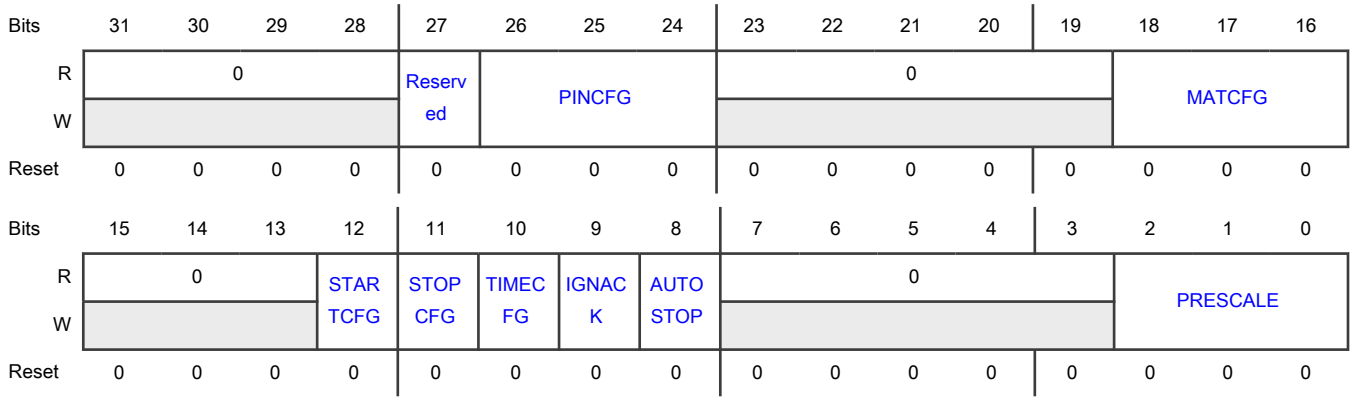
Register	Offset
MCFGR1	24h

Function

Contains controls for pin configuration, clock prescaler, and various other control settings.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 —	Reserved
26-24 PINCFG	Pin Configuration Configures the pin mode for LPI2C. 000b - Two-pin open drain mode. SCL/SDA pins: Bidirectional open drain for controller and target. SCLS/SDAS pins: Not used. 001b - Two-pin output only mode (Ultra-Fast mode). SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller and target. SCLS/SDAS pins: Not used. 010b - Two-pin push-pull mode. SCL/SDA pins: Bidirectional push-pull for controller and target. SCLS/SDAS pins: Not used. 011b - Four-pin push-pull mode. SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Output-only push-pull for controller and target. 100b - Two-pin open-drain mode with separate LPI2C target. SCL/SDA pins: Bidirectional open drain for controller. SCLS/SDAS pins: Bidirectional open drain for target. 101b - Two-pin output only mode (Ultra-Fast mode) with separate LPI2C target. SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller. SCLS/SDAS pins: Output-only open drain for target. 110b - Two-pin push-pull mode with separate LPI2C target. SCL/SDA pins: Bidirectional push-pull for controller. SCLS/SDAS pins: Bidirectional push-pull for target. 111b - Four-pin push-pull mode (inverted outputs). SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Inverted output-only push-pull for controller and target.
23-19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 MATCFG	Match Configuration Configures the condition that sets MSR[DMF]. See Controller Data Match (MDMR). 000b - Match is disabled 001b - Reserved 010b - Match is enabled: first data word equals MDMR[MATCH0] OR MDMR[MATCH1] 011b - Match is enabled: any data word equals MDMR[MATCH0] OR MDMR[MATCH1] 100b - Match is enabled: (first data word equals MDMR[MATCH0]) AND (second data word equals MDMR[MATCH1) 101b - Match is enabled: (any data word equals MDMR[MATCH0]) AND (next data word equals MDMR[MATCH1) 110b - Match is enabled: (first data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1]) 111b - Match is enabled: (any data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1])
15-13 —	Reserved
12 STARTCFG	Start Configuration Configures the conditions that set MSR[STF] when a Start condition occurs. When this field is 0, MSR[STF] is set on a Start condition when both the I2C bus and LPI2C are idle. In other words, any nonrepeated Start condition is initiated by any controller on the bus except the LPI2C controller. When this field is 1, MSR[STF] is set on a Start condition when the I2C bus is idle. In other words, any nonrepeated Start condition is initiated by any controller on the bus including the LPI2C controller. 0b - Sets when both I2C bus and LPI2C controller are idle 1b - Sets when I2C bus is idle
11 STOPCFG	Stop Configuration Configures the conditions that set MSR[SDF]. When this field is 0, any Stop condition generated by the LPI2C controller sets SDF. When this field is 1, the last Stop condition before the LPI2C controller is idle sets SDF. In this case, the transmit FIFO is empty at the time of the Stop condition. 0b - Any Stop condition 1b - Last Stop condition
10 TIMECFG	Timeout Configuration Configures which signals must be low for longer than the configured timeout to set MSR[PLTF]. When this field is 0, MSR[PLTF] is set when SCL is low for longer than the configured timeout.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - SCL 1b - SCL or SDA
9 IGNACK	Ignore NACK Determines whether the LPI2C controller ignores a received NACK and treats it as an ACK. In this case, MSR[NDF] is never set. This field must be 1 in Ultra-Fast mode. 0b - No effect 1b - Treat a received NACK as an ACK
8 AUTOSTOP	Automatic Stop Generation Determines whether a Stop condition is generated when the LPI2C controller is busy and the transmit FIFO is empty. A Stop condition can also be generated using a transmit FIFO command. When this field is 1, a Stop condition is automatically generated when the transmit FIFO is empty and the LPI2C controller is busy. 0b - No effect 1b - Stop automatically generated
7-3 —	Reserved
2-0 PRESCALE	Prescaler Configures the clock prescaler used for all LPI2C controller logic except the digital glitch filters. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

62.7.1.10 Controller Configuration 2 (MCFGR2)

Offset

Register	Offset
MCFGR2	28h

Function

Contains the configuration for the bus idle timeout and glitch filters for SDA and SCL.

Write to this register only when the I2C controller is disabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0				BUSIDLE											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C controller digital glitch filters for the SDA input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C controller digital glitch filters for SCL input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. These cycles are based on the functional clock. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.
15-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-0 BUSIDLE	Bus Idle Timeout Configures the bus idle timeout period, in clock cycles. If both SCL and SDA are high for longer than the number of cycles defined by this field, the I2C bus is assumed to be idle and the controller can generate a Start condition. Writing 0 to this field disables the bus idle timeout.

62.7.1.11 Controller Configuration 3 (MCFGR3)

Offset

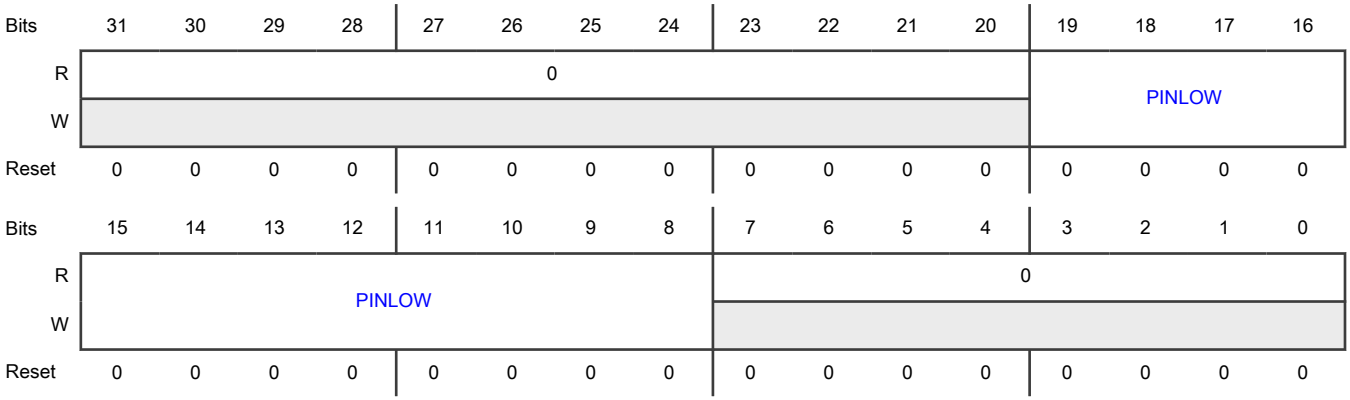
Register	Offset
MCFGR3	2Ch

Function

Configures the threshold value for the pin low timeout flag.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-8 PINLOW	Pin Low Timeout Configures the threshold value, in clock cycles, that sets MSR[PLTF].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If SCL or SDA (selected by MCFGR1[TIMECFG]) is low for longer than (PINLOW × 256) cycles, MSR[PLTF] is set. When this field is 0, the pin low timeout feature is disabled.
7-0 —	Reserved

62.7.1.12 Controller Data Match (MDMR)

Offset

Register	Offset
MDMR	40h

Function

Contains data match values.

Write to this register only when the I2C controller is disabled or idle.

Diagram

7-0 MATCH0	Match 0 Value Specifies match 0 value that is compared to the received data when receive data match is enabled.

62.7.1.13 Controller Clock Configuration 0 (MCCR0)

Offset

Register	Offset
MCCR0	48h

Function

Configures various clock controls.

You cannot make changes to this register when the I2C controller is enabled and is used for standard, fast, fast-mode plus, and ultra-fast transfers.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies the minimum number of cycles (minus one) used as the data hold time for SDA. This value must be less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Specifies the minimum number of cycles (minus one) used by the controller for these conditions: • Hold time for a Start • Setup and hold time for a repeated Start • Setup time for a Stop The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock high. The SCL high time is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.

62.7.1.14 Controller Clock Configuration 1 (MCCR1)

Offset

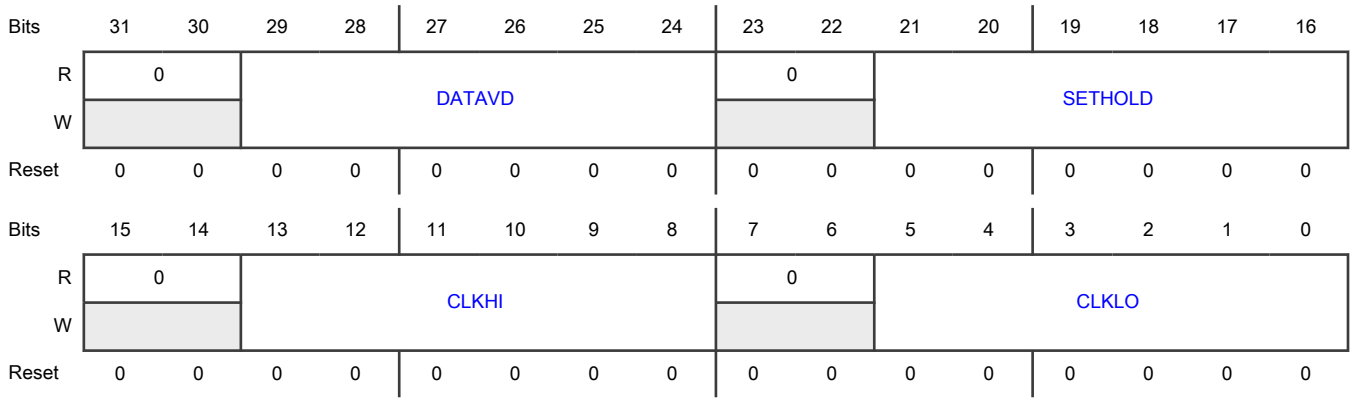
Register	Offset
MCCR1	50h

Function

Configures various clock controls.

You cannot makes changes to this register when the I2C controller is enabled and is used for HS mode transfers. The separate clock configuration for HS mode allows arbitration to take place in Fast mode (with timing configured by Controller Clock Configuration 0 (MCCR0)), before switching to HS mode (with timing configured by MCCR1).

Diagram



Fields

	any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.

62.7.1.15 Controller FIFO Control (MFCR)

Offset

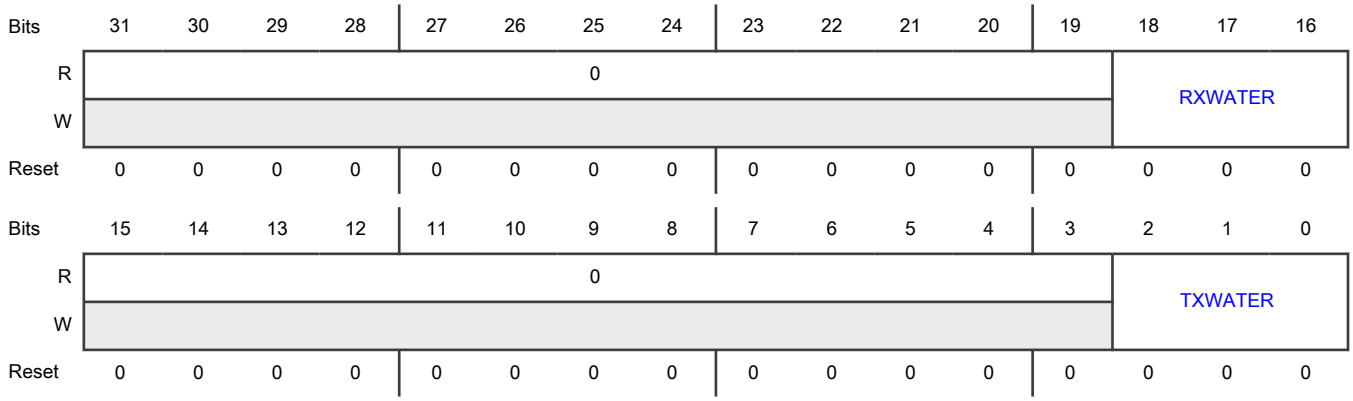
Register	Offset
MFCR	58h

Function

Controls the receive and transmit FIFO watermark values.

This register is used only in Stop mode, when this register is static (not changing).

Diagram



Fields

Field	Function
31-19	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
18-16 RXWATER	Receive FIFO Watermark Determines the watermark for setting SSR[RDF]. That flag is set when the number of words in the receive FIFO is greater than the value of this field. Writing a value equal to or greater than the FIFO size truncates the value.
15-3 —	Reserved
2-0 TXWATER	Transmit FIFO Watermark Determines the watermark for setting SSR[TDF]. That flag is set when the number of words in the transmit FIFO is equal or less than the value of this field. Writing a value equal to or greater than the FIFO size truncates the value.

62.7.1.16 Controller FIFO Status (MFSR)

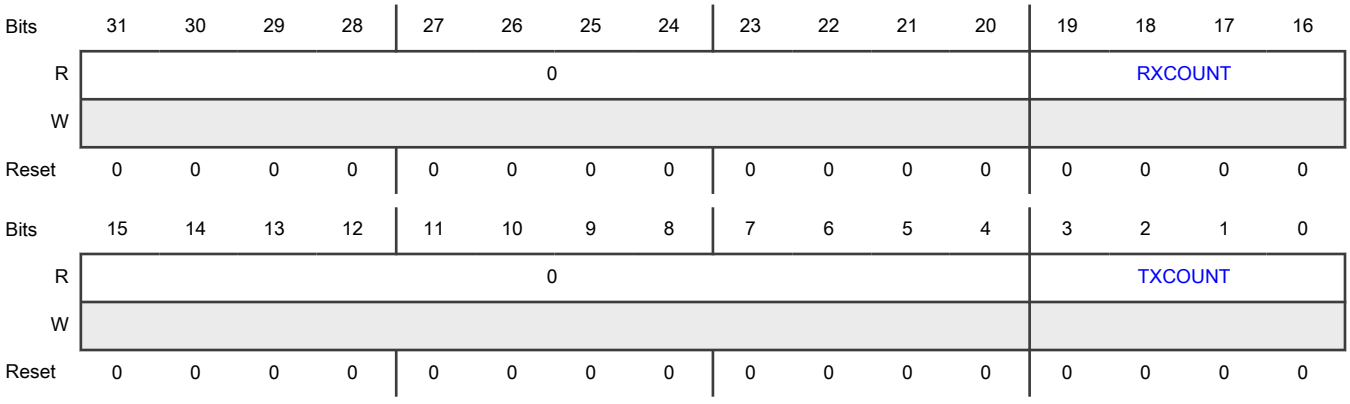
Offset

Register	Offset
MFSR	5Ch

Function

Specifies the number of words in the transmit and receive FIFOs.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 RXCOUNT	Receive FIFO Count Specifies the number of words in the receive FIFO.
15-4 —	Reserved
3-0 TXCOUNT	Transmit FIFO Count Specifies the number of words in the transmit FIFO.

62.7.1.17 Controller Transmit Data (MTDR)

Offset

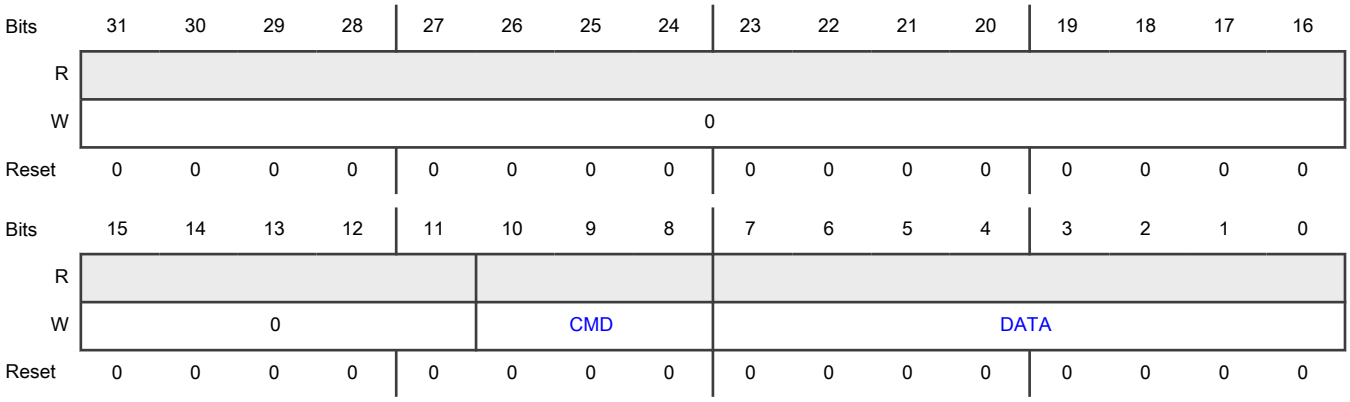
Register	Offset
MTDR	60h

Function

Configures transmit data:

- An 8-bit write to MTDR[CMD] is ignored and does not increment the FIFO write pointer.
- An 8-bit write to MTDR[DATA] zero-extends the value of MTDR[CMD] and increments the FIFO write pointer.
- A 16-bit or 32-bit write operation writes to both MTDR[CMD] and MTDR[DATA] and increments the FIFO write pointer.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-8 CMD	Command Data Selects command transmitted by controller. 000b - Transmit the value in DATA[7:0] 001b - Receive (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes and check each for a data match (if configured) before storing the received data in the receive FIFO. 010b - Generate Stop condition on I2C bus 011b - Receive and discard (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes but do not check for a data match or store those bytes in the receive FIFO. 100b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] 101b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] (this transfer expects a NACK to be returned) 110b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode 111b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode (this transfer expects a NACK to be returned)
7-0 DATA	Transmit Data Contains data used by the commands listed in MTDR[CMD]. Performing an 8-bit write to this field zero-extends the value of MTDR[CMD].

62.7.1.18 Controller Receive Data (MRDR)

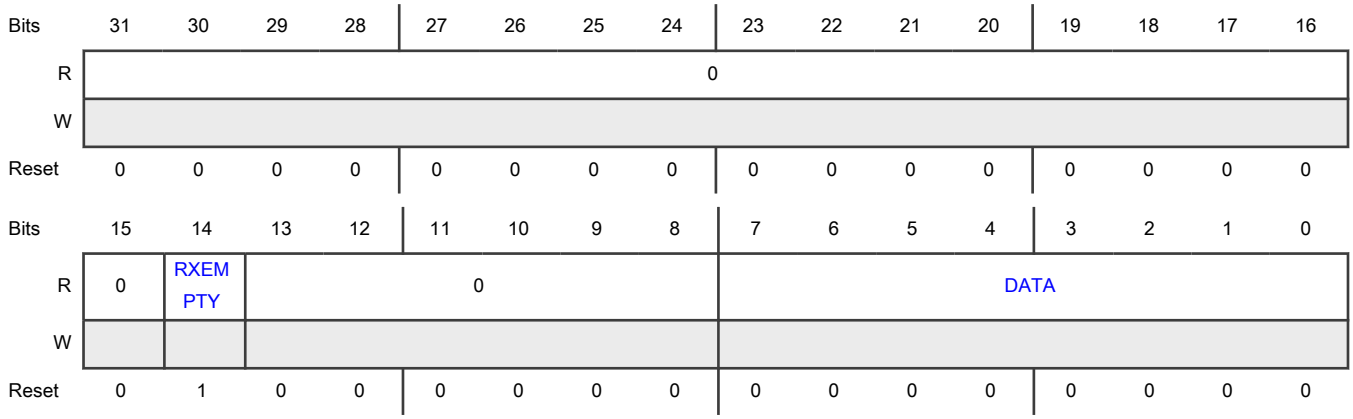
Offset

Register	Offset
MRDR	70h

Function

Contains the status of the receive FIFO and the data received by the I2C controller that has not been discarded.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 RXEMPTY	Receive Empty Indicates whether the controller receive data FIFO is empty. 0b - Not empty 1b - Empty
13-8 —	Reserved
7-0 DATA	Receive Data Contains data received by the I2C controller that has not been discarded. Received data can be discarded due to the command in MTDR[CMD], or the controller can be configured to discard nonmatching data.

62.7.1.19 Controller Receive Data Read Only (MRDROR)

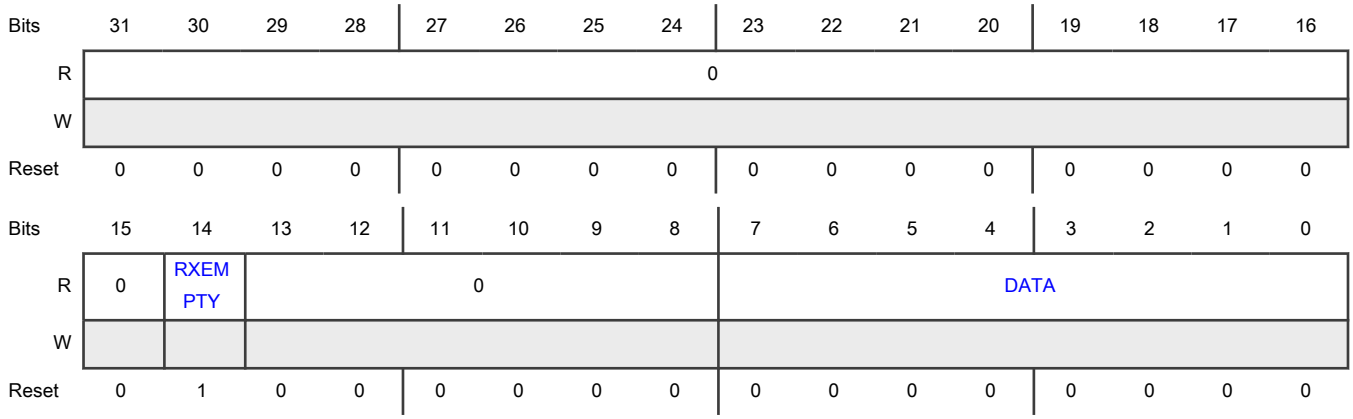
Offset

Register	Offset
MRDROR	78h

Function

Contains the status of the receive FIFO and returns the data received by the I2C controller, but does not pull the data from the FIFO.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 RXEMPTY	RX Empty Indicates whether the receive data FIFO is empty. 0b - Not empty 1b - Empty
13-8 —	Reserved
7-0 DATA	Receive Data

62.7.1.20 Target Control (SCR)

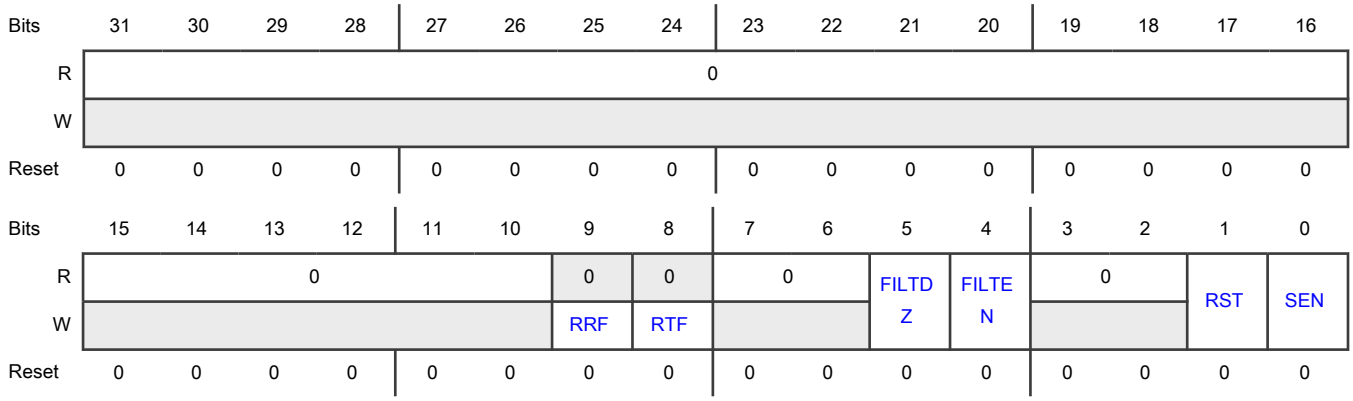
Offset

Register	Offset
SCR	110h

Function

Contains resets and other target control settings.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Empties the receive FIFO in Target Receive Data (SRDR). 0b - No effect 1b - SRDR is now empty
8 RTF	Reset Transmit FIFO Empties the transmit FIFO in Target Transmit Data (STDR). 0b - No effect 1b - STDR is now empty
7-6 —	Reserved
5 FILTDZ	Filter Doze Enable Enables filter in Doze mode. Update this field only when the I2C target is disabled. 0b - Enable 1b - Disable
4 FILTEN	Filter Enable Enables digital filter and output delay counter for target mode. Update this field only when the I2C target is disabled. 0b - Disable 1b - Enable
3-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 RST	Software Reset Resets target mode logic. The reset takes effect immediately. The value of this field remains 1 until you write 0 to it. There is no minimum delay required before clearing the software reset. 0b - Not reset 1b - Reset
0 SEN	Target Enable Enables I2C Target mode. 0b - Disable 1b - Enable

62.7.1.21 Target Status (SSR)

Offset

Register	Offset
SSR	114h

Function

Contains status flags for transmit and receive data, for error conditions, and for bus and target busy or idle status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W					W1C	W1C	W1C	W1C								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates whether an I2C bus is idle or busy. 0b - Idle 1b - Busy
24 SBF	Target Busy Flag Indicates whether an I2C target is idle or busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 SARF	SMBus Alert Response Flag Indicates whether an SMBus alert response has been detected. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Disabled or not detected 1b - Enabled and detected
14 GCF	General Call Flag Indicates whether a target has detected the general call address. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - General call address disabled or not detected 1b - General call address detected
13 AM1F	Address Match 1 Flag Indicates whether the received address matches the value in ADDR1, or it falls within the ADDR0 to ADDR1 range as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Matching address not received 1b - Matching address received
12	Address Match 0 Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
AM0F	Indicates whether the received address matches the ADDR0 field, as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - ADDR0 matching address not received 1b - ADDR0 matching address received
11 FEF	FIFO Error Flag Indicates whether there is a FIFO error. This flag can only be set when clock stretching is disabled. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
10 BEF	Bit Error Flag Indicates whether the LPI2C target has transmitted a logic 1 and detects a logic 0 on the I2C bus. The target ignores the rest of the transfer until the next (repeated) Start condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No bit error occurred 1b - Bit error occurred When writing 0b - No effect 1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C target detects a Stop condition, and if the LPI2C target matched the last address byte. When SCFGR1[SDCFG] = 1, this flag is set on any Stop condition. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No Stop detected 1b - Stop detected When writing 0b - No effect 1b - Clear the flag
8 RSF	Repeated Start Flag Indicates whether the LPI2C target detects a repeated Start condition and if the LPI2C target matched the last address byte. When SCFGR1[RSCFG] = 1, this flag is set on any repeated Start condition. This flag is not set when the target first detects a Start condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No repeated Start detected 1b - Repeated Start detected When writing 0b - No effect 1b - Clear the flag
7-4 —	Reserved
3 TAF	Transmit ACK Flag Indicates whether a transmit ACK or NACK is required. You can clear this flag by writing to Target Transmit ACK (STAR). 0b - Not required 1b - Required
2 AVF	Address Valid Flag Indicates whether the contents of Target Address Status (SASR) are valid. You can clear this flag by reading SASR. When SCFGR1[RXCFG] = 1, this flag is also cleared by reading Target Receive Data (SRDR). 0b - Not valid 1b - Valid
1 RDF	Receive Data Flag Indicates whether receive data is ready. You can clear this flag by reading Target Receive Data (SRDR). When SCFGR1[RXCFG] = 1, this flag is not cleared when reading Target Receive Data (SRDR) if SSR[AVF] = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not ready 1b - Ready
0 TDF	Transmit Data Flag Indicates whether transmit data has been requested. This flag is cleared by writing to Target Transmit Data (STDR). When SCFGR1[TXCFG] = 0, if a NACK, repeated Start, or Stop condition is detected, this flag is also cleared. 0b - Transmit data not requested 1b - Transmit data is requested

62.7.1.22 Target Interrupt Enable (SIER)

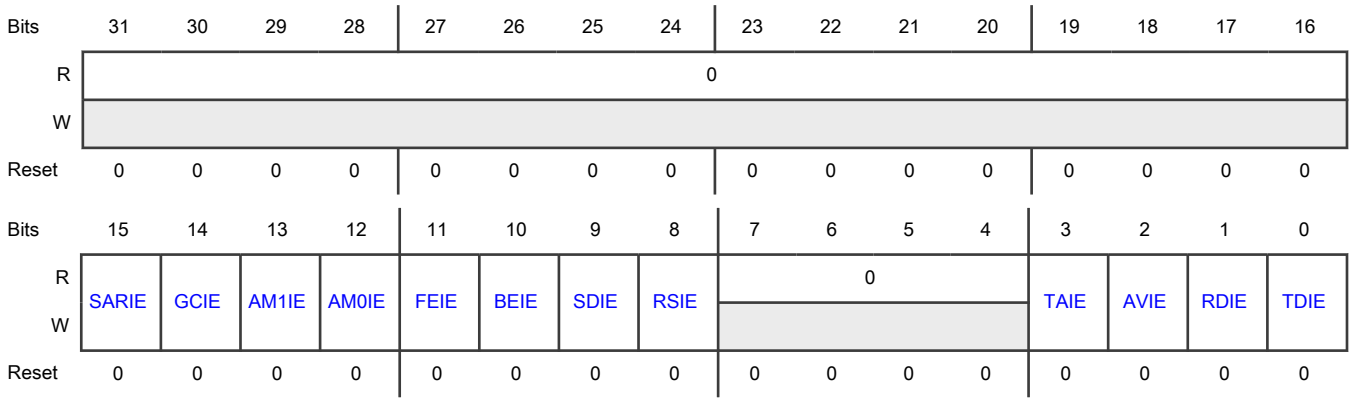
Offset

Register	Offset
SIER	118h

Function

Contains transmit and receive data interrupt enables, start and stop detect interrupt enables, and other target interrupt enables.

Diagram



Fields

Field	Function
31-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 SARIE	SMBus Alert Response Interrupt Enable Enables interrupt for SMBus alert response. 0b - Disable 1b - Enable
14 GCIE	General Call Interrupt Enable Enables interrupt for general call. 0b - Disabled 1b - Enabled
13 AM1IE	Address Match 1 Interrupt Enable Enables interrupt for address match 1. 0b - Disable 1b - Enable
12 AM0IE	Address Match 0 Interrupt Enable Enables interrupt for address match 0. 0b - Disable 1b - Enable
11 FEIE	FIFO Error Interrupt Enable Enables interrupt for FIFO error. 0b - Disable 1b - Enable
10 BEIE	Bit Error Interrupt Enable Enables interrupt for bit error. 0b - Disable 1b - Enable
9 SDIE	Stop Detect Interrupt Enable Enables interrupt for Stop detection. 0b - Disable 1b - Enable
8 RSIE	Repeated Start Interrupt Enable Enables interrupt for repeated start. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
7-4 —	Reserved
3 TAIE	Transmit ACK Interrupt Enable Enables interrupt for transmit ACK. 0b - Disable 1b - Enable
2 AVIE	Address Valid Interrupt Enable Enables interrupt for valid address. 0b - Disable 1b - Enable
1 RDIE	Receive Data Interrupt Enable Enables interrupt for receive data. 0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable Enables interrupt for transmit data. 0b - Disable 1b - Enable

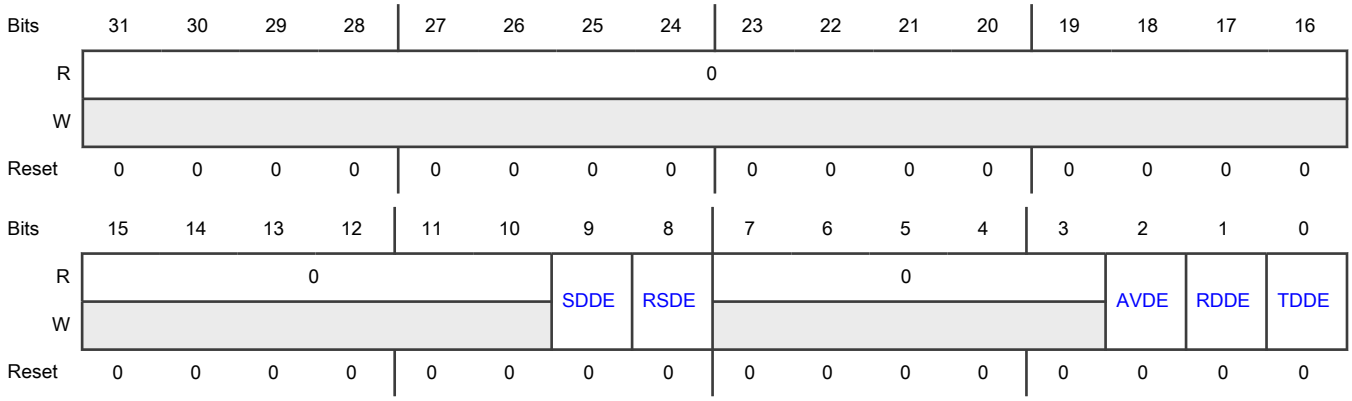
62.7.1.23 Target DMA Enable (SDER)

Offset

Register	Offset
SDER	11Ch

Function
Contains the transmit, request, and receive enables for DMA.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 SDDE	Stop Detect DMA Enable Enables DMA end-of-packet processing on stop detection. Reading Target Receive Data (SRDR) when it is empty: • Generates a DMA end-of-packet response. • Returns 0000_40FFh. • Writes 0 to MSR[SDF]. 0b - Disable 1b - Enable
8 RSDE	Repeated Start DMA Enable Enables DMA end-of-packet processing on repeated start. Reading Target Receive Data (SRDR) when it is empty: • Generates a DMA end-of-packet response. • Returns 0000_40FFh. • Writes 0 to MSR[RDF]. 0b - Disable 1b - Enable
7-3 —	Reserved
2 AVDE	Address Valid DMA Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables address valid DMA request. The address valid DMA request is shared with the receive data DMA request. If both are enabled, write 1 to SCFGR1[RXCFG] to allow the DMA to read the address from Target Receive Data (SRDR). 0b - Disable 1b - Enable
1 RDDE	Receive Data DMA Enable Enables receive data for DMA. 0b - Disable DMA request 1b - Enable DMA request
0 TDDE	Transmit Data DMA Enable Enables transmit data for DMA. 0b - Disable 1b - Enable

62.7.1.24 Target Configuration 0 (SCFGR0)

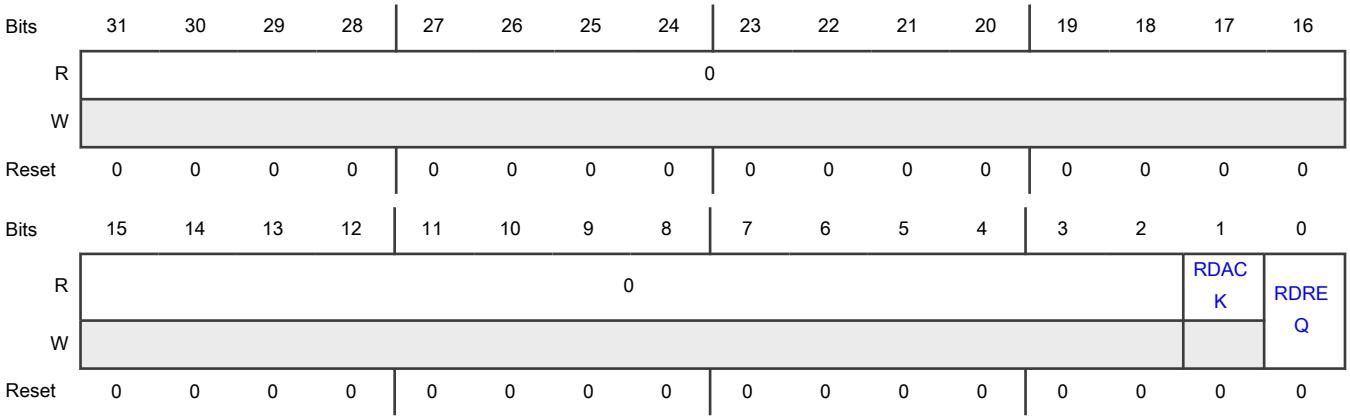
Offset

Register	Offset
SCFGR0	120h

Function

Configures the read request feature.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDACK	Read Acknowledge Flag Indicates whether a Start then Stop sequence with one SCL pulse between them acknowledged the read request while SCFGR0[RDREQ] = 1. You can clear this flag by writing 0 to SCFGR0[RDREQ]. 0b - Read Request not acknowledged 1b - Read Request acknowledged
0 RDREQ	Read Request Enables read request. When the I2C bus is idle, writing 1 to this field causes the LPI2C target to drive SDA low, triggering a Start condition. The LPI2C target releases SDA on the next falling edge of SCL or when you write 0 to this field. To initiate a second read request (for example, following I2C bus activity that did not acknowledge the request), write 0 then 1 to this field. When the I2C bus is busy, writing to this register always writes 0 to this field. 0b - Disable 1b - Enable

62.7.1.25 Target Configuration 1 (SCFGR1)

Offset

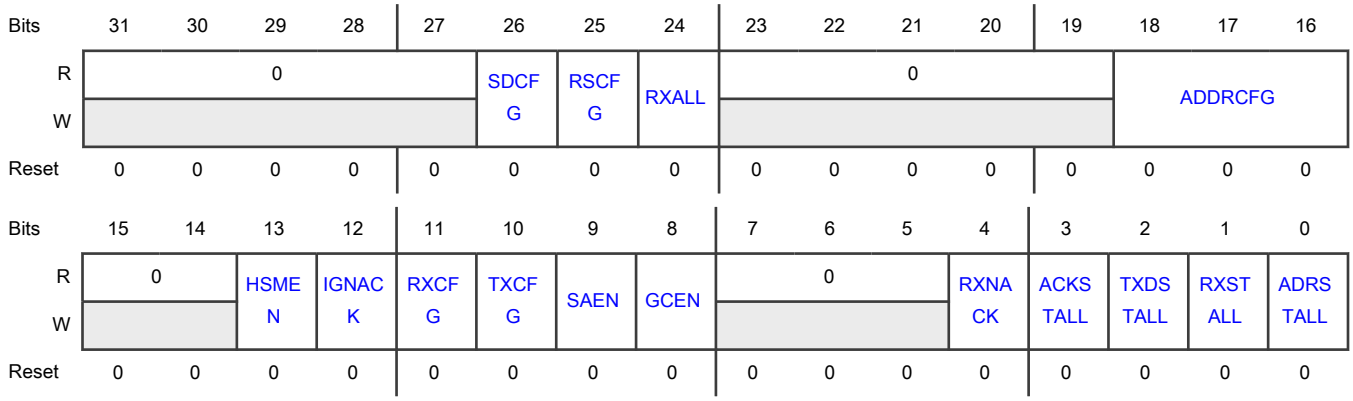
Register	Offset
SCFGR1	124h

Function

Configures various aspects of the target.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26 SDCFG	Stop Detect Configuration Configures the conditions that set MSR[SDF]. 0b - Any Stop condition following an address match 1b - Any Stop condition
25 RSCFG	Repeated Start Configuration Configures the conditions that set MSR[STF]. 0b - Any repeated Start condition following an address match 1b - Any repeated Start condition
24 RXALL	Receive All Enables receive-all functionality. When enabled, the LPI2C target stores all addresses on the I2C bus in Target Address Status (SASR) and all data on the I2C bus in Target Receive Data (SRDR). However, the LPI2C target does not drive SDA (for ACK or target-transmit transfer) unless there is an address match. The LPI2C target can drive SCL if clock stretching is enabled. When this field is 1, the LPI2C target only supports 7-bit addressing modes (you must configure SCFGR1[ADDRCFG] for 7-bit address match). Software can support 10-bit addresses, however. The first byte of a 10-bit address is saved to Target Address Match (SAMR). The second byte is saved as the first data byte in Target Receive Data (SRDR). Use this field to aid debugging of the I2C bus by saving all data on the bus without altering the state of the bus. When this field is 1, it is recommended to also write 1 to SCFGR1[RSCFG] and SCFGR1[SDCFG] so you can track the full state of the I2C bus. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-19 —	Reserved
18-16 ADDRCFG	Address Configuration Configures the condition that causes an address to match. 000b - Address match 0 (7-bit) 001b - Address match 0 (10-bit) 010b - Address match 0 (7-bit) or address match 1 (7-bit) 011b - Address match 0 (10-bit) or address match 1 (10-bit) 100b - Address match 0 (7-bit) or address match 1 (10-bit) 101b - Address match 0 (10-bit) or address match 1 (7-bit) 110b - From address match 0 (7-bit) to address match 1 (7-bit) 111b - From address match 0 (10-bit) to address match 1 (10-bit)
15-14 —	Reserved
13 HSMEN	HS Mode Enable Enables detection of the HS mode controller code of target address 0000_1XX, but does not cause an address match on this code. When this field is 1 and any HS mode controller code is detected, SCR[FILTEN] and SCFGR1[ACKSTALL] are ignored until the next Stop condition is detected. 0b - Disable 1b - Enable
12 IGNACK	Ignore NACK Determines whether the target ends transfer when a NACK condition is detected. When this field is 1, the LPI2C target continues transfers after a NACK is detected. This field is required to be 1 in Ultra-Fast mode. 0b - End transfer on NACK 1b - Do not end transfer on NACK
11 RXCFG	Receive Data Configuration Configures which data is returned and which flags are cleared when reading Target Receive Data (SRDR). When this field is 0, reading SRDR returns received data and clears MSR[RDF]. When this field is 1, reading SRDR: • Returns the value of Target Address Status (SASR) and clears SSR[AVF] when SSR[AVF] is set. • Returns received data and clears MSR[RDF] when SSR[AVF] is not set. 0b - Return received data, clear MSR[RDF]

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Return SASR and clear SSR[AVF] when SSR[AVF] is set, return received data and clear MSR[RDF] when SSR[AFV] is not set
10 TXCFG	Transmit Flag Configuration Determines which conditions set MSR[TDF]. This field always becomes 1 before a NACK is detected at the end of a target-transmit transfer. This change can cause an extra word to be written to the transmit data FIFO. When this field is 0, Target Transmit Data (STDR) is automatically emptied when a target-transmit transfer is detected. MSR[TDF] is set when a target-transmit transfer is detected, and MSR[TDF] is cleared at the end of the target-transmit transfer. When this field is 1, MSR[TDF] is set when STDR is empty, and MSR[TDF] is cleared when STDR is full. This setting allows STDR to be filled before a target-transmit transfer is detected. However, it can cause STDR to be written before a NACK is detected on the last byte of a target-transmit transfer. 0b - MSR[TDF] is set only during a target-transmit transfer when STDR is empty 1b - MSR[TDF] is set whenever STDR is empty
9 SAEN	SMBus Alert Enable Enables a match on an SMBus alert. 0b - Disable 1b - Enable
8 GCEN	General Call Enable Enables a general call address. 0b - Disable 1b - Enable
7-5 —	Reserved
4 RXNACK	Receive NACK Determines whether to override the setting of STAR[TXNACK] when the LPI2C receives a matching address during an overrun. When this field is 1, the LPI2C target responds with a NACK under the following conditions: • SSR[AVF] would be set due to matching an address, but that flag is already 1 (address overrun). • SSR[RDF] would be set due to receiving data, but that flag is already 1 (receive data overrun). 0b - ACK or NACK always determined by STAR[TXNACK] 1b - NACK always generated on address overrun or receive data overrun, otherwise ACK or NACK is determined by STAR[TXNACK]
3	ACK SCL Stall

Table continues on the next page...

Table continued from the previous page...

Field	Function
ACKSTALL	Enables SCL clock stretching during target-transmit address bytes and target-receiver address and data bytes, so you can write to Target Transmit ACK (STAR) before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the ninth bit, and is therefore not compatible with HS mode. If this field is 1: • You do not need to write 1 to SCFGR1[RXSTALL] or SCFGR1[ADRSTALL]. • When there is an address match on the first byte of a 10-bit address, SSR[AVF] is set, allowing you to read the received address before writing to Target Transmit ACK (STAR). 0b - Disable 1b - Enable
2 TXDSTALL	Transmit Data SCL Stall Enables SCL clock stretching when SSR[TDF] = 1 during a target-transmit transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when SSR[RDF] = 1 during a target-receive transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when SSR[AVF] = 1. Clock stretching only occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable

62.7.1.26 Target Configuration 2 (SCFGR2)

Offset

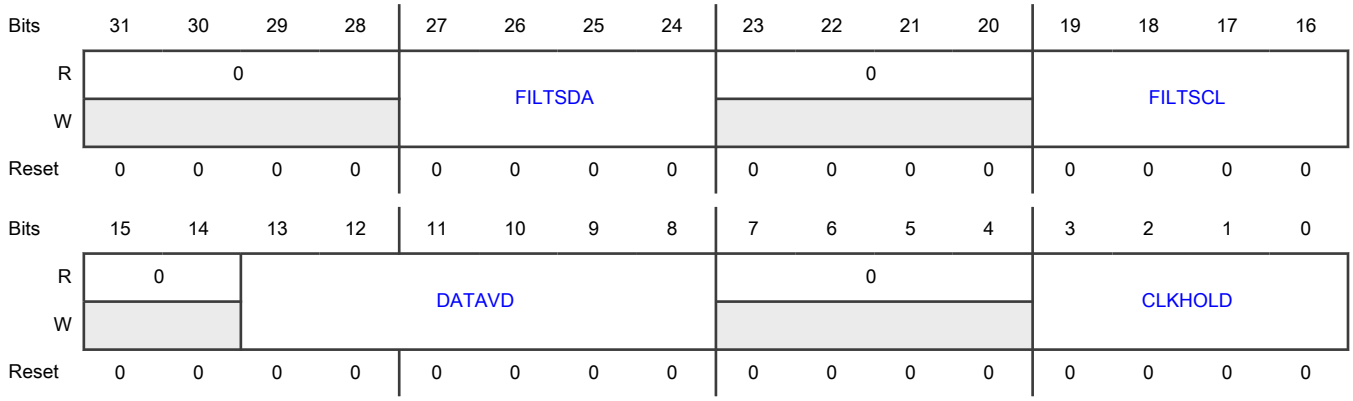
Register	Offset
SCFGR2	128h

Function

Configures data valid delay, clock hold time, and glitch filters for SDA and SCL.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C target digital glitch filters for SDA input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C target digital glitch filters for SCL input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
15-14 —	Reserved
13-8	Data Valid Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
DATAVD	Configures the SDA data valid delay time for the I2C target, which is equal to FILTSCL + DATAVD + 3 cycles. The data valid delay must be configured to be less than the minimum SCL low period. MCFGR1[PRESCALE] does not affect the I2C target data valid delay time, and the I2C target data valid delay time is disabled in HS mode.
7-4 —	Reserved
3-0 CLKHOLD	Clock Hold Time Configures the minimum clock hold time for the I2C target, when clock stretching is enabled. The minimum hold time is equal to the number of cycles defined by this field + 3. MCFGR1[PRESCALE] does not affect the I2C target clock hold time, and the I2C target clock hold time is disabled in HS mode.

62.7.1.27 Target Address Match (SAMR)

Offset

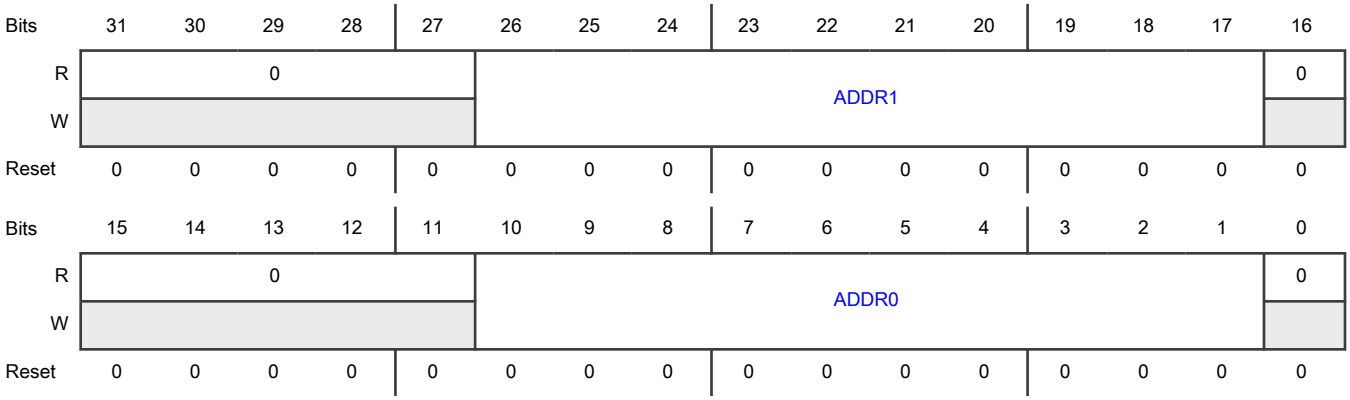
Register	Offset
SAMR	140h

Function

Contains address values for received target match comparison.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-17 ADDR1	Address 1 Value Contains the value of address 1, which is compared to the received address to detect the target address. In 10-bit mode, the first address byte is compared to {11110, ADDR1[26:25]} and the second address byte is compared to ADDR1[24:17]. In 7-bit mode, the address is compared to ADDR1[23:17].
16-11 —	Reserved
10-1 ADDR0	Address 0 Value Contains the value of address 0, which is compared to the received address to detect the target address. In 10-bit mode, the first address byte is compared to {11110, ADDR0[10:9]} and the second address byte is compared to ADDR0[8:1]. In 7-bit mode, the address is compared to ADDR0[7:1].
0 —	Reserved

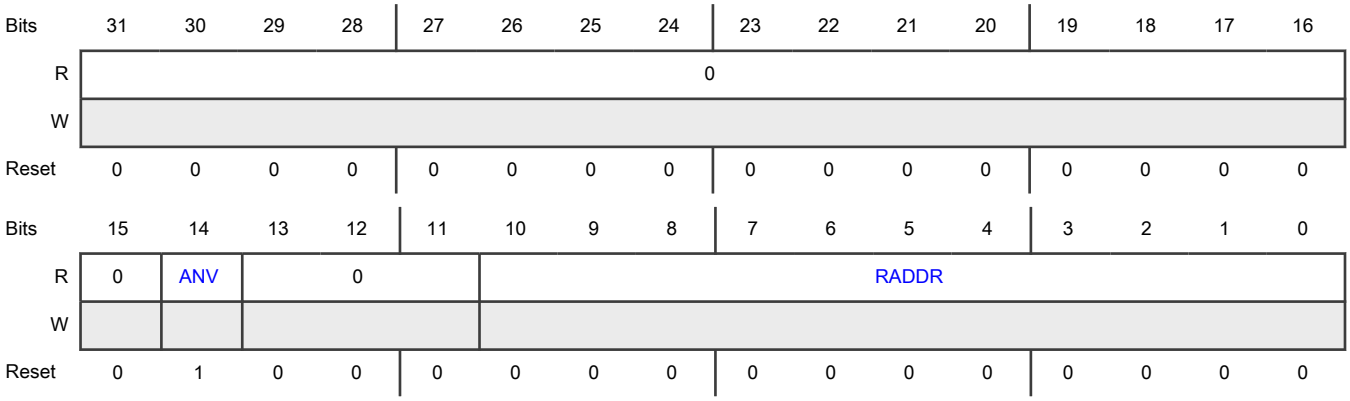
62.7.1.28 Target Address Status (SASR)

Offset

Register	Offset
SASR	150h

Function
Contains the received address and its validity.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 ANV	Address Not Valid Indicates whether SASR[RADDR] is valid. 0b - Valid 1b - Not valid
13-11 —	Reserved
10-0 RADDR	Received Address Contains the received address. Updates whenever SSR[AM0F] or SSR[AM1F] is set. Reading Target Address Status (SASR) clears SSR[AM0F] and SSR[AM1F]. In 7-bit mode, the address byte is stored in RADDR[7:0]. In 10-bit mode, the first address byte is {11110, RADDR[10:9], RADDR[0]} and the second address byte is RADDR[8:1]. The Read-or-Write bit is therefore always stored in RADDR[0]. When SCFGR1[ACKSTALL] = 1, if the first address byte matches in 10-bit mode, the first address byte is stored in RADDR[7:0] so you can read this field before writing the Transmit ACK. If the second address byte matches, this field is then updated with the full 10-bit address.

62.7.1.29 Target Transmit ACK (STAR)

Offset

Register	Offset
STAR	154h

Function

Configures choice of ACK or NACK on each received word.

You can write to this register only when SCFGR1[ACKSTALL] = 1.

SCFGR1[ACKSTALL] enables clock stretching during the ACK-or-NACK bit slot. During this time, you can write to this register.

The logic ensures that the clock stretching continues for at least one bus clock cycle after this register is updated.

This clock stretching time can be extended via SCFGR2[CLKHOLD].

R	0															TXNACK
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-1 —	Reserved
0 TXNACK	Transmit NACK Selects whether transmit ACK (logic 0) or NACK (logic 1) is returned on the bus by the I2C target after receiving each word. • When SCFGR1[ACKSTALL] = 1, a transmit NACK signal must be written once for each matching address byte and each received word. SCFGR1[ACKSTALL] must be 1, because that setting stalls the data transfer until software reads the received word (and determines whether to respond with an ACK or NACK). • To configure the default (ACK or NACK), you can write to this field when LPI2C target is disabled or idle. 0b - Transmit ACK 1b - Transmit NACK

62.7.1.30 Target Transmit Data (STDR)

Offset

Register	Offset
STDR	160h

Function

Contains the I2C target data to transmit.

Clock stretching (enabled or disabled) affects when the transmit data is transferred. SCFGR1[TXDSTALL] enables clock stretching during the first data bit of a target-transmit transfer.

If clock stretching is enabled (SCFGR1[TXDSTALL] = 1), the transmit data transfer is stalled until this register is updated. Clock stretching is extended by at least 1 bus clock cycle after this register is updated. Clock stretching can be delayed further by using SCFGR2[CLKHOLD].

If clock stretching is disabled (SCFGR1[TXDSTALL] = 0), the transmit data must be written before the start of the target-transmit transfer, otherwise SSR[FEF] is set.

10-8 RADDR	Received Address Contains address received by the LPI2C target. When both SCFGR1[RXCFG] and SSR[AVF] are 1, bits [10:8] of SASR[RADDR] are returned. Otherwise, this field returns zero.
7-0 DATA	Receive Data Contains data received by the LPI2C target. When both SCFGR1[RXCFG] and SSR[AVF] are 1, bits [7:0] of SASR[RADDR] are returned.

62.7.1.33 Controller Transmit Command Burst (MTCBR0 - MTCBR127)

Offset

For n = 0 to 127:

Register	Offset
MTCBRn	200h + (n × 4h)

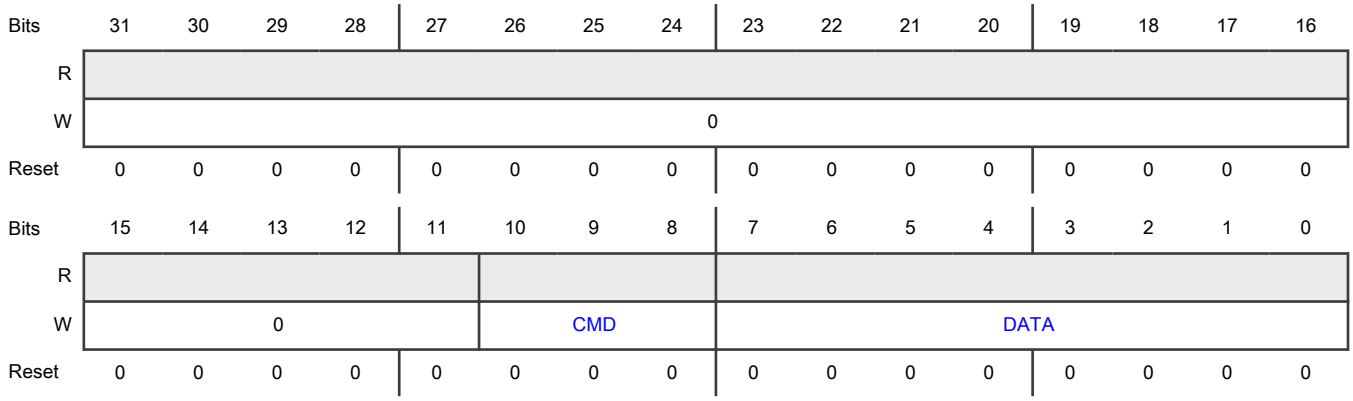
Function

Contains transmit Command and Data fields to support burst transfers.

Is an alias of the Controller Transmit Data Register designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using aligned 8-bit, 16-bit, or 32-bit writes. The size of the Controller Transmit Data Burst Register is 512-bytes.

- An aligned 32-bit write in this region pushes one entry into the transmit FIFO.
- An aligned 16-bit write in this region to MTCBRn[15:0] pushes one entry into the transmit FIFO.
- An 8-bit write in this region to MTCBRn[7:0] updates DATA[7:0], but does not push the data into the transmit FIFO.
- An 8-bit write in this region to MTCBRn[15:8] pushes the data written to CMD[2:0] plus the previously written DATA[7:0] into the transmit FIFO.
- An 8-bit or 16-bit write in this region to MTXBRn[31:16] is ignored.

Diagram



Fields

31-11 —	Reserved
10-8 CMD	Command Command is written to the Controller Transmit Data Register.
7-0 DATA	Data Data is written to the Controller Transmit Data Register.

62.7.1.34 Transmit Data Burst (MTDBR0 - MTDBR255)

Offset

For n = 0 to 255:

Register	Offset
MTDBRn	400h + (n × 4h)

Function

Contains transmit Data fields to support burst transfers.

Is an alias of the Transmit Data Register designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using 8-bit, 16-bit, or 32-bit writes. The CMD field is always zero-extended for transmit data. The size of the Transmit Data Burst Register is 1024 bytes.

- An aligned 32-bit write in this region pushes four zero-extended DATA entries into the transmit FIFO (DATA0 byte first). Note that the register access is extended by 3 wait states.
- An aligned 16-bit write in this region to either half of a 32-bit word pushes two zero-extended DATA entries into the transmit FIFO (DATA0 or DATA2 first). Note that the register access is extended by 1 wait state.
- An 8-bit write in this region pushes one zero-extended DATA entry into the transmit FIFO.

NOTE

The LPSPI output triggers are not connected.

63.2 Overview

LPSPI provides an efficient interface to a SPI bus, either as a master or slave. A SPI bus is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

63.2.1 Block diagram

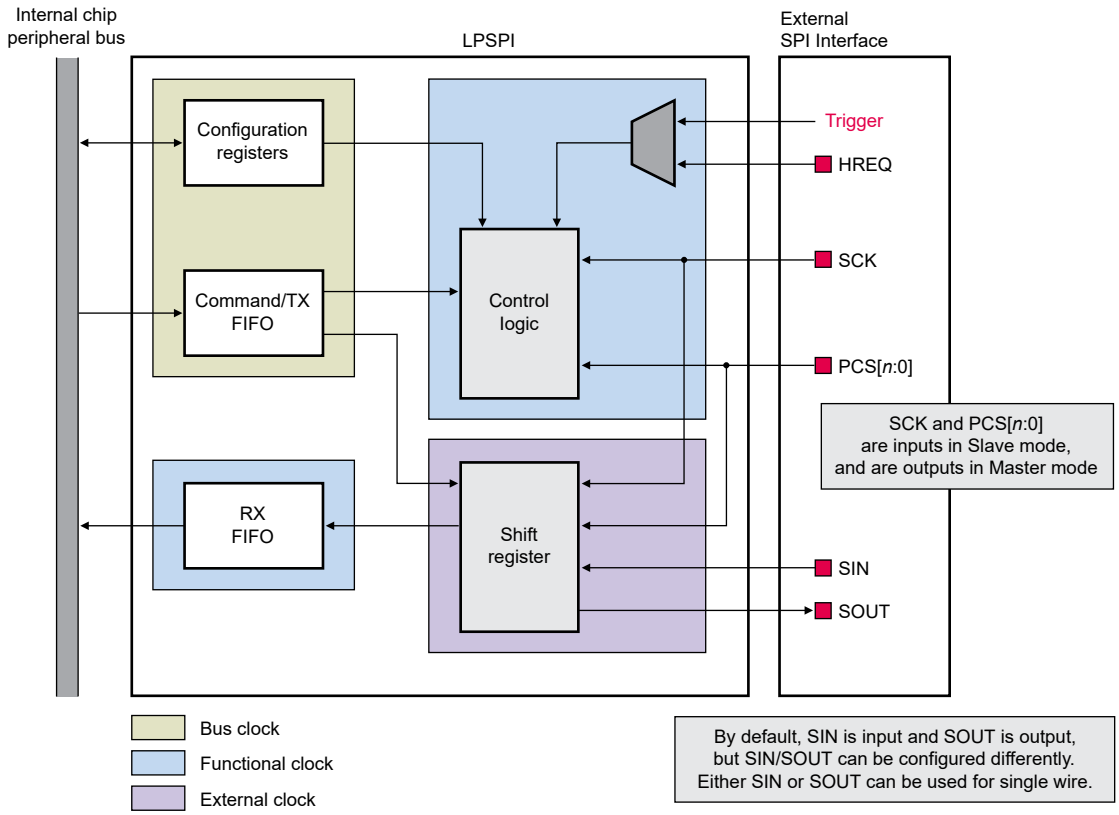

Figure 467. Block diagram

63.2.2 Features

- Requires minimal CPU overhead, with FIFO register access supported by DMA transmit and receive requests.
- Continues operating in Stop mode, if configured to do so and an appropriate clock is available
- 32-bit word size
- Configurable clock polarity and phase
- Master mode—supports 4 peripheral chip selects
- Slave mode
- 16-word transmit and command FIFO
- 16-word receive FIFO
- Flexible timing parameters in Master mode, including SCK frequency and duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep PCS asserted across multiple frames
- Full-duplex transfers support 1-bit transmit and receive on each clock edge
- Half-duplex transfers support:
  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge
  - 4-bit transmit or receive on each clock edge

- Can use host request to control the start of a SPI bus transfer
- Receive data match logic supports discard of non-matching data and interrupt on data match

63.3 Functional description

63.3.1 Master mode

63.3.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words.

- You store transmit data words to the transmit and command FIFO, by writing to Transmit Data (TDR).
- You store command words to the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend upon whether the LPSPI module is busy or between frames. See TCR[CONT] and TCR[CONTC].

Table 1025. Possible actions when a command word is at the top of the transmit and command FIFO

Condition	Action
LPSPI is enabled and idle	The command word is pulled from the FIFO, and that command word controls all subsequent transfers.
LPSPI is busy and the Continuing Command field (TCR[CONTC]) is 0	The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value.
LPSPI is busy, the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1	The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the FRAMESZ value), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] = 1, only the lower 24-bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely.

About TCR[CONT] and TCR[CONTC]:

- TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.
- TCR[CONTC] = 1 specifies that this command word should not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least 3 LPSPI functional clock cycles for TCR to update after TCR is written (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing the TCR does not initiate a SPI bus transfer, unless the TCR[TXMSK] = 1. When the TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the TCR[FRAMESZ] value); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Master mode, the LPSPI command word in TCR controls SPI attributes based on selections in register fields.

Table 1026. Command word in Master mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock polarity	Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin.	N
CPHA	Clock phase	Specifies the clock phase of the transfer.	N
PRESCALE	Prescaler value	Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables the LPSPI module to connect to different slave devices at different frequencies.	N
PCS	Peripheral chip select	Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1, do not select PCS[3:2].	N
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.	Y
CONT	Continuous transfer	Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new command word to cause PCS to negate. Also supports changing the command word at the frame size boundaries.	Y
CONTC	Continuing command	Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary.	Y
RXMSK	Receive data mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.	Y
TXMSK	Transmit data mask	Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.	Y
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and either TXMSK or RXMSK must also be 1.	Y
FRAMESZ	Frame size	Configures the frame size in number of bits equal to (FRAMESZ + 1).	Y

Table continues on the next page...

Table 1026. Command word in Master mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
		• The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.	

63.3.1.1.1 SPI bus transfers

LPSPI initiates a SPI bus transfer when all of the following conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and uses the timing parameters in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the FRAMESZ value have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked when PCS is negated.

63.3.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI master to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags do not update. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO while Circular FIFO mode is enabled.

63.3.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO.

- Received data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple-word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] = 0) while waiting for new transmit data or for a command word to be written.

LPSPI provides a receive data match function that can match received data against one of two words in DMR0 and DMR1, or against a masked data word. The received data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded due to the TCR[RXMSK] field cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.

- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to the CFGR0[RDMO] field, then write 0 to SR[DMF].

63.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the TCR[PRESCALE] selection. Although you cannot change Clock Configuration (CCR) when the LPSPI module is busy, to support interfacing to different slave devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers using Transmit Command (TCR).

NOTE

The minimum value below is the minimum counter value, but the clock configuration register values must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 1027. Timing parameters

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Min	Max
Field	Name			
SCKSET	SCK setup phase	Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
SCKHLD	SCK hold phase	Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
PCSPCS	PCS-to-PCS delay	Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (512 cycles)
SCKSCK	SCK-to-SCK delay	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK + 1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer.	0 (1 cycle)	255 (256 cycles)

Table continues on the next page...

Table 1027. Timing parameters (continued)

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Min	Max
Field	Name			
PCSSCK	PCS-to-SCK delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS delay	Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

This figure shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]
- CCR1[SCKSET]
- CCR1[SCKHLD]

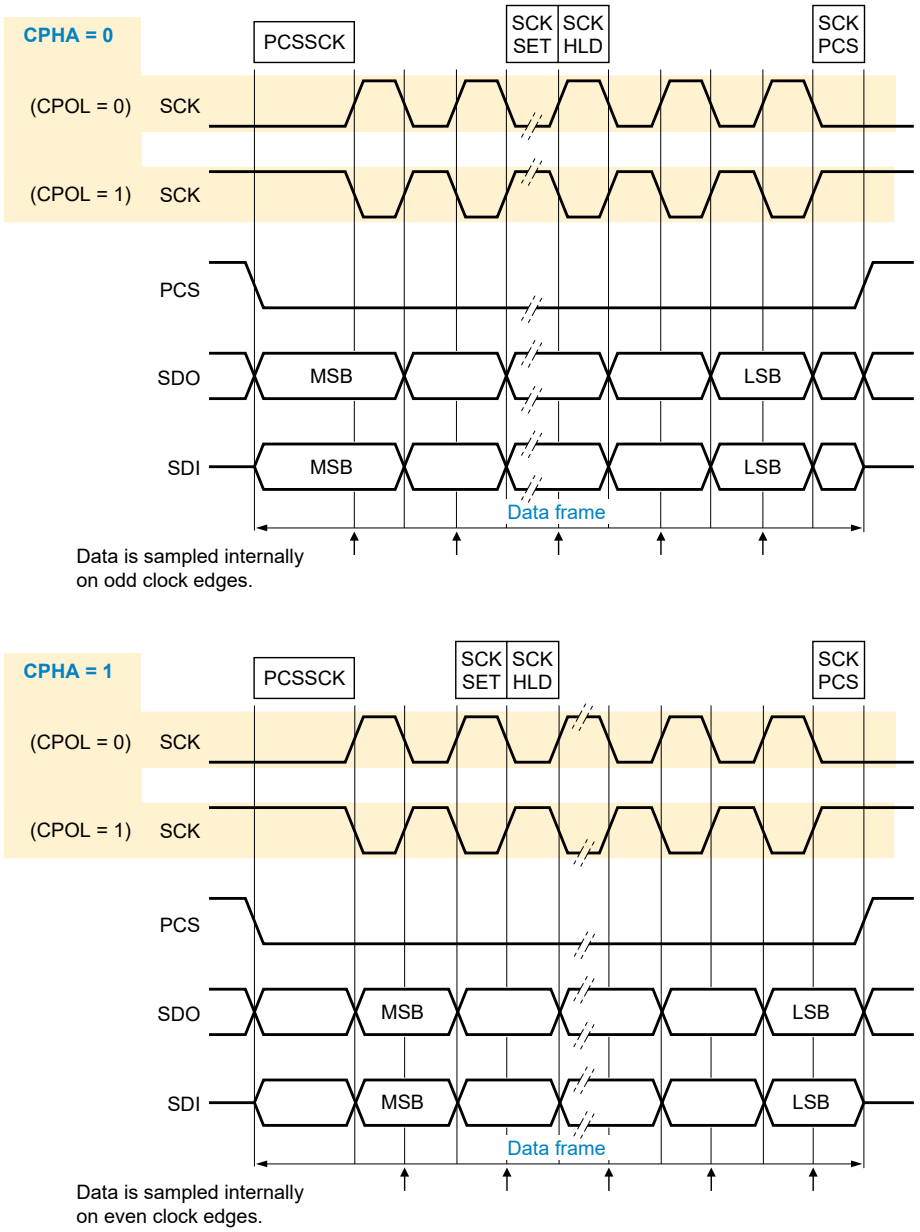

Figure 468. Clock phase (TCR[CPHA]) timing diagram example

To configure for a baud rate of 10 MHz with 50/50 duty cycle and with a functional clock frequency of 100 MHz, use the following settings:

- CCR1[SCKSET] = 0x4 (5 cycles)
- CCR1[SCKHLD] = 0x4 (5 cycles)
- CCR1[PCSPCS] = 0x8 (10 cycles)
- CCR1[SCKSCK] = 0x4 (5 cycles)
- CRR[PCSSCK] = 0x4 (5 cycles)
- CRR[SCKPCS] = 0x4 (5 cycles)
- TCR[PRESCALE] = 0x0 (divide by 1)

63.3.1.4 Pin configuration

- To swap directions or support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring for half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).
- When performing half-duplex 2-bit transfers, you can set CFGR1[PCSCFG] to any value.
- When performing half-duplex 4-bit transfers, you must set CFGR1[PCSCFG] to 1h.

63.3.1.5 Clock loopback

Configure the LPSPI master to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK can improve the setup time of the input data from the slave.

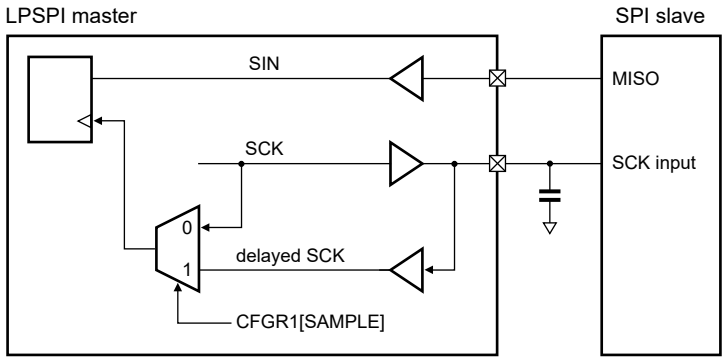

Figure 469. Clock loopback

See the chip data sheet for the specific input setup time in Master Loopback mode.

63.3.2 Slave mode

LPSPI slave mode:

- Uses the same shift register and logic that master mode uses.
- Does not use Clock Configuration Register (CCR).
- Requires that Transmit Command (TCR) remain static (unchanging) during SPI bus transfers.

63.3.2.1 Transmit and command FIFO commands

Before enabling LPSPI in Slave mode, initialize Transmit Command (TCR), although TCR does not update until after LPSPI is enabled. After LPSPI is enabled, only change TCR when LPSPI is idle. In Slave mode, the LPSPI command word in TCR controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 1028. Command word in Slave mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock polarity	Specifies the polarity of the external SCK input.
CPHA	Clock phase	Specifies the clock phase of transfer.
PRESCALE	Prescaler value	Specifies the LPSPI functional clock prescaler.
PCS	Peripheral chip select	Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins.
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.
CONT	Continuous transfer	When continuous transfer is selected in Slave mode, after the number of bits indicated by FRAMESZ are transferred, the LPSPI will passthrough and transmit the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data as if there were a 32-bit shift register.
CONTC	Continuing command	When continuing command is enabled in Slave mode, after the number of bits indicated by FRAMESZ are transferred, then RXMSK is considered equal to 1 and TXMSK is considered equal to 0 until the next PCS negation. CONTC can be used to change the direction of a transfer after the number of bits indicated by FRAMESZ.
RXMSK	Receive data mask	Masks the receive data; LPSPI does not store masked receive data to the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.
TXMSK	Transmit data mask	Masks the transmit data, so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and at least one of TCR[TXMSK] or TCR[RXMSK] must be 1.
FRAMESZ	Frame size	Specifies the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.

63.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of two words in the DMR0 and DMR1 registers or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- The receiver match function can also be configured to discard all received data until a data match is detected, using the CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the CFGR0[RDMO] bit, then clear the SR[DMF] bit.

63.3.2.3 Partial received word

When the PCS pin deasserts and the receive shift register has shifted in a partial word, the receive shift register can be configured to either discard the partial word or to store it in the receive FIFO. You specify this using CFGR1[PARTIAL].

A partial word is defined as less than FRAMESZ bits (when FRAMESZ is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when FRAMESZ is greater than 32 bits and not the last word in a multi-word frame).

A single-bit frame is not supported. A partial received word of 1 bit is fine, but a partial received frame of 1 bit is not supported.

63.3.2.4 Clocked interface

LPSPI supports interfacing to external masters that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOLn] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1), CFGR1[PCSPOL*n*] could be used to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the TCR[PRESCALE] selection) is required between the last SCK edge of one word and the first SCK edge of the next word.

63.3.3 Low-power modes

Table 1029. Low-power modes

Chip mode	LPSPI operation
Run	Normal operation
Stop	Can continue operating in Stop mode if CR[DOZEN] = 0 and LPSPI is using an external or internal clock source that remains operating during Stop mode

63.3.4 Debug mode

Table 1030. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug/ Halted mode)	Can continue operating in Debug mode, if the CR[DBGEN] = 1.

63.3.5 Interrupts and DMA requests

The following table lists the Slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit and receive DMA requests.

Table 1031. Interrupts and DMA requests

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit data flag	Data can be written to transmit FIFO, as configured by the transmit FIFO watermark FCR[TXWATER]	Y	TX	Y
RDF	Receive data flag	Data can be read from the receive FIFO, as configured by the receive FIFO watermark FCR[RXWATER]	Y	RX	Y
WCF	Word complete flag	Word is complete, the last bit of the word has been sampled	Y	N	Y
FCF	Frame complete flag	Frame is complete, and PCS has deasserted	Y	RX	Y
TCF	Transfer complete flag	Transfer is complete, PCS has deasserted, and the transmit and command FIFO is empty	Y	N	Y
TEF	Transmit error flag	Indicates a transmit and command FIFO underrun. In Master mode when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), the Transmit Error Flag cannot set.	Y	N	Y
REF	Receive error flag	Indicates a receive FIFO overflow. In Master mode when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), the Receive Error Flag cannot set.	Y	N	Y
DMF	Data match flag	Indicates that the received data has matched the configured data match value	Y	N	Y
MBF	Module busy flag	LPSPI is busy performing a SPI bus transfer	N	N	N

63.3.5.1 End of packet DMA transfer

The end of packet functionality is designed for serial interfaces where the size of the transfer may not be known by software in advance and the data is being pushed by an external device. Examples include UART receive, I2C Slave mode and SPI Slave

mode. The end of packet processing is intended to ensure data does not become stranded in either the receive FIFO or the DMA receive buffer. Support for end of packet processing must be implemented in both the serial interfaces and the DMA controller.

The condition that signals the end of packet is different for each serial interface but is processed by the serial peripheral and DMA in the same way. For example, UART end of packet is signaled by idle line condition, I2C end of packet by STOP and/or Repeated START condition, and SPI end of packet by PCS negation.

When the serial peripheral is configured to signal end of packet condition to the DMA and an end of packet condition is detected by the serial interface, it asserts the DMA request for the receive FIFO irrespective of the watermark configuration. For larger watermark configurations, this ensures the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end of packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO is the start of a new packet, then data is not pulled from the receive FIFO and the serial interface signals an end of packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO is not the start of a new packet, the DMA will transfer the receive data as normal.

Since the DMA may be transferring multiple words on each request, the end of packet condition persists until the DMA minor loop has completed and no additional data is pulled from the receive FIFO. The status flag that triggered the end of packet condition is cleared when the minor loop completes following end of packet being signaled to the DMA controller.

When the DMA detects the end of packet condition, it writes all received words up to the end of packet into system memory and saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking and scatter/gather. The final destination address can optionally be saved to system memory or is available in the destination address register.

Since the DMA terminates the major loop, no servicing of the receive FIFO occurs until the DMA is reconfigured through either software or hardware (for example, channel linking or scatter-gather). This delay should be minimized to avoid receiver FIFO overrun. The automatic DMA end of packet processing is not recommended when there are only a few words transferred between end of packet conditions since the DMA will spend more time processing the end of packet than transferring the data. For example, the UART idle line length should be increased as needed to avoid an excessive number of idle conditions.

63.3.6 Clocks

Table 1032. LPSPI clocks

LPSPI functional clock	• Asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups, in both Master and Slave modes. • LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least 2 times faster than the SPI external clock frequency (SCK).
External clock	• The LPSPI shift register is clocked directly by the SCK clock. • How the SCK clock is generated or supplied depends upon the mode (Master or Slave): — In Master mode: the SCK clock is generated internally. — In Slave mode: the SCK clock is supplied externally.
Bus clock	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

See the chip-specific LPSPI information.

63.3.7 Resets

Table 1033. Resets

Chip reset	Resets the LPSPI logic and registers to their default state.
Software reset	• Resets the LPSPI logic and registers to their default state, except for the Control Register. • The LPSPI software reset is controlled using CR[RST].
FIFO resets	• Resets the transmit and command FIFO and the receive FIFO. • The Reset Transmit FIFO field, CR[RTF], and the Reset Receive FIFO field, CR[RRF], are write only. • After being reset, a FIFO is empty.

63.3.8 Peripheral triggers

The connection of the LPSPI peripheral triggers to other peripherals depend upon the specific device being used.

Table 1034. Peripheral triggers

Trigger	Description	Notes
Frame output trigger	The frame output trigger: • Asserts at the end of each frame (when PCS deasserts) • Remains asserted for one cycle of LPSPI functional clock divided by the PRESCALE configuration	LPSPI generates two output triggers that can be connected to other peripherals on the chip.
Word output trigger	The word output trigger: • Asserts at the end of each received word • Remains asserted for one cycle of LPSPI functional clock divided by the PRESCALE configuration	
Input trigger	To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input. • The LPSPI input trigger is synchronized, and must assert for at least 2 cycles of the LPSPI functional clock divided by the PRESCALE configuration, so that the input trigger can be detected. • When the LPSPI module is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • Both HREQ and the LPSPI input trigger are ignored when the module is busy. They are used to start a new transfer when the module is idle.	

63.4 Signals

Table 1035. Signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in Slave mode • Output in Master mode	I/O

Table continues on the next page...

Table 1035. Signals (continued)

Signal	Name	Description	I/O
PCS[0]	Peripheral chip select	• Input in Slave mode • Output in Master mode	I/O
PCS[1] / HREQ	Peripheral chip select or host request	Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0 • Input in either Slave mode or when used as master host request • Output in either Master mode or when used as slave host request	I/O
PCS[2] / DATA[2]	Peripheral chip select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[3] / DATA[3]	Peripheral chip select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
SOUT / DATA[0]	Serial data output	Can be configured as serial data input signal • Used as data pin 0 in half-duplex parallel data transfers	I/O
SIN / DATA[1]	Serial data input	Can be configured as serial data output signal • Used as data pin 1 in half-duplex parallel data transfers	I/O

63.5 Memory map and registers

NOTE

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

63.5.1 LPSPI register descriptions

LPSPI provides an efficient interface to a SPI bus, either as a master or slave. A SPI bus is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

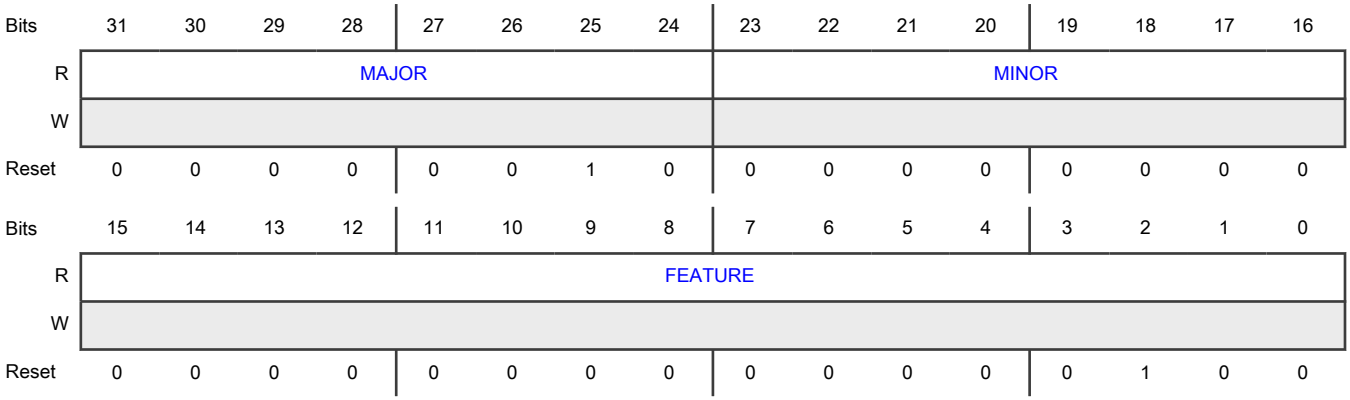
63.5.1.2 Version ID (VERID)

Offset

Register	Offset
VERID	0h

Function
Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number for the module specification.
23-16 MINOR	Minor Version Number Indicates the minor version number for the module specification.
15-0 FEATURE	Module Identification Number Indicates the feature set number. 0000_0000_0000_0100b - Standard feature set supporting a 32-bit shift register. All other values are reserved.

63.5.1.3 Parameter (PARAM)

Offset

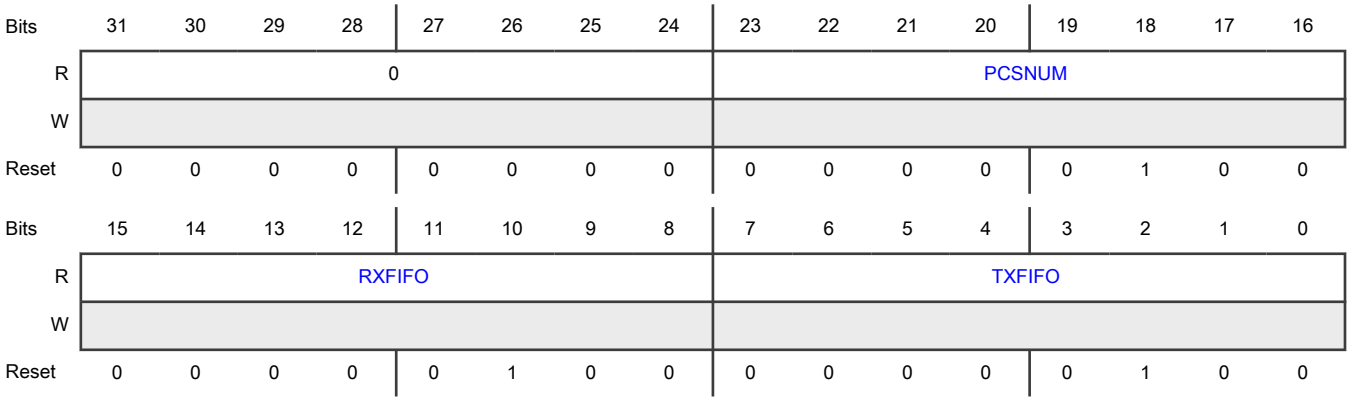
Register	Offset
PARAM	4h

Function

Contains:

- Number of PCS pins
- Receive FIFO size
- Transmit FIFO size

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 PCSNUM	PCS Number Indicates the number of PCS pins supported.
15-8 RXFIFO	Receive FIFO Size Indicates the maximum number of words in the receive FIFO. The maximum number of words is 2^{RXFIFO}.
7-0 TXFIFO	Transmit FIFO Size Indicates the maximum number of words in the transmit FIFO. The maximum number of words is 2^{TXFIFO}.

63.5.1.4 Control (CR)

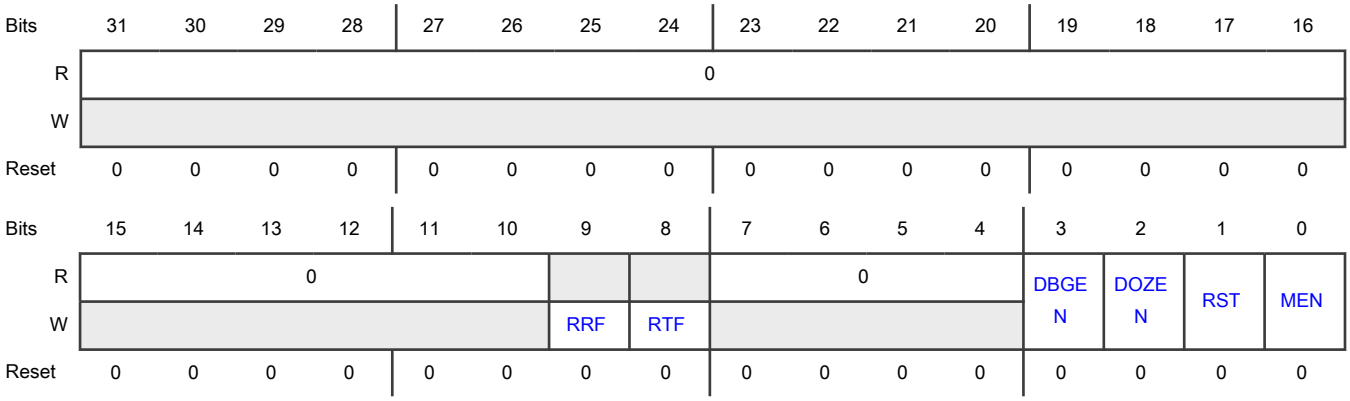
Offset

Register	Offset
CR	10h

Function

Contains fields that control module operation.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Deletes all entries in the receive FIFO. This field always reads 0. 0b - No effect 1b - Reset
8 RTF	Reset Transmit FIFO Deletes all entries in the transmit FIFO. This field always reads 0. 0b - No effect 1b - Reset
7-4 —	Reserved
3 DBGEN	Debug Enable Enables LPSPI in when the CPU is in Debug mode. When this field is 0, LPSPI is disabled when the CPU is halted; the PCS pin is deasserted after the transmit FIFO is empty regardless of the state of Transmit Command (TCR). Update this field only when the LPSPI module is disabled (MEN = 0). 0b - Disable 1b - Enable
2 DOZEN	Doze Mode Enable Enables LPSPI when the chip is in Doze mode. Update this field only when the LPSPI module is disabled (MEN = 0).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enable 1b - Disable
1 RST	Software Reset Resets all internal logic and registers, except Control (CR). The reset takes effect immediately and remains asserted until you write 0 to it. There is no minimum delay required before clearing the software reset by writing 0. 0b - Not reset 1b - Reset
0 MEN	Module Enable After writing 0, MEN remains set until the LPSPI has completed the current transfer and is idle. 0b - Disable 1b - Enable

63.5.1.5 Status (SR)

Offset

Register	Offset
SR	14h

Function
Contains data flow status.

63.5.1.8 Configuration 0 (CFGR0)

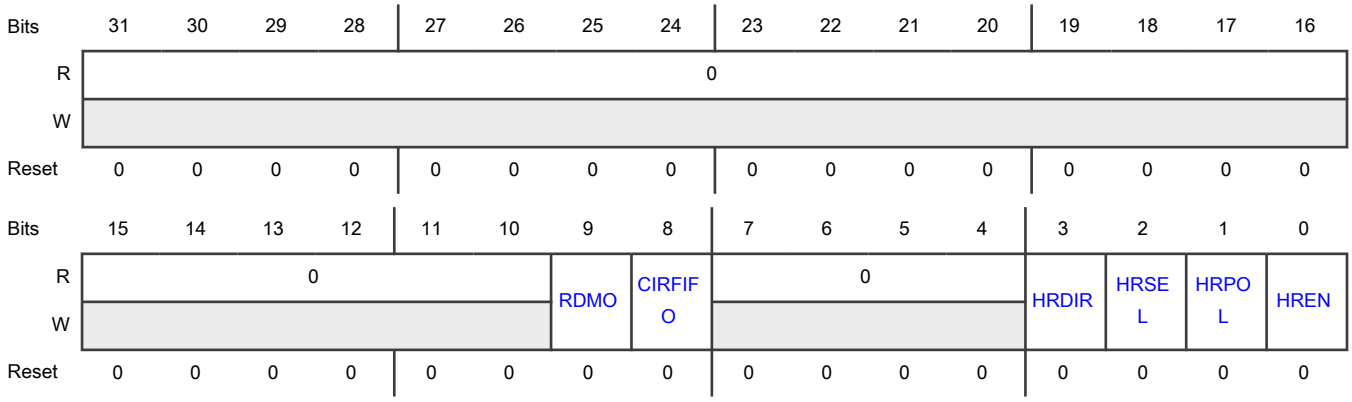
Offset

Register	Offset
CFGR0	20h

Function

Includes fields to configure LPSPI.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RDMO	Receive Data Match Only When enabled, all received data that does not cause the Data Match Flag (SR[DMF]) to assert is discarded. • Write 1 to this field when LPSPI is idle and SR[DMF] = 0. • After SR[DMF] = 1, this field is ignored. • To ensure that no receive data is lost when disabling RDMO, write 0 to this field before clearing SR[DMF]. See CFGR1[MATCFG] for the received data matching options. When disabled, all received data is stored in the receive FIFO. 0b - Disable 1b - Enable
8 CIRFIFO	Circular FIFO Enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as in normal operation, but when LPSPI is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly. **NOTE** The read pointer is restored for as long as this field is 1. Writing additional words to the FIFO when this field is 1 adds them to the end of the FIFO, up to the size of the transmit FIFO. 0b - Disable 1b - Enable
7-4 —	Reserved
3 HRDIR	Host Request Direction Specifies the direction of the HREQ pin. Only configure the HREQ pin as an output when LPSPI is in Slave mode. The HREQ pin direction must be an input for Master mode. 0b - Input 1b - Output
2 HRSEL	Host Request Select Specifies the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled. 0b - HREQ pin 1b - Input trigger

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 HRPOL	Host Request Polarity Specifies the polarity of the HREQ pin or input trigger. 0b - Active high 1b - Active low
0 HREN	Host Request Enable In Master mode, allows LPSPI to start a new SPI bus transfer only if the host request input is asserted. When LPSPI is busy, the host request input is ignored. In Slave mode, causes the HREQ output pin to assert when data is available to be transmitted. 0b - Disable 1b - Enable

63.5.1.9 Configuration 1 (CFGR1)

Offset

Register	Offset
CFGR1	24h

Function

Includes fields to configure LPSPI. Write to this register only when LPSPI is disabled.

Table continued from the previous page...

Field	Function
	NOTE The entire PCSPOL field is not fully supported in every LPSPI module instance. See the LPSPI chip-specific information.
7-5 —	Reserved
4 PARTIAL	Partial Enable Specifies whether LPSPI, when in Slave mode, stores a partial received word in the receive FIFO, or discards it, when PCS deasserts. See Partial received word. 0b - Discard 1b - Store
3 NOSTALL	No Stall Disables a normal operating feature that causes LPSPI, when in Master mode, to stall transfers when the transmit FIFO is empty or when the receive FIFO is full. This feature prevents transmit FIFO underruns and receive FIFO overruns. Writing 1 to this field disables this functionality. 0b - Disable 1b - Enable
2 AUTOPCS	Automatic PCS Enables automatic PCS generation. For correct operation in Slave mode, LPSPI requires the PCS signal to deassert between frames. Writing 1 to this field generates an internal PCS signal at the end of each transfer word when TCR[CPHA] = 1. When this field is 1, SCK must remain idle for at least 4 LPSPI functional clock cycles, divided by the prescaler selected (see TCR[PRESCALE]) between each word, to ensure correct operation. This field is ignored in Master mode. 0b - Disable 1b - Enable
1 SAMPLE	Sample Point Specifies the SCK clock edge on which LPSPI, when in Master mode, samples input data. Writing 1 to this field causes LPSPI to sample input data on a delayed loopback SCK clock edge, which improves the setup time when sampling data (see Clock loopback). In this configuration. The input data setup time in Master mode is equal to the input data setup time in Slave mode. In Slave mode, this field is ignored. **NOTE** When SAMPLE = 1 both the input buffer and output buffer must be enabled for the SCK pin. 0b - SCK edge 1b - Delayed SCK edge

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 MASTER	Master Mode Specifies the LPSPI operating mode—either Master or Slave. This field directly controls the direction of the SCK and PCS pins. 0b - Slave mode 1b - Master mode

63.5.1.10 Data Match 0 (DMR0)

Offset

Register	Offset
DMR0	30h

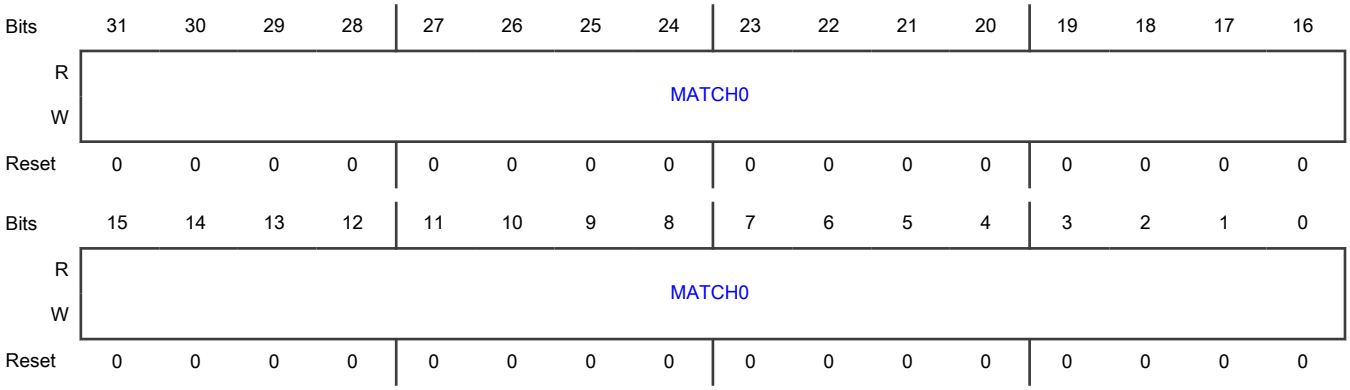
Function

Specifies match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register while CFGR1[MATCFG] > 0.

Diagram



Fields

Field	Function
31-0 MATCH0	Match 0 Value MATCH0 value to be compared against received data.

63.5.1.11 Data Match 1 (DMR1)

Offset

Register	Offset
DMR1	34h

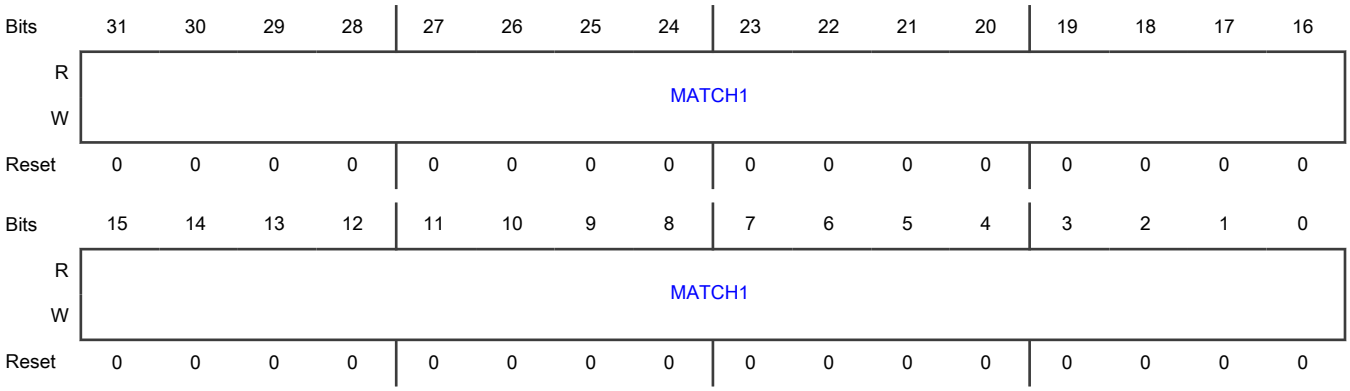
Function

Specifies match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register while CFGR1[MATCFG] > 0.

Diagram



Fields

Field	Function
31-0 MATCH1	Match 1 Value MATCH1 value to be compared against received data.

63.5.1.12 Clock Configuration (CCR)

Offset

Register	Offset
CCR	40h

Function

Contains clock configuration fields. These fields are only used in Master mode and you can only change them when LPSPI is disabled (CR[MEN] = 0).

Warning

Writing a 32-bit value to this register overwrites Clock Configuration 1 (CCR1); DBT and SCKDIV always read 0.

To avoid overwriting CCR1:

- Either write all 4 CCR register fields simultaneously and only once in a 32-bit data.
- Or to modify SCKPCS and/or PCSSCK values, write only these 2 upper bytes in a 16-bit data or one of them in an 8-bit data.
- Or to modify CCR1[PCSPCS] and CCR1[SCKSCK] fields only or CCR1[SCKSET] and CCR1[SCKHLD] fields only, write respectively CCR[DBT] or CCR[SCKDIV] in 8-bit data

Diagram

Fields

Field	Function
31-24 SCKPCS	SCK-to-PCS Delay In Master mode: configures the delay from the last SCK edge to the PCS negation. • The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. See Figure 468.
23-16 PCSSCK	PCS-to-SCK Delay In Master mode: configures the delay from the PCS assertion to the first SCK edge. • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. See Figure 468.
15-8 DBT	Delay Between Transfers Writing this field updates the contents of CCR1[PCSPCS] and CCR1[SCKSCK].
7-0	SCK Divider

Table continues on the next page...

Table continued from the previous page...

Field	Function
SCKDIV	Writing this field updates the contents of CCR1[SCKSET] and CCR1[SCKHLD]. Baud rate = Function clock / (2^PRESCALE * (SCKSET+SCKHLD+2))

63.5.1.13 Clock Configuration 1 (CCR1)

Offset

Register	Offset
CCR1	44h

Function

Contains clock configuration fields. These fields are only used in Master mode and you can only change them when LPSPI is disabled (CR[MEN] = 0).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SCKSCK								PCSPCS							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SCKHLD								SCKSET							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 SCKSCK	SCK Inter-Frame Delay In Master mode: • Configures the delay from the last SCK pulse of a frame and the first SCK pulse of the following frame, in a continuous transfer. • The delay is equal to (SCKSCK + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE For backward compatibility, writing CCR[DBT] updates CCR1[SCKSCK] with the value written.
23-16 PCSPCS	PCS to PCS delay In Master mode: • Configures the delay from the PCS negation to the next PCS assertion. • The delay is equal to (PCSPCS + PCSPCS + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 2 cycles. • Half of the delay (PCSPCS + 1) occurs before PCS assertion and the other half of the delay (PCSPCS + 1) occurs after PCS negation. If the command word is updated between 2 transfers, then the command word is updated halfway between the PCS negation of the last transfer and PCS assertion of the next transfer. • The command word specifies which PCS signal is used, the polarity and phase of the SCK signal, and the prescaler selected. **NOTE** For backward compatibility, writing CCR[DBT] updates this field with (DBT÷2) rounded up.
15-8 SCKHLD	SCK Hold In Master mode, this field configures the hold phase of the SCK pin. • The hold phase is the delay between the SCK edge that samples the receive data and the SCK edge that drives the transmit data. • This is the SCK low period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. This is the SCK high period when CPHA = 0, CPOL = 0 and CPHA = 1, CPOL = 1. • The SCK hold phase delay is equal to (SCKHLD + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. Configure both fields to the same value for 50/50 duty cycle. See Figure 468. **NOTE** For backward compatibility, writing CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded down.
7-0 SCKSET	SCK Setup In Master mode, the SCK Setup configures the setup phase of the SCK pin.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The setup phase is the delay between the SCK edge that drives the transmit data and the SCK edge that samples the receive data. • This is the SCK high period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. This is the SCK low period when CPHA = 0 and CPOL = 0, or CPHA = 1 and CPOL = 1. • The SCK setup phase delay is equal to (SCKSET + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD, configure both fields to the same value for 50/50 duty cycle. See Figure 468. **NOTE** For backward compatibility, writing CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded up.

63.5.1.14 FIFO Control (FCR)

Offset

Register	Offset
FCR	58h

Function

Contains the receive FIFO and transmit FIFO watermark values.

Diagram

Fields

Field	Function
31-24 —	Reserved
23-21 —	Reserved
20-16 RXCOUNT	Receive FIFO Count Indicates the number of words currently stored in the receive FIFO.
15-8 —	Reserved
7-5 —	Reserved
4-0 TXCOUNT	Transmit FIFO Count Indicates the number of words currently stored in the transmit FIFO.

63.5.1.16 Transmit Command (TCR)

Offset

Register	Offset
TCR	60h

Function

Writes to either this register or Transmit Data (TDR) push the data into the transmit FIFO, in the order written. Only write to this register using 32-bit writes. Writes are tagged and cause the command register to update, after that entry reaches the top of the FIFO and the LPSPI is enabled. This allows changes to the command word and the transmit data itself to be interleaved. That is, the writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word.

- **In Master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is 1. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK = 1). Hardware writes 0 to TXMSK when the PCS deasserts.
- **In Master mode,** if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word then updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is 1 and the command word is written on a frame size boundary.
- **In Slave mode,** the command word should be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid resetting the Transmit FIFO after writing to the Transmit Command Register, wait for the command register to update from the FIFO first.

Avoid register reading problems: Reading the Transmit Command Register returns the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended to:

- Read the Transmit Command Register when the transmit FIFO is empty,
- Read the Transmit Command Register more than once and then compare the returned values.

Fields

Field	Function
31 CPOL	Clock Polarity Specifies the value of SCK when it is idle. This field can only be updated when PCS deasserted. See Figure 468. 0b - Inactive low 1b - Inactive high
30 CPHA	Clock Phase This field can only be updated when PCS deasserted. See Figure 468. 0b - Captured. Data is captured on the leading edge of SCK and changed on the following edge of SCK 1b - Changed. Data is changed on the leading edge of SCK and captured on the following edge of SCK
29-27 PRESCALE	Prescaler Value For all SPI bus transfers, this value is applied to Clock Configuration (CCR) clock. This field can only be updated when PCS deasserted. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4

Table continues on the next page...

Table continued from the previous page...

Field	Function
	011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128
26 —	Reserved
25-24 PCS	Peripheral Chip Select Configures the peripheral chip select used for the transfer. The Peripheral Chip Select field is only updated when PCS deasserted. **NOTE** The entire PCS field is not fully supported in every LPSPI module instance. See the chip-specific LPSPI information. 00b - Transfer using PCS[0] 01b - Transfer using PCS[1] 10b - Transfer using PCS[2] 11b - Transfer using PCS[3]
23 LSBF	LSB First 0b - Data is transferred MSB first 1b - Data is transferred LSB first
22 BYSW	Byte Swap Swaps the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Disabled 1b - Enabled
21 CONT	Continuous Transfer • In Master mode, CONT keeps the PCS asserted at the end of the frame size, until a command word is received that starts a new frame. • In Slave mode, when CONT is enabled, LPSPI only transmits the first FRAMESZ bits; after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation. 0b - Continuous transfer is disabled 1b - Continuous transfer is enabled
20	Continuing Command

Table continues on the next page...

Table continued from the previous page...

Field	Function
CONTC	In Master mode, this field enables the command word to be changed within a continuous transfer. • The initial command word must enable continuous transfer (CONT = 1). • The continuing command must have CONTC = 1. • The continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary. In Slave mode, the Continuing Command bit modifies the internal RXMSK/TXMSK configuration after the first FRAMESZ bits and until the PCS negation. • Receive data is discarded after the first FRAMESZ bits. If CONT is also 1 this does not block the transmission of received data. • Transmit data is not masked after the first FRAMESZ bits, this allows the first FRAMESZ bits to be received and a response transmitted. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19 RXMSK	Receive Data Mask Masks receive data (receive data is not stored in receive FIFO). 0b - Normal transfer 1b - Receive data is masked
18 TXMSK	Transmit Data Mask Masks transmit data (no data is loaded from transmit FIFO and the output pin is 3-stated). In Master mode, TXMSK initiates a new transfer which cannot be aborted by another command word. TXMSK automatically transitions to 0 at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width Configures serial (1-bit) or parallel transfers. For half-duplex parallel transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be 1. 00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
15-12 —	Reserved
11-0	Frame Size

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRAMESZ	Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.

63.5.1.17 Transmit Data (TDR)

Offset

Register	Offset
TDR	64h

Function

Writes to either Transmit Command (TCR) or this register push the data into the transmit FIFO, in the order that the data is written. You can write to TDR using 32-, 16-, or 8-bit writes, but each write pushes data into the FIFO with zero pushed in unwritten bytes.

Diagram

NOTE

See clock and Power chapter for details about low-power modes available in this chip.

64.2 Overview

LPUART provides asynchronous, serial communication capabilities with external devices. It supports the non-return-to-zero (NRZ) encoding format and infrared data association (IrDA)-compatible, low-speed serial infrared (SIR) protocol. LPUART can continue operating when the processor is in Low-Power mode, if an appropriate peripheral clock is available.

64.2.1 Block diagram

Figure 470 shows the transmitter portion of LPUART.

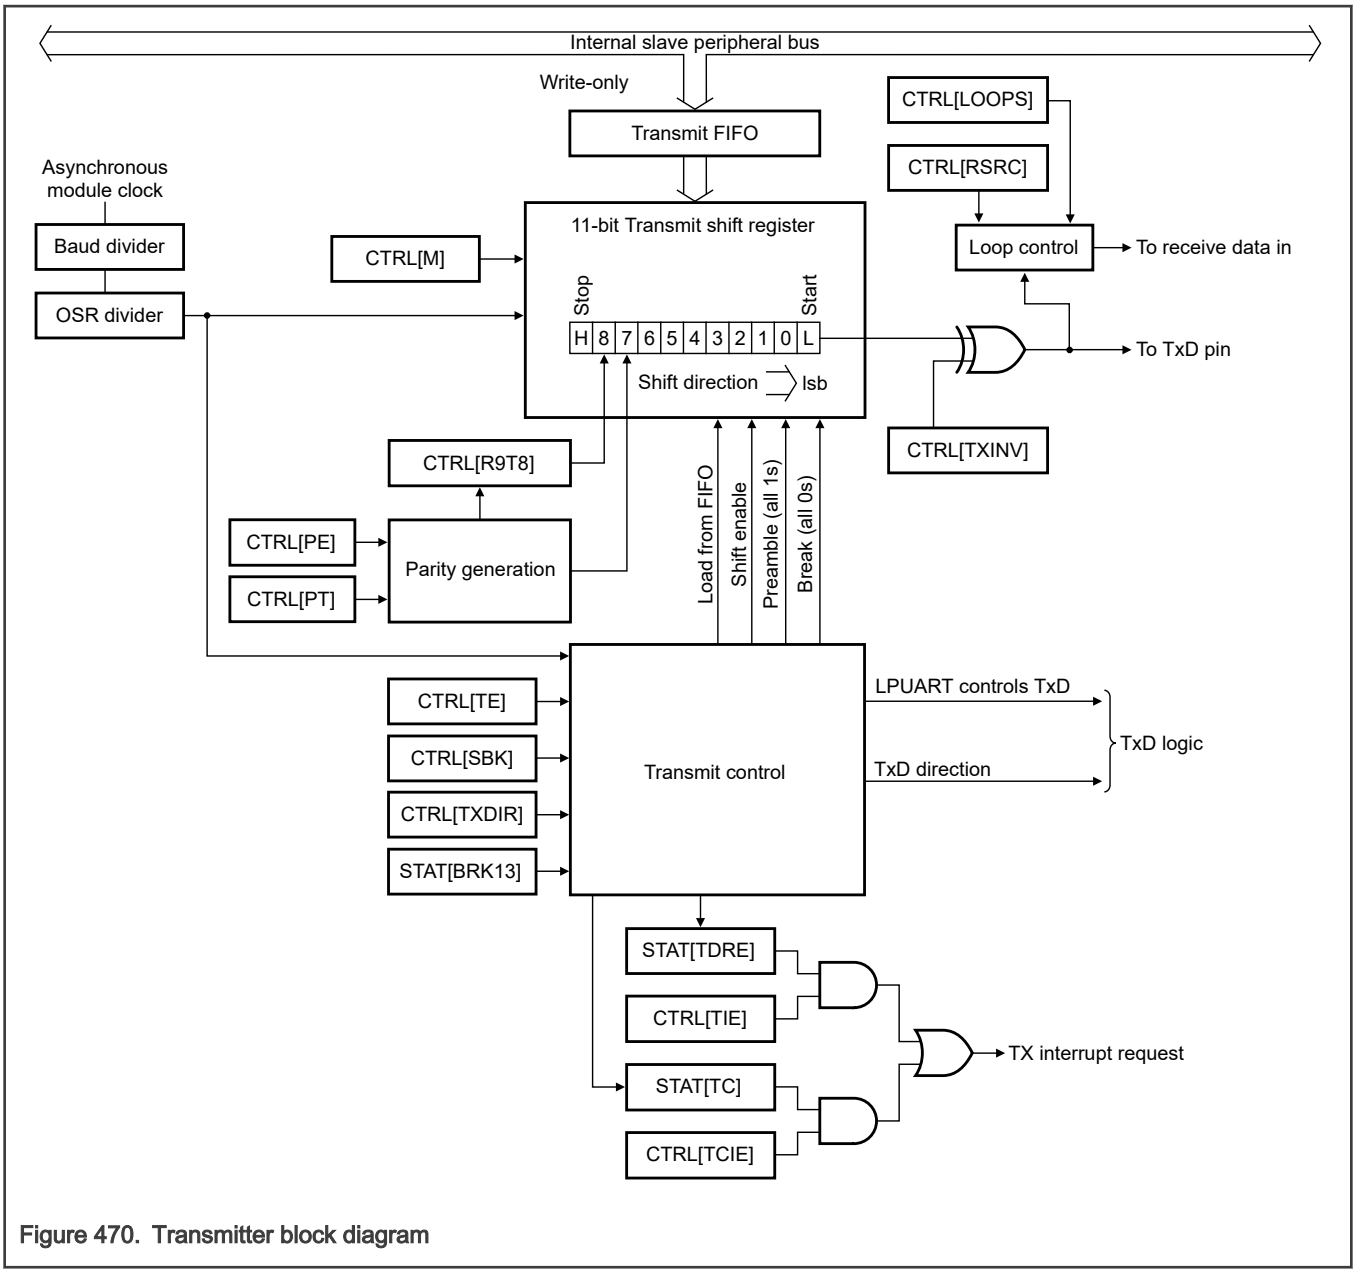

Figure 470. Transmitter block diagram

Figure 471 shows the receiver portion of LPUART.

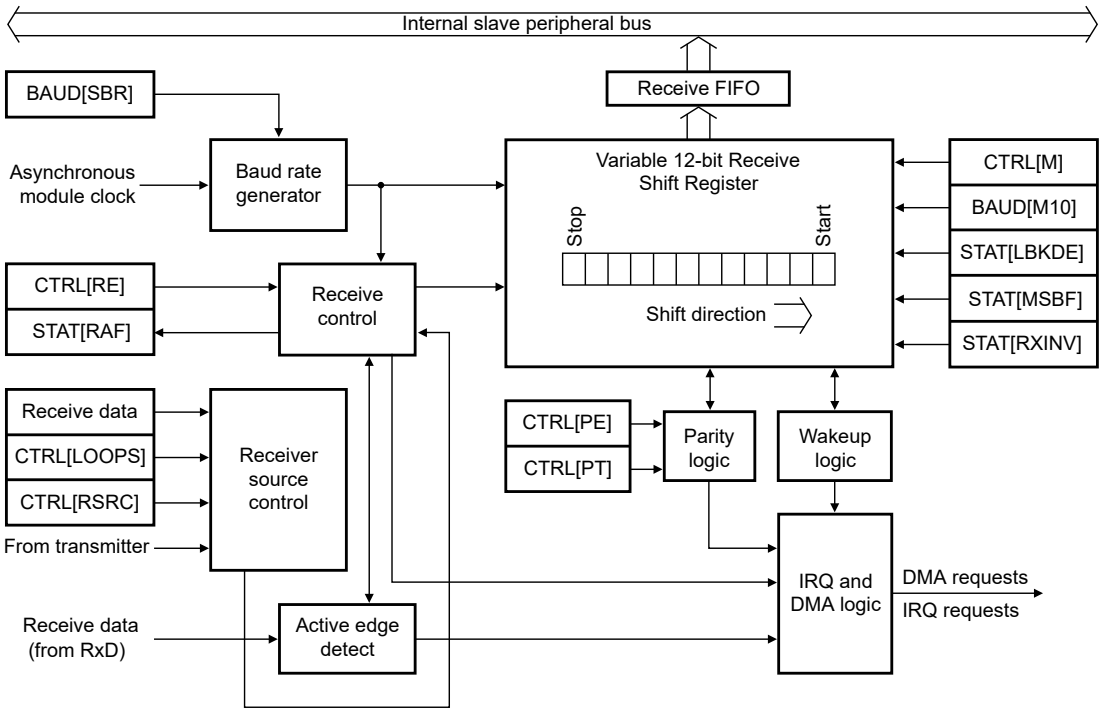

Figure 471. Receiver block diagram

64.2.2 Features

- Full-duplex, standard NRZ format
- Programmable baud rates (13-bit modulo divider) with a configurable oversampling ratio (OSR) from 4× to 32×
- Asynchronous operation of transmit and receive baud rates with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency.
  - Operation in Low-Power modes is supported.
- Interrupt, DMA, or polled operations:
  - Transmit data empty and transmission complete
  - Receive data full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit, or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wake-up methods:
  - Idle line wake-up

  - Address mark wake-up
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit and 11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with a programmable pulse width
- Independent FIFO structure for transmit and receive functions:
  - Separate configurable watermarks for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters, if receive FIFO is not empty

64.3 Functional description

LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following sections describe all LPUART blocks.

64.3.1 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and transmitter. The value, ranging from 1 to 8191, written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while a bit clock, generated from the baud rate clock divided by the OSR, drives the transmitter. Depending on the OSR, the receiver has an acquisition rate of 4 to 32 samples per bit time.

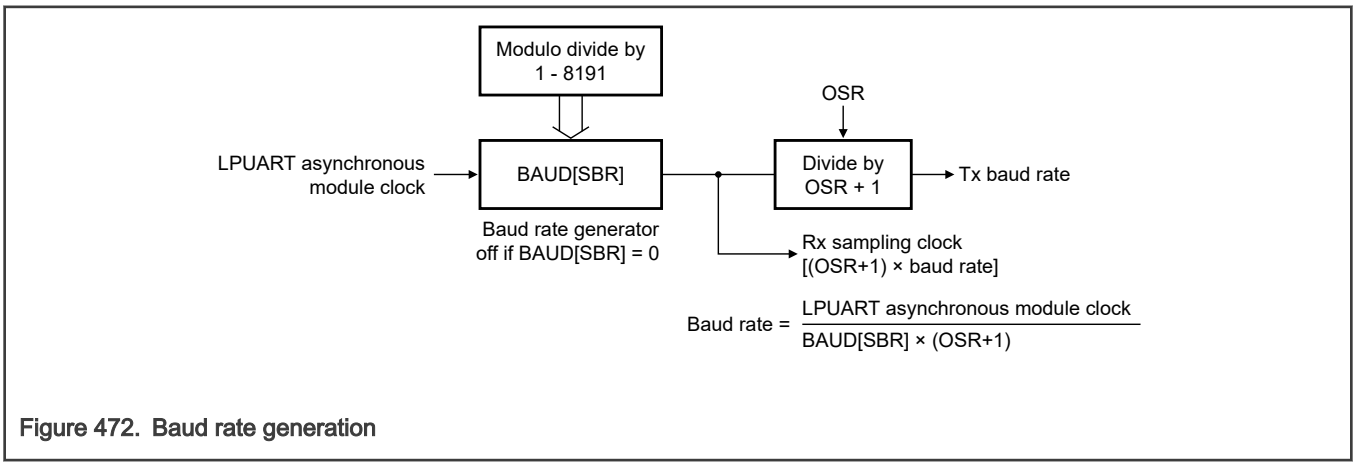

Figure 472. Baud rate generation

Baud rate generation is subject to these sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can lead to a phase shift.

Baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher ratio and/or sampling on both edges of the clock slightly improves LPUART's tolerance to baud rate mismatch between the received data and LPUART configured baud rate. However, the three data samples in each bit (see Data sampling technique) are also closer together, which may impact noise sensitivity.

64.3.2 Baud rate tolerance

A transmitting device may operate at a baud rate below or above that of the receiver.

Accumulated bit time misalignment can cause one of the three stop bit data samples to fall outside the actual stop bit. A noise error will occur if the three samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the three stop bit samples are a logic zero.

As the receiver samples an incoming frame, it may re-synchronize the oversampling clock on any valid falling edge within the frame. Resynchronization within frames will correct a misalignment between transmitter bit times and receiver bit times.

In general, increasing the number of samples per bit will increase the baud rate tolerance and decreasing the number of samples per bit will reduce the baud rate tolerance. Note that since LPUART implements triple voting on consecutive receive data samples, increasing the number of samples per bit will move those samples closer together which would reduce the width of noise that can be filtered by the triple voting logic.

64.3.3 Calculating baud rate tolerance

Using the following definitions:

- SAM is the number of sample points per bit (valid range from 8 to 32; equal to (OSR + 1) × (BOTHEDGE + 1)).
- BIT is the number of bits in a character including start, data and stop bits (valid range from 9 to 13).

The ideal baud rate tolerance can be calculated as follows:

- Slow data rate tolerance = ((SAM ÷ 2) - 1) ÷ ((SAM × BIT) - (SAM ÷ 2) + 2)
- Fast data rate tolerance = ((SAM ÷ 2) - 2) ÷ (SAM × BIT)

As an example, if configured for 8-bit data, 1 stop bit (BIT = 10) and with OSR=0x7 and BOTHEDGE = 1 (SAM = 16):

- Slow data rate tolerance = (8 - 1) ÷ (160 - 8 + 2) = 7 ÷ 154 = 4.54%
- Fast data rate tolerance = (8 - 2) ÷ 160 = 6 ÷ 160 = 3.75%

If configured for 9-bit data with 1 stop bit (BIT = 11) with same oversampling configuration, then:

- Slow data rate tolerance = (8 - 1) ÷ (176 - 8 + 2) = 7 ÷ 170 = 4.12%
- Fast data rate tolerance = (8 - 2) ÷ 176 = 6 ÷ 176 = 3.41%

NOTE

Additional factors can contribute to a lower baud rate tolerance than the ideal. These include clock uncertainty or jitter on the LPUART functional clock source, differences in rise and fall times on the transmitter output and synchronization of the external receive pin to the local LPUART functional clock.

64.3.4 Transmitter functional description

This section describes the functioning of the LPUART transmitter, as shown in the transmitter portion of Block diagram, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted when you write 1 to CTRL[TXINV], which becomes 0 following reset. You can enable the transmitter by writing 1 to CTRL[TE]. This queues a preamble character that is one full character frame of the Idle state. The transmitter then remains idle until data is available in the transmit FIFO and programs store data in the transmit FIFO by writing to Data (DATA).

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the settings of CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS]. Going forward in this discussion, assume that CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] are 0, selecting the normal 8-bit Data mode, in which the shift register holds a start bit, eight data

bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in transmit FIFO is transferred to the transmit shift register, synchronized with the baud rate clock, and STAT[TDRE] becomes 1 to indicate that another character may be written to the transmit FIFO at Data (DATA).

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character, or break character), although the transmitter does not start transmitting another character.

64.3.4.1 Break character length

CTRL[SBK] sends break characters, originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times, including the start and stop bits. You can enable a longer break of 13-bit times by writing 1 to STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, the program writes 1 and then writes 0 to CTRL[SBK]. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized with the baud rate clock, an additional break character is queued. When LPUART is the receiving module, it receives a break character as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

You can also transmit a break character by writing to Data (DATA) with DATA[FRETSC] = 1 and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows DMA to transmit a break character.

When idle line wake-up is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, write 0 and then write 1 to CTRL[TE]. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] becomes 0, the LPUART transmitter does not release control of the TXD pin.

You can also write to Data (DATA) to transmit an idle character, with DATA[FRETSC] and DATA[R9T9] = 1 and the values of all the other fields = 0. This supports transmitting the idle character as part of the normal data stream and also allows DMA to transmit an idle character.

As shown in the following table, STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] affect the length of the break character.

Table 1037. Break character length

STAT[BRK13]	CTRL[M]	BAUD[M10]	CTRL[M7]	BAUD[SBNS]	Break character length (in bit times)
0	0	0	0	0	10
0	0	0	0	1	11
0	0	0	1	0	9
0	0	0	1	1	10
0	1	0	—	0	11
0	1	0	—	1	12
0	—	1	—	0	12
0	—	1	—	1	13
1	0	0	0	0	13
1	0	0	0	1	13
1	0	0	1	0	12

Table continues on the next page...

Table 1037. Break character length (continued)

STAT[BRK13]	CTRL[M]	BAUD[M10]	CTRL[M7]	BAUD[SBNS]	Break character length (in bit times)
1	0	0	1	1	12
1	1	0	—	0	14
1	1	0	—	1	14
1	—	1	—	0	15
1	—	1	—	1	15

64.3.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the CTS operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register is complete. Any characters in the FIFO wait for CTS_B to assert again, and TXD remains in the mark state (idle state) until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee that a new transmission is started when the transmitter is idle with CTS.

If the CTS operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can be enabled even if the same LPUART receiver's RTS_B signal is disabled.

64.3.4.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the RTS operation is enabled, when a character is placed into an empty transmit shift register, RTS_B asserts 1-bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmit shift register has any characters. RTS_B deasserts 1-bit time after all characters in the transmit FIFO and shift register are completely sent, including the last stop bit. In other words, when RTS_B is used as a transceiver enable, RTS_B asserts 1-bit time before the transmitter starts transmitting and negates 1-bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled mid-way through a data transfer.

You can configure HDCR[RTSEXT] to the desired length by delaying the transmitter's RTS_B negation by up to 256-bit clock (baud rate) after the last stop bit.

64.3.4.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is three-stated unless LPUART is driving. The transmitter can use the RTS_B signal to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

The following figure shows the receiver enable signal asserted. This connection can also connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled when driving. A pullup can pull RXD to a nonfloating value during this time. You can refine this option further by operating LPUART in Single-Wire mode, freeing the RXD pin for other uses.

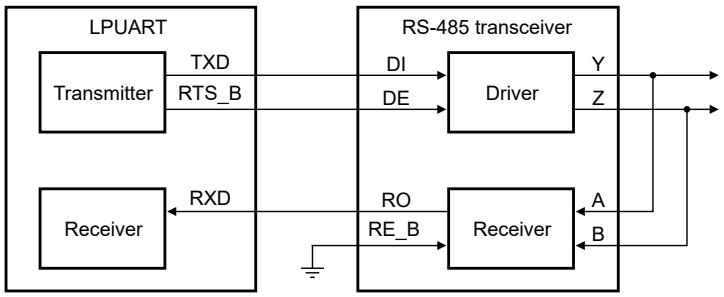

Figure 473. Transceiver driver enable using RTS_B

64.3.5 Receiver functional description

This section discusses the functioning of the LPUART receiver, as shown in the receiver portion of Block diagram. The section also discusses:

- The data sampling technique used to reconstruct receiver data.
- Different variations of the receiver wake-up function.

You can invert the receiver input by writing 1 to STAT[RXINV] and enable the receiver by writing 1 to CTRL[RE]. Character frames consist of a start bit of logic 0, along with N (7, 8, 9, 10) bits (MSB or LSB first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit, or 10-bit Data mode, see Data modes. Going forward in this discussion, assume that LPUART is configured for a normal 8-bit Data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full (STAT[RDRF] = 0), the data character is transferred to the receive FIFO, resulting in STAT[RDRF] becoming 1. However, if STAT[RDRF] is already 1, indicating that the receive data buffer is already full, STAT[OR] becomes 1 and the new data is lost.

Because the LPUART receiver is separate from the receive FIFO, the receive shift register can receive the next word when the receive FIFO is full, and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if the FIFO is full.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the FIFO by reading Data (DATA). See Interrupts for details about flag clearing.

64.3.5.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by considering logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2 to ensure that this is a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes they are synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2, to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, noise flag (STAT[NF]) becomes 1 when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE] = 1), the number of segments in each received bit is effectively doubled (from 1 to OSR× 2). The start and data bits are then sampled at OSR, OSR + 1, and OSR + 2. You must enable sampling on both edges of the clock for oversampling rates of 4× to 7×. This sampling is optional for higher oversampling rates.

The synchronization feature of LPUART synchronizes the internal oversampling counter with a detected falling edge on the receive signal, and to adjust the data sampling window. The falling edge detection needs three consecutive 1s prior to the "1->0" (one to zero) transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter after another falling edge is detected. This synchronization to the start bit is termed as resynchronizarion.

When BAUD[RESYNCDIS] is 0, you perform this falling edge detection and resynchronization not only for the start bit but also for the rest of the character reception after the start bit.

When BAUD[RESYNCDIS] is 1, you perform the falling edge detection and resynchronization only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

The following table and figure explain LPUART resynchronization.

Table 1038. LPUART resynchronization settings

Resynchronization	BAUD[RESYNCDIS] = 0	BAUD[RESYNCDIS] = 1
For the starting bit falling edge	Yes	Yes
For all falling edges after the start bit	Yes	No

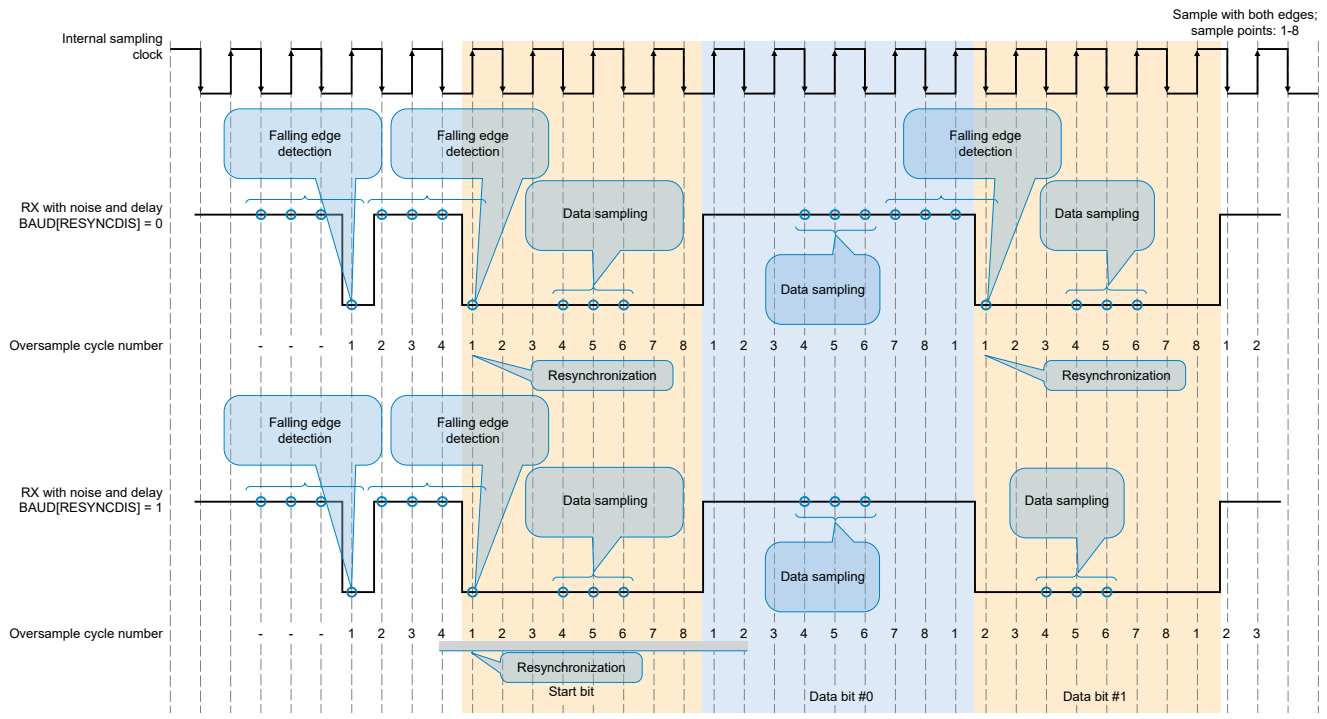

Figure 474. LPUART resynchronization diagram

64.3.5.2 Receiver wake-up operation

Receiver wake-up and receiver address matching are hardware mechanisms that allow an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wake-up, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write 1 to CTRL[RWU].

When CTRL[RWU] and STAT[RWUID] are 1, the status fields associated with the receiver, with the exception of STAT[IDLE], are inhibited from becoming 1, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to become 0. This results in all receivers waking up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 1039. Receiver wake-up options

CTRL[RWU]	BAUD[MAEN1] | BAUD[MAEN2]	BAUD[MATCFG]	CTRL[WAKE]: STAT[RWUID]	Receiver wake-up
0	0	X	X	Normal operation
1	0	00	00	Receiver wake-up on idle line; STAT[IDLE] = 0
1	0	00	01	Receiver wake-up on idle line; STAT[IDLE] = 1
1	0	00	10	Receiver wake-up on address mark
1	1	11	10	Receiver wake-up on data match
0	1	00	X0	Address mark address match; STAT[IDLE] = 0 for discarded characters
0	1	00	X1	Address mark address match; STAT[IDLE] = 1 for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Match on and match off; STAT[IDLE] = 0 for discarded characters
0	1	10	X1	Match on and match off; STAT[IDLE] = 1 for discarded characters

64.3.5.2.1 Idle line wake-up

When CTRL[WAKE] is 0, you can configure the receiver for an idle line wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a full character time of the idle-line level.

CTRL[M], CTRL[M7], and BAUD[M10] select 7-bit to 10-bit Data mode and BAUD[SBNS] selects a 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is 1 and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not lead to STAT[IDLE] becoming 1. The receiver wakes up and waits for the first data character of the next message that leads to STAT[RDRF] becoming 1 and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition leads to STAT[IDLE] becoming 1 and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

These are the ways to detect an idle line:

- When CTRL[ILT] is 0, the idle bit counter starts after the start bit so that the stop bit and any logic 1s at the end of a character count to calculate the full character time of idle.
- When CTRL[ILT] is 1, the idle bit counter does not start until after the stop bit time so that the data in the last character of the previous message does not impact the idle detection.

64.3.5.2.2 Address mark wake-up

When CTRL[WAKE] is 1, you can configure the receiver for an address mark wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address mark wake-up.

Address mark wake-up allows messages to contain idle characters, but requires one bit to be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame writes 0 to CTRL[RWU] and writes 1 to STAT[RDRF]. In this case, the character with the address mark bit is received even if the receiver is sleeping during most of this character time.

64.3.5.2.3 Data match wake-up

When CTRL[RWU] and CTRL[WAKE] are 1, and BAUD[MATCFG] equals 11, the receiver is configured for a data match wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a character that matches MATCH[MA1] when BAUD[MAEN1] is 1, or that matches MATCH[MA2] when BAUD[MAEN2] is 1.

64.3.5.2.4 Address match operation

You can enable the address match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 0. In this function, a character that the RXD pin receives with a logic 1 in the most significant bit (or the second most significant bit when parity is enabled) is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is only transferred to the receive buffer, and STAT[RDRF] becomes 1 if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or the second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs, no transfer is made to the receive FIFO, and all the characters that follow, with logic 0 in the most significant bit (or second most significant bit when parity is enabled), are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

The address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, a marked address is compared only to the associated Match Address (MATCH) and data is transferred to the receive FIFO only on a match.
- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, a marked address is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

64.3.5.2.5 Idle match operation

You can enable the idle match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 1. In this function, the first character that the RXD pin receives after an idle line condition is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is transferred only to the receive buffer, and STAT[RDRF] becomes 1, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive FIFO until the next idle line condition is detected. If no address match occurs, no transfer is made to the receive FIFO, and all the frames that follow, until the next idle condition, are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

An idle match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, the first character after an idle line is compared only to the associated Data (DATA) and data is transferred to the receive FIFO only on a match.

- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, the first character after an idle line is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

64.3.5.2.6 Match on, match off operation

The match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are 1 and BAUD[MATCFG] = 10. In this function, a character that the RXD pin receives matches MATCH[MA1] and is transferred to the receive buffer, and STAT[RDRF] becomes 1. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character that matches MATCH[MA2] is received. The character that matches MATCH[MA2], along with all subsequent characters, is discarded; and this continues until another character that matches MATCH[MA1] is received. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

NOTE

The match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be 1.

64.3.5.3 Hardware flow control

To support hardware flow control, you can program the receiver to automatically assert and deassert RTS_B:

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more information.
- If the receiver RTS functionality is enabled, the receiver automatically deasserts RTS_B if STAT[RDRF] is 1 or a start bit is detected that causes STAT[RDRF] to become 1.
- The receiver asserts RTS_B when STAT[RDRF] is 0 and has not detected a start bit that causes STAT[RDRF] to become 1. There is no impact if STAT[RDRF] is 1 already.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver RTS functionality is disabled, the receiver's RTS_B remains deasserted.

64.3.6 Additional LPUART functions

64.3.6.1 Data modes

You can configure the LPUART transmitter and receiver to operate in 7-bit Data mode by writing 1 to CTRL[M7], 9-bit Data mode by writing 1 to CTRL[M], or 10-bit Data mode by writing 1 to BAUD[M10]. In 9-bit Data mode, there exists a ninth data bit and in 10-bit mode, there exists a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the ninth and tenth bits are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, you must write to CTRL[T8] and CTRL[T9] before writing to Data (DATA)[7:0]. However, if the values in CTRL[T8] or CTRL[T9] do not need to change, it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to Data (DATA).

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10 bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the ninth and tenth bits are held in CTRL[R8] and CTRL[R9] but you must read them before reading Data (DATA). A 16-bit or 32-bit read of the receive FIFO returns all 10 bits in Data (DATA).

The 9-bit Data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with the address mark wake-up so that the ninth data bit can serve as the wake-up bit. The 10-bit Data mode is typically used with parity and address mark wake-up so that the ninth data bit can serve as the wake-up bit and the tenth bit can serve as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

64.3.6.2 Idle length

An idle character is one where the start bit, all data bits, and stop bits are in the mark position (idle state, generally logic 1). You can configure CTRL[ILT] to start detecting an idle character from the previous start bit (any data bits and stop bits count for idle character detection) or from the previous stop bit.

You can also use CTRL[IDLECFG] to configure the number of idle characters that must be received before an idle line condition is detected. This field configures the number of idle characters that must be received before STAT[IDLE] becomes 1, STAT[RAF] becomes 0, and DATA[IDLINE] becomes 1 with the next received character.

CTRL[IDLECFG] also affects the idle line wake-up and idle match operations. When either the address match or match on/off operation is enabled, writing 1 to STAT[RWUID] causes any discarded characters to be treated as idle characters.

After the extended idle time is enabled for the receiver, you can configure an idle line condition by using REIR[IDTIME], which specifies the number of bits (baud rate) since the last stop bit that is required for an idle condition to be detected. This replaces the configuration of CTRL[ILT] and CTRL[IDLECFG].

The transmitter can also enable the extended idle time. In this case, any idle character queued through the transmit FIFO forces the transmitter to be idled for the configured number of bit clocks before the idle character is read from the FIFO and the transmitter continues.

After you enable the transmitter extended idle time, the transmitter does not automatically queue an idle character whenever it is enabled.

64.3.6.3 Loop mode

Enable Loop mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 0. You, sometimes, use Loop mode to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and LPUART does not use the RXD pin.

Loop mode also internally connects the RTS_B output to the CTS_B input and the DTR_B output to the DSR_B input.

64.3.6.4 Single-Wire mode

Enable Single-Wire mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 1. Single-Wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and TXD pin (the RXD pin is not used).

In Single-Wire mode, CTRL[TXDIR] controls the direction of serial data on the TXD pin. When CTRL[TXDIR] becomes 0, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so that an external device can send serial data to the receiver. When CTRL[TXDIR] = 1, the TXD pin is an output that the transmitter drives. The internal loop back connection is disabled, and as a result, the receiver is unable to receive characters that the transmitter sends out.

Half Duplex Control (HDCR) replaces the implementation of CTRL[LOOPS] and CTRL[RSRC], and you can use this register to configure various options for both Single-Wire and Half-Duplex operations, using independent RXD and TXD pins:

- HDCR[TXSTALL] replaces the CTRL[TXDIR] functionality and prevents the transmitter from becoming busy or asserting the RTS_B transmitter if STAT[RAF] is 1.
- You can select the TXD pin, as the source for the receiver, to configure HDCR[RXSEL] for a single-wire operation. If HDCR[RXSEL] is 1, you must configure the TXD pin for an open-drain operation.
- HDCR[RXMSK] masks the receiver input when the RTS_B transmitter is asserted (this applies even if you have not configured RTS_B as an output).
- HDCR[RXWRMSK] blocks storage of the receive data in the receive FIFO when the RTS_B transmitter is asserted. This setting does not affect the receiver idle functionality.
- HDCR[RTSEXT] delays the negation of the RTS_B transmitter by the configured number of bit clocks (baud rate).

64.3.6.5 Timeout counter

LPUART implements four general-purpose timeout counters; counters 0 and 1 are used to monitor the receiver and counters 2 and 3 are used to monitor the transmitter. When enabled, you can configure each counter to monitor one of the following conditions:

- Idle time in number of bits, starting to increment when first enabled and an idle condition is detected. The counter restarts whenever a character is received or transmitted.
- Idle time in number of bits, starting to increment after the next character is received or transmitted. The counter restarts whenever a character is received or transmitted.

- Idle time is more than the timeout interval, in number of bits, but less than the extended idle timeout. The counter restarts whenever a character is received or transmitted. You can use this to detect a gap between characters that is greater than a threshold (timeout) but less than the configured extended idle time. This configuration requires the extended idle feature for the transmitter or receiver to be enabled for a proper operation.
- Number of characters received or transmitted is equal to the configured timeout. The counter asserts at the start of the character that equals the timeout value.

The timeout counters restart counting whenever the counter is disabled and then enabled. These timeout counters are disabled when the corresponding STAT[TSF] field is 1. If the timeout enable is still set after STAT[TSF] becomes 0, the timeout counter restarts as if the counter had been disabled and then enabled. You can measure the idle time in bit times from the end of the last stop bit and until a start bit is validated.

64.3.7 Peripheral triggers

The connection of the LPUART peripheral triggers with other peripherals is chip-specific.

64.3.7.1 Output triggers

LPUART generates the following output triggers that can be connected to other peripherals on the chip:

- The transmit word trigger asserts at the end of each transmitted word and negates after 1-bit period.
- The transmit data trigger is identical to the TXD pin output, but without support for input trigger modulation.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when STAT[IDLE] becomes 1, and negates when the next valid start bit is detected.

64.3.7.2 Input trigger

LPUART supports a peripheral input trigger that you can configure in one of the following ways:

- By enabling the CTS function: You can connect the input trigger instead of the CTS_B pin input. The input trigger must assert for longer than 1-bit clock period when the transmitter is idle, with data to send, to guarantee a new transmission.
- By making the input trigger modulate the transmit data output (trigger is logically ANDed with the TXD output): The input trigger is expected to be a free-running clock (carrier signal) that generates from a timer or PWM source with a frequency that is greater than the bit-clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- By connecting the input trigger instead of the RXD pin input: The input trigger is expected to be generated from a receive data source, such as an analog comparator or external pin.

64.3.8 Infrared (IR) interface

LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses, transforming them to serial bits, which are then sent to LPUART. The IrDA physical layer specification defines a half-duplex IR communication link for exchanging data. The full standard includes data rates up to 16 Mbit/s. The LPUART IrDA support is limited to SIR mode that supports data rates only between 2.4 kbit/s and 115.2 kbit/s.

LPUART has an infrared transmit encoder and a receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format, which the receiver uses. It also has an OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. LPUART transmits serial bits of data, which the infrared submodule encodes, to transmit a narrow pulse for every zero bit. No pulse is transmitted for every single bit. When receiving data, an IR photo diode (external to LPUART) detects the IR pulses. The IR receive decoder transforms them to CMOS levels. The infrared receive decoder then stretches the narrow pulses to get back to a serial bit stream that LPUART receives. You can invert the polarity of transmitted pulses and expected receive pulses so that a direct connection can be made to external IrDA transceiver modules that use active-high pulses.

The IR submodule receives its clock sources from LPUART. The submodule selects one of these clocks to generate either 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulses during transmission.

64.3.8.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from the transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse is transmitted for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is 0, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is 1.

64.3.8.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is 0, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is 1. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

64.3.8.3 Start-bit detection

When STAT[RXINV] is 0, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently of each other.

64.3.8.4 Noise filtering

The decoder ignores any rising edges detected during the first half of the infrared decoder counter, and can leave any pulses less than one oversampling baud clock as undetected. This is regardless of whether the pulse is seen in the first or second half of the count.

64.3.8.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as 0, which is sent to the receiver. The decoder counter is also reset.

64.3.8.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, the decoder sends a 1 to the receiver.

If the next bit is 0, which arrives late, a low bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, the delay of a 0 is not recorded as noise.

64.3.9 MODBUS protocol

64.3.9.1 MODBUS frame structure

MODBUS is an application layer messaging protocol, positioned at level 7 of the OSI model. It provides client and server communication between devices connected on different types of buses or networks.

The MODBUS protocol defines a simple protocol data unit (PDU) independent of the underlying communication layers. The mapping of the MODBUS protocol on specific buses or network can introduce some additional fields on the application data unit (ADU).

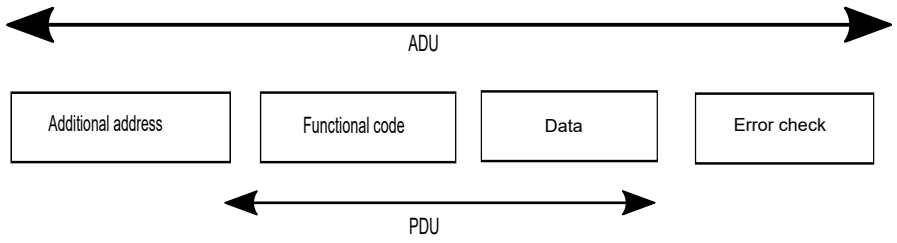

Figure 475. MODBUS frame structure

The function code field informs the server about which action to perform, as requested by the client (only the client can initiate the communication), where the data field contains additional information that the server uses to take the action defined by the function code. MODBUS PDU for serial line communication = 256 - server address (1 byte) - CRC (2 bytes) = 253 bytes.

You can set up a MODBUS controller to communicate on standard MODBUS networks using either of the two transmission modes: ASCII or RTU. RTU mode allows better character density and throughput for the same baud rate as the ASCII format allows 7 bits to represent a character where RTU keeps 8 bits for data representation in each packet.

64.3.9.2 MODBUS frame for LPUART

Though the protocol resides in the application layer, it can also be checked at the physical layer using LPUART by considering the frame structure shown in the following figure, following RTU mode of data transmission.

Start	Address	Function	Data	CRC	End
3.5 Char time	8 Bit	8 Bit	N * 8Bit	16 Bit	3.5 Char time

Figure 476. MODBUS frame for LPUART

An entire message frame of MODBUS must contain start character, address, function code, data, and end character. LPUART does not support CRC calculation for TX and RX, instead, each LPUART packet containing frame information is transmitted with its individual parity, and the same is checked in RX. Following the last transmitted character, a similar interval of at least 3.5 character times marks the end of the message and a new message can begin after this interval. The entire message frame must be transmitted as a continuous stream. If a silent interval of more than 1.5 character times occurs before the completion of the frame, the receiving device flushes the incomplete message, and assumes that the next byte is the address field of a new message. The correctness of timeout logic ensures the correctness of the MODBUS frame using LPUART.

Registers such as REIR, TEIR, TOCR, TOSR, TIMEOUT[0 - 3], TCBR, and TDBR are useful for realizing MODBUS using LPUART. The TX IDLE time is configured by using TEIR[IDTIME].

For higher baud rates, MODBUS recommends adopting fixed t1.5 and t3.5 times of 750us ms and 1.75 ms. The receiver idle line wake-up can be used by a MODBUS device to only wake-up on a matching address or broadcast address received after a valid idle time. The receiver end-of-packet DMA transfer can be used to offload the reception of a MODBUS packet onto the DMA controller.

64.3.9.3 MODBUS TX and RX programming sequence

The following programming sequences can be useful for sending and receiving MODBUS frames using LPUART.

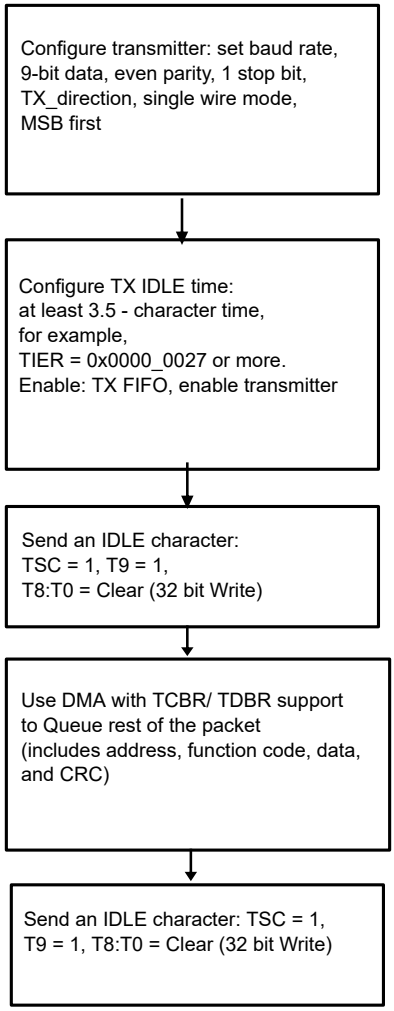

Figure 477. MODBUS TX programming

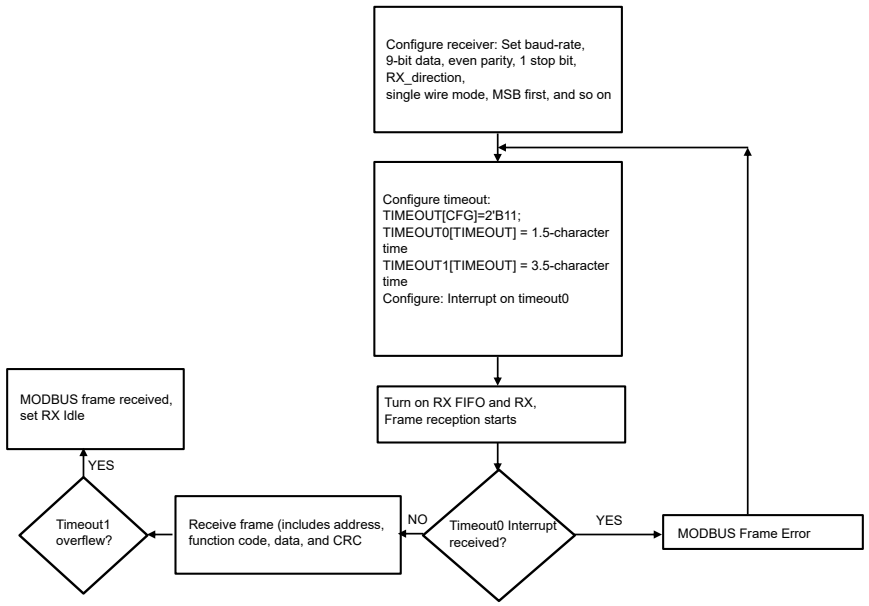

Figure 478. MODBUS RX programming

64.3.10 Modes of operation

64.3.10.1 Low-Power modes

LPUART remains functional during low-power modes, provided CTRL[DOZEEN] is 0 and the LPUART functional clock is enabled. LPUART can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPUART to be disabled in low-power modes, when CTRL[DOZEEN] is 1. In this case, the transmitter and receiver finish transmitting and receiving the current word.

If LPUART is disabled in low-power modes, it can generate a wake-up via STAT[RXEDGIF] if the receiver detects an active edge.

NOTE

See the chip-specific information for specific low-power modes available on your chip.

64.3.10.2 Debug mode

LPUART remains functional in Debug mode.

64.3.11 Clocking

Table 1040. Types of clocks

Clock	Description
Functional	Is asynchronous to the bus clock and can remain enabled in Low-Power modes to support transmit and/or receive functions, including low-power wake-up.
Bus	Is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

64.3.12 Reset

Table 1041. Types of resets

Reset	Description
Chip	Enables the logic and registers for the LPUART transmitter and receiver to reset to their default states.
Software	Resets the LPUART logic and registers to their default states, except for Global (GLOBAL). GLOBAL[RST] controls the LPUART software reset.
FIFO	Implements write-only control fields that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO becomes empty.

64.3.13 Interrupts

The LPUART transmitter has two status fields that can optionally generate hardware interrupt requests. If STAT[TDRE] is 1, it indicates that there is room in the transmit FIFO to write another transmit character to Data (DATA). If CTRL[TIE] is 1, a hardware interrupt is requested when STAT[TDRE] is 1.

STAT[TC] indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This field is often used in systems with modems to determine when it is safe to turn off the modem. If CTRL[TCIE] is 1, a hardware interrupt is requested when STAT[TC] is 1. Instead of hardware interrupts, software polling may be used to monitor STAT[TDRE] and STAT[TC] if the corresponding CTRL[TIE] or CTRL[TCIE] field is 0.

When a program detects that STAT[RDRF] is 1, it gets the data from this field by reading Data (DATA). The field becomes 0 by reading Data (DATA).

STAT[IDLE] includes logic that prevents it from becoming 1 repeatedly when the RXD line remains idle for an extended period of time. STAT[IDLE] becomes 0 when you write 1 to it, and cannot become 1 again until the receiver has received at least one new character and has 1 as the value of STAT[RDRF].

If the associated error is detected in the received character that caused STAT[RDRF] to become 1, STAT[NF], STAT[FE], and STAT[PF] become 1 at the same time STAT[RDRF] becomes 1. These flags do not become 1 in overrun cases.

If STAT[RDRF] is already 1 when a new character is ready to be transferred from the receive shifter to the receive FIFO, STAT[OR] becomes 1, instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition getting lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2], then STAT[MA1F] and/or STAT[MA2F] become 1 at the same time that STAT[RDRF] becomes 1.

At any time, an active edge on the RXD serial data input pin causes STAT[RXEDGIF] to become 1. STAT[RXEDGIF] becomes 0 when you write 1 to it. This function depends on the receiver being enabled (the value of CTRL[RE] being 1).

MODEM Status (MSR) can generate an interrupt from a configured status field, which STAT[MSF] indicates.

Timeout Status (TOSR) can generate an interrupt from a configured status field, which STAT[TSF] indicates.

64.3.14 DMA

64.3.14.1 DMA burst support

To support efficient DMA transfers to the transmit FIFO, two alias regions are implemented to support incrementing 8-bit, 16-bit, or 32-bit write accesses to the transmit FIFO:

- Transmit Command Burst (TCBR0 - TCBR127) is a 512-byte region that supports pushing 16-bit data into the transmit FIFO.
- Transmit Data Burst (TDBR0 - TDBR255) is a 1024-byte region that supports pushing zero extended 8-bit data into the transmit FIFO.

The aforementioned regions are contiguous, so a DMA transfer can start in Transmit Command Burst (TCBR0 - TCBR127) to initialize the transfer including address mark, idle word, or break character, and then complete the transfer in Transmit Data Burst (TDBR0 - TDBR255) with the data to transmit, without changing the transfer size.

The transmit FIFO block writes overflow the FIFO, but that does not signal an error. Do not perform 32-bit writes to Transmit Data Burst (TDBR0 - TDBR255) unless there are four empty slots in the transmit FIFO, and do not perform 16-bit writes to this register unless there are two empty slots in the transmit FIFO.

64.3.14.2 End-of-packet DMA transfers

The end-of-packet functionality is designed for serial interfaces where you may not know the size of the transfer in advance and the data is being pushed by an external device. The end-of-packet processing ensures that data does not become stranded in either the receive FIFO or the DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and DMA controller.

The condition that signals the end of packet is different for each serial interface, but the serial peripheral and DMA process it in the same way. For example, an idle line condition signals the UART end of packet, the Stop and/or Repeated Start condition signals the I2C end of packet, and PCS negation signals the SPI end of packet.

When the serial peripheral is configured to signal the end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO irrespective of the watermark configuration. For larger watermark configurations, this ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end of packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO is the start of a new packet, data is not pulled from the receive FIFO and the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO is not the start of a new packet, the DMA transfers the receive data as normal.

Because the DMA may be transferring multiple words on each request, the end-of-packet condition persists until the DMA minor loop has completed and no additional data is pulled from the receive FIFO. The field that triggered the end-of-packet condition becomes 0 when the minor loop completes following the end of packet being signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of packet into the system memory and saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking, and scatter-gather. You can, optionally, save the final destination address to the system memory. The final destination address is also available in the destination address register.

Because the DMA terminates the major loop, no servicing of the receive FIFO occurs until you or the hardware reconfigures the DMA (for example, channel linking or scatter-gather). You must minimize this delay to avoid receiver FIFO overrun. The automatic DMA end-of-packet processing is not recommended when there are only a few words transferred between end-of-packet conditions. This is because the DMA spends more time processing the end of packet than transferring the data. For example, the UART idle line length must be increased as needed to avoid an excessive number of idle conditions.

64.4 External signals

Table 1042. External signals

Signal	Description	I/O
TXD	Transmit data: This pin is normally an output, but is an input (tristated) in Single-Wire mode whenever the transmitter is disabled or the transmit direction is configured for receive data.	I/O

Table continues on the next page...

Table 1042. External signals (continued)

Signal	Description	I/O
RXD	Receive data	I
CTS_B	Clear-to-send	I
RTS_B	Request-to-send	O
DTR_B	Data terminal ready	O
DSR_B	Data set ready	I
DCD_B	Data carrier detect	I
RIN_B	Ring indicator	I

64.5 Initialization

This module does not require initialization.

64.6 Register definition

LPUART includes registers to control baud rate, select options, report status, and store transmit and receive data. Access to an address outside the valid memory map generates a bus error.

NOTE

Writing to a read-only (RO) register or reading a write-only (WO) register can cause bus errors. LPUART does not verify whether programmed values in the registers are correct; you must write valid values to them.

23 TDMAE	Transmitter DMA Enable Enables STAT[TDRE] to generate a DMA request. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable Enables STAT[RDRF] to generate a DMA request. 0b - Disable 1b - Enable
20 RIDMAE	Receiver Idle DMA Enable Enables STAT[IDLE] to generate a DMA request. If this field is 1, reading Data (DATA) when either DATA[RXEMPT] or DATA[IDLINE] is 1 generates an end-of-packet response until the completion of the DMA minor loop. During an end-of-packet response, reading Data (DATA) returns 0000_33FFh and does not pull data from the receive FIFO. STAT[IDLE] becomes 0 on completion of the minor loop, provided an end-of-packet response is generated and either the receive FIFO is empty or the receiver is active. 0b - Disable 1b - Enable
19-18 MATCFG	Match Configuration Configures the match addressing mode used. You must change the value of this field only when both the transmitter and receiver are disabled. 00b - Address match wake-up 01b - Idle match wake-up 10b - Match on and match off 11b - Enables RWU on data match and match on or off for the transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given OSR. This field must be 1 for OSRs between x4 and x7 and is optional for higher OSRs. You must change the value of this field only when the receiver is disabled. If this field is 0, the receiver samples input data using the rising edge of the baud rate clock. If this field is 1, the receiver samples input data using the rising and falling edges of the baud rate clock. 0b - Rising edge 1b - Both rising and falling edges
16 RESYNCDIS	Resynchronization Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Disables resynchronization of the received data word when a data one followed by data zero transition is detected. You must change the value of this field only when the receiver is disabled. 0b - Enable 1b - Disable
15 LBKDIE	LIN Break Detect Interrupt Enable Enables STAT[LBKDIF] to generate hardware interrupt requests. If this field is 0, hardware interrupts from STAT[LBKDIF] (uses polling) are disabled. If this field is 1, hardware interrupts are requested when STAT[LBKDIF] is 1. 0b - Disable 1b - Enable
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables STAT[RXEDGIF] to generate interrupt requests. If this field is 0, hardware interrupts from STAT[RXEDGIF] are disabled. If this field is 1, hardware interrupts are requested when STAT[RXEDGIF] is 1. Changing the value of CTRL[LOOPS] or CTRL[RSRC] when this field (RXEDGIE) is 1 can cause STAT[RXEDGIF] to become 1. 0b - Disable 1b - Enable
13 SBNS	Stop Bit Number Select Determines whether data characters include one or two stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - One stop bit 1b - Two stop bits
12-0 SBR	Baud Rate Modulo Divisor Sets the modulo divide rate for the baud rate generator. • If SBR is 0, baud rate generator is disabled. • If SBR is 1–8191, baud rate = baud clock ÷ ((OSR + 1) × SBR). You must update the 13-bit baud rate setting [SBR12:SBR0] only when both the transmitter and receiver are disabled (both CTRL[RE] and CTRL[TE] are 0).

64.6.1.7 Status (STAT)

Offset

Register	Offset
STAT	14h

Function

Provides the module status.

Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag Indicates whether a LIN break character is detected. This field becomes 1 when the LIN break detect circuitry is enabled and a LIN break character is detected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag Indicates whether an active edge on the receive pin has occurred.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 whenever the receiver is enabled and an active edge (falling if STAT[RXINV] is 0; rising if STAT[RXINV] is 1) on the RXD pin occurs. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not occurred 1b - Occurred When writing 0b - No effect 1b - Clear the flag
29 MSBF	MSB First Specifies the first bit that is transmitted after the start bit. If this field is 0, LSB (bit 0) is the first bit transmitted after the start bit (which means, the first bit received after the start bit is identified as bit 0). If this field is 1, MSB (identified as bit 9, bit 8, bit 7, or bit 6) is the first bit that is transmitted, after the start bit, depending on the settings of CTRL[M], CTRL[PE], and BAUD[M10]. Writing 1 to this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - LSB 1b - MSB
28 RXINV	Receive Data Inversion Specifies whether receive data is inverted. Writing 1 to this field reverses the polarity of the received data input. You must change the value of this field only when the receiver is disabled. **NOTE** Writing 1 to this field inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Inverted 1b - Not inverted
27 RWUID	Receive Wake Up Idle Detect Controls, for CTRL[RWU] on idle character detection, whether the idle character that wakes up the receiver writes 1 to STAT[IDLE]. For address match wake-up, this field controls whether STAT[IDLE] = 1 when the address does not match. You must change the value of this field only when the receiver is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] does not become 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] does not become 1 when an address does not match. If this field is 1, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] becomes 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] becomes 1 when an address does not match. 0b - STAT[IDLE] does not become 1 1b - STAT[IDLE] becomes 1
26 BRK13	Break Character Generation Length Selects the longer transmitted break character length. The state of this field does not affect the detection of a framing error. You must change the value of this field only when the transmitter is disabled. You can send a break character by writing 1 to CTRL[SBK], or by writing the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0. 0b - 9 to 13 bit times 1b - 12 to 15 bit times
25 LBKDE	LIN Break Detection Enable Enables LIN break detection. If this field is 0, LIN break detect is disabled, and only a normal break character can be detected. If this field is 1, LIN break detect is enabled and the LIN break character is detected at a length of 11 bit times (if CTRL[M] is 0), 12 bit times (if CTRL[M] is 1), or 13 bit times (if BAUD[M10] is 1). This field selects a longer break character detection length. When the field is 1, receive data is not stored in the receive FIFO. **NOTE** This field enables the LIN break detect circuit and disables writing receive data to FIFO. Therefore, it ignores all characters except a LIN break. 0b - Disable 1b - Enable
24 RAF	Receiver Active Flag Indicates whether the LPUART receiver is idle or active. This field becomes 1 when the receiver detects the beginning of a valid start bit, and the field becomes 0 automatically when the receiver detects an idle line. 0b - Idle, waiting for a start bit 1b - Receiver active (RXD pin input not idle)
23 TDRE	Transmit Data Register Empty Flag Indicates whether the transmit FIFO level is greater than, equal to, or less than the watermark.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	After the transmit FIFO is enabled, this field becomes 1 when the number of datawords in the transmit FIFO is equal to, or less than the number that WATER[TXWATER] indicates. To make the value of this field 0, write to it until the number of words in the transmit FIFO is greater than the number that WATER[TXWATER] indicates. After the transmit FIFO is disabled, this field becomes 1 to indicate that the FIFO level is less than the watermark. To make the value of this field 0 again, write to Data (DATA). This register is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character. 0b - Greater than watermark 1b - Equal to or less than watermark
22 TC	Transmission Complete Flag Indicates whether the transmitter is active. This field becomes 0 when a transmission is in progress or a preamble or break character is loaded; in other words, when the transmitter is active (sending data, a preamble, or a break). The field becomes 1 when the transmit buffer is empty and no data, preamble, or break character is being transmitted; in other words, when the transmission activity is complete. When this happens, the transmit data output signal becomes idle (logic 1). This field becomes 0 after you write to Data (DATA) to transmit new data, queuing a preamble by first writing 0 and then writing 1 to CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0b - Transmitter active 1b - Transmitter idle
21 RDRF	Receive Data Register Full Flag Indicates whether the receive FIFO level is less than, equal to, or greater than the watermark. This field becomes 1 when the number of datawords in the receive buffer is greater than the number that WATER[RXWATER] indicates and the receive FIFO is enabled. To write 0 to this field, read Data (DATA) until the number of datawords in the receive FIFO is equal to, or less than the number that WATER[RXWATER] indicates. When the receive FIFO is disabled, this field (RDRF) becomes 1 if the receive buffer (Data (DATA)) is full. To make this field 0, read Data (DATA). A character that is in the process of being received does not cause a change in this field until the entire character is received. Even if this field is 1, the character continues to be received until an overrun condition occurs after the entire character is received. 0b - Equal to or less than watermark 1b - Greater than watermark
20 IDLE	Idle Line Flag Indicates whether an idle line is detected. This field becomes 1 when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is 0, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bit time count towards the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. After CTRL[ILT] becomes 1, the receiver does not start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end

Table continues on the next page...

Table continued from the previous page...

Field	Function
	of the previous character do not count towards the full character time of logic high needed for the receiver to detect an idle line. For this field to become 0, write 1 to it. After the field becomes 0, you cannot write 1 to it again until after a new character is stored in the receive buffer or a LIN break character writes 1 to STAT[LBKDIF]. This field becomes 1 only once, even if the receive line remains idle for an extended period. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Idle line detected 1b - Idle line not detected When writing 0b - No effect 1b - Clear the flag
19 OR	Receiver Overrun Flag Indicates whether there is receive overrun. This field becomes 1 when you cannot prevent STAT[RDRF] from overflowing with data. The field becomes 1 immediately after the stop bit is completely received for the dataword that overflows the buffer and all the other error fields (STAT[FE], STAT[NF], and STAT[PF]) are prevented from becoming 1. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If STAT[LBKDE] is enabled and a LIN break is detected, this field becomes 1 if STAT[LBKDIF] is not 0 before the next data character is received. When this field is 1, no additional data is stored in the receive FIFO even if sufficient room exists. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overrun 1b - Receive overrun (new LPUART data is lost) When writing 0b - No effect 1b - Clear the flag
18 NF	Noise Flag Indicates whether noise is detected in the received character of Data (DATA). The advanced sampling technique used in the receiver takes three samples in each of the received bits. If some of these samples disagree with the rest of the samples within any bit time in the frame, then noise is detected for that character. This field becomes 1 whenever the next character to be read from Data (DATA) is received with noise detected within the character.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No noise detected 1b - Noise detected When writing 0b - No effect 1b - Clear the flag
17 FE	Framing Error Flag Indicates whether a framing error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) is received with logic 0 detected where a stop bit was expected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No framing error detected (this does not guarantee that the framing is correct) 1b - Framing error detected When writing 0b - No effect 1b - Clear the flag
16 PF	Parity Error Flag Indicates whether a parity error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) is received when parity is enabled (CTRL[PE] is 1) and the parity bit in the received character does not agree with the expected parity value. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No parity error detected 1b - Parity error detected When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 MA1F	Match 1 Flag Indicates whether the received data is equal to MATCH[MA1]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA1]. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not equal to MA1 1b - Equal to MA1 When writing 0b - No effect 1b - Clear the flag
14 MA2F	Match 2 Flag Indicates whether the received data is equal to MATCH[MA2]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA2]. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not equal to MA2 1b - Equal to MA2 When writing 0b - No effect 1b - Clear the flag
13-10 —	Reserved
9 TSF	Timeout Status Flag Indicates whether a field in Timeout Status (TOSR) is 1 and configured to generate an interrupt. 0b - Field is 0 1b - Field is 1
8 MSF	MODEM Status Flag Indicates whether a field in MODEM Status (MSR) is 1 and configured to generate an interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Field is 0 1b - Field is 1
7-2 —	Reserved
1 AME	Address Mark Enable Configures the location of the address mark when configured for MSB first transfers. This field has no effect when configured for LSB first and you must change the value of this field only when both the transmitter and receiver are disabled. If this field is 0, address mark in character is MSB. If this field is 1, the address mark is stored in Data (DATA) at MSB (or MSB-1 when the parity bit is enabled). In other words, the address mark in character is the last bit before the stop bit (or parity bit when enabled). 0b - Disable 1b - Enable
0 LBKFE	LIN Break Flag Enable Enables the LIN break flag to assert whenever a LIN break character is detected. Unlike STAT[LBKDE], this does not impact data being stored in the receive data buffer, but does cause STAT[LBKDIF] to become 1 whenever a LIN break is detected. Because a LIN break is longer than a normal character, the LIN break triggers a write to STAT[RDRF] with the data fields as 0 and STAT[FE] as 1. The character following the LIN break has DATA[LINBRK] as 1 to indicate that the previous character was a LIN break. You must change the value of this field only when both the transmitter and receiver are disabled. If this field is 1, the LIN break character is detected at a length of 11-bit times (if CTRL[M] is 0), 12 (if CTRL[M] is 1), or 13 (if BAUD[M10] is 1). 0b - Disable 1b - Enable

64.6.1.8 Control (CTRL)

Offset

Register	Offset
CTRL	18h

Function

Controls various optional features of the LPUART system.

You must write to the fields of this register only when both the transmitter and receiver are disabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 R8T9	Receive Bit 8 Transmit Bit 9 Contains R8 and T9 that correspond to different functions. R8 is the ninth data bit received after you configure LPUART for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading Data (DATA). T9 is the tenth data bit transmitted after you configure LPUART for 10-bit data formats. When writing 10-bit data, write T9 before writing to Data (DATA). If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R8 is a read-only bit and T9 is a write-only bit; the value read is different from the value written.
30 R9T8	Receive Bit 9 Transmit Bit 8 Contains R9 and T8 that correspond to different functions. R9 is the tenth data bit received after you configure LPUART for 10-bit data formats. When reading 10-bit data, read R9 before reading Data (DATA). T8 is the ninth data bit transmitted after you configure LPUART for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing to Data (DATA). If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R9 is a read-only field and T8 is a write-only field; the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode Determines the direction of data at the TXD pin, in Single-Wire mode, when LPUART is configured for a single-wire half-duplex operation (CTRL[LOOPS] and CTRL[RSRC] are 1). When writing 0 to this field, the transmitter finishes transmitting the current character (if any) before the receiver starts receiving data from the TXD pin.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Input 1b - Output
28 TXINV	Transmit Data Inversion Specifies whether transmit data is inverted. Writing 1 to this field reverses the polarity of the transmitted data output. This action inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Not inverted 1b - Inverted
27 ORIE	Overrun Interrupt Enable Enables STAT[OR] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when OR interrupts are disabled. 0b - Disable 1b - Enable
26 NEIE	Noise Error Interrupt Enable Enables STAT[NF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when NF interrupts are disabled. 0b - Disable 1b - Enable
25 FEIE	Framing Error Interrupt Enable Enables STAT[FE] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when FE interrupts are disabled. 0b - Disable 1b - Enable
24 PEIE	Parity Error Interrupt Enable Enables STAT[PF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when PF interrupts are disabled. 0b - Disable 1b - Enable
23 TIE	Transmit Interrupt Enable Enables STAT[TDRE] to generate interrupt requests if STAT[TDRE] is 1. 0b - Disable 1b - Enable
22	Transmission Complete Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TCIE	Enables STAT[TC] to generate interrupt requests if STAT[TC] is 1. 0b - Disable 1b - Enable
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate hardware interrupt requests if STAT[RDRF] is 1. 0b - Disable 1b - Enable
20 ILIE	Idle Line Interrupt Enable Enables hardware interrupts. This field enables STAT[IDLE] to generate interrupt requests. If this field is 0, hardware interrupts from STAT[IDLE] are disabled and polling is used, and if this field is 1, hardware interrupts are enabled when STAT[IDLE] is 1. 0b - Disable 1b - Enable
19 TE	Transmitter Enable Enables the LPUART transmitter. Using this field, you can also queue an idle preamble by first writing 0 and then writing 1 to this field. After this field becomes 0, the field reads 1 until the transmitter has completed the current character and the TXD pin is tristated. You can also queue a single idle character by writing to the transmit FIFO with DATA[FRETSC] and DATA[R9T9] = 1. 0b - Disable 1b - Enable
18 RE	Receiver Enable Enables the LPUART receiver. After you write 0 to this field, this field remains 1 until the receiver finishes receiving the current character (if any). 0b - Disable 1b - Enable
17 RWU	Receiver Wake-Up Control Specifies whether the LPUART receiver in standby is waiting for a wake-up condition. You can write 1 to this field to place the LPUART receiver in a Standby state. The field becomes 0 automatically when an RWU event occurs, that is, in case of an idle event when CTRL[WAKE] is 0 or an address match when CTRL[WAKE] is 1 and STAT[RWUID] is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE You must write 1 to this field only when CTRL[WAKE] is 0 (wake-up on idle), if the channel is currently not idle. You can determine this by the value of STAT[RAF]. If the field is 1 to wake up an idle event and the channel is already idle, LPUART, possibly, discards the data. This is because the data must be received or a LIN break is detected after an Idle condition is detected before the IDLE flag is allowed to be reasserted. 0b - Normal receiver operation 1b - LPUART receiver in standby, waiting for a wake-up condition
16 SBK	Send Break Specifies whether queue break character(s) are to be sent. Writing 1 and then 0 to this field queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is 1, and bit times of logic 0 are queued as long as this field is 1. Depending on the timing when this field is 1 and 0, relative to the character currently being transmitted, a second break character may be queued before you write 0 to this field. If the time taken to write 0 to this field is too long, for example, if the field does not become 0 by the end of the first break character, a second break character is sent. This is compared to queuing a break character through the transmit FIFO that guarantees only one break character is sent. You can also queue a single break character by writing to the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0. 0b - Normal transmitter operation 1b - Queue break character(s) to be sent
15 MA1IE	Match 1 (MA1F) Interrupt Enable Enables the MA1F interrupt. 0b - Disable 1b - Enable
14 MA2IE	Match 2 (MA2F) Interrupt Enable Enables the MA2F interrupt. 0b - Disable 1b - Enable
13 —	Reserved
12 —	Reserved
11 M7	7-Bit Mode Select Specifies the data characters that the receiver and transmitter use.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You must change the value of this field only after both the transmitter and receiver are disabled. 0b - 8-bit to 10-bit 1b - 7-bit
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before you write 1 to STAT[IDLE]. 000b - 1 001b - 2 010b - 4 011b - 8 100b - 16 101b - 32 110b - 64 111b - 128
7 LOOPS	Loop Mode Select Selects Loop mode. After this field becomes 1, the RXD pin is disconnected from LPUART and the transmitter output is internally connected to the receiver input. The transmitter and receiver must be enabled to use the loop function. In Loop mode or Single-Wire mode, the transmitter outputs are internally connected to the receiver input (see CTRL[RSRC]). 0b - Normal operation: RXD and TXD use separate pins 1b - Loop mode or Single-Wire mode
6 DOZEEN	Doze Mode Enables LPUART in Doze mode. If this field is 1, LPUART remains active when not in Doze mode. 0b - Enable 1b - Disable
5 RSRC	Receiver Source Select Determines the source of the receiver shift register input if CTRL[LOOPS] is 1. This field has no effect unless CTRL[LOOPS] is 1. If this field is 0, internal Loopback mode is selected. LPUART does not use the RXD pin. Additionally, the CTS_B pin is not used and internally driven by the RTS_B output. If this field is 1, single-wire LPUART mode is selected where the TXD pin is connected to the transmitter output and receiver input.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Internal Loopback mode 1b - Single-wire mode
4 M	9-Bit Or 8-Bit Mode Select Specifies the data characters that the receiver and transmitter use. 0b - 8-bit 1b - 9-bit
3 WAKE	Receiver Wake-Up Method Select Determines which condition wakes up LPUART when CTRL[RWU] = 1 and BAUD[MATCFG] = 0 (this field must be 1 when BAUD[MATCFG] = 11): • Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character • An idle condition on the receive pin input signal If this field is 0, CTRL[RWU] is configured for idle line wake-up, and if this field is 1, CTRL[RWU] is configured with address mark wake-up. 0b - Idle 1b - Mark
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or the stop bit. If the count begins after the start bit, a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE** In case you write 1 to this field, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0b - After the start bit 1b - After the stop bit
1 PE	Parity Enable Enables hardware parity generation and checking. If parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - Disable 1b - Enable
0 PT	Parity Type Selects the type of parity, even or odd, if parity is enabled (CTRL[PE] = 1):

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Odd parity means that the total number of logic 1 bits in the data character, including the parity bit, is odd. • Even parity means that the total number of 1s in the data character, including the parity bit, is even. 0b - Even parity 1b - Odd parity

64.6.1.9 Data (DATA)

Offset

Register	Offset
DATA	1Ch

Function

Supports 8-bit, 16-bit, or 32-bit writes, each type of write performing a separate function. An 8-bit write to DATA[7:0] pushes {CTRL[R8T9], CTRL[R9T8], DATA[7:0]} the transmit FIFO with TSC clear. A 16-bit or 32-bit write pushes the data written into the FIFO and does not update the value of CTRL[R8T9] or CTRL[R9T8].

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status fields.

NOTE

Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO, making this register work as a set of two separate registers.

Fields

Field	Function
31-16 —	Reserved
15 NOISY	Noisy Data Received Indicates whether the current received dataword contained in DATA[R9:R0] is received with noise. 0b - Received without noise 1b - Received with noise
14 PARITYE	Parity Error Indicates whether the current received dataword contained in DATA[R9:R0] is received with a parity error. 0b - Received without a parity error 1b - Received with a parity error
13 FRETSC	Frame Error Transmit Special Character Specifies the way the dataword is received. For reads, this field indicates that the current received dataword contained in DATA[R9:R0] is received with a frame error. For writes, the field indicates that a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 indicates a break character when it is 0 and indicates an idle character when it is 1. The contents of DATA[T8:T0] must be 0. 0b - Received without a frame error on reads or transmits a normal character on writes 1b - Received with a frame error on reads or transmits an idle or break character on writes
12 RXEMPT	Receive Buffer Empty Indicates whether the receive buffer contains valid data. This field becomes 1 when there is no data in the receive buffer. The field does not consider data in the receive shift register. 0b - Valid data 1b - Invalid data and empty
11 IDLINE	Idle Line Indicates whether the receiver line was idle before receiving the character in DATA[9:0]. It can be read as “1” on the first character when the receiver is first enabled. The difference between this field and STAT[IDLE] is that, STAT[IDLE] flag does not set on an idle line after the receiver is first enabled, it needs to receive a character before it can become set, whereas this field does not have this limitation and can be set on the first character received if an idle line is detected beforehand. 0b - Not idle 1b - Idle
10	LIN Break

Table continues on the next page...

Table continued from the previous page...

Field	Function
LINBRK	Indicates whether the receiver line detected a LIN break before receiving the character in DATA[9:0]. This field requires the value of STAT[LBKDIF] to be 1. If this field is 0, the LIN break detect circuitry is disabled. 0b - Not detected 1b - Detected
9 R9T9	Read receive FIFO bit 9 or write transmit FIFO bit 9
8 R8T8	Read receive FIFO bit 8 or write transmit FIFO bit 8
7 R7T7	Read receive FIFO bit 7 or write transmit FIFO bit 7
6 R6T6	Read receive FIFO bit 6 or write transmit FIFO bit 6
5 R5T5	Read receive FIFO bit 5 or write transmit FIFO bit 5
4 R4T4	Read receive FIFO bit 4 or write transmit FIFO bit 4
3 R3T3	Read receive FIFO bit 3 or write transmit FIFO bit 3
2 R2T2	Read receive FIFO bit 2 or write transmit FIFO bit 2
1 R1T1	Read receive FIFO bit 1 or write transmit FIFO bit 1
0 R0T0	Read receive FIFO bit 0 or write transmit FIFO bit 0

64.6.1.10 Match Address (MATCH)

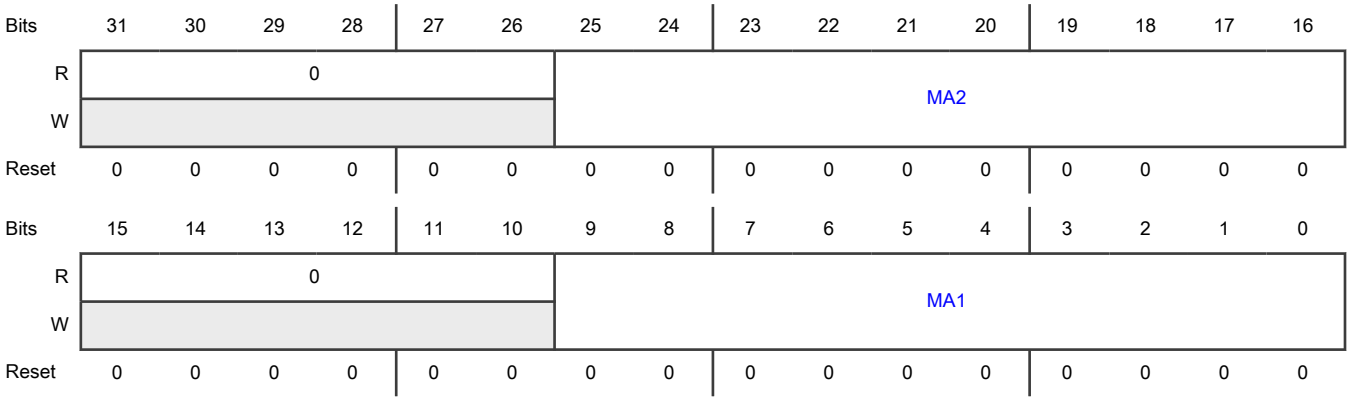
Offset

Register	Offset
MATCH	20h

Function

Provides addresses for address matching during the receiver operation.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 MA2	Match Address 2 Is compared to input data addresses when the most significant bit is 1 and the associated Baud Rate (BAUD) field is 1. If a match occurs, the data that follows is transferred to Data (DATA). If a match fails, the data that follows is discarded. You must write to MATCH[MA1] and MATCH[MA2] only when the associated Baud Rate (BAUD) field is 0.
15-10 —	Reserved
9-0 MA1	Match Address 1 Is compared to input data addresses when the most significant bit is 1 and the associated Baud Rate (BAUD) field is 1. If a match occurs, the data that follows is transferred to Data (DATA). If a match fails, the data that follows is discarded. You must write to MATCH[MA1] and MATCH[MA2] fields only when the associated field in Baud Rate (BAUD) is 0.

64.6.1.11 MODEM IrDA (MODIR)

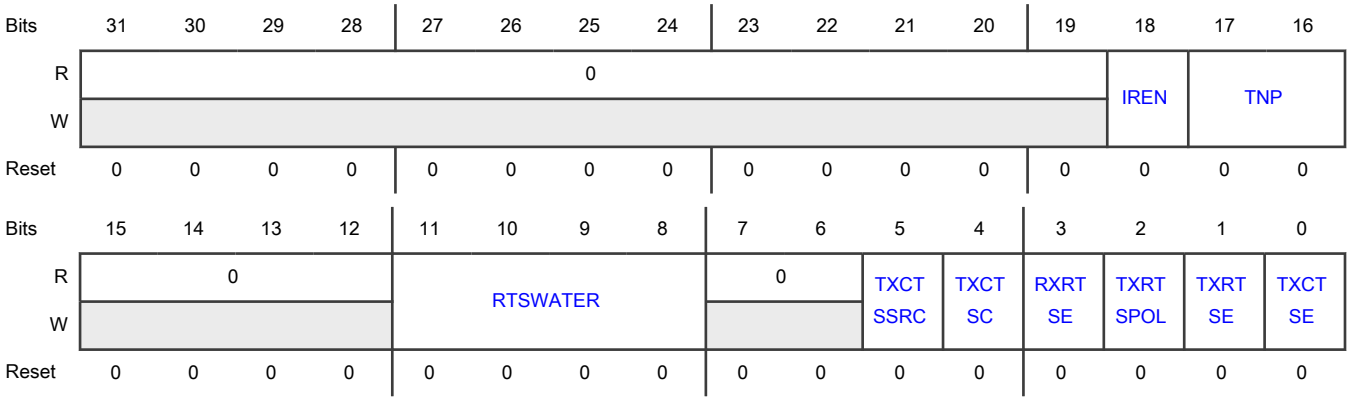
Offset

Register	Offset
MODIR	24h

Function

Controls options for setting the MODEM configuration.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 IREN	IR Enable Enables IR modulation and demodulation. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - Disable 1b - Enable
17-16 TNP	Transmitter Narrow Pulse Specifies whether LPUART transmits a 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulse when the IR pulse is enabled. You must change the value of this field only when both the transmitter and receiver are disabled. The IR pulse width must be configured to less than half of the OSR. Common pulse widths are 3 ÷ 16, 1 ÷ 16, 1 ÷ 32, or 1 ÷ 4 of the bit length. You can configure these by selecting the appropriate OSR and pulse width. 00b - 1 ÷ OSR 01b - 2 ÷ OSR 10b - 3 ÷ OSR 11b - 4 ÷ OSR
15-12 —	Reserved
11-8	Receive RTS Configuration

Table continues on the next page...

Table continued from the previous page...

Field	Function
RTSWATER	Configures the assertion and negation of the receiver's RTS_B output. The receiver's RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to the value of this field. If this field is 0, the RTS_B pin negates when the receive FIFO is full. For the purpose of receive RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both receive RTS_B and address or data matching is enabled, RTS_B could assert at the end of a character if there exists no match. You must change the value of this field only when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0b - The CTS_B pin 1b - An internal connection to the receiver address match result
4 TXCTSC	Transmit CTS Configuration Configures whether the CTS state or input is checked or sampled at the start of each character or only when the transmitter is idle. 0b - Sampled at the start of each character 1b - Sampled when the transmitter is idle
3 RXRTSE	Receiver RTS Enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. You must change the value of this field only when the receiver is disabled. If this field is 0, the receiver has no effect on RTS. If this field is 1, RTS is deasserted if STAT[RDRF] is 1 or a start bit is detected that causes STAT[RDRF] to become 1. RTS is asserted if STAT[RDRF] is 0 and has not detected a start bit that causes STAT[RDRF] to become 1. **NOTE** Do not write 1 to both MODIR[RXRTSE] and MODIR[TXRTSE]. 0b - Disable 1b - Enable
2 TXRTSPOL	Transmitter RTS Polarity Controls the polarity of the transmitter RTS. This field does not affect the polarity of the receiver RTS that remains negated in the active-low state unless MODIR[TXRTSE] is 1. You must change the value of this field only when the transmitter is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Active low 1b - Active high
1 TXRTSE	Transmitter RTS Enable Controls the operation of RTS before and after a transmission. You must change the value of this field only when the transmitter is disabled. If this field is 0, the transmitter has no effect on RTS, and if this field is 1, a character is placed into an empty transmit shift register. RTS asserts 1-bit time before the start bit is transmitted and deasserts 1-bit time after all characters in the transmitter FIFO and shift register are completely sent, including the last stop bit. 0b - Disable 1b - Enable
0 TXCTSE	Transmitter CTS Enable Enables the operation of the transmitter. You can write 1 to this field irrespective of the states of MODIR[TXRTSE] and MODIR[RXRTSE]. If this field is 1, the transmitter checks the state of the CTS signal each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the TXD signal remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS, when a character is being sent, do not affect its transmission. 0b - Disable 1b - Enable

64.6.1.12 FIFO (FIFO)

Offset

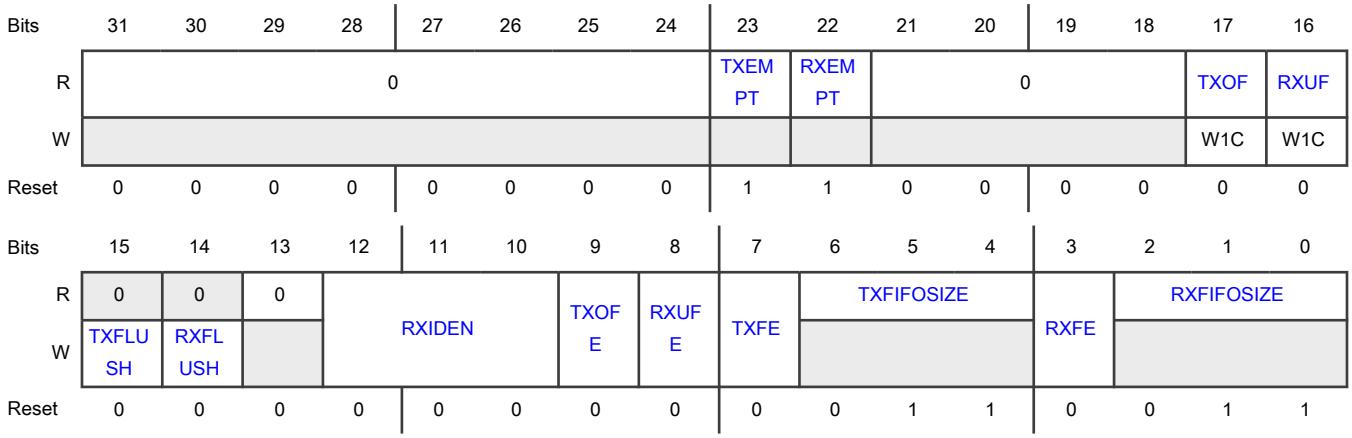
Register	Offset
FIFO	28h

Function

Provides you the ability to turn on and turn off the FIFO functionality.

This register also provides you the size of the FIFO that has been implemented. You can read this register at any time and must write to it only when CTRL[RE] and CTRL[TE] are 0 and the FIFO is empty.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 TXEMPT	Transmit FIFO Or Buffer Empty Indicates whether the transmit buffer is empty. This field becomes 1 when there is no data in the transmit FIFO or buffer. The field does not consider data in the transmit shift register. 0b - Not empty 1b - Empty
22 RXEMPT	Receive FIFO Or Buffer Empty Indicates whether the receive buffer is empty. This field becomes 1 when there is no data in the receive FIFO or buffer. The field does not consider data in the receive shift register. 0b - Not empty 1b - Empty
21-18 —	Reserved
17 TXOF	Transmitter FIFO Overflow Flag Indicates whether more data has been written to the transmit FIFO than it can hold. If this field is 0, no transmit FIFO overflow has occurred since the last time the field was cleared, and if this field is 1, at least one transmit FIFO overflow has occurred since the last time the field was cleared. This field becomes 1 regardless of the value of FIFO[TXOFE]. However, an interrupt is issued to the host only if FIFO[TXOFE] is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No overflow 1b - Overflow When writing 0b - No effect 1b - Clear the flag
16 RXUF	Receiver FIFO Underflow Flag Indicates whether more data has been read from the receive FIFO than was present. If this field is 0, no receive FIFO underflow has occurred since the last time the field was cleared, and if this field is 1, at least one receive FIFO underflow has occurred since the last time the field was cleared. This field becomes 1 regardless of the value of FIFO[RXUFE]. However, an interrupt is issued to the host only if FIFO[RXUFE] is 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underflow 1b - Underflow When writing 0b - No effect 1b - Clear the flag
15 TXFLUSH	Transmit FIFO Flush Causes all data that is stored in the transmit FIFO to be flushed. If you write 0 to this field, no flush operation occurs, and if you write 1 to this field, all data in the transmit FIFO or buffer clears out. This does not affect data in the transmit shift register. 0b - No effect 1b - All data flushed out
14 RXFLUSH	Receive FIFO Flush Causes all data that is stored in the receive FIFO to be flushed. If you write 0 to this field, no flush operation occurs, and if you write 1 to this field, all data in the receive FIFO or buffer clears out.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This does not affect data in the receive shift register. 0b - No effect 1b - All data flushed out
13 —	Reserved
12-10 RXIDEN	Receiver Idle Empty Enable Enables STAT[RDRF] to become 1 when the receiver is idle for a number of idle characters and the FIFO is not empty. This feature is not supported when the receiver extended idle time is enabled. 000b - Disable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle 001b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for one character 010b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for two characters 011b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for four characters 100b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for eight characters 101b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for 16 characters 110b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for 32 characters 111b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for 64 characters
9 TXOFE	Transmit FIFO Overflow Interrupt Enable Enables FIFO[TXOF] to generate an interrupt to the host. 0b - Disable 1b - Enable
8 RXUFE	Receive FIFO Underflow Interrupt Enable Enables FIFO[RXUF] to generate an interrupt to the host. 0b - Disable 1b - Enable
7 TXFE	Transmit FIFO Enable Enables the transmit FIFO. If this field is 0, the transmit buffer operates as a FIFO of depth equal to 1 dataword, regardless of the value in FIFO[TXFIFOSIZE]. Both CTRL[TE] and CTRL[RE] must be 0 before you change the value of this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, the built-in FIFO structure for the transmit buffer is enabled. FIFO[TXFIFOSIZE] indicates the size of the FIFO structure. 0b - Disable 1b - Enable
6-4 TXFIFOSIZE	Transmit FIFO Buffer Depth Indicates the maximum number of transmit datawords (transmit FIFO buffer depth) that can be stored in the transmit buffer. 000b - 1 001b - 4 010b - 8 011b - 16 100b - 32 101b - 64 110b - 128 111b - 256
3 RXFE	Receive FIFO Enable Enables the receive FIFO. If this field is 0, the receive buffer operates as a FIFO of depth equal to 1 dataword, regardless of the value in FIFO[RXFIFOSIZE]. Both CTRL[RE] and CTRL[TE] must be 0 before you change the value of this field. If this field is 1, the built-in FIFO structure for the receive buffer is enabled. FIFO[RXFIFOSIZE] indicates the size of the FIFO structure. 0b - Disable 1b - Enable
2-0 RXFIFOSIZE	Receive FIFO Buffer Depth Indicates the maximum number of receive datawords (receive FIFO buffer depth) that can be stored in the receive buffer before an overrun occurs. 000b - 1 001b - 4 010b - 8 011b - 16 100b - 32 101b - 64 110b - 128 111b - 256

64.6.1.13 Watermark (WATER)

Offset

Register	Offset
WATER	2Ch

Function

Provides the ability to set a programmable threshold for notification, or sets the programmable thresholds to indicate that transmit data can be written or receive data can be read.

You may read this register at any time but must write to it only when CTRL[TE] is 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-29 —	Reserved
28-24 RXCOUNT	Receive Counter Indicates the number of datawords in the receive FIFO or buffer. If a dataword is being received in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate the room left in the receive FIFO or buffer.
23-20 —	Reserved
19-16 RXWATER	Receive Watermark Generates an interrupt or a DMA request if the number of datawords in the receive FIFO or buffer is greater than the value of this field. For proper operation, the value of this field must be less than the size of the receive FIFO or buffer, as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-13 —	Reserved
12-8 TXCOUNT	Transmit Counter Indicates the number of datawords in the transmit FIFO or buffer. If a dataword is being transmitted to the transmit shift register, it is not included in the count. This value may be used in conjunction with the value of FIFO[TXFIFOSIZE] to calculate the room left in the transmit FIFO or buffer.
7-4 —	Reserved
3-0 TXWATER	Transmit Watermark Generates an interrupt or a DMA request when the number of datawords in the transmit FIFO or buffer is equal to or less than the value of this field. For proper operation, the value of this field must be less than the size of the transmit buffer or FIFO, as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

64.6.1.14 Data Read-Only (DATARO)

Offset

Register	Offset
DATARO	30h

Function
Indicates the first entry in the receive FIFO, but does not pull data from the FIFO.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Receive Data Indicates the first entry from the receive FIFO. This register has the same functionality as that of Data (DATA).

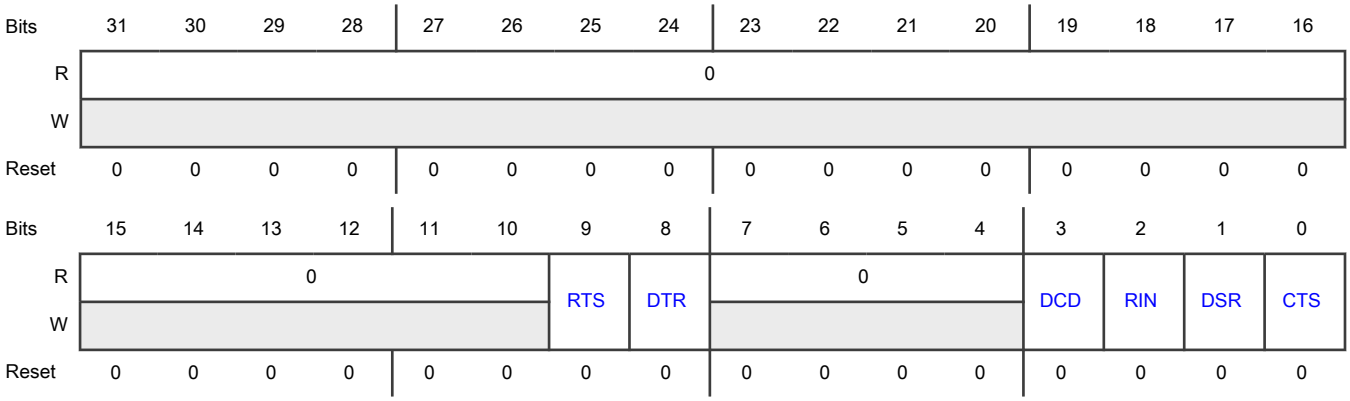
64.6.1.15 MODEM Control (MCR)

Offset

Register	Offset
MCR	40h

Function
Controls the operation of the MODEM pins.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RTS	Request To Send Configures the default state of the RTS_B pin when the function is disabled. 0b - Logic one

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Logic zero
8 DTR	Data Terminal Ready Configures the default state of the DTR_B pin. 0b - Logic one 1b - Logic zero
7-4 —	Reserved
3 DCD	Data Carrier Detect Configures the interrupt, DCD_B, for change of state of the DCD_B pin. 0b - Disable interrupt 1b - Enable interrupt
2 RIN	Ring Indicator Configures the interrupt, RIN_B, for change of state on the RIN_B pin. 0b - Disable interrupt 1b - Enable interrupt
1 DSR	Data Set Ready Configures the interrupt, DSR_B, for change of state on the DSR_B pin. 0b - Disable interrupt 1b - Enable interrupt
0 CTS	Clear To Send Configures the interrupt, CTS_B, for change of state on the CTS_B pin. 0b - Disable interrupt 1b - Enable interrupt

64.6.1.16 MODEM Status (MSR)

Offset

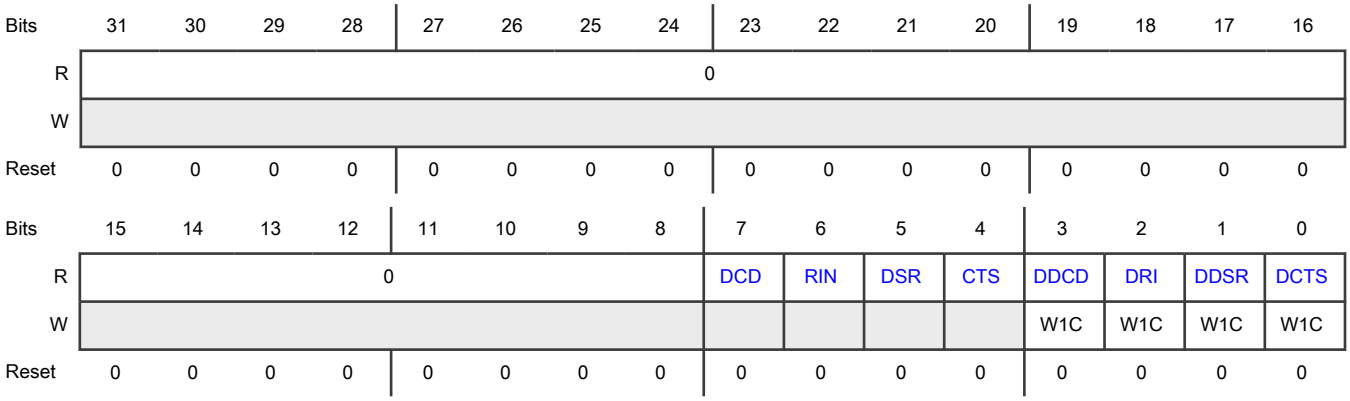
Register	Offset
MSR	44h

Function
Indicates the status of the MODEM pins.

NOTE

You must appropriately configure the PAD connecting to DCD_B, RIN_B, DSR_B, and CTS_B inputs to get appropriate reset values for the MSR register fields.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 DCD	Data Carrier Detect Indicates the state of the DCD_B pin. 0b - Logic one 1b - Logic zero
6 RIN	Ring Indicator Indicates the state of the RIN_B pin. 0b - Logic one 1b - Logic zero
5 DSR	Data Set Ready Indicates the state of the DSR_B pin. 0b - Logic one 1b - Logic zero
4 CTS	Clear To Send Indicates the state of the CTS_B pin. 0b - Logic one 1b - Logic zero

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 DDCD	Delta Data Carrier Detect Indicates whether the DCD_B pin changed state since the last time this field was 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not change state 1b - Changed state When writing 0b - No effect 1b - Clear the flag
2 DRI	Delta Ring Indicator Indicates whether the RIN_B pin changed state since the last time this field was 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not change state 1b - Changed state When writing 0b - No effect 1b - Clear the flag
1 DDSR	Delta Data Set Ready Indicates whether the DSR_B pin changed state since the last time this field was 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not change state 1b - Changed state When writing 0b - No effect 1b - Clear the flag
0 DCTS	Delta Clear To Send Indicates whether the CTS_B pin changed state since the last time this field was 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Did not change state 1b - Changed state When writing 0b - No effect 1b - Clear the flag

64.6.1.17 Receiver Extended Idle (REIR)

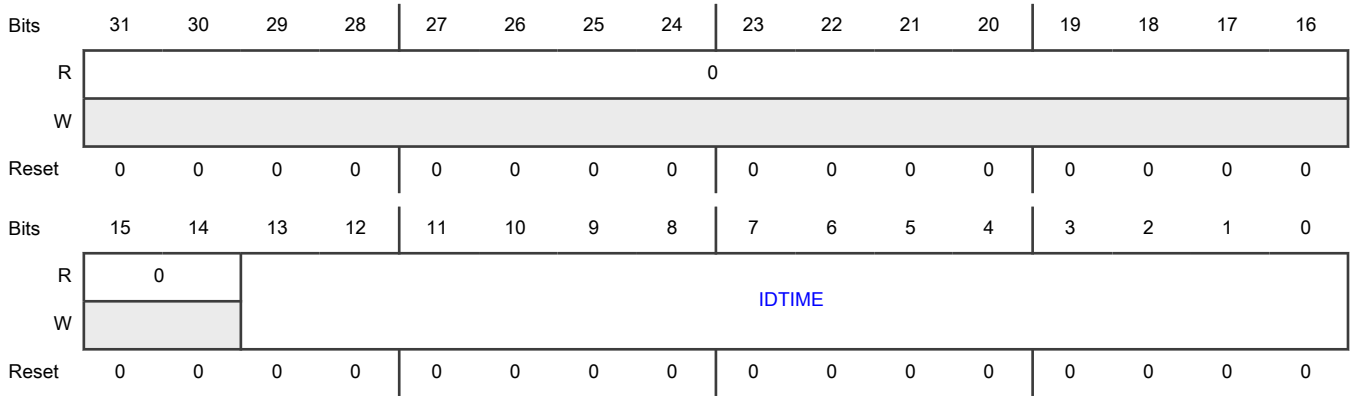
Offset

Register	Offset
REIR	48h

Function

Configures the receiver extended idle functionality. You must not change this value when the receiver is enabled.

Diagram



Fields

Field	Function
31-14 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
13-0 IDTIME	Idle Time Configures the idle length in number of bits (baud rate) since the end of the last stop bit. This affects the behavior of the idle wake-up, STAT[IDLE], DATA[IDLINE], and STAT[RAF]. The minimum supported extended idle time is equal to one idle character. The extended idle feature is disabled when this field is 0.

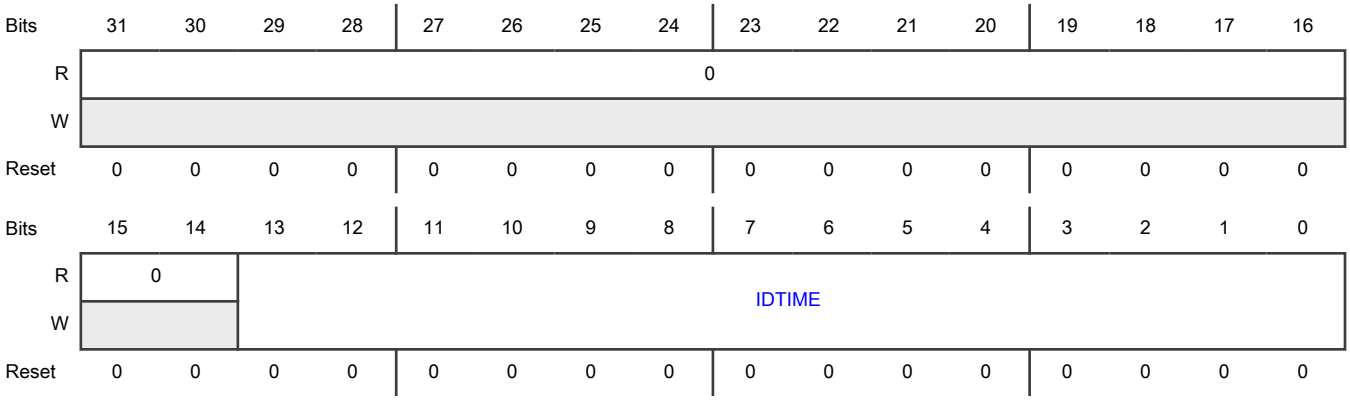
64.6.1.18 Transmitter Extended Idle (TEIR)

Offset

Register	Offset
TEIR	4Ch

Function
Configures the transmitter extended idle functionality. You must not change this value when the transmitter is enabled.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-0 IDTIME	Idle Time Configures the transmitter idle time in number of bits (baud rate) whenever an idle character is queued through the transmit FIFO. An idle character is not automatically queued whenever the transmitter is enabled. The minimum supported extended idle time equals one idle character. The extended idle feature is disabled when this field is 0.

64.6.1.19 Half Duplex Control (HDCR)

Offset

Register	Offset
HDCR	50h

Function

Provides control for half-duplex-related operations.

You can use this register instead of CTRL[LOOPS], CTRL[RSRC], and CTRL[TXDIR] functions, although you can use CTRL[LOOPS] to loop-back the transmitter outputs to the receiver.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 —	Reserved
15-8 RTSEXT	RTS Extended Specifies RTS extension. The transmit RTS_B remains asserted for (RTSEXT + 1) bit times after the end of the last stop bit. This applies even when the transmitter's RTS_B output is disabled and is only used internally to mask the receiver.
7-4 —	Reserved
3 RXMSK	Receive Mask Specifies whether the transmitter RTS_B masks the receive data pin. When enabled, the transmitter RTS_B masks the receive data pin. 0b - Do not mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Mask
2 RXWRMSK	Receive FIFO Write Mask Specifies whether the transmitter RTS_B masks writes to the receive FIFO. When enabled, the transmitter RTS_B masks receive FIFO writes, but the idle flag is not affected. 0b - Do not mask 1b - Mask
1 RXSEL	Receive Select Specifies the receive data pin. When enabled, the receive data is sourced from the TXD pin. 0b - RXD 1b - TXD
0 TXSTALL	Transmit Stall Specifies whether the transmitter becomes busy when the receiver is active. When enabled, the transmitter does not become busy or asserts transmitter RTS_B when the receiver is active (STAT[RAF] is 1). 0b - No effect 1b - Does not become busy

64.6.1.20 Timeout Control (TOCR)

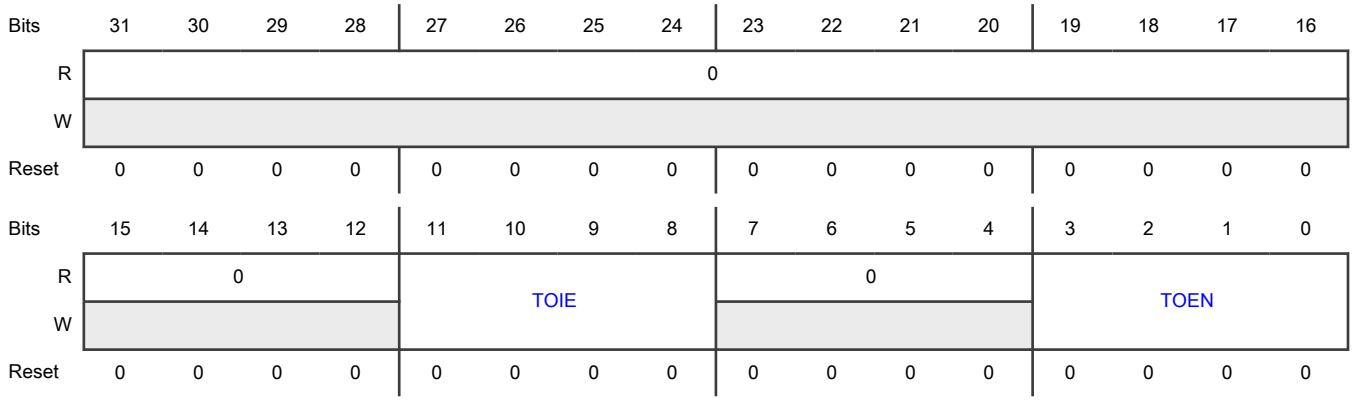
Offset

Register	Offset
TOCR	58h

Function

Configures the behavior of the timeout logic. Timeouts 0 and 1 are used to monitor the receiver and timeouts 2 and 3 are used to monitor the transmitter.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-8 TOIE	Timeout Interrupt Enable Enables the corresponding timeout flag to generate an interrupt.
7-4 —	Reserved
3-0 TOEN	Timeout Enable Enables the corresponding timeout counter.

64.6.1.21 Timeout Status (TOSR)

Offset

Register	Offset
TOSR	5Ch

Function

Indicates the status of the timeout logic. Timeouts 0 and 1 are used to monitor the receiver and timeouts 2 and 3 are used to monitor the transmitter.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Fields

Field	Function
31-12 —	Reserved
11-8 TOF	Timeout Flag Indicates whether the corresponding timeout occurred. The timeout counter is disabled when this field is 1. **NOTE** This field behaves differently for register reads and writes. When reading 0000b - Not occurred 0001b - Occurred When writing 0000b - No effect 0001b - Clear the flag
7-4 —	Reserved
3-0 TOZ	Timeout Zero Indicates whether the corresponding timeout counter equals 0.

64.6.1.22 Timeout N (TIMEOUT0 - TIMEOUT3)

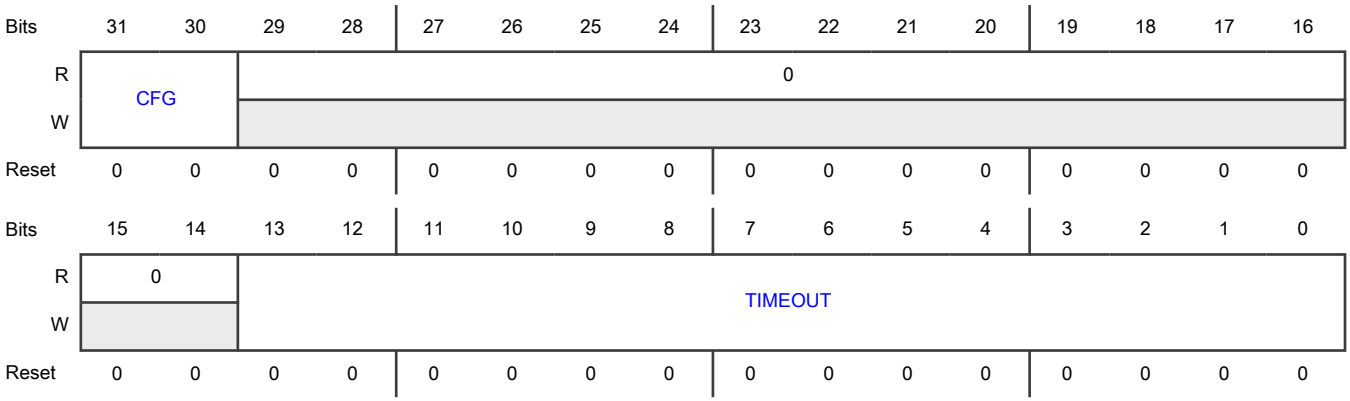
Offset

Register	Offset
TIMEOUT0	60h
TIMEOUT1	64h
TIMEOUT2	68h
TIMEOUT3	6Ch

Function

Configures the corresponding timeout counter and status field. Timeouts 0 and 1 are used to monitor the receiver and timeouts 2 and 3 are used to monitor the transmitter. You must write to this register only when the corresponding timeout is disabled or when the value of the corresponding timeout field is 1.

Diagram



Fields

Field	Function
31-30 CFG	Idle Configuration Configures the behavior of TIMEOUT[TIMEOUT]. 00b - Becomes 1 after timeout characters are received 01b - Becomes 1 when idle for timeout bit clocks 10b - Becomes 1 when idle for timeout bit clocks following the next character 11b - Becomes 1 when idle for at least timeout bit clocks, but a new character is detected before the extended idle timeout is reached
29-14 —	Reserved
13-0 TIMEOUT	Timeout Value Configures the timeout value.

64.6.1.23 Transmit Command Burst (TCBR0 - TCBR127)

Offset

For a = 0 to 127:

Register	Offset
TCBRa	200h + (a × 4h)

Function

Acts as an alias of Data (DATA), designed to support incrementing burst transfers to the transmit FIFO by a DMA controller, using aligned 8-bit, 16-bit, or 32-bit writes. The size of this register is 512 bytes:

- An aligned 32-bit write in this region pushes one entry into the transmit FIFO.
- An aligned 16-bit write in this region to TCBR*x*[15:0] pushes one entry into the transmit FIFO.
- An 8-bit write in this region to TCBR*x*[7:0] updates DATA[7:0], but does not push the data into the transmit FIFO.
- An 8-bit write in this region to TCBR*x*[15:8] pushes the data written to DATA[15:8] plus the previously written DATA[7:0] into the transmit FIFO.
- An 8-bit or 16-bit write in this region to TXBR*x*[31:16] is ignored.

64.6.1.24 Transmit Data Burst (TDBR0 - TDBR255)

Offset

For a = 0 to 255:

Register	Offset
TDBRa	400h + (a × 4h)

Function

Acts as an alias of Data (DATA), designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using 8-bit, 16-bit, or 32-bit writes. The size of this register is 1024 bytes:

- An aligned 32-bit write in this region pushes four DATA byte entries into the transmit FIFO (DATA0 byte first). The register access is extended by three wait states.
- An aligned 16-bit write in this region to either half of a 32-bit word pushes two DATA byte entries into the transmit FIFO (DATA0 or DATA2 first). The register access is extended by one wait state.
- An 8-bit write in this region pushes one DATA byte entry into the transmit FIFO.

Byte writes to Data (DATA) use the contents of CTRL[R9T8] for the ninth data bit, CTRL[R8T9] for the tenth data bit, and zero extend DATA[FRETSC].

65.2 I3C Target Reset functionality

A Target Reset pattern detector is connected with of I3C module in this device. This functionality is active when related I3C module is configured as I3C target, that is, MCONFIG. MSTENA[0] = 0 . I3C Controller can set Reset action via defining byte of Broadcast or Direct write RSTACT CCC and read the same via Direct read RSTACT CCC. With default action set, on detection of any Target Reset Pattern a flag SSTATUS[SLVRST] is set and an interrupt is generated to system if enabled in SINTSET [SLVRST]. System can decide how to use this interrupt for any purpose, viz Reset to this module or any peripheral, or system etc. After taking action, the host clears the interrupt. Supported values of defining bytes in RSTACT CCC are 0x00 and 0x01.

65.3 Overview

I3C is a communications processor that improves upon the use and power of I2C, and provides an alternative to SPI for mid-speed applications.

The I3C bus protocol supports:

- In-band interrupts (IBI): these interrupts move from target to controller without extra wires, and the controller knows which target sent the interrupt
- Common command codes (CCC)
- Dynamic addressing
- Multi-controller and multi-drop

- Hot-Join (HJ)
- I2C compatibility

I3C supports all required and many optional features of the MIPI Alliance Specification for I3C, v1.0, except for ternary data rates (HDR-TSP and HDR-TSL). See Features for more information.

65.3.1 Block diagram

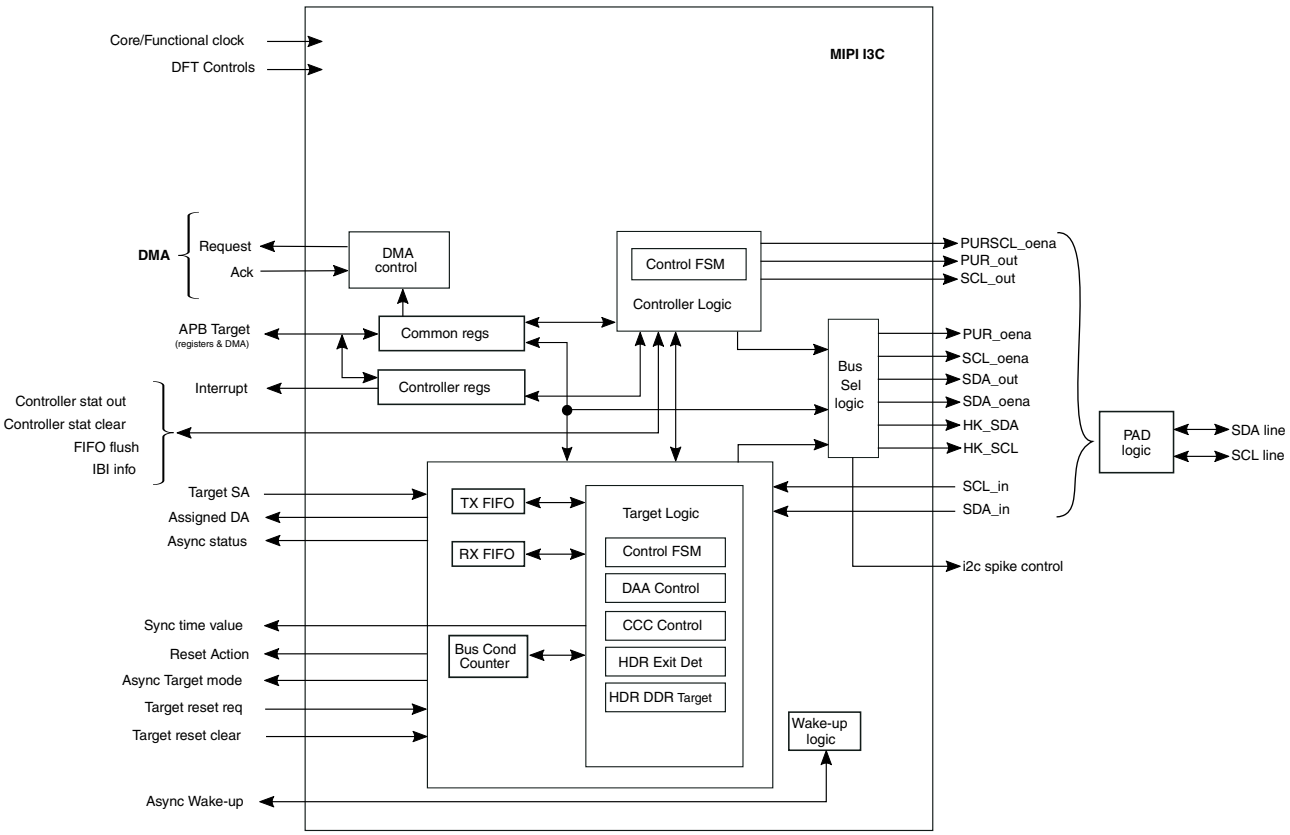

Figure 479. Block diagram

65.3.2 Features

- Two-wire multidrop bus that is capable of up to 12.5 MHz clock speeds with up to 11 devices:
  - Uses standard pads with 4 mA drive.
  - Dynamically assigns target addresses, and targets do not require static addresses (SAs). However, targets can have an I2C static address assigned at startup, so the target can operate on an I2C bus. By default, I3C supports 7-bit I2C-style addresses.
  - Supports extended I2C 10-bit addressing through Map Feature Control 1 (SMAPCTRL1).
  - Allows targets to use the inbound SCL clock as the peripheral clock (instead of the clock from the controller) so that devices can have slow or inaccurate clocks internally.
  - Allows simple targets, such as temperature sensors, to have no internal clock.
  - I3C controller supports handoff from Open-Drain to Push-Pull mode for ACK to data transfer.
  - Generally, the controller terminates the read, but for I3C, the target can also end the read.
- IBIs that allow targets to send notifications to a controller:

  - Can be equivalent to a separate GPIO, but can also be directly data-bearing.
  - Can be prioritized. When multiple targets send interrupts to a controller at the same time, the order is resolved. Dynamic addresses (DAs) establish the priority of the targets, so the controller controls the priority of the targets.

    Targets with lower-value DAs are higher-priority level IBIs.
  - Can start interrupts even when the controller is not active on the bus. A free-running clock is not required, but starting an interrupt requires a Bus Available condition.
  - Can resolve an initial event via a time-stamping option, not requiring an interrupt.
- Built-in commands for applications created in software or firmware by using the register interface maintained in a separate space. These commands do not collide with normal controller-to-target messages and:
  - Control bus behavior, modes and states, low-power state, inquiries, and more.
  - Have an extra room for new built-in commands for other groups.
- Organized forms of multicontroller modes that are secondary controllers using clean handoffs between different controllers.
- Hot-Join onto I3C bus allows devices to connect to the bus later than when the bus starts. This:
  - Enables a device or module to access the I3C bus after power up or when physically inserted onto the I3C bus.
  - Provides a clean method for notification when new devices or modules access the I3C bus.
- I3C can use both I2C and I3C buses:
  - I3C supports specific legacy I2C devices on the bus.
  - I3C target devices can operate on I2C buses.
  - A reset output is available for I2C mode SW reset for application usage. Asserted when the module in I2C Target and gets a I2C software General command from Controller.
- Higher data rate modes are available:
  - I3C has a high data rate: double data rate (HDR-DDR) mode, which is double the data rate of SDR .
  - Only the controller and the specific targets, which are capable and configured to work with HDR-DDR, support the higher data rate (the other targets can ignore it).

I3C supports most of the I3C features (see Target Capabilities (SCAPABILITIES) and Target Capabilities 2 (SCAPABILITIES2)), except for the ternary data rates (HDR-TSP and HDR-TSL), HDR-BT modes, and peer-to-peer messaging.

65.4 Functional description

65.4.1 Operating modes

This section describes all functional operation modes of the I3C module.

65.4.1.1 Target and controller roles for I3C

The I3C protocol defines these roles for devices on the I3C bus:

- Main controller: initially configures the I3C bus and serves as the first active controller
- Secondary controller: accepts the controller role from any active controller to become the new active controller (the secondary controller may then pass the controller role along: either back to the previous active controller, or on to any other controller-capable device)
- Target: responds to commands from any I3C controller
- I2C target: responds to compatible commands from any I3C controller

The I3C peripheral contains both controller and target components and can be configured to be either controller or target, or as target with secondary controller capability. However, if I3C is chosen to be a controller, then the I3C peripheral supports Target mode to facilitate handoffs to multiple controllers.

In general, any I3C controller can be a controller or a target because a controller becomes a target when giving over control to another controller. The only exceptions to this rule occur when using point-to-point communication or when using a controller that never shares controllership.

65.4.1.1.1 Controller requirements

Controller mode uses software that supports the requirements of the controller (including as a secondary controller):

- Managing the enter dynamic address assignment (ENTDAA) assigning dynamic addresses (DAs) to each target. The I3C peripheral supports this process but requires you to make choices.
- Driving the serial data (SDA) signal in both Open-Drain and Push-Pull modes. After START command, SDA is in Open-Drain mode and after Repeated START command, it is in Push-Pull mode:
  - SDA is subject to arbitration because both controller and target can drive the SDA line (arbitration is also useful for handoff from controller to target).
  - The ninth bit of SDA controller write data is an odd parity bit.
- Building a table of targets and their capabilities to control which actions and commands may be sent to the targets.
- Managing requests such as IBI and controller requests (handoff).
- Adjusting clock speed or write-to-read timing to match the limitations of the target. This adjustment can be done in hardware using dividers and uneven duty cycles, but you must decide how.
- Adjusting the maximum data length.
- Being a target after the controller role handoff to another controller-capable device.

The controller needs an accurate clock capable of running at a frequency that is the multiple of a frequency between 11 MHz and 12.5 MHz. Following are the possible clock frequencies:

- 24 MHz (multiple of 12 MHz)

If required to use a lower I3C SCL value, for example as small as 5 MHz (although the lower value does not support a mixed bus system):

- The controller clock can be a multiplier of that value.
- A lower SCL can also be achieved using a higher PPBAUD value.

65.4.1.1.2 I3C target acts like I2C target on I3C buses

If the target is assigned an I2C static address, the I3C target acts like an I2C device when it first powers on. If the I3C target is placed on an I2C bus with an I2C controller, then the I3C target stays in I2C mode and operates normally. The software is aware that the I3C target is in I2C mode because:

- There has not been an interrupt (see SSTATUS[DACHG]) indicating that a dynamic address was assigned.

For full I2C support of Fast mode (Fm) and Fast-mode Plus (Fm+), the pads must support a 50-ns spike filter. This filter must be turned off when the I3C 7Eh broadcast address is received (indicating an I3C controller). You can turn off the spike filters via hardware using the raw net indicating that the address was received, or via software. I3C does not need a 50-ns spike filter to operate on an I2C bus. Therefore, the spike filter is not a requirement for the I3C peripheral.

Depending on the configuration, the module supports most I2C features, except for clock stretching. Supported features include an extended 10-bit address, DeviceID, and software reset. See Target Capabilities (SCAPABILITIES) and Target Capabilities 2 (SCAPABILITIES2) for more information.

65.4.1.1.3 How a target rejoins the I3C bus

When a target tries to rejoin the I3C bus following a power-up or hard reset, the target needs a new dynamic address (DA). The target can rejoin the I3C bus in these ways:

- If the DA is lost, Hot-Join is used.
- If the DA is retained in the peripheral (for example, with state retention flip-flops), SCONFIG[OFFLINE] is used.

When SCONFIG[SLVENA] is 1, SCONFIG[OFFLINE] may become 1. This setting causes the peripheral to rejoin the bus safely. It does so by ensuring that the I3C bus is not in HDR mode, using the same approach as TE0 or TE1 exit. The peripheral waits for the HDR exit pattern from the controller, or for 60 µs of SCL and SDA lines not changing, whichever occurs first.

After using SCONFIG[OFFLINE], the I3C peripheral cannot safely use IBI until SSTATUS[STOP] becomes 1. This status ensures that the next START is safe to use for IBI.

If the application has to perform an IBI, it must wait for SSTATUS[STOP] to become 1, or for SCL and SDA lines to remain high for 200 µs. You can perform this process using the SSTATUS and SINTSET controls:

- If Target Status (SSTATUS) indicates that the bus is not busy and the peripheral interrupts on START or STOP, use a timer to measure 200 µs. If the timer finishes with no START or STOP, it is safe to use IBI.
- If a START causes an interrupt, then the timer must be turned off and the application must wait for a STOP.
- If a STOP causes an interrupt, it is safe to use IBI.

65.4.1.2 Using the I3C controller for I2C and I3C

The I3C controller operates with the following set of built-in capabilities with the application flow:

- Built-in enter dynamic address assignment (ENTDAA) mechanism to simplify the assignment of dynamic addresses to targets. This feature is used when set dynamic address from static address (SETDASA) is not available.

  NOTE

  When SETDASA CCC is available, use SETDASA CCC before using ENTDAA CCC; all targets without assigned dynamic addresses respond to ENTDAA CCC.

- Request for START + address with IBI support, including both I2C and I3C modes.
- SDR write flow via FIFO, with automatic parity in I3C and ACK or NACK detection in I2C.
- SDR read flow via the FIFO, with an automatic NACK generator for I2C, and optional use of a terminate generator for I3C.
- Request for Repeated START + address or STOP when finished with the previous request, including both I2C and I3C.
- Auto-IBI mode, which responds immediately to a target-initiated IBI and can be used when in Sleep or Deep Sleep mode.
- Special message mode for SDR and DDR to simplify DMA use.
- Automated SCL, SDA, pullup, and High-Keeper controls.
- I2C and I3C frequency and duty cycle configurations from functional clock.

  NOTE

  You must configure Controller Configuration (MCONFIG) and Controller In-band Interrupt Registry and Rules (MIBIRULES) before using the controller.

65.4.1.3 Protocol modes and states

The following modes are activated in I3C:

- I2C mode is the default mode on startup:
  - If no I2C static address is used, this mode has no effect other than to track frames looking for I3C transitional frames.

- If an I2C static address is used, the device can interact with the I2C bus controller using the address.

- When in I2C mode, I3C Transitory Frame mode occurs whenever the I3C broadcast address is received (7Eh). In particular:
  - This mode occurs when 7Eh is broadcast followed by SETDASA from the controller. If there is a static address match or 01h, the target is assigned a dynamic address and it enters I3C SDR mode.
  - This mode occurs when 7Eh is broadcast followed by ENTDAA from the controller. If the target can send a 48-bit provisioned ID (48b ID), a dynamic address is assigned, and the target enters I3C SDR mode.
  - If a Hot-Join arbitrated event occurs (sending 02h when the controller generates another address such as 7Eh), there is a conceptual Hot-Join mode. ENTDAA or SETDASA sets a dynamic address to resolve the event, and the target enters I3C SDR mode.

NOTE

An I3C target can operate as a normal I2C target only when it has a static address. Otherwise, it matches nothing in I2C and waits for the aforementioned events.

- I3C SDR mode is the standard mode after I3C activates, which is defined by a dynamic address being assigned. This mode is the resting mode of I3C, and all devices are normally in SDR mode:
  - RSTDAA CCC causes an exit from SDR mode and a return to I2C mode. This transition is not normally used.

    RSTDAA can be issued to ensure all I3C targets participate in an upcoming dynamic address assignment process, before the I3C controller starts assigning the target address.
  - SETNEWDA does not affect the SDR mode; it only changes the dynamic address of an I3C device that already had a dynamic address assigned.
  - When in SDR mode, the device ignores messages to or from its original I2C static address.
- The I3C CCC command submode of type Direct or Broadcast. Following are the options to exit the CCC:
  - Exit the Broadcast CCC submode by a Repeated START or by a STOP.
  - Exit the Direct CCC submode by a 7Eh broadcast address after a Repeated START or by a STOP.
  - I3C dynamic address assignment (DAA) CCC command enters DAA mode. This mode is a special mode for dynamic addressing. Use STOP to exit. If a target has a dynamic address, the command is ignored.
- I3C SETDASA CCC command enters Static Address Match submode, which allows matching the static address of the device (if any). The command is ignored when a target has a dynamic address, or when the target in I2C mode has no static address.

NOTE

The special point-to-point address is also matched.

- I3C HDR modes are activated by ENTHDR*n* CCC commands, where *n* represents the type of HDR (0 to 7). This mode is valid until an HDR exit pattern is detected, irrespective of whether HDR mode for a target is supported.

  Exit-pattern detection must always be on to prevent errors. Alternatively, you could set it to be activated only on ENTHDR.
- Internal states such as IBI or no-IBI and Low-Power mode are flagged internally (see SSTATUS[EVDET] for more information). These states are exported to the application and affect the engine to restrain it from performing a prohibited operation.

65.4.1.4 Address match

For an address match to occur, the target matches the I3C broadcast address and either the I2C-style static address or I3C dynamic address (see Table 1044).

The address match is inactive (just listening) for all Repeated START commands and also for the START command, unless an IBI, CR, or Hot-Join has been activated. If inactive, it simply tries to match. If not matched, it waits for a Repeated START or

STOP command. If an IBI, CR, or Hot-Join has been activated, the arbitration mechanism is used for START (but never for a Repeated START).

When matching the 7Eh broadcast address, it looks for a CCC until the next Repeated START or STOP command.

Table 1044. Address match conditions

For	Match condition occurs when	Notes
I3C broadcast address	The address is 111 1110b (written as 7Eh).	
I2C-style static address	• The device has a static address. • The device is not in I3C mode.	When in I3C mode, the address matches only until the ENTDAA, SETDASA, or SETAASA command has a dynamic address assigned. SETDASA matches the static address or the special one-controller-to-one-target point-to-point address.
I3C dynamic address	ENTDAA or SETDASA assigns it, or SETNEWDA modifies it.	

65.4.2 Operations

This section describes the operations of the module.

65.4.2.1 Reading and writing I2C messages using the normal method

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when the module completes an MCTRL request.
   - COMPLETE: Indicates when data is finished sending or being received.
   - RXPEND: Used for read operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use this field to allow DMA to read out data.
   - TXNOTFULL: Used for write operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use this field to allow DMA to supply data.
   - IBIWON: Indicates that an IBI, CR, or HJ has won the arbitration on a header address.
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Configure the following fields in Controller Control (MCTRL) simultaneously:
   a. Write 1 to REQUEST (EmitStartAddr).
   b. Write 1 to TYPE (I2C).
   c. Configure IBIRESP to respond to IBIs in your chosen manner.
   d. Write 1 to DIR for read, or write 0 for write.
   e. Write the static address of the I2C target to ADDR.
   f. Configure RDTERM to the maximum length for read operations, to auto-terminate, or set it to STOP as the data is read out. For example, write 1 (with MCTRL[REQUEST] = 0) to stop after the next character.
3. Write or read the data.
   - For write operations, write to Controller Write Data Byte (MWDATAB) for each byte before the last byte, and then write to Controller Write Data Byte End (MWDATABE) for the last byte:

— You can perform or start this operation before setting up interrupts.

— If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level. This interrupt allows the application to provide more data or to use DMA.

- For read operations, wait for RXPEND, and then read out data via Controller Read Data Byte (MRDATAB). DMA may also be used.

4. After message transfer is complete (MSTATUS[COMPLETE] = 1), the message may end with a STOP condition, or a new message may start with a Repeated START condition:
   a. Write 2 to MCTRL[REQUEST] (EmitStop to STOP). Then wait for the MCTRLDONE status to be asserted for its completion. (When sending STOP in I2C mode, MCONFIG[ODSTOP] and MCTRL[TYPE] must be 1.)
   b. Write 1 to MCTRL[REQUEST] (EmitStartAddr to restart). IBI is not possible in this case.

NOTE

I2C Fm and I2C Fm+ modes are supported for legacy I2C devices as per the I3C standard specifications. See I2C configuration to meet timing requirements for Fm and Fm+ modes for more information.

65.4.2.2 Reading and writing I3C messages using the normal methods (SDR and HDR-DDR)

The normal method for I3C is the same as the method for I2C with a few differences:

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when the I3C module completes an MCTRL request.
   - COMPLETE: Indicates when data is finished sending or being received.
   - RXPEND: Used for read operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use it to allow DMA to read out bytes.
   - TXNOTFULL: Used for write operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use it to allow DMA to supply bytes.
   - IBIWON: Indicates that an IBI, CR, or HJ has won the arbitration on a header address.
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Set up Controller Control (MCTRL).
   - Option 1: Configure the following fields of Controller Control (MCTRL) simultaneously in this way:
     a. Write 1 to REQUEST (EmitStartAddr).
     b. Write 0 to TYPE for I3C Single Data Rate (SDR) mode or write 2 for Double Data Rate (DDR) mode.
     c. Configure IBIRESP to respond to IBIs in your chosen manner.
     d. Write 1 to DIR for read, or write 0 for write.
     e. Write the dynamic address of the I3C target to ADDR.
     f. For read operations, you can configure RDTERM to the maximum length to terminate automatically.
     g. For write operations, prewriting the data (MWDATAB or MWDATAH) is preferred to ensure that there are no time delays waiting for the data.

        For DMA with MCTRL, use Controller Write Byte Data 1 (to Bus) (MWDATAB1).

NOTE

HDR-DDR mode requires writing an 8-bit command value for read or write. This value must be written into the TX FIFO via Controller Write Data Byte (MWDATAB). The END field is not used for this byte.

- Option 2: This option is preferred when stopped (bus free condition) in SDR mode, and not in HDR-DDR mode. It allows any target to issue an IBI and avoids collisions with an IBI address. Also, it is faster (when the MSB of the dynamic address is always 0).

  Configure the following fields of Controller Control (MCTRL) in this way:

  a. Write 1 to REQUEST (EmitStartAddr). No prewritten transmit data can be in the FIFO.
  b. Write 0 to TYPE (I3C).
  c. Configure IBIRESP to respond to IBIs in your chosen manner.
  d. Write 0 to DIR.
  e. Write 7Eh to ADDR.
  f. Wait for MCTRLDONE (via interrupt, for example), then proceed as in option 1. The option 2 method has advantages for IBIs when 7Eh is sent on START (but not on Repeated START conditions).

3. Write or read the data.
   - For write operations, write to MWDATAB for each byte before the last byte, and then write to Controller Write Data Byte End (MWDATABE) for the last byte. For HDR-DDR, the byte with END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs:
     — You can perform or start this operation before step 1 (REQUEST = 1) of the option 1 method, but not before the option 2 method.
     — If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level. This interrupt allows the application to provide more data or to use DMA.
   - For read operations, wait for RXPEND, and then read out data via Controller Read Data Byte (MRDATAB) or Controller Read Data Halfword (MRDATAH). DMA may also be used. When using DMA, read using the same registers.
4. After message transfer is complete (MSTATUS[COMPLETE] = 1), the message may be ended with STOP (or EXIT in HDR mode). Alternatively, a new message may be started with a Repeated START (or HDR-Restart in HDR mode):
   - In SDR mode, write 2 to MCTRL[REQUEST] (EmitStop to STOP). Then wait for the MCTRLDONE status to be asserted for its completion.
   - For HDR mode, write 6 to MCTRL[REQUEST] (ForceExit) to end HDR mode. Then wait for the MCTRLDONE status to be asserted for its completion. When sending the HDR exit pattern, MCONFIG[ODSTOP] must be 0.
   - Write 1 to MCTRL[REQUEST] (EmitStartAddr to start another message). IBI is not possible in this case.

65.4.2.3 Determining bus types and modes

The settings of MCTRL[TYPE] and MCTRL[REQUEST] determine bus types and modes.

Table 1045. Determining bus types and modes

Value of MCTRL[TYPE]	Meaning when MCTRL[REQUEST] = 1 (EmitStartAddr)	Meaning when MCTRL[REQUEST] = 2 (EmitStop)	Meaning when MCTRL[REQUEST] = 6 (ForceExit)
0	SDR mode of I3C	SDR mode of I3C	Exit pattern
1	Standard I2C protocol	Standard I2C protocol	Reserved
2	The bus enters DDR mode (7E and then ENTHDR0), if the module is not in DDR mode already. The first byte written to the transmit FIFO must be a command and	Reserved	Target reset

Table continues on the next page...

Table 1045. Determining bus types and modes (continued)

Value of MCTRL[TYPE]	Meaning when MCTRL[REQUEST] = 1 (EmitStartAddr)	Meaning when MCTRL[REQUEST] = 2 (EmitStop)	Meaning when MCTRL[REQUEST] = 6 (ForceExit)
	already in the FIFO. To end DDR mode, use ForceExit.		
3	If not already in HDR-BT, the bus automatically enters BT mode (7E and then ENTHDR3). You must also configure the MHDRBTCFG register for multilane and CMD rules.	Reserved	Reserved

65.4.2.4 Sending a CCC to I3C targets

The normal common command code (CCC) method uses an I3C write operation with an address of 7Eh (the CCC is the first byte):

- For broadcast type, any remaining bytes are sent with the CCC. This operation ends with a STOP or a Repeated START and 7Eh.
- For direct type, only the CCC byte is sent (or by a CCC and a defining byte, if required by the CCC).

  These bytes are followed by a Repeated START and the address of the I3C target (for SETDASA, this address is its I2C static address). This sequence may be repeated with more Repeated START conditions and addresses until done. It may end in STOP or a Repeated START and 7Eh. After the Repeated START and target address, the values are read or written depending on the CCC.
- I3C provides interrupts (by hardware) for unhandled and handled CCC when received by the target. Its state is reflected in Target Status (SSTATUS).

The first broadcast 7Eh must meet an open-drain timing check:

- Use the configurations (MCONFIG[ODHPP] = 0 and the normal MCONFIG[ODBAUD]), ensuring at least 200 ns for the open-drain SCL half-clock period.
- Follow with a Repeated START or a STOP.

All subsequent messages must use MCONFIG[ODHPP] = 1.

I3C controllers require to emit a single START, 7E/W sequence with both SCL high and SCL low half periods at full open-drain timing (for example, 200 ns). This sequence allows I3C targets acting as I2C legacy devices to turn off their I2C 50-ns spike filters, if they have them.

NOTE

START, 7E/W is a notation indicating a START command, followed by the 7Eh broadcast address and then by a write command.

After that sequence, addresses following START may be sent with Open-Drain Low (for example, 200 ns) but high of Push-Pull timing (for example, 40 ns). The I3C controller must emit this START, 7E/W sequence with MCONFIG[ODHPP] = 0. ODHPP is Open-Drain High period at Push-Pull speeds, and MCONFIG[ODHPP] is usually 1.

NOTE

- MCONFIG[ODHPP] is ignored when sending a message to an I2C legacy device on an I3C bus.
- Each Repeated START is a new EmitStart request. This request can be chained by an interrupt or pushed by a message model using DMA.

65.4.2.5 IBI handling

An IBI occurs when a target sends its address after a START, and that address is numerically the lowest. That is, it is lower than the address sent by the controller and addresses sent by any other targets. When the controller sends 7Eh, the controller always loses the arbitration.

The IBI can occur unexpectedly when any new START (not a Repeated START) is sent. The IBI can also occur in response to a target pulling SDA low. This condition can occur in one of these ways:

- The controller has set the request to AutoIBI mode, so the IBI occurs automatically. The controller sends 7Eh to allow the target to win the arbitration.
- The application receives the SLVSTART (target START request) interrupt, so it sends 7Eh.

The IBI response is configured by MCTRL[IBIRESP], which can be set to:

- NACK (always reject the IBI).
- ACK (always accept the IBI):
  - You must configure Controller In-band Interrupt Registry and Rules (MIBIRULES) so that the engine knows whether IBI bytes follow.
  - If IBI bytes follow (also known as IBI mandatory byte), then the COMPLETE field does not become 1 when IBIWON becomes 1. RXPEND becomes 1 for one or more bytes in the receive FIFO. When the last byte is received, then the COMPLETE field becomes 1. The controller automatically stops IBI data after 9 bytes (including the mandatory data byte). MCTRL[RDTERM] can be used with MCTRL[REQUEST] = 0 to end the process of receiving data sooner. I3C supports address ACK to mandatory byte transition during IBI from Open_Drain (controller acknowledges the target address) to Push Pull (target sends SDR data).
  - I3C target supports up to 7 bytes (maximum limit is defined by IBIEXT1[MAX]) of extended IBI data following a mandatory data byte. Extended data to send, if any, is present in Extended IBI Data 1 (IBIEXT1) and Extended IBI Data 2 (IBIEXT2).
- Manual (allow the decision to be made by the application on a case-by-case basis):
  - The application rewrites it when stopped, pending an IBI.
  - The application can ACK or NACK the IBI based on the IBI address defined in MSTATUS.
  - This mode selects whether there is an IBI byte when accepting the IBI request from targets.

Accurate timestamping of I3C target data is supported in I3C though Async mode 0. In I3C Asynchronous Timing Control mode, a target device timestamp event occurs within that target. The target notifies the controller about the event by generating an IBI.

65.4.2.6 Assigning dynamic addresses to I3C devices

If dynamic addresses (DAs) are all assigned below 40h (7-bit values from 3Fh down to 03h, except where not allowed), then MIBIRULES[MSB0] can be 1. This setting optimizes the START timing. When dynamic addresses are assigned, you must program Controller In-band Interrupt Registry and Rules (MIBIRULES) based on which I3C target uses IBI bytes (present in SIDEXT[BCR]).

Any SETDASA assignments can be performed via the normal CCC model. These assignments cannot be performed when using the static address for the directed part.

There is a built-in mechanism to process DAA mode:

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when a target has sent its ID and BCR or DCR, and a new DA is needed.
   - COMPLETE: Indicates when DAA is done (NACKed by all targets).
   - RXPEND: Indicates the reading of the IDs of the targets. You can also use this field to allow DMA to read out bytes.
   - IBIWON: Indicates when an IBI has occurred (normally there are no IBI conditions when assigning dynamic addresses to the I3C device).

- Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.

2. Configure Controller Control (MCTRL):
   a. Write 4 to MCTRL[REQUEST] (ProcessDAA).
   b. Set MCTRL[IBIRESP] to IBI response, if possible. If not possible, set to the first target assignment.
3. Wait for the MCTRLDONE interrupt when reading ID using the RXPEND interrupt. If MSTATUS[STATE] = 5 (DAA mode) and MSTATUS[BETWEEN] = 1, it is waiting to write a dynamic address:
   a. Write the dynamic address into Controller Write Data Byte (MWDATAB) using bits 6:0, such as 14h for DA = 7'h14.
   b. Write 4 to MSTATUS[STATE] (ProcessDAA again). This option writes the DA, then moves to the next DA.
   c. If MSTATUS[COMPLETE] = 1 and MSTATUS[STATE] = 0, then all targets are assigned.
   d. If MSTATUS indicates NACK after writing a new DA, the DA is not accepted by the target. The next step is to write 2 to MCTRL[REQUEST] (EmitStop) and start over. It is also acceptable to write 4 to MCTRL[REQUEST] (ProcessDAA again).

65.4.2.7 Using Controller Message mode

Controller Message mode is intended for use with DMA although Message mode can also be used by the processor. In Message mode, all writes are to the same location, including control and data. Reads occur from an associated location.

NOTE

The data writes for Message mode work in the same way as the halfword access registers, Controller Write Data Halfword (MWDATAH) and Controller Read Data Halfword (MRDATAH).

To send a message via Single Data Rate (SDR), follow these steps (from DMA or processor):

1. Write the control request to Controller Write Message Control in SDR mode (MWMSG_SDR_CONTROL). This request includes the following items:
   - The address.
   - I2C or I3C.
   - Read or write.
   - The count of bytes to process.
   - How to end (on STOP or ready for Repeated START).
2. Process the data:
   - For write operations, write the rest of the data to Controller Write Message Data in SDR mode (MWMSG_SDR_DATA). Use the DMA trigger (or interrupt) to keep the transmit FIFO full, and the controller stops using the data when it has already consumed the number of bytes configured in the LEN field.
   - For read operations, a DMA trigger (or interrupt) indicates when the RX FIFO is ready to be read out via Controller Read Message in SDR mode (MRMSG_SDR).
3. Select the in-band interrupt (IBI) behavior in MCTRL[IBIRESP].
4. Use END type STOP (MCTRL[REQUEST] = 2) with a zero-length message or by using Controller Control (MCTRL). To exit Message mode with the original message, use END type STOP (MCTRL[REQUEST] = 2) with a zero-length message or by using the MCTRL register.

To send a message via Double Data Rate (DDR), follow these steps (from DMA or processor):

1. Write the control request to Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL). This request includes:
   - The count of byte pairs.

- How to end the message (through HDR exit or to wait for HDR restart).

2. Write the second control data to MWMSG_DDR_CONTROL. This second write includes:
   - The address.
   - Read or write.
   - The 7-bit command value.
3. Process the data:
   - For write operations, write the rest of the data to MWMSG_DDR_DATA. Use the DMA trigger (or interrupt) to keep the transmit FIFO full, and the controller stops using the data when the program count MWMSG_DDR_CONTROL register reaches 0.
   - For read operations, a DMA trigger (or interrupt) indicates when the receive FIFO is ready to be read out.
4. Select in-band interrupt (IBI) behavior in MCTRL[IBIRESP].
5. Use END type exit (MCTRL[REQUEST] = 6) with a zero-length message or by using the MCTRL register to exit DDR Message mode with the original message.

65.4.2.8 Handing off controllership to another target and getting it back

To hand off controllership, the controller can perform either of the following actions:

- Wait for a controller request (CR) (that is, MSTATUS[IBIWON] = 1 interrupt), indicating that the CR is using MSTATUS[IBITYPE].
- Push the request manually.

In either case, the controller sends a GETACCMST request, which is a directed GET informing the target that it is being assigned controllership. If the target accepts this request, it returns its dynamic address in bits 7:1 and the negative parity of its dynamic address in bit 0. A STOP must be issued, and MCONFIG[MSTENA] must be set to 2 (switching to Target mode).

To gain controllership, the target sends a CR using Target Control (SCTRL):

- If MCONFIG[MSTENA] is 2, the GETACCCR CCC is ACKed.
- If MCONFIG[MSTENA] is not 2, the GETACCCR CCC is NACKed.

After controllership is granted, MSTATUS[NOWMASTER] becomes 1. The application must enable MINTSET[NOWMASTER], so the application is interrupted when a controllership transfer occurs.

65.4.2.9 Controller engine flow diagram

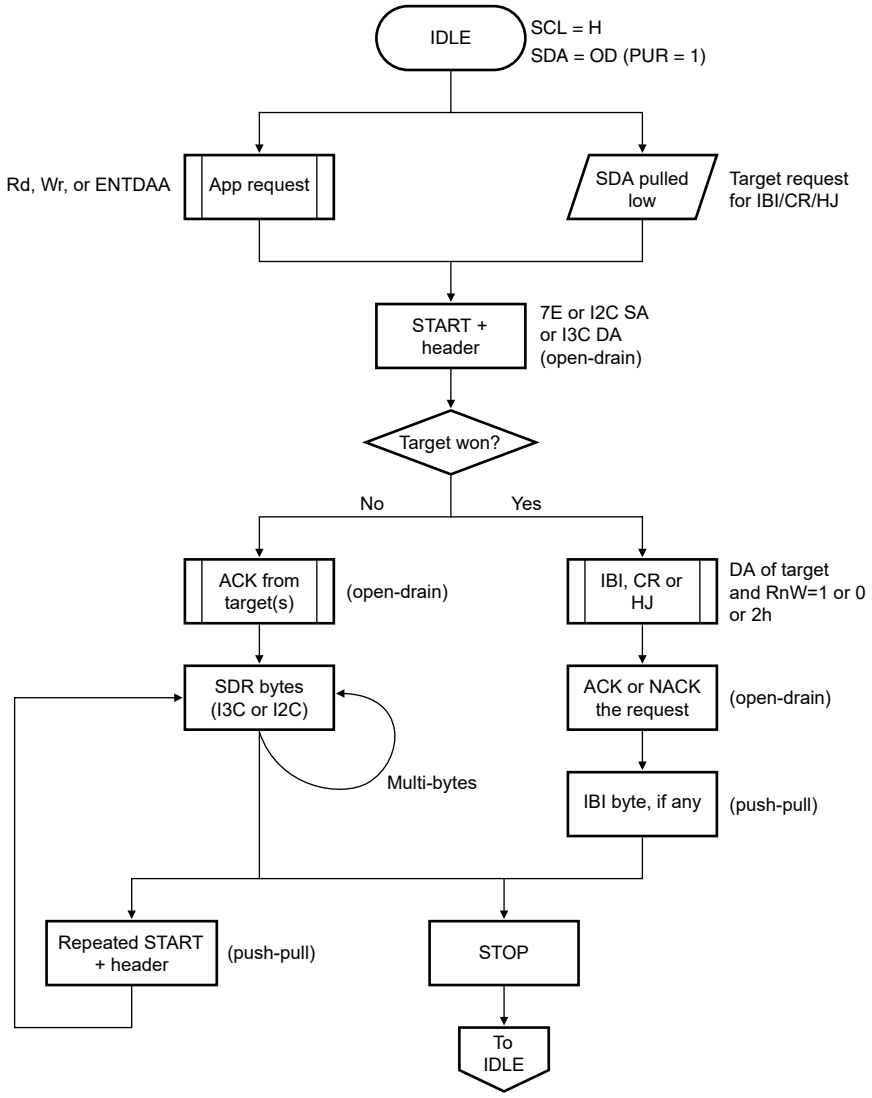

Figure 480. Controller engine flow diagram for SDR (HDR flow progresses from SDR bytes)

65.4.2.10 Target receives data from controller

When the address match is valid for the target dynamic address and the type is W (write from controller), the target ACKs the address. It does so unless some condition prevents it, such as a full buffer. On ACK, the Write state is entered. Once ACKed, it waits for each complete data byte. This process occurs in two steps:

1. Eight bits are clocked in and stored in the next buffer location when in the Write state.
2. On the ninth bit:
   - In I3C mode, the W9TH state (in I3C, the ninth data bit written by the controller is the parity of the preceding eight data bits) is used and the parity is checked. The buffer is marked as complete with or without a parity error.
   - In I2C mode, the W9TH state (in I2C, the ninth data bit written by the controller is an ACK by the target) is used and the data is ACKed and stored.

When the address match is valid for the 7Eh broadcast address, the target acknowledges it. After first data completion, it sets the in_ccc broadcast or direct flag (based on bit 7 of the command). If recognized, it parses the command, setting that bit as well. The

recognized commands are for dynamic address work and modes. The CCC and DAA blocks handle the workload afterward. If not supported, then the commands are passed up to the system.

65.4.2.11 Target sends data to controller

When the address match is valid for the target dynamic address, and the type is R (read by controller), the target ACKs the address. The target does so unless there is no data waiting for the read. On ACK, the Read state is entered.

After being ACKed, it emits the data byte at a time, with the ninth bit using the R9TH state. In I2C, the ninth data bit from target to controller is an ACK by the controller. In I3C, this bit allows the target to end a read, and allows the controller to abort a read:

- In I3C mode, the T bit is emitted to allow the device to indicate whether this byte is the last. If it is not the last byte, the controller may terminate the read via the T bit.
- In I2C mode, the ninth bit allows the controller to terminate via NACK, or else it allows the read to continue via ACK. On completion of each byte read, the "done" signal is pulsed to get the next byte.

If the read is terminated by the controller unexpectedly (abort in I3C, NACK before END marked), the application is notified.

65.4.3 Clocking

The controller works on the following primary clocks:

- The system clock, which controls access to the memory-mapped registers.
- A functional clock (FCLK), which is used to generate the SCL clock rate on the I2C or I3C bus.

I3C supports adjusting clock frequency and accuracy via Target Time Control Clock (STCCLOCK).

FCLK is used to check conditions such as bus availability, bus free for IBI, or HJ:

- To determine the Bus Available condition for IBI, the target needs a clock to generate the ~1 µs timing. To support this requirement, a slow clock (CLK_SLOW) is provided to save on power.

I3C supports a timeout when stalled for too long in a frame. This timeout occurs when:

- The transmit FIFO or receive FIFO is not handled and the bus is stuck in the middle of a message.
- No STOP is issued and the bus is between messages.
- IBI manual is used and no decision is made.

65.4.4 Reset

- Global or system reset fed into the module: Everything is reset by this global or system reset. Release is assumed to be synchronized with the system clock. It is not synchronized with SCL or SDA. These signals must not be active when the reset is released; otherwise, I3C enters Hot-Join mode and remains inactive.
- Software reset

65.4.5 Interrupts

This section describes all the interrupts (IRQs) that this module generates. All status interrupts are updated in Controller Status (MSTATUS) and Target Status (SSTATUS).

Supported interrupts occur:

- For pending IBI, CR, or Hot-Join that have been sent by a target.
- When a CCC is received and is handled by the module (SSTATUS[CHANDLED]).
- When an error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR, or CRC error.
- When a CCC is received that is unhandled by I3C. CCC Mask for Unhandled CCCs (SCCCMASK) allows you to suppress any CCC which is intended to be unhandled.

65.5 External signals

Table 1046. External signals

Signal	Description	Direction
SCL	Serial clock	Input or output
SDA	Serial data	Input or output
PUR	Pull up resistance. There is an internal pull-up resistance on SDA, which is controlled by the I3C controller. If the internal pullup is not enough, PUR can be used to control an external pull-up resistance on SDA actively.	Output

65.6 Initialization

65.6.1 Controller configuration

Certain configuration is performed when initializing this module. Controller Configuration (MCONFIG) controls the frequencies, duty cycle, optimizations for performance, and other parameters.

Table 1047. Configuration for module initialization

Configuration parameter		Description
MSTENA	Controller enable	Determines whether the peripheral starts in Controller mode (main controller in I3C terms) or starts in Target mode (and switches to Controller mode later).
HKEEP	High-Keeper	Determines how the high-keeper (weak pullup) is implemented, depending on the device capabilities.
PPBAUD	Push-Pull baud	Sets the push-pull frequency as a divider from the FCLK (alternative clock fed to the peripheral). This frequency sets the SCL half-clock period baseline (used at least for the high time of SCL). The formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL frequency (in MHz) = FCLK ÷ ((2 + 2 × PPBAUD) + PPLOW) If PPLOW is 0, then SCL high = SCL low (in ns) = (1 + PPBAUD) × 1000 ÷ FCLK (in MHz) Examples: • If FCLK = 24 MHz, then PPBAUD = 0 yields 12 MHz (42.67 ns per half period) • If FCLK = 50 MHz, then PPBAUD = 1 yields 12.5 MHz (20 + 20 = 40 ns per half period)
PPLOW	Push-Pull low	Changes the duty cycle for Push-Pull. It indicates how many more FCLK cycles to use for low. The formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL frequency (in MHz) = FCLK ÷ ((2 + 2 × PPBAUD) + PPLOW) If PPLOW is a nonzero value, then: • SCL high (in ns) = (1 + PPBAUD) × 1000 ÷ FCLK (in MHz) • SCL low (in ns) = (1 + PPBAUD + PPLOW) × 1000 ÷ FCLK (in MHz) For example, when FCLK is 50 MHz, PPBAUD is 1, and PPLOW is 1, then the periods are: • (1 + 1) × 1000 ÷ 50 = 20 + 20 = 40 ns high

Table continues on the next page...

Table 1047. Configuration for module initialization (continued)

Configuration parameter		Description
		• (1 + 1 + 1) × 1000 ÷ 50 = 20 + 20 + 20 = 60 ns low This timing is equivalent to 10 MHz SCL, but this timing maintains the 40 ns high needed; therefore, I2C devices do not see the high periods. **NOTE** The PPLOW value does not have any impact on Open-Drain mode and I2C mode SCL rate calculations.
ODBAUD	Open-Drain baud	Determines the number of PPBAUD periods to make up one I3C Open-Drain half-clock baseline. If ODHPP is 0, the ODBAUD half-clock time period = (ODBAUD + 1) × PPBAUD high period. If ODHPP is 0, the formula for SCL in Open-Drain mode is: SCL (in MHz) = FCLK ÷ (2 + 2 × PPBAUD) × (ODBAUD + 1) Target to get open-drain half-clock period is 200 ns. For example: • If PPBAUD yields 12.5 MHz (40 ns per PPBAUD period), then ODBAUD = 4 can be used to get 200 ns. See ODHPP for details on short high and long low. • If PPBAUD = 1, FCLK = 50 MHz, and ODBAUD = 4, then open-drain SCL = 50 ÷ (2 + 2 × 1) × 5 = 2.5 MHz.
ODHPP	Open-Drain High Push-Pull	Optional field that allows the I3C open drain to be long low and short high. The high period of SCL is the PPBAUD period. This period leaves enough time for the pull-up resistor to pull the SDA high when SCL is low. It is also quick when SCL is high and there are no changes happening. ODBAUD low half-clock time period = (ODBAUD + 1) × PPBAUD high period. ODBAUD high half-clock time period = PPBAUD high period If ODHPP is 1, the formula for SCL in Open-Drain mode is: SCL (in MHz) = FCLK ÷ (1 + PPBAUD) × (ODBAUD + 1) + (1 + PBAUD) For example: • If PPBAUD produces 12.5 MHz (40 ns per PPBAUD period), then ODBAUD = 4 and ODHPP = 1. These settings provide a high period of 40 ns and a low period of 200 ns. • If PPBAUD = 1, FCLK = 50 MHz, and ODBAUD = 4, then open-drain SCL = 50 ÷ (1 + 1) × 5 + (1 + 1) = 4.16 MHz.
I2CBAUD	I2C baud	Indicates the number of ODBAUD periods that are required to communicate with I2C devices (MCTRL[TYPE] = 2 or MWMSG_SDR_CONTROL[I2C] = 1). For example, if ODBAUD gives 200 ns, and the goal is Fm+ (Fast Mode, 1 MHz), then the sum must be 1 µs. I2CBAUD acts differently for odd and even values. For example: • If I2CBAUD = 3, it gives three ODBAUD periods low and two ODBAUD periods high.

Table continues on the next page...

Table 1047. Configuration for module initialization (continued)

Configuration parameter		Description
		• If I2CBAUD = 4, it gives four ODBAUD periods for low and four ODBAUD periods for high. • Also, if I2CBAUD = 3, this yields 200 × 3 = 600 ns and 200 × 2 = 400 ns, with the sum 600 + 400 = 1000 ns = 1 µs.
SKEW	Skew	The normal SDA skew from SCL is handled by using the time for the SCL to reach its pad and return. This time is normally 2 ns to 5 ns (or sometimes more). If the skew is too fast, then add more delay. The skew allows specifying the number of FCLKs to insert.

Additional optimizations:

- Use MIBIRULES[MSB0] to obtain faster start header times. If the controller application assigns all I3C dynamic addresses to be less than 40h (it does not have MSB set), you can write 1 to MIBIRULES[MSB0]. When the controller emits 7Eh (broadcast) and a target does not drive the first bit low, the rest of the header can be at push-pull speeds. This speed is two times faster or more, depending on optimizations.
- Auto-emit 7Eh speeds up the frame when used with MIBIRULES[MSB0]. It allows the processor to sleep when the frame starts automatically (in response to a target).

65.6.2 Interrupt service flow

Set up interrupts for Controller Status (MSTATUS) in Controller Interrupt Set (MINTSET).

Set up interrupts for Target Status (SSTATUS) in Target Interrupt Set (SINTSET).

65.7 Application information

65.7.1 I2C configuration to meet timing requirements for Fm and Fm+ modes

I2C Fm and I2C Fm+ modes are supported according to the I3C standard specifications.

Table 1048 shows the configuration for Fm mode, where frequency is close to 400 kHz but timing requirement is not met (T_{SU_STA} is not met) because the actual value is 600 ns. Rest of the requirements are met per the I2C specifications in the chip data sheet.

Table 1049 shows the configuration for Fm mode, where all timing requirements are met.

Table 1048. Configuration for Fm mode with not all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	4	11	370 kHz	T_{SU_STA} - 353 ns

Table 1049. Configuration for Fm mode with all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	1	2	9	363 kHz	All requirements met per the I2C specifications in the chip data sheet

Table 1050 shows the configuration for Fm+ mode, where the frequency is close to 1 MHz. In this case, the T_{SU_STA} timing requirement is not met because the actual value is 260 ns. Rest of the requirements are met per the I2C specifications in the chip data sheet.

Table 1051 shows the configuration for Fm+ mode, where all timing requirements are met. To meet all the timing specifications, frequency may differ from 1 MHz. Use the configurations listed in Table 1051.

Table 1050. Configuration for Fm+ mode with not all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	4	3	960 kHz	T_{SU_STA} - 228 ns

Table 1051. Configuration for Fm+ mode with all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	3	6	749 kHz	All requirements met per the I2C specifications in the chip data sheet

NOTE

The controller module provides an option to slow down the clock for standard speed mode to support legacy I2C standard targets as well (although this option may not necessarily meet the exact timing requirement of the standard mode according to the standard I2C timing specification).

For the timing requirements under consideration, see the "I3C timing requirements when communicating with I2C legacy devices" table in the MIPI I3C v1.1.1 specification available on www.mipi.org.

65.8 I3C register descriptions

Writing to a read-only (RO) register, except to Controller Interrupt Mask (MINTMASKED), causes bus errors. This module does not verify whether programmed values in the registers are correct. You must ensure that valid programmed values are written.

However, the peripheral ignores writes to RO registers and returns 0 for reads from WO or nonexistent registers. It requires all 32-bit registers to be read and written as 32-bit and aligned to 32 bits. The peripheral uses the advanced peripheral bus (APB: AMBA 3 APB Protocol Specification v1.0); therefore, the peripheral does not know whether partial read or write operations (less than 32 bits) are used.

Field	Function
31-28 I2CBAUD	I2C Baud Rate Specifies the I2C low and high times in ODBAUD counts: • I2CBAUD >> 1 is the main count load, and it is count - 1. So, I2CBAUD >> 1: I2CBAUD = 0 for one ODBAUD beat and I2CBAUD = 1 for two ODBAUD beats. • If I2CBAUD[28] is 1, then the low time has one extra ODBAUD beat. The I2CBAUD field is normally 3, where ODBAUD gives 200 ns. For I2CBAUD >> 1, I2CBAUD = 1, which means two ODBAUD beats. To meet the requirements for Fast-mode Plus (Fm+), (2 + 1) × 200 = 600 ns low, with 2 × 200 = 400 ns high for 1 µs period. For Fast mode (Fm), I2CBAUD is normally 11 (giving 2.6 µs) or 6 (giving 2.4 µs).
27-25 SKEW	Skew Specifies the number of FCLK counts for an SDA change after SCL for I3C push-pull. This skew is in addition to the roundtrip of the SCL line from the pad back to the module (6 ns or more): • SKEW is normally not needed, so assign SKEW = 0. • SKEW is only used if SDA is not naturally skewing from an SCL change. • I2C automatically skews SDA (but not PUR) to match I2C rules. Use the following values: • In I3C Controller mode, use SKEW = 0.
24 ODHPP	Open Drain High Push-Pull Enables ODHPP. If you write 0 to this field, open-drain SCL high half-clock period is the same as the open-drain low SCL half period. If you write 1 to this field, open-drain high SCL half-lock period is one PPBAUD count for I3C messages. This setting is faster and works for I3C devices. Any legacy I2C devices on the bus do not see the SCL high level at all (less than the spike filter period). For open-drain timing, check upon the first 7Eh broadcast allowing I3C peripherals acting as I2C legacy devices to turn off their I2C 50-ns spike filters. See Sending a CCC to I3C targets for more information. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-16 ODBAUD	Open Drain Baud Rate Specifies the open drain baud rate. ODBAUD is configured in terms of number of PPBAUD counts - 1. This field must not be 0; this setting is not the same as push-pull. See Controller configuration for more information. The open-drain baud rate is usually 200 ns (see I2CBAUD for I2C counts). When used with MCONFIG[ODHPP], this setting produces 250 ns per clock in I3C. In this case, if MCONFIG[PPBAUD] provides 12 MHz, then one PPBAUD count is half of 12 MHz, or 41.67 ns. To obtain a rate around 200 ns, use a value of 5 - 1 = 4 for ODBAUD.
15-12 PPLOW	Push-Pull Low Acts as an adder for push-pull low to create a duty cycle with a longer low period, with up to 15 more FCLK cycles low than high. PPLOW = 0 produces a 50/50 duty cycle.
11-8 PPBAUD	Push-Pull Baud Rate Specifies the push-pull baud rate. The number of FCLK counts makes each push-pull low and normally high period. PPBAUD = 0 when run at 1/2 input FCLK speed. For example, a 24 MHz FCLK produces a 12 MHz SCL because each FCLK is SCL low or SCL high. MCONFIG[PPLOW] has an effect on the duty cycle. For example, 24 MHz with 50/50 duty cycle is 12 MHz. However, when PPLOW adds three more low beats, the push-pull baud rate becomes 4.8 MHz (from 24 MHz or 5 beats).
7 —	Reserved
6 ODSTOP	Open Drain Stop Enables open-drain stop. If you write 0 to this field, open-drain stop is disabled. ODSTOP must be disabled when sending an HDR exit pattern. If you write 1 to this field, open-drain stop is enabled. STOP condition is emitted at open-drain speeds even for I3C messages. In legacy devices, this feature can ensure that the legacy devices see the STOP condition. 0b - Disable 1b - Enable
5-4 HKEEP	High-Keeper Indicates how High-Keeper is supported. If this field is 0b, use pull-up resistor (PUR). No separate pin_HK_SDA or pin_HK_SCL is used. Only pin_PUR_oena is used for SDA. The pin_SCL_oena pin is held high in this mode, SCL clock is push-pull, and pin_SCL_out toggles, which is the actual clock. If this field is 1b, High-Keeper controls are in place; pin_HK_SDA or pin_HK_SCL (High-Keeper) controls are used. SCL may use an HK or that signal (pin_HK_SCL) may only OR into pin_SCL_oena. The pin_HK_SDA pin is used as well for SDA high keeper, along with pin_PUR_oena.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 10b, the functionality is passive on SDA, can Hi-Z (high-impedance) for bus free (Idle) and hold. The pins, pin_HK_SDA and pin_HK_SCL, are not used; only a combination of SDA_oena and pin_PUR_oena are used. If this field is 11b, the functionality is passive on SDA and SCL, can Hi-Z (high-impedance) both for bus free (Idle), and can Hi-Z SDA for hold. This is for I2C Clock Stretching mode, where both SCL and SDA are open drain. Use HKEEP = 2 for I2C modes. Use HKEEP = 0/1 for I3C modes. **NOTE** Your chip may not support any or all High-Keeper methods. You must check the availability of High-Keeper methods. 00b - None 01b - WIRED_IN 10b - PASSIVE_SDA 11b - PASSIVE_ON_SDA_SCL
3 DISTO	Disable Timeout Disables the timeout that produces application errors. If the controller is left in a state other than Stopped for more than 100 µs (because 10 kHz is the slowest allowed I3C speed), the timeout sends a MERRWARN interrupt. To prevent the MERRWARN interrupt during development or testing, write 1 to DISTO to disable the timeout. In systems that support timeouts, timeout is disabled automatically during debug. 0b - Enabled 1b - Disabled, if configured
2 —	Reserved
1-0 MSTENA	Controller Enable Indicates whether the controller is enabled and the states it can use. If this field is 0b, the controller is disabled. The module can only use Target mode. If this field is 1b, the controller is enabled. When used upon start-up, this module is the main controller by default. I3C controls the bus unless the controller is handed off. When this happens, MSTENA must become 2 so that it has the capability to become the controller again. Performing the handoff means emitting the GETACCMST CCC command. If the command is accepted, I3C emits a STOP condition and sets this field to 2 (or 0). If this field is 10b, I3C is controller-capable, but is operating as a target now. When used from the start, I3C starts as a target, but is prepared to switch to Controller mode. To switch to this mode, the target emits a controller request (CR) or receives a GETACCMST CCC command and accepts it (to switch on the STOP condition).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - CONTROLLER_OFF 01b - CONTROLLER_ON 10b - CONTROLLER_CAPABLE 11b - Reserved

65.8.3 Target Configuration (SCONFIG)

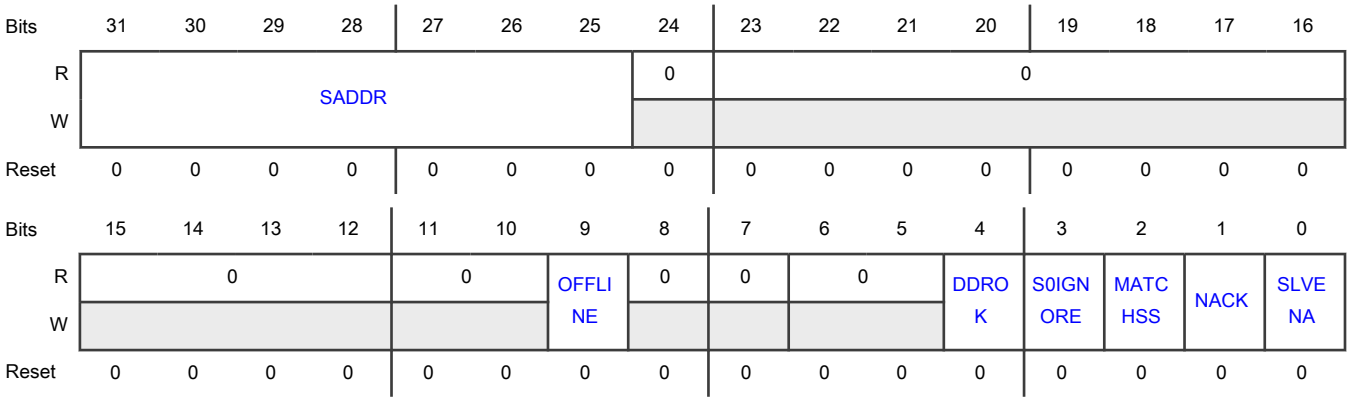
Offset

Register	Offset
SCONFIG	4h

Function

Contains fields that must be configured before the module is activated.

Diagram



Fields

Field	Function
31-25 SADDR	Static Address Sets the I2C 7-bit static address, which otherwise must be 0.
24 —	Reserved
23-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-12 —	Reserved
11-10 —	Reserved
9 OFFLINE	Offline Enables wait to ensure that the bus is not in HDR mode. If this field is 1 when SCONFIG[SLVENA] is 1, then I3C waits for either 60 µs of bus quiet or an HDR exit pattern. This waiting ensures that the bus is not in HDR mode, and so can safely monitor the next activity in Single Data Rate (SDR) mode. 0b - Disable 1b - Enable
8 —	Reserved
7 —	Reserved
6-5 —	Reserved
4 DDROK	Double Data Rate OK Allows HDR-DDR messaging. If DDROK = 1, write 1 to the corresponding SIDEXT[BCR] field to indicate that high data rate (HDR) is available, and configure the corresponding HDRCAP HDR-DDR field to allow using DDR mode. **NOTE** DDROK must be 1 before the target can connect to the I3C bus. The target peripheral indicates to the controller whether the target can support the feature during dynamic address assignment. 0b - Do not allow HDR-DDR messaging 1b - Allow HDR-DDR messaging
3 S0IGNORE	Ignore TE0 or TE1 Errors Ignores TE0 or TE1 errors. If you write 1 to this field, the target does not detect TE0 or TE1 errors, so it does not lock up waiting on an exit pattern. You must not use this setting when the bus does not use HDR mode. 0b - Do not ignore TE0 or TE1 errors 1b - Ignore TE0 or TE1 errors

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 MATCHSS	Match Start or Stop Enables match START or STOP condition. If you write 1 to this field, SINTSET[START] and SINTSET[STOP] become 1 only when SSTATUS[MATCHED] is 1. This setting allows the START and STOP fields to be used to detect the end of a message to or from this target. 0b - Disable 1b - Enable
1 NACK	Not Acknowledge Controls the ACK or NACK capability. If you write 1 to this field, the target rejects all requests, except for a CCC broadcast. NACK = 1 must be used with caution because the controller may decide that the target is missing, if NACK is overused. 0b - Always disable NACK mode 1b - Always enable NACK mode (works normally)
0 SLVENA	Target Enable Enables the target. If you write 0 to this field, the target ignores the I2C or I3C bus. If you write 1 to this field, the target can operate on the I2C or I3C bus. You must not write 1 to this field before registers such as Target Configuration (SCONFIG), Target ID Part Number (SIDPARTNO), Target ID Extension (SIDEXT), and others are configured because these registers affect the data to and from the controller. Target enable is configured just once before the bus comes up. If target enable is used at other times, SCAPABILITIES[IBI_MR_HJ] must be 1 before writing 1 to SLVENA so that the device does not see a START or STOP condition incorrectly. 0b - Disable 1b - Enable

65.8.4 Target Status (SSTATUS)

Offset

Register	Offset
SSTATUS	8h

Function

Indicates the sticky status for interrupts, states, and modes related to the I3C bus. Not all fields of the register are used if the module only acts as a target. The fields are divided into current activity, interrupt maskable actions, and then states and modes on the bus.

Diagram

Fields

Field	Function
31-30 TIMECTRL	Time Control Indicates whether time control is enabled, and in which mode. 00b - NO_TIME_CONTROL (no time control is enabled) 01b - SYNC_MODE (Synchronous mode is enabled) 10b - ASYNC_MODE (Asynchronous standard mode (0 or 1) is enabled) 11b - BOTHSYNCASYNC (both Synchronous and Asynchronous modes are enabled)
29-28 ACTSTATE	Activity State from Common Command Codes (CCC) Indicates the activity state from CCC. 00b - NO_LATENCY (normal bus operations) 01b - LATENCY_1MS (1 ms of latency) 10b - LATENCY_100MS (100 ms of latency) 11b - LATENCY_10S (10 seconds of latency)
27 HJDIS	Hot-Join Disabled Indicates whether hot-join is disabled. When hot-join is disabled, CTRL requests are not responded to. 0b - Enabled 1b - Disabled
26 —	Reserved
25 MRDIS	Controller Requests Disable Indicates whether controller requests are disabled. When controller requests are disabled, CTRL requests are not responded to.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enabled 1b - Disabled
24 IBIDIS	In-Band Interrupts Disable Indicates whether in-band interrupts are disabled. When in-band interrupts are disabled, CTRL requests are not responded to. 0b - Enabled 1b - Disabled
23-22 —	Reserved
21-20 EVDET	Event Details Indicates current details of the last (EVENT = 1) or pending event. 00b - NONE (no event or no pending event) 01b - NO_REQUEST (request is not sent yet; either there is no START condition yet, or is waiting for Bus-Available or Bus-Idle (HJ)) 10b - NACKed (not acknowledged, request sent and rejected); I3C tries again 11b - ACKed (acknowledged; request sent and accepted), so done (unless the time control data is still being sent)
19 SLVRST	Target Reset Flag Helps you perform follow-up tasks such as reinitialization (target reset to peripheral (not whole chip)).
18 EVENT	Event Flag Indicates, for a target, whether a pending in-band interrupt (IBI), controller request (CR), or hot-join (HJ) has been sent as requested. See the upper status register fields for details. This field becomes 1 only when acknowledged by a controller. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No event occurred 1b - IBI, CR, or HJ occurred When writing 0b - No effect 1b - Clear the flag
17 CHANDLED	Common Command Code Handled Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether an HDRMATCH CCC is being handled by I3C. This field is for notification only, but it may result in updates to this register. **NOTE** This field behaves differently for register reads and writes. When reading 0b - CCC handling not in progress 1b - CCC handling in progress When writing 0b - No effect 1b - Clear the flag
16 HDRMATCH	High Data Rate Command Match Flag Indicates whether the HDR command matched the I3C dynamic address of this device. The HDR command is available as the first byte, with RXPEND = 1. The MSB of the command byte indicates whether it is a read or a write command. If the HDR command is a read, and there are to-bus bytes waiting, then the command is ACKed and the data is sent back. Otherwise, the HDR command is NACKed. **NOTE** When this field is 1, you must check SSTATUS[ERRWARN] because the HPAR error may occur after signaling this HDR command. The parity occurs after the destination address and command. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not match 1b - Matched the I3C dynamic address When writing 0b - No effect 1b - Clear the flag
15 ERRWARN	Error Warning Indicates that an error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR CRC error, or other error or warning condition (see Target Errors and Warnings (SERRWARN) for more information).
14 CCC	Common Command Code Flag Indicates whether a CCC has been received, and is not handled by I3C. There are two types of common command codes: • Broadcast CCC, which corresponds with RXPEND, and the first byte is the CCC (command).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Direct CCC, which may never be directed to this device. If the direct CCC is directed to this device, then TXSEND or RXPEND are triggered, and RXPEND contains the command. **NOTE** This field behaves differently for register reads and writes. When reading 0b - CCC not received 1b - CCC received When writing 0b - No effect 1b - Clear the flag
13 DACHG	Dynamic Address Change Flag Indicates an occurrence of dynamic address (DA) change. Actual DA can be seen in the DYNADDR register. If this field is 1, DA change is detected. The target DA has been assigned, reassigned, or reset (lost) and is now in the state of being valid or none. This field is also used when the MAP auto feature is configured, changing one or more MAP items. See DYNADDR and MAPCTRL*n* for more information. DYNAADDR for the main DA (0) indicates whether the last change was because of Auto-MAP. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No DA change detected 1b - DA change detected When writing 0b - No effect 1b - Clear the flag
12 TXNOTFULL	Transmit Buffer Not Full Indicates that the transmit buffer is not full. If DMA is enabled for transmitting, then it is also signaled to provide more data. To-bus buffer or FIFO can accept more data to be transmitted. For all but external FIFOs, this process uses SDATACTRL[TXTRIG], which defaults to "not full". 0b - Transmit buffer full 1b - Transmit buffer not full
11 RX_PEND	Received Message Pending Indicates whether a received message is pending. The field indicates when a message from the controller that is not being handled by I3C (not a CCC message) is received. I3C processes such messages internally. For all but external FIFOs, this process uses SDATACTRL[RXTRIG], which

Table continues on the next page...

Table continued from the previous page...

Field	Function
	defaults to "not empty". If DMA is enabled for receiving, then DMA is signaled as well. This field automatically becomes 0 if data is read (from FIFO and non-FIFO sources). 0b - No received message pending 1b - Received message pending
10 STOP	Stop Flag Indicates whether the Stopped state is detected. The STNOTSTOP state also indicates when the module is in Stop mode. A fast STOP and START combination may not trigger the Stop status. In that case, the Start status is always set. If this field is 1, it indicates that the Stop state was present on the bus since the bus was last cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stopped state detected 1b - Stopped state detected When writing 0b - No effect 1b - Clear the flag
9 MATCHED	Matched Flag Indicates whether an incoming header matched the I3C dynamic or I2C static address (if any) of this device since the bus was last cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Header not matched 1b - Header matched When writing 0b - No effect 1b - Clear the flag
8 START	Start Flag Indicates whether a START or Repeated START was detected after this flag was last cleared. This flag is not usually needed, but can be used for wake events.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
7 —	Reserved
6 STHDR	Status High Data Rate Indicates whether the I3C bus is in HDR-DDR mode, regardless of whether HDR mode is supported by this module, and regardless of whether the message is intended for this module or some other module. 0b - I3C bus not in HDR-DDR mode 1b - I3C bus in HDR-DDR mode
5 STDAA	Status Dynamic Address Assignment Indicates whether the I3C bus is in Enter Dynamic Address Assignment (ENTDAA) mode, regardless of whether this bus target has a dynamic address. 0b - Not in ENTDAA mode 1b - In ENTDAA mode
4 STREQWR	Status Request Write Indicates whether the REQ in process is SDR write data from the controller to this bus target (or all targets), but not in ENTDAA mode. See status high data rate (STHDR) for double data rate (DDR) handling. 0b - Not an SDR write 1b - SDR write data from the controller, but not in ENTDAA mode
3 STREQRD	Status Request Read Indicates whether the REQ in process is an SDR read from this target. See status high data rate (STHDR) for double data rate (DDR) handling. 0b - Not an SDR read 1b - SDR read from this target or an IBI is being pushed out
2	Status Common Command Code Handler

Table continues on the next page...

Table continued from the previous page...

Field	Function
STCCCH	Indicates whether a CCC message is being handled automatically. 0b - No CCC message handled 1b - Handled automatically
1 STMSG	Status Message Indicates whether the bus target is busy (listening to the bus traffic or responding). If STNOSTOP = 1, STMSG is 0 when a nonmatching address is seen, until the next Repeated START or STOP condition occurs. 0b - Idle 1b - Busy
0 STNOTSTOP	Status not Stop Indicates the status of the bus. If this field is 0, I3C is in a STOP condition. If this field is 1, the bus is busy (has activity). Other fields of this register may also be set when busy. STNOTSTOP can also become 1 after a TE0 or TE1 error, when I3C is waiting for an exit pattern. 0b - In STOP condition 1b - Busy

65.8.5 Target Control (SCTRL)

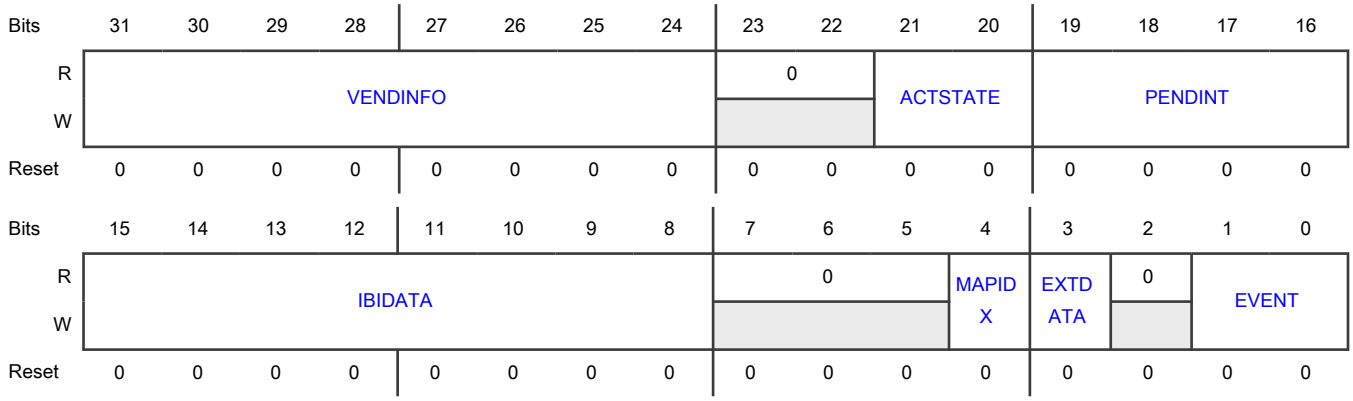
Offset

Register	Offset
SCTRL	Ch

Function

Contains controls for the active use of the I3C bus (for example, event generation such as interrupts to the controller). Only if I3C is configured to support various special operations for the target, this register is used to activate those operations. These events include IBI and GETSTATUS fields (except the protocol error, which is automatically set).

Diagram



Fields

Field	Function
31-24 VENDINFO	Vendor Information Controls vendor information that the GETSTATUS CCC returns. You must set this field to the Vendor Reserved field that the GETSTATUS CCC returns. The application must maintain the vendor information because the controller reads this field. If this field is not configured, then the GETSTATUS field always returns 0.
23-22 —	Reserved
21-20 ACTSTATE	Activity State of Target Controls the activity state of the target. You must set this field to the activity state of the target that the GETSTATUS CCC command returns as activity mode. The application must maintain the activity state because the controller reads this field. If you do not configure the activity state, then the GETSTATUS command always returns 0.
19-16 PENDINT	Pending Interrupt Specifies whether an IBI interrupt is pending. You must set this field to the pending interrupt that the GETSTATUS CCC command returns. The application must maintain the pending interrupt because the controller reads this field. If PENDINT = 0: • The GETSTATUS command returns 1 if an IBI interrupt is pending. • The GETSTATUS field returns 0 if an IBI interrupt is not pending.
15-8 IBIDATA	In-Band Interrupt Data Controls the data byte accompanying the IBI, if the module is enabled for IBI. If SCTRL[IBIDATA] is enabled, then IBI is required.
7-5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 MAPIDX	Map Index Controls the index of the dynamic address of the IBI. This index is 0 for the main or base dynamic address. This field is used only if mapping is enabled. See Controller Dynamic Address (MDYNADDR) for more information.
3 EXTDATA	Extended Data Enables extended data. After IBIDATA is emitted, extended data is acquired from IBIEXT1 and IBIEXT2, if configured. If extended data is used with time control, the data follows the time information. See IBIEXT1[MAX] for more information. 0b - Disable 1b - Enable
2 —	Reserved
1-0 EVENT	Event Requests an event. If this field is 0b, it indicates Normal mode, in which if this field becomes 0 from a nonzero value and event processing has not yet started, the event processing is canceled. However, event processing is not canceled if it has already started. If this field is 1b, an IBI is pushed onto the I3C bus. If there is data associated with the IBI, the data is read from SCTRL[IBIDATA]. If time control is enabled, this data includes any time-control-related bytes. Additionally, SCTRL[IBIDATA][7] becomes 1 automatically (as is required for time control). The IBI interrupt occurs after the first (mandatory) IBIDATA, if any. If this field is 10b, a controller request is started; the meaning depends on SIDEXT[BCR] configured in I3C. If this field is 11b, a hot-join (HJ) request is started, which is used when the device is powered on after the I3C bus is already powered up. It is also used when the device is connected using hot-insertion methods (the device is powered up when it is physically inserted in the powered-up I3C bus). The HJ waits for Bus Idle, and SCTRL[EVENT] = HOT_JOIN_REQUEST must be set before the target enable (SCONFIG[SLVENA]). If this field is a nonzero value, it requests an event. After the request, SSTATUS[EVENT] and SSTATUS[EVDET] show the status as it progresses. After completion, this field automatically returns to 0. After this field becomes a nonzero value, you can write only 0 it (to cancel) until the event processing is finished. 00b - NORMAL_MODE 01b - IBI 10b - CONTROLLER_REQUEST 11b - HOT_JOIN_REQUEST

65.8.6 Target Interrupt Set (SINTSET)

Offset

Register	Offset
SINTSET	10h

Function

Sets interrupt enables for select Target Status (SSTATUS) fields. Reading this register (SINTSET) returns the status of the interrupt enable:

- To activate an interrupt enable, write 1 to its corresponding field in this register (SINTSET).
- To disable an interrupt, write 1 to its corresponding field in Target Interrupt Clear (SINTCLR). Writing 0 to the interrupt enable in this register (SINTSET) does not disable the interrupt.

The Interrupt registers allow the masking of interrupt sources. They also allow the checking of which interrupts are activated. The normal method is to enable an interrupt, and then after the interrupt occurs, clear the interrupt either by writing to Target Status (SSTATUS) or by performing an action on the corresponding data register. The interrupt is level-held, meaning the interrupt stays set until the cause is cleared by some method. The module prevents races; if a new event occurs, that new event is not lost:

- SINTSET sets interrupt enables for Target Status (SSTATUS) fields. Reading the SINTSET register returns the status of the interrupt enables.
- SINTCLR clears interrupt enables for the SSTATUS fields.
- SINTMASKED returns the value of the SSTATUS fields ANDed with their interrupt enables.

Fields

Field	Function
31-20 —	Reserved
19 SLVRST	Target Reset Enables target reset interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field specifies whether target reset pattern is detected and action is set to reset peripheral. The field helps you perform follow-up tasks such as reinitialization. You must reset peripheral or verify that it is correct. This interrupt must not be unmasked. Used only if SLVRST is configured. 0b - Disable 1b - Enable
18 EVENT	Event Interrupt Enable Enables event interrupts. This field indicates, for a target, whether a pending in-band interrupt (IBI), controller request (CR), or hot-join (HJ) has been sent as requested. The field is configured to support events. See SSTATUS[EVDET] for more information. 0b - Disable 1b - Enable
17 CHANDLED	Common Command Code (CCC) Interrupt Enable Enables CCC interrupts. This field specifies whether CCC is being handled by I3C. Target Status (SSTATUS) shows new results. You can use this field to track when activity states and masks on events (for example, IBIs) occur. The field is used for CCCs that are enabled. 0b - Disable 1b - Enable
16 DDRMATCHED	Double Data Rate Interrupt Enable Enables DDR match for read or write command. This field indicates when DDR matches for read or write command, and the field is used only if HDR is enabled. 0b - Disable 1b - Enable
15 ERRWARN	Error or Warning Interrupt Enable Enables error or warning interrupts. This field indicates whether an error or warning has occurred, such as data underrun, data overrun, parity error, or HDR-DDR CRC error, or any other error or warning condition. See Target Errors and Warnings (SERRWARN) for cause of error. Only available for errors related to configured features. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
14 CCC	Common Command Code (CCC) Interrupt Enable Enables CCC interrupts. This field indicates whether a CCC has been received, and is not handled by I3C. For CCCs that the block does not handle, RXPEND also interrupts, and SSTATUS[STREQRD] indicates that it is a CCC sending a read request. 0b - Disable 1b - Enable
13 DACHG	Dynamic Address Change Interrupt Enable Enables dynamic address change interrupts: interrupt on dynamic address defined (SETDASA or ENTDAA) or lost (RSTDAA). See Controller Dynamic Address (MDYNADDR) for more information. 0b - Disable 1b - Enable
12 TXSEND	Transmit Interrupt Enable Enables transmit interrupts. This field indicates whether to-bus buffer or FIFO can accept more data to be transmitted. The corresponding interrupt occurs when the controller requests data to read from this target. This interrupt occurs on the first request (header) as well as when it is ready for more data. The corresponding interrupt occurs when the controller requests data to be read from this target. If this interrupt is for a FIFO, it triggers on the transmit emptiness trigger. If this interrupt is for DMA, then it indicates message end (DMA end or termination). 0b - Disable 1b - Enable
11 RXPEND	Receive Interrupt Enable Enables receive interrupts. This field specifies when a message from the controller that is not being handled by the module is received. For example, where data is consumed by hardware directly when it goes into the FIFO (excludes CCCs being handled automatically). If this interrupt is for a FIFO, it indicates a receive fullness trigger. If this interrupt is for DMA, then it indicates message end. 0b - Disable 1b - Enable
10 STOP	Stop Interrupt Enable Enables stop interrupts. This field detects the Stopped state present on the bus since the bus was last cleared.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Use SINTSET[START] as the preferred interrupt when needed. This interrupt may not trigger for a quick STOP and START combination because it relates to the state of being stopped. 0b - Disable 1b - Enable
9 MATCHED	Match Interrupt Enable Enables match interrupts. Incoming header matched the I3C dynamic or I2C static address of this device since the bus was last cleared. If configured and if no dynamic address is set, this interrupt is also for matching a header on an I2C static address. See Controller Dynamic Address (MDYNADDR) for related information. 0b - Disable 1b - Enable
8 START	Start Interrupt Enable Enables start interrupts. A START or Repeated START (such as wakeup) is seen after this field last became 0. See SINTSET[STOP] for related information. 0b - Disable 1b - Enable
7-0 —	Reserved

65.8.7 Target Interrupt Clear (SINTCLR)

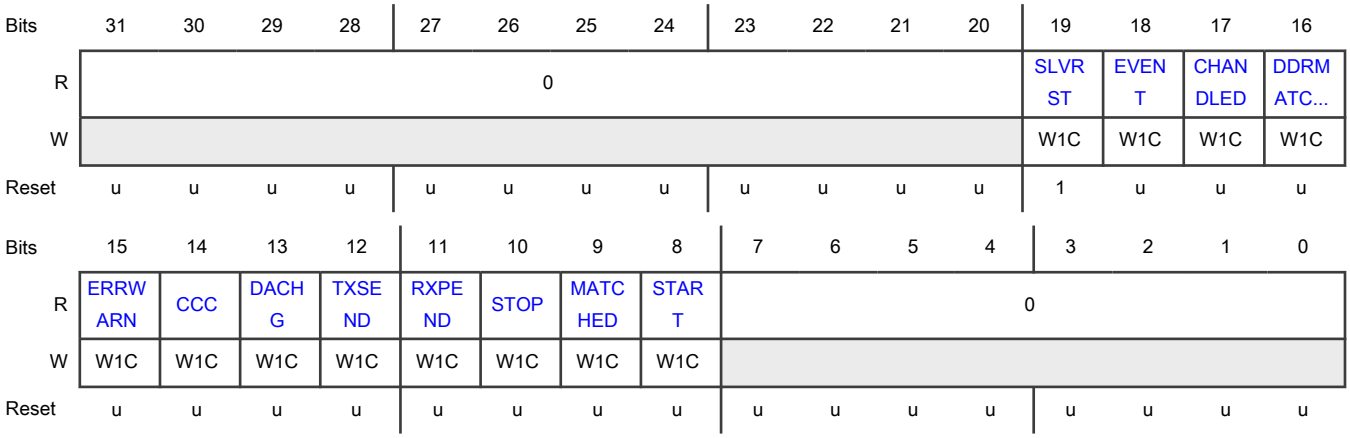
Offset

Register	Offset
SINTCLR	14h

Function

Clears interrupt enables for select Target Status (SSTATUS) fields. To clear an interrupt enable, write 1 to the corresponding field in this register (SINTCLR). Writing 0 has no effect.

Diagram



Fields

Field	Function
31-20 —	Reserved

65.8.9 Target Errors and Warnings (SERRWARN)

Offset

Register	Offset
SERRWARN	1Ch

Function

Contains errors and warnings from I3C and I2C protocols. This includes internal issues such as overrun and underrun, detected errors and conditions like parity errors, CRC errors, and read terminations by the controller. See SSTATUS[ERRWARN] and SINTSET[ERRWARN] for related information.

Diagram

21 —	Reserved
20-18 —	Reserved
17 OWRITE	Over-Write Error Flag Indicates that Target Write Data Byte (SWDATAB) or Target Write Data Byte End (SWDATABE) was written to when full. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No overwrite error 1b - Overwrite error When writing 0b - No effect 1b - Clear the flag
16 OREAD	Over-Read Error Flag Indicates that Target Read Data Byte (SRDATAB) was read for more bytes than were available, by the application. This field also indicates over-read errors for Target Read Data Halfword (SRDATAH), if it is enabled. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No over-read error 1b - Over-read error When writing 0b - No effect 1b - Clear the flag
15-14 —	Reserved
13 —	Reserved
12 —	Reserved
11 S0S1	TE0 or TE1 Error Flag Indicates whether a TE0 or TE1 error occurred and the target is locked and waiting for an HDR exit pattern. Writing 1 to S0S1 causes I3C to release the lock, but this method must be used with great care. S0S1 becomes 0 automatically when an exit pattern is detected, so writing 1 to S0S1 must be used under controlled circumstances to avoid problems. Before starting to operate normally after this error, I3C waits for a START (or Repeated START) or STOP state. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No TE0 or TE1 error occurred

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - TE0 or TE1 error occurred When writing 0b - No effect 1b - Clear the flag
10 HCRC	HDR-DDR CRC Error Flag Indicates whether an HDR-DDR CRC error occurred on a message from the controller. Error reasons include an HDR restart and an exit being issued before an HDR-DDR message from the controller has finished. This error calls into question the data from the entire DDR command frame. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No HDR-DDR CRC error occurred 1b - HDR-DDR CRC error occurred When writing 0b - No effect 1b - Clear the flag
9 HPAR	HDR Parity Error Flag Indicates when an HDR parity error or framing error on a message from the controller occurs. The corresponding command or data that has the error is usually in the RX buffer, which can be read using Target Read Data Byte (SRDATAB). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No HDR parity error 1b - HDR parity error When writing 0b - No effect 1b - Clear the flag
8 SPAR	SDR Parity Error Flag Indicates when an SDR parity error on a message from the controller occurs. This error also sets the GETSTATUS protocol error field (which becomes 0 after a GETSTATUS read). For read operations, this field becomes 1 when a read abort (timeout) occurs because of the controller not driving clock for more than 100 µs during an SDR read.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No SDR parity error 1b - SDR parity error When writing 0b - No effect 1b - Clear the flag
7-5 —	Reserved
4 INVSTART	Invalid Start Error Flag Indicates an invalid condition with SCL falling before SDA falls, so there is no start. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No invalid start error 1b - Invalid start error When writing 0b - No effect 1b - Clear the flag
3 TERM	Terminated Error Flag Indicates when the controller terminates a read from a target, if an END is not set by the target (on the same read or the previous read). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No terminated error 1b - Terminated error When writing 0b - No effect 1b - Clear the flag
2	Underrun and Not Acknowledged (NACKed) Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
URUNNACK	Indicates when the internal to-bus buffer or FIFO is underrun in the read header and so the module NACKed the header. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun; not acknowledged error 1b - Underrun; not acknowledged error When writing 0b - No effect 1b - Clear the flag
1 URUN	Underrun Error Flag Indicates when the internal to-bus buffer or FIFO is underrun during data read (the application is not providing the data fast enough). The END field or register must be used if the read was the last one. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun error 1b - Underrun error When writing 0b - No effect 1b - Clear the flag
0 ORUN	Overrun Error Flag Indicates when the internal from-bus buffer or FIFO has overrun (arrival of too many characters that you cannot process fast enough). Cutting off the RX_FIFO too close to the boundary when DUT is a target for SDR write or HDR-DDR write can cause an ORUN error when the FIFO is full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overrun error 1b - Overrun error When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Field	Function

65.8.10 Target DMA Control (SDMACTRL)

Offset

Register	Offset
SDMACTRL	20h

Function

Allows DMA to be used for inbound and outbound messages. This register is limited in value for target use because the target must be reactive. These are the two common use case models:

- To avoid an overrun in from-bus collection: if SCONFIG[MATCHSS] becomes 1, then the processor enables the interrupts for START and STOP and enables the DMA to collect the data. The START or STOP interrupt only occurs after a message is directed to the target (MATCHED is 1). The DMA copied data can then be examined.

  NOTE

  Do not enable DMA after a transaction starts. To avoid an RX FIFO overrun, DMA must be enabled only when enabling the target and interrupts.

- To perform larger reads from the to-bus: I3C and I2C reads are preceded by a write that indicates what will be read (or in response to an IBI from the target). Because of this process, the DMA can be used to push through the data:
  - For I3C, the processor must manage the last value, unless the DMA moves wider words and is able to write 1 to the END field. These values are 16-bit values when in Byte mode or 32-bit values when in Halfword mode.
  - For I2C, the controller determines the last value, so the DMA may end early or run out when the controller expects more values.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
7-6 —	Reserved
5-4 DMAWIDTH	Width of DMA Operations Indicates the width of DMA operations, if configured to allow halfword data accesses. 00b,01b - Byte 10b - Halfword (16 bits) (this value ensures that two bytes are available in the FIFO) 11b - Reserved
3-2 DMATB	DMA Write (To-Bus) Trigger Enables DMA writes. If this field is enabled, it starts a request DMA on a transmit trigger (see Target Data Control (SDATACTRL)). DMATB requests until full, unless the DMA is set up as a trigger. DMATB becomes 0 when MSTATUS[ERRWARN] becomes 1. If you write 1b to this field, DMA is enabled for one frame (ended by DMA or terminated). DMATB automatically becomes 0 after a STOP or START. See SCONFIG[MATCHSS] for more information. If you write 10b to this field, DMA is enabled until turned off. The value must only be used with Controller Message mode. 00b - DMA not used 01b - DMA enabled for one frame 10b - DMA enabled until turned off 11b - Reserved
1-0 DMAFB	DMA Read (From-Bus) Trigger Enables DMA reads. If this field is enabled, DMAFB requests DMA on receive trigger (see SDATACTRL). It requests until empty, unless the DMA is set up as a trigger. This field becomes 0 when SSTATUS[ERRWARN] becomes 1. If this field is 1b (DMA is enabled for one frame), it automatically becomes 0 on STOP or Repeated START. See SCONFIG[MATCHSS] for more information. **NOTE** Do not enable DMA after a transaction starts. It must be enabled only when enabling the target and interrupts to avoid any kind of RX FIFO overrun. 00b - DMA not used 01b - DMA enabled for one frame

Table continued from the previous page...

Field	Function
	10b - DMA enabled until turned off 11b - Reserved

65.8.11 Target Data Control (SDATACTRL)

Offset

Register	Offset
SDATACTRL	2Ch

Function

Assists in data control when no FIFO is used. Also assists in data control of FIFO when the FIFO is available (regardless of size) allowing some control over the FIFO behavior. This register controls when to interrupt based on fullness or emptiness of a buffer or FIFO. It also controls behavior related to width, when the buffer or FIFO is not 1 byte wide.

Diagram

21 —	Reserved
20-16 TXCOUNT	Count of Bytes in Transmit
15-8 —	Reserved
7-6 RXTRIG	Receive Trigger Level Indicates the trigger level for receive fullness when using a FIFO. The field affects the RXPEND interrupt. 00b - Trigger when not empty 01b - Trigger when 1/4 or more full 10b - Trigger when 1/2 or more full 11b - Trigger when 3/4 or more full
5-4 TXTRIG	Transmit Trigger Level Indicates the trigger level for transmit emptiness when using a FIFO. The field affects the TXNOTFULL interrupt. 00b - Trigger when empty 01b - Trigger when 1/4 full or less 10b - Trigger when 1/2 full or less 11b - Default (trigger when 1 less than full or less)
3 UNLOCK	Unlock Indicates whether the RXTRIG and TXTRIG fields can be changed on a write. This field must be 1 in the same cycle while writing to TXTRIG or RXTRIG. 0b - Cannot be changed 1b - Can be changed
2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 FLUSHFB	Flush From-Bus Buffer or FIFO Not normally used.
0 FLUSHTB	Flush To-Bus Buffer or FIFO Indicates when the controller terminates a to-bus (read) message prematurely.

65.8.12 Target Write Data Byte (SWDATAB)

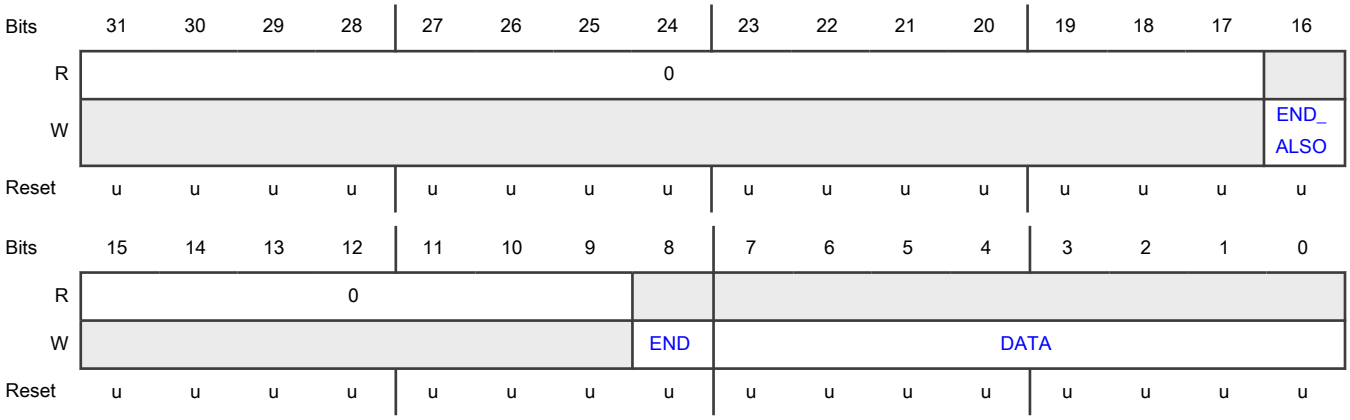
Offset

Register	Offset
SWDATAB	30h

Function

Allows writing a byte to the bus (to the controller) unless an external FIFO is used. Writing a byte requires a byte plus an end-of-data (last) marker bit. A byte must not be written unless there is room, indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END_ALSO	End Also Marks the last byte of the message. This field is required for I3C, but is optional for I2C.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0, it indicates that there are more bytes in the message. For HDR-DDR, the byte with END_ALSO must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
15-9 —	Reserved
8 END	End Marks the last byte of the message. If this field is 0, it indicates that there are more bytes in the message. This field is required for I3C, but is optional for I2C. For HDR-DDR, the byte with END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
7-0 DATA	Data Indicates the data byte to be sent to the controller.

65.8.13 Target Write Data Byte End (SWDATABE)

Offset

Register	Offset
SWDATABE	34h

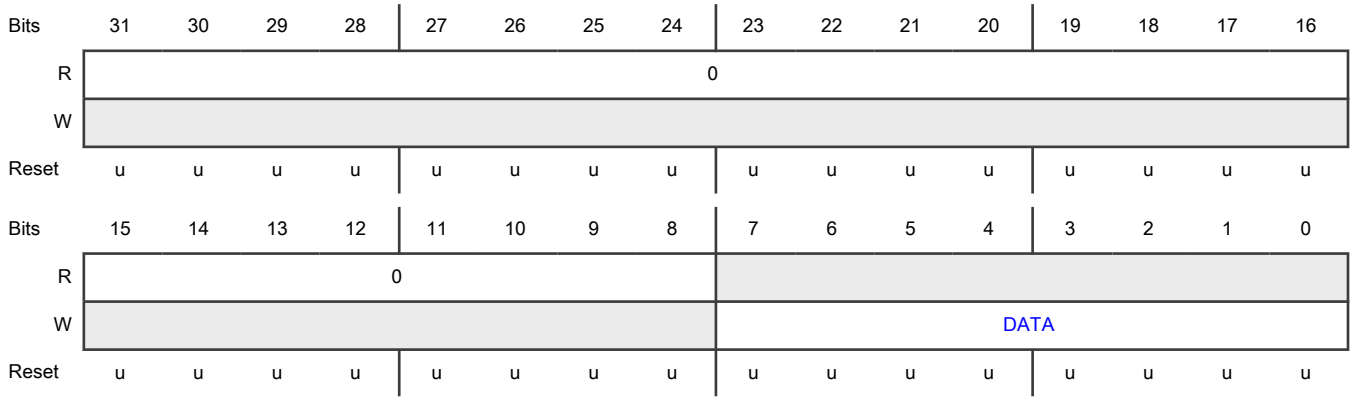
Function

Allows writing a byte to the bus (to the controller) unless an external FIFO is used.

Unlike Target Write Data Byte (SWDATAB), writing a byte only requires the byte itself, and is marked as end-of-data (last byte). A byte must not be written unless there is room, indicated by SSTATUS[TXNOTFULL] = 1.

For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	Data Indicates the data byte to be sent to the controller.

65.8.14 Target Write Data Halfword (SWDATAH)

Offset

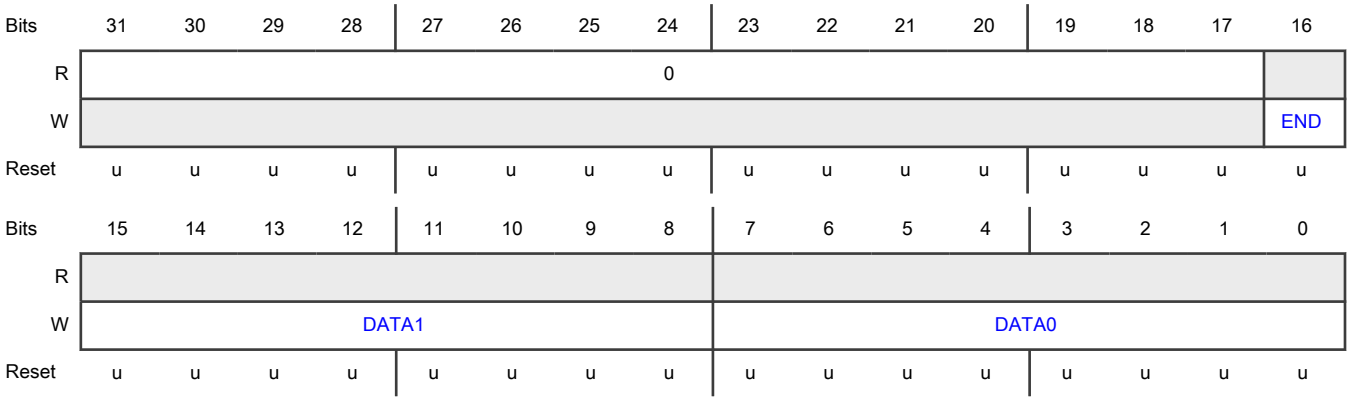
Register	Offset
SWDATAH	38h

Function

Allows writing a halfword (pair of bytes) to the bus unless an external FIFO is used. The low byte is followed by the high byte. The 16th bit marks the end; that is, the last byte of the halfword is the end.

An end-of-data (last) marker bit is allowed (or must be 0). A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or SDATACTRL[TXCOUNT].

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of Message Marks the last byte of the message. This field always marks DATA1 as the end. The field is required for I3C, but is optional for I2C. If this field is 0, it indicates that there are more bytes in the message. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
15-8 DATA1	Data 1 Indicates the second byte to be sent to the controller.
7-0 DATA0	Data 0 Indicates the first byte to be sent to the controller.

65.8.15 Target Write Data Halfword End (SWDATAHE)

Offset

Register	Offset
SWDATAHE	3Ch

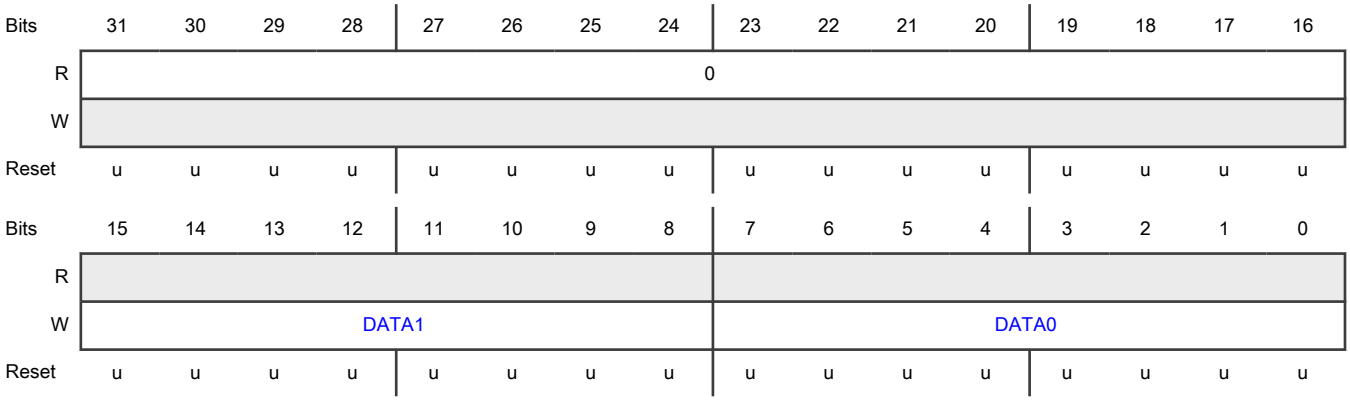
Function

Allows writing a halfword of data, which is the end (the last byte of the halfword is the end). The target writes the halfword (byte pair) in the same way it writes to Target Write Data Halfword (SWDATAH), but marks the second byte as end-of-data (last byte).

For HDR-DDR, the byte with the END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs.

A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or SDATACTRL[TXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data 1 Indicates the second byte to be sent to the controller.
7-0 DATA0	Data 0 Indicates the first byte to be sent to the controller.

65.8.16 Target Read Data Byte (SRDATAB)

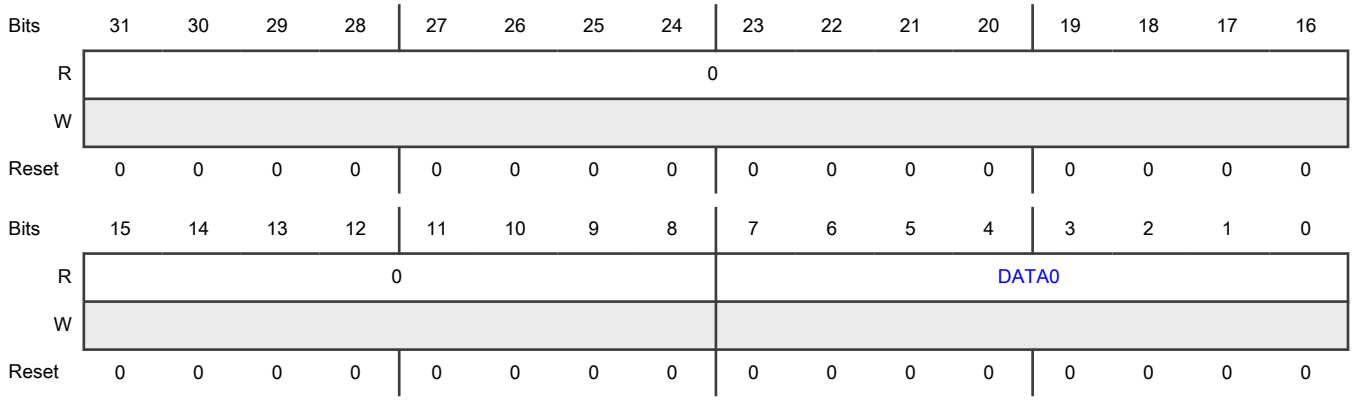
Offset

Register	Offset
SRDATAB	40h

Function

Allows reading a byte from the bus (controller). A byte must not be read unless there is data waiting, as indicated by SSTATUS[RX_PEND] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA0	Data 0 Indicates the byte read from the controller.

65.8.17 Target Read Data Halfword (SRDATAH)

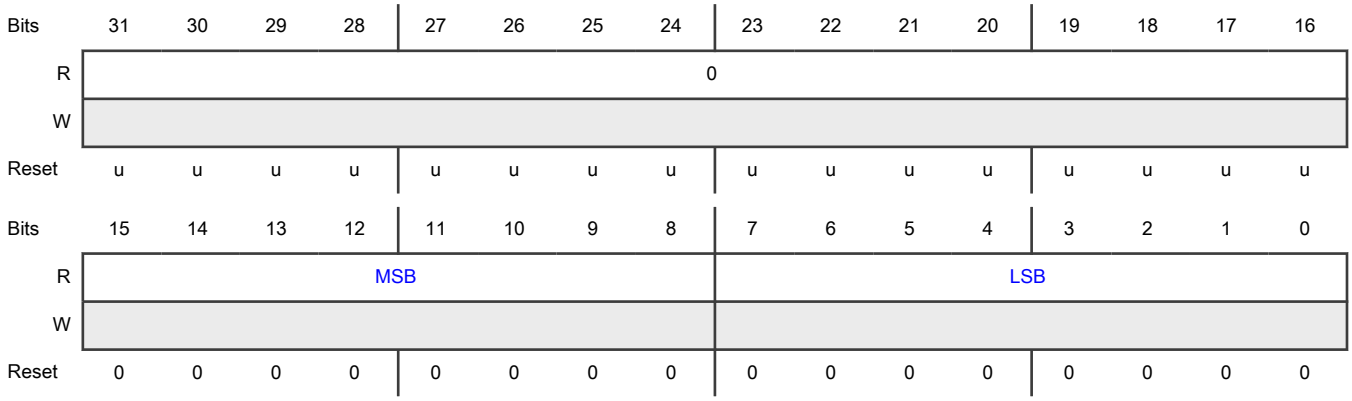
Offset

Register	Offset
SRDATAH	48h

Function

Allows reading a halfword (byte pair) written by the target after an SDR read or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively. A halfword must not be read unless there are at least two bytes of data waiting, as indicated by the use of receive FIFO level trigger or SDATACTRL[RXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	High Byte Indicates the second byte read from the target.
7-0 LSB	Low Byte Indicates the first byte read from the target.

65.8.18 Target Write Data Byte (SWDATAB1)

Offset

Register	Offset
SWDATAB1	54h

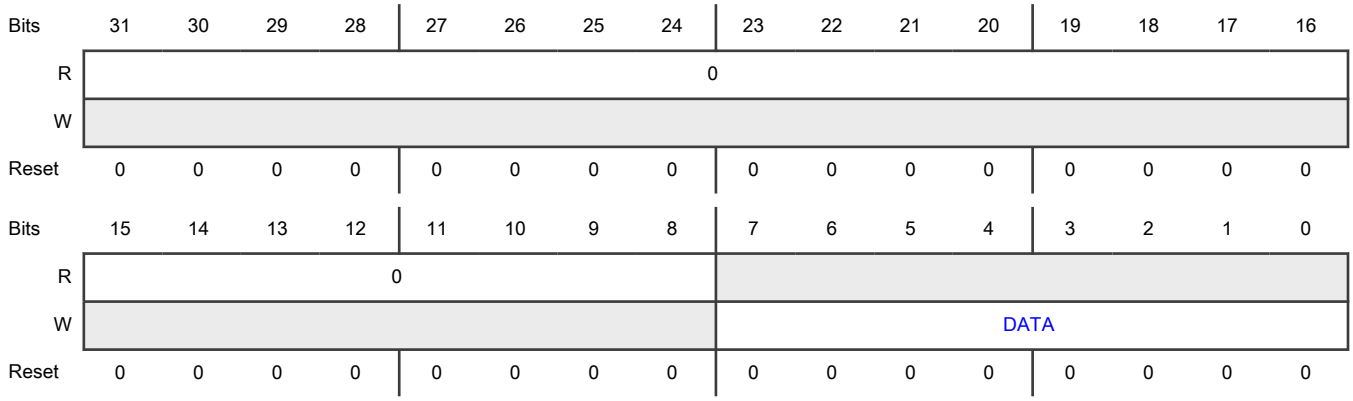
Function

Allows writing a single byte to the bus (to the controller) in a way that only bits 7:0 are used.

This register is intended to be used by DMAs (the upper bytes of the APB word are ignored).

A byte must not be written unless there is room, as indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	Data Indicates the byte to be sent to the controller.

65.8.19 Target Capabilities 2 (SCAPABILITIES2)

Offset

Register	Offset
SCAPABILITIES2	5Ch

Function

Indicates which features are available and supported in this module, including controller and target capabilities, HDR modes, and others.

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 INT	Interrupts Indicates whether interrupts are supported. 0b - Not supported 1b - Supported
29-28 FIFORX	FIFO Receive Indicates the size of receive (from-bus) FIFO. **NOTE** Controller and target use the same receive FIFO, so size is the same for the controller receive FIFO as well. FIFO size of SDR and HDR-DDR is in bytes. 00b - Two or three 01b - Four 10b - Eight 11b - 16 or larger
27-26 FIFOTX	FIFO Transmit Indicates the size of transmit (to-bus) FIFO. **NOTE** Controller and target use the same transmit FIFO, so size is the same for the controller transmit FIFO as well. FIFO size of SDR and HDR-DDR is in bytes. 00b - Two 01b - Four 10b - Eight 11b - 16 or larger
25-23 EXTFIFO	External FIFO Indicates whether external FIFOs are enabled. If they are not enabled, then check FIFOTX and FIFORX for the internal FIFO. 000b - No external FIFO available 001b - Standard available or free external FIFO 010b - Request track external FIFO All other values are reserved.
22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 TIMECTRL	Time Control Specifies whether any time-control type is supported. 0b - No time control supported 1b - At least one time-control type supported
20-16 IBI_MR_HJ	In-Band Interrupts, Controller Requests, Hot-Join Events Indicates which events (IBI, CR, and HJ) are allowed. For example, if this field is 00011b, IBI (bit 0) and IBI_HAS_DATA (bit 1) functionality are both enabled. 0_0000b - Application cannot generate IBI, CR, or HJ 1_xxxxb - Application can use SCONFIG[BAMATCH] for bus-available timing x_1xxxb - Application can generate a Hot-Join event x_x1xxb - Application can generate a controller request for a secondary controller x_xx1xb - When bit 0 = 1, the IBI has data from the SCTRL register x_xxx1b - Application can generate an IBI
15-12 CCCHANDLE	Common Command Codes Handling Indicates what manages CCC between I3C and the application. 0000b - All handling features disabled 1xxxb - GETSTATUS CCC returns the value of SCTRL[VENDINFO] x1xxb - GETSTATUS CCC returns the values of SCTRL[PENDINT] and SCTRL[ACTSTATE] xx1xb - The I3C module manages maximum read and write lengths, and max data speed xxx1b - The I3C module manages events, activities, status, HDR, and if enabled for it, ID and static-address-related items
11-10 SADDR	Static Address Indicates how the static address is managed. 00b - No static address 01b - Static address is fixed in hardware 10b - Hardware controls the static address dynamically (for example, from the pin strap) 11b - SCONFIG register supplies the static address
9 MASTER	Controller Specifies whether controller capability is supported. 0b - Not supported 1b - Supported
8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
7-6 HDRSUPP	High Data Rate Support Indicates which HDR modes are supported. 00b - No HDR modes supported 01b - DDR mode supported All other values are reserved.
5-2 IDREG	ID Register Indicates which ID features are available in the configurable registers. 0000b - All ID register features disabled 1xxxb - A Bus Characteristics Register (BCR) is available x1xxb - A Device Characteristic Register (DCR) is available xx1xb - An ID Random field is available xxx1b - ID Instance is a register; used if there is no PARTNO register
1-0 IDENA	ID 48b Handler Indicates what handles the 48-bit ID value. 00b - Application 01b - Hardware 10b - Hardware, but the I3C module instance handles ID 48b 11b - A part number register (PARTNO)

65.8.21 Target Maximum Limits (SMAXLIMITS)

Offset

Register	Offset
SMAXLIMITS	68h

Function

Indicates the limits set by the controller (or the originally requested limits). The maximum limits are not enabled in the hardware design, including maximum read and write lengths. If the maximum read and write lengths are enabled, then the current setting (including the default request) shows up in this register (SMAXLIMITS).

Diagram

R	0				MAXRD											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-16 MAXWR	Maximum Write Length Indicates the maximum write length, which must be between 8 to 4095 (saturation). The application must not set the maximum write length to a higher value than the maximum write length set by the controller.
15-12 —	Reserved
11-0 MAXRD	Maximum Read Length Indicates the maximum read length, which must be between 16 to 4095 (saturation). The application must not set the maximum read length to a higher value than the maximum read length set by the controller.

65.8.22 Target ID Part Number (SIDPARTNO)

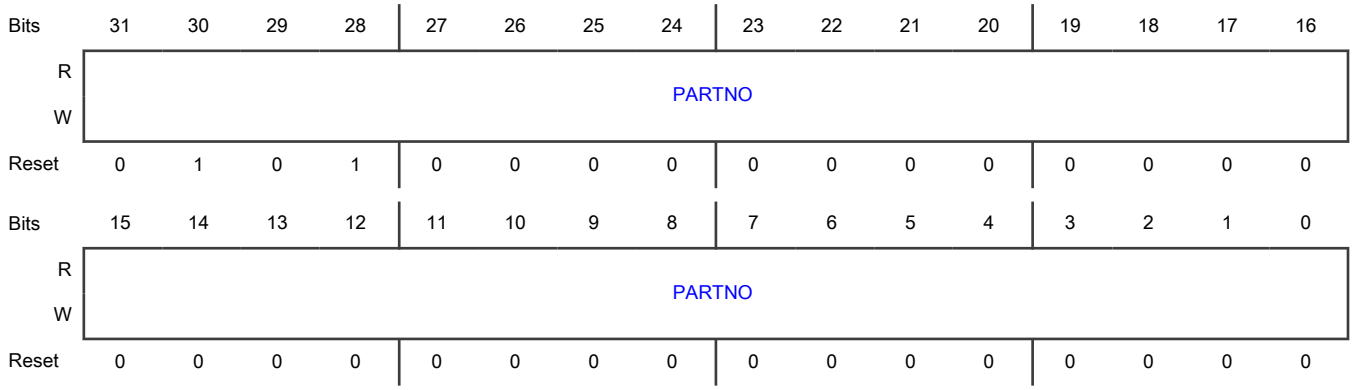
Offset

Register	Offset
SIDPARTNO	6Ch

Function

Allows you to write the ID part number. You must write a nonzero value into the PARTNO field because 0 is not valid.

Diagram



Fields

Field	Function
31-0 PARTNO	Part Number

65.8.23 Target ID Extension (SIDEXT)

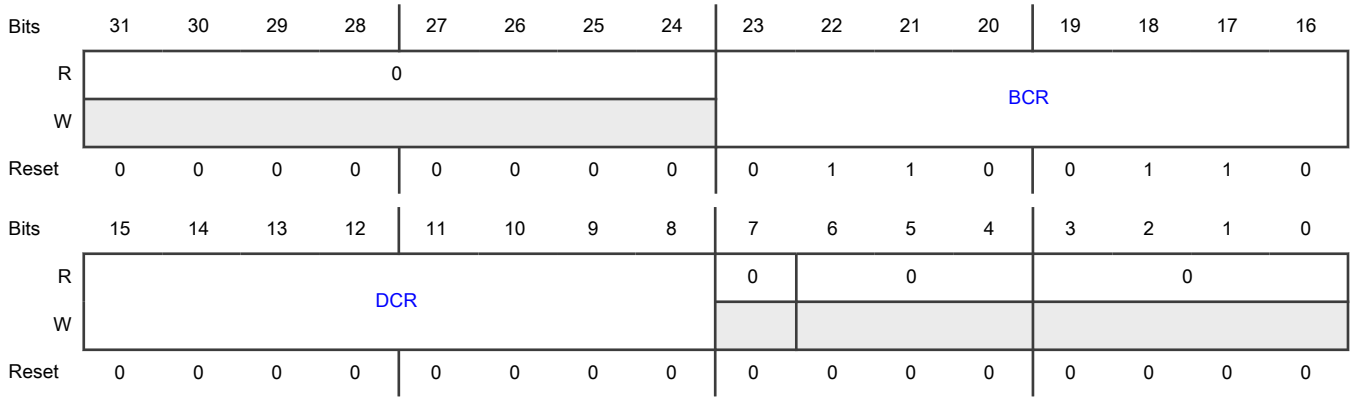
Offset

Register	Offset
SIDEXT	70h

Function

Allows you to write the ID extension of DCR and/or BCR.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 BCR	Bus Characteristics Register Sets the value for BCR, if this field is configured. Otherwise, the default value is considered. This field controls features such as secondary controller and slow-speed requirements.
15-8 DCR	Device Characteristic Register Sets the value for DCR, if this field is configured. Otherwise, the default value is considered.
7 —	Reserved
6-4 —	Reserved
3-0 —	Reserved

65.8.24 Target Vendor ID (SVENDORID)

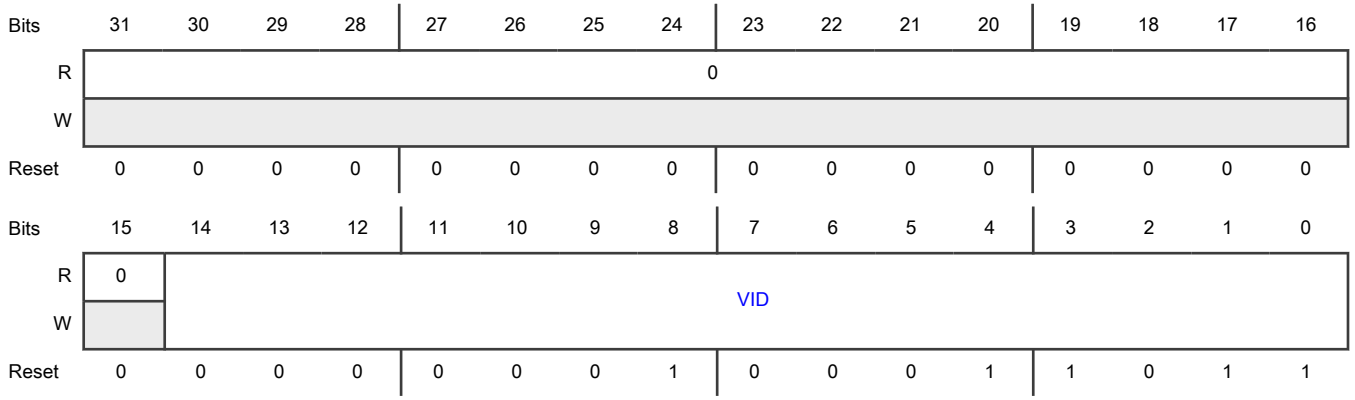
Offset

Register	Offset
SVENDORID	74h

Function

Allows you to write the vendor ID. The default value is the chip vendor ID, and is set from the constant field. When using the chip vendor ID, the part number (PARTNO) does not collide with other uses. The MIPI vendor ID is available to all companies (MIPI membership is not required). To get a vendor ID, make a request at the mipi.org website.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-0 VID	Vendor ID Configures the 15-bit MIPI vendor ID. If not configured, the default value is considered.

65.8.25 Target Time Control Clock (STCCLOCK)

Offset

Register	Offset
STCCLOCK	78h

Function

Allows you to dynamically set the time control clock and accuracy information. The clock frequency and accuracy are constants set by the hardware. If the clock can be adjusted (that is, divided) or if the accuracy could vary with knowable information, then the clock may be set via this register, which must be updated whenever the clock source is changed.

Fields

Field	Function
31-16 —	Reserved
15-8 FREQ	Clock Frequency Indicates the clock frequency in 0.5 MHz steps. For example, a value of 20 in this field indicates a frequency of 10 MHz. Default set by parameters if configured.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 ACCURACY	Clock Accuracy Indicates the clock accuracy in 1/10ths of %. For example, a value of 15 indicates an accuracy of 1.5%. Default set by parameters if configured.

65.8.26 Target Message Map Address (SMSGMAPADDR)

Offset

Register	Offset
SMSGMAPADDR	7Ch

Function

Allows you to determine which address is matched when STATUS[MATCHED] = 1. This register is used when the DYNADDR register builds a list of extra DAs or SAs to match. It holds the last three matches.

Diagram

Table continued from the previous page...

Field	Function
11-8 MAPLASTM1	Matched Previous Address Index 1 Indicates index 1 of the previous matched address (0 for the base address).
7-5 —	Reserved
4 LASTSTATIC	Last Static Address Matched Indicates whether the last matched address was an I2C static address or an I3C dynamic address. 0b - I3C dynamic address 1b - I2C static address
3-0 MAPLAST	Matched Address Index Indicates the matched address index for current or last matched message (0 for the base address).

65.8.27 Controller Control (MCTRL)

Offset

Register	Offset
MCTRL	84h

Function

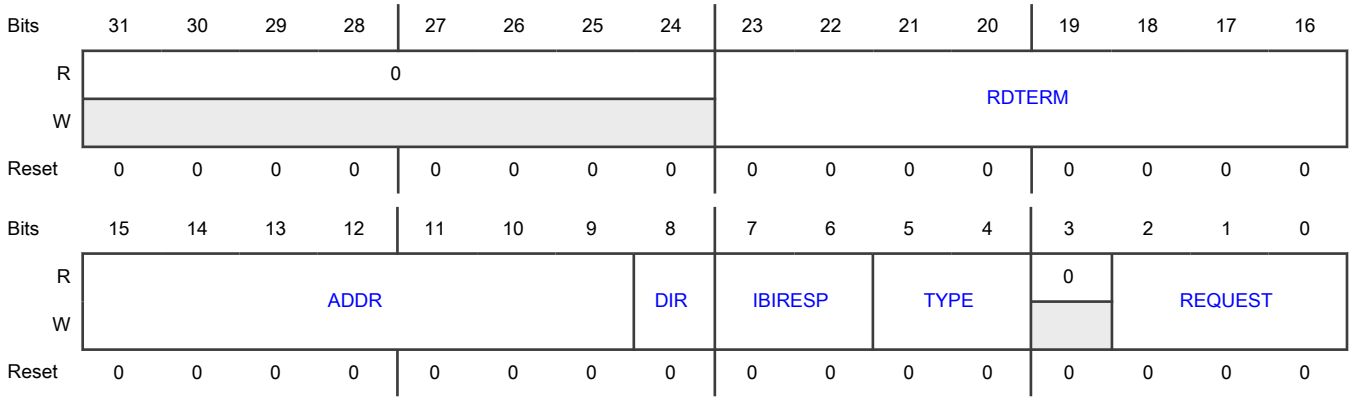
Starts activities on the I3C or I2C bus (see the MWMSG registers). A request cannot be changed when a message is in progress; the REQUEST field becomes 0 automatically.

You must write to MCTRL fields as per use case or as mentioned in Operating modes. Bit read and write checking may not work independently.

NOTE

If MCONFIG[MSTENA] is configured for I2C Controller mode (legacy I2C), only REQUEST = 1 and REQUEST = 2 are accepted. Also, fields are constrained to I2C-supported fields.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RDTERM	Read Terminate Counter Determines when to terminate a read operation: • For I2C, this field controls when to NACK a read. • For I3C, this field can be used to terminate (end) a read: — If RDTERM is 0, it has no effect. — If RDTERM is 1, the read terminates after the next character. — If RDTERM is 2, the read terminates after the next two characters. The field supports up to 255 characters. In DDR mode, RDTERM terminates the read based on word counts (for DDR) instead of byte counts (for SDR). The field self-clears when MSTATUS[COMPLETE] becomes 1. **NOTE** You may write 1 to this field anytime, but a value greater than 1 must be written when starting EmitStartAddress.
15-9 ADDR	Address Indicates the type of address: I3C dynamic address or I2C static address. Some values are not allowed based on the bus that is used (I3C or I2C).
8 DIR	Direction Indicates the direction, write or read. 0b - Write 1b - Read
7-6	In-Band Interrupt Response

Table continues on the next page...

Table continued from the previous page...

Field	Function
IBIRESP	Indicates the response to use when you get an IBI from START, and when to force using an IBI ACK NACK request when completing a manual IBI. Completion of a manual IBI means that the target DA is known, and so the mandatory byte (or not) is specified by the application when acknowledging. This field is also used when a message is emitted in Message mode using the MWMSG_SDR or MWMSG_DDR registers. If an IBI with MDB (mandatory byte) is ACKed, the controller limits it to a maximum of eight more bytes after the MDB. RDTERM = 1 can be used with REQUEST = NONE to terminate data from a target sooner. If this field is 0b, it indicates ACK (acknowledge). When REQUEST = 1 (EmitStartAddr) or REQUEST = 7 (AutoIBI), Controller In-band Interrupt Registry and Rules (MIBIRULES) decides whether to ACK with mandatory byte. When REQUEST = 3 (IBIAckNack), ACK with no mandatory byte. If this field is 1b, it indicates NACK (reject) or no acknowledgement. If this field is 10b, it indicates acknowledge with mandatory byte. When REQUEST = 1 or REQUEST = 7, ignore Controller In-band Interrupt Registry and Rules (MIBIRULES). Do not use this setting unless only targets with a mandatory byte can cause an IBI. When REQUEST = 3, ACK with mandatory byte. If this field is 11b, it indicates manual. When REQUEST = 1 or REQUEST = 7, stop and wait for a decision using the IBI ACK NACK request. When REQUEST = 3, this field is reserved. **NOTE** A CR and HJ always cause IBIRESP to become 3 (manual) so the application must decide. 00b - ACK (acknowledge) 01b - NACK (reject) 10b - Acknowledge with mandatory byte 11b - Manual
5-4 TYPE	Bus Type with EmitStartAddr Works with REQUEST to determine the bus type. See Determining bus types and modes for more information. The following values are valid only if REQUEST is 1. 00b - I3C 01b - I2C 10b - DDR 11b - Reserved
3 —	Reserved
2-0 REQUEST	Request Emits the requested operation when performing in pieces, instead of performing by message. You must check Controller Status (MSTATUS) because some requests can only be made in some states. For

Table continues on the next page...

Table continued from the previous page...

Field	Function
	example, the system cannot enter SDR mode from DDR mode, and it cannot use an incorrect request in DAA mode. If this field is 0b, it indicates that no request is present (NONE). The REQUEST field returns to NONE after finishing a request. Controller Status (MSTATUS) indicates the state of the controller. See AutoIBI mode. NONE is written as 0 only in these cases: when writing 1 to MCTRL[RDTERM] (to stop a read in progress) or when configuring MCTRL[IBIRESP] for MSG use. If this field is 1b, it emits START with address and direction (EMITSTARTADDR), either from Stopped state or in the middle of a single data rate (SDR) message. If from Stopped state (Idle), then EmitStart may be prevented by an event (such as IBI, CR, HJ). In this case, an appropriate interrupt is signaled. EmitStart can be resubmitted. If this field is 10b, it emits a STOP on bus (EMITSTOP). Must be in SDR mode. In DAA mode, emitting STOP exits DAA mode. If this field is 11b, it indicates manual IBI ACK or NACK (IBIACKNACK). When MCTRL[IBIRESP] indicates a hold on an IBI to allow a manual decision, this request completes it. The field uses MCTRL[IBIRESP] to provide the information. If this field is 100b, and if currently not in DAA mode, it emits START, 7E, ENTDAA sequence, and then emits 7E/R to process the first target (PROCESSDAA). Stops just before the new dynamic address (DA) is to be emitted. The DA is written using Controller Write Data Byte (MWDATAB), then process DAA is requested again to write the new address, and then it starts the next unless marked to STOP. An MSTATUS indicating NACK means DA was not accepted (for example, parity error). If PROCESSDAA is NACKed on the 7E/R request, meaning no more targets need a DA, then a COMPLETE is signaled (along with DONE) and a STOP issued. If this field is 110b, it emits an exit pattern from any state (force exit and target reset). End DDR mode (including MSGDDR), including a STOP afterward. If this field is 111b, the target is held in a Stopped state, but autoemits a START, 7E sequence when the target holds SDA low for an IBI (AUTOIBI). Actual IBI handling is defined by MCTRL[IBIRESP]. 000b - NONE 001b - EMITSTARTADDR 010b - EMITSTOP 011b - IBIACKNACK 100b - PROCESSDAA 101b - Reserved 110b - Force Exit and Target Reset 111b - AUTOIBI

65.8.28 Controller Status (MSTATUS)

Offset

Register	Offset
MSTATUS	88h

Function

Indicates the controller status, including which events cause interrupts. The peripherals share the IRQ (called parallel-to-target status).

Because a peripheral can either be in Controller or Target mode, but not both at the same time, only one (target or controller peripheral) can cause the IRQ. If there is an IRQ and the peripheral is a controller, then this register (MSTATUS) indicates the status.

If there is an IRQ and the peripheral is a target, then Target Status (SSTATUS) indicates the status.

This register self-clears if the COMPLETE field becomes 1.

If the MCONFIG register is configured only for I2C, some states and fields never remain active (for example, DAA or IBI).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W			W1C			W1C	W1C	W1C								
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30-24 IBIADDR	IBI Address Indicates the address of: • The IBI when MSTATUS[IBITYPE] = 1. • The CR, when MSTATUS[IBITYPE] = 2. • 7'h2 when HJ, when MSTATUS[IBITYPE] = 3.
23-20 —	Reserved
19 NOWMASTER	Module is now Controller Flag Indicates whether the module is now a controller. That is, it was previously a target, and controllership acceptance was requested from the previous controller and controllership was accepted. The reverse operation (controller becomes a target) does not need an interrupt because the application grants it through the GETACCMST CCC.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not a controller 1b - Controller When writing 0b - No effect 1b - Clear the flag
18-16 —	Reserved
15 ERRWARN	Error or Warning Indicates whether an error occurred, such as improper register use, overrun, or underrun of FIFO or buffer, or invalid parity or CRC in a DDR read. See Controller Errors and Warnings (MERRWARN) for more information. 0b - No error or warning 1b - Error or warning
14 —	Reserved
13 IBIWON	In-Band Interrupt (IBI) Won Flag Indicates whether an IBI, CR, or HJ has won the arbitration on a header address, regardless of whether it was NACKed or ACKed. Arbitration requires manual intervention for CR and HJ, and optionally requires it for IBI if MCTRL[IBIRESP] = 3 (manual). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No IBI arbitration won 1b - IBI arbitration won When writing 0b - No effect 1b - Clear the flag
12 TXNOTFULL	TX Buffer or FIFO Not Full

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether the buffer, FIFOm, or message register can accept another byte or halfword. FIFO uses trigger level. If DMA is enabled for transmitting, it transfers data as long as it is not full. 0b - Receive buffer or FIFO full 1b - Receive buffer or FIFO not full
11 RXPEND	RXPEND Indicates whether a message is being received from a target and bytes are in the input buffer or FIFO: • When using a FIFO, this message is at least one FIFO trigger's worth (a minimum of one byte in the FIFO). • When DMA is enabled for receiving, the DMA is signaled. RXPEND becomes 0 when the data is read. 0b - No receive message pending 1b - Receive message pending
10 COMPLETE	Complete Flag Indicates whether a message is complete: • With MWMSG_SDR or MWMSG_DDR, the COMPLETE condition occurs when MWMSG_SDR_CONTROL[LEN] or MWMSG_DDR_CONTROL[LEN] reaches 0. • When MCTRL[REQUEST] = 1 (EmitStartAddr), this COMPLETE condition occurs after the end of a write operation, or after a read operation has terminated or ended. • With an IBI (AutoIBI or EmitStartAddr), the COMPLETE condition occurs at the end of IBI data (if any). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
9 MCTRLDONE	Controller Control Done Flag Indicates whether the module has completed an MCTRL request. MCTRLDONE automatically becomes 0 when writing a new control. If MCTRL[REQUEST] = 1 (EmitStartAddr), MCTRLDONE becomes 1 when the address goes out (and is ACKed, NACKed, or ended in an IBI). If ACKed, MSTATUS[COMPLETE] becomes 1 after the write or read data is complete.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If MCTRL[REQUEST] = 4 (ProcessDAA), MCTRLDONE becomes 1 when the module is ready to emit the dynamic address (DA) for the target, or when no more targets are ACKing. This condition can be determined by using the MSTATUS[BETWEEN] and MSTATUS[STATE] fields. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not done 1b - Done When writing 0b - No effect 1b - Clear the flag
8 SLVSTART	Target Start Flag Indicates whether a target is or was requesting a START by holding SDA low. Handling starts automatically when MCTRL[REQUEST] = 7 (AutoIBI). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Target not requesting START 1b - Target requesting START When writing 0b - No effect 1b - Clear the flag
7-6 IBITYPE	In-Band Interrupt (IBI) Type Indicates the type of IBI of the last event that won the arbitration, whether the interrupt was ACKed, NACKed, or pending. 00b - NONE (no IBI: this status occurs when MSTATUS[IBIWON] becomes 0) 01b - IBI 10b - CR 11b - HJ
5 NACKED	Not Acknowledged Indicates whether the last start and address sequence was NACKed (was not ACKed by the addressed target). 0b - Not NACKed 1b - NACKed (not acknowledged)

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 BETWEEN	Between Indicates whether the controller is active between messages or dynamic address assignments (DAA). It is active when: • MSTATUS[STATE] is MSGSDR, DDR, or DAA, or NORMACT, and the state is between messages or DAAs. It is expecting a new message or DAA to start (or STOP or exit). • MSTATUS[STATE] is NORMACT. The module is waiting for the transmit FIFO to be not empty or the receive FIFO to be not full. 0b - Inactive (for other cases) 1b - Active
3 —	Reserved
2-0 STATE	State of the Controller Indicates the current controller state. If this field is 0b, it indicates that the controller is idle (the bus has stopped.) If this field is 1b, it indicates target request. The bus has stopped but a target is holding SDA low. When using auto-emit IBI (MCTRL[REQUEST] = 7), the controller does not remain in this state. If this field is 10b, it indicates entry into Single Data Rate Message mode, using MWMSG_SDR. If this field is 11b, it indicates entry into normal active SDR mode, using MCTRL, MWDATA*n*, and MRDATA*n* registers. The controller remains in this state until a STOP is issued. If this field is 100b, it indicates entry into Double Data Rate Message mode, using MWMSG_DDR or the normal method with DDR. The controller remains in the DDR state until the controller exits using EXIT (emitting the Exit pattern). If this field is 101b, it indicates entry into Dynamic Address Assignment (ENTDAA) mode. If this field is 110b, it indicates wait for an IBI ACK/NACK decision. If this field is 111b, it indicates receiving an IBI. This state is used after IBI, CR, or HJ has won an arbitration. The IBIRCV state is also used for IBI mandatory byte (if any) and any bytes that follow. 000b - IDLE (bus has stopped) 001b - SLVREQ (target request) 010b - MSGSDR 011b - NORMACT 100b - MSGDDR 101b - DAA 110b - IBIACK 111b - IBIRCV

65.8.29 Controller In-band Interrupt Registry and Rules (MIBIRULES)

Offset

Register	Offset
MIBIRULES	8Ch

Function

Contains the rules for using IBI, and keeps a registry of the targets that use the IBI byte.

This register defines the IBI mandatory byte rules for the targets and determines which targets do (or do not) have a mandatory byte.

Concerning ADDR*n* fields: The address has 6 bits. Assuming that MIBIRULES[MSB0] = 1, the most significant bit of each address is 0. In this case, each address is 7 bits (usually written as A7 to A1) and A7 must be 0. If the application does not use that optimal convention, the "manual" method of IBI ACK handling must be used (see MCTRL[IBIRESP] for more information).

By default, the ADDR*n* values indicate the targets with a mandatory byte. If MIBIRULES[NOBYTE] = 1, the ADDR*n* values indicate targets that do not have a mandatory IBI byte.

NOTE

A7 = 0 is only needed for targets that use IBI. For legacy I2C devices, A7 can use any valid value because I2C devices cannot cause an IBI.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	NOBYTE	MSB0	ADDR4						ADDR3				ADDR2

Fields

Field	Function
31 NOBYTE	No IBI byte Specifies whether the ADDR*n* fields refer to targets with or without a mandatory IBI byte. 0b - With mandatory IBI byte 1b - Without mandatory IBI byte
30 MSB0	Most Significant Address Bit is 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies whether MSB is 0 for all I3C dynamic addresses. Assigning 1 to this field allows the START header to be optimized. 0b - MSB is not 0 1b - MSB is 0
29-24 ADDR4	ADDR4 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
23-18 ADDR3	ADDR3 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
17-12 ADDR2	ADDR2 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
11-6 ADDR1	ADDR1 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
5-0 ADDR0	ADDR0 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.

65.8.30 Controller Interrupt Set (MINTSET)

Offset

Register	Offset
MINTSET	90h

Function

Returns the status of the interrupt enables when read. This register sets interrupt enables for select fields in Controller Status (MSTATUS):

- To activate an interrupt enable, write 1 to its corresponding field.
- To disable an interrupt enable, write 1 to the appropriate field in Controller Interrupt Clear (MINTCLR). Writing 0 to the interrupt enable in MINTSET does not disable the interrupt.

The interrupt registers allow masking of interrupt sources as well as checking which interrupts are activated in Controller Status (MSTATUS). The normal method is to enable an interrupt and then after that interrupt fires, clear the interrupt either by writing to Controller Status (MSTATUS) or via an action on the corresponding data register. The interrupt is level-held, meaning that the interrupt remains 1 until the cause is cleared by some method. The module prevents races; if a new event comes in, that new event is not lost.

These interrupts are parallel to Target Interrupt Set (SINTSET) and Target Interrupt Clear (SINTCLR), and only one interrupt set is active depending on the state (controller or target operation):

- MINTSET: Sets interrupt enables for MSTATUS fields. Reading the MINTSET register returns the status of the interrupt enables.
- MINTCLR: Clears interrupt enables for MSTATUS fields.
- MINTMASKED: Returns the value of the MSTATUS fields ANDed with their interrupt enables.

Field	Function
31-20 —	Reserved
19 NOWMASTER	Now Controller Interrupt Enable Enables the corresponding interrupt to indicate whether the module is now a controller (now this I3C module is a controller). That is, it was previously a target; controllership acceptance was requested from the previous controller and it was accepted. 0b - Disable 1b - Enable
18-16 —	Reserved
15 ERRWARN	Error or Warning (ERRWARN) Interrupt Enable Enables the corresponding interrupt to indicate whether an error occurred, such as improper register use, overrun or underrun of FIFO or buffer, or invalid parity or CRC in a DDR read. 0b - Disable 1b - Enable
14 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 IBIWON	IBI Won Interrupt Enable Enables the corresponding interrupt to indicate whether an IBI, CR, or HJ has won the arbitration on a header address, regardless of whether it was NACKed or ACKed. 0b - Disable 1b - Enable
12 TXNOTFULL	Transmit Buffer/FIFO Not Full Interrupt Enable Enables the corresponding interrupt to indicate whether the buffer, FIFOm, or message register can accept another byte or halfword. 0b - Disable 1b - Enable
11 RXPEND	Receive Pending Interrupt Enable Enables the corresponding interrupt to indicate whether a message is being received from a target and bytes are in the input buffer or FIFO.
10 COMPLETE	Completed Message Interrupt Enable Enables the corresponding interrupt to indicate whether a message is complete. 0b - Disable 1b - Enable
9 MCTRLDONE	Controller Control Done Interrupt Enable Enables the corresponding interrupt to indicate whether the module has completed an MCTRL request. 0b - Disable 1b - Enable
8 SLVSTART	Target Start Interrupt Enable Enables the corresponding interrupt to indicate whether a target is or was requesting a START by holding SDA low. 0b - Disable 1b - Enable
7-0 —	Reserved

65.8.31 Controller Interrupt Clear (MINTCLR)

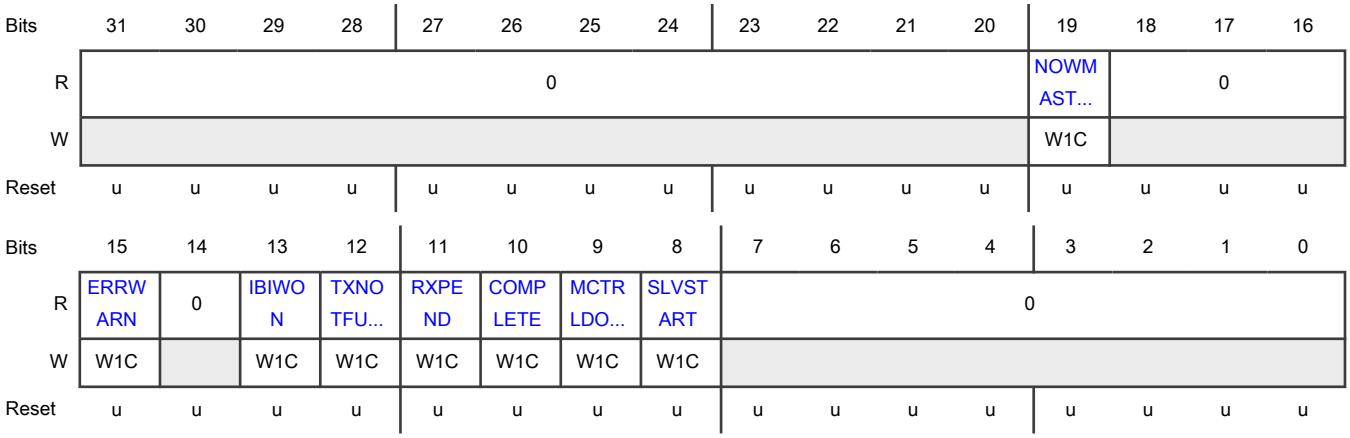
Offset

Register	Offset
MINTCLR	94h

Function

Clears interrupt enables for select fields in Controller Status (MSTATUS). Writing 1 clears the corresponding interrupt enable. Writing 0 has no effect.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 NOWMASTER	NOWCONTROLLER Interrupt Enable Clear Flag Clears the corresponding NOWCONTROLLER interrupt enable. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No effect 1b - Interrupt enable cleared When writing 0b - No effect 1b - Clear the flag

65.8.33 Controller Errors and Warnings (MERRWARN)

Offset

Register	Offset
MERRWARN	9Ch

Function

Contains errors and warnings. When any errors or warnings are not 0, then MSTATUS[ERRWARN] is 1.

Parallel-to-target ERRWARN:

- In Controller mode, use this register (MERRWARN).
- In Target mode, use Target Errors and Warnings (SERRWARN).

The error fields in both registers (MERRWARN and SERRWARN) are similar in meaning.

Diagram

Fields

Field	Function
31-22 —	Reserved
21 —	Reserved
20 TIMEOUT	Timeout Error Flag Indicates an error caused by the module stalling for too long in a frame. This stalling occurs when: • The transmit FIFO or receive FIFO is not handled, and the bus is stuck in the middle of a message. • No STOP is issued after data transfer (there is a gap between messages). • IBI manual is used and no decision has been made. The maximum stall period is 10 kHz or 100 µs. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
19 INVREQ	Invalid Request Error Flag Indicates an error caused by an invalid use of a request: • Not using IBI ACK NACK when stopped in manual hold for IBI acknowledgment. • Using a request other than ForceStop or ForceExit when in a message. Other requests are valid when the message is done. • Other mismatched uses (for example, IBI ACK NACK in normal states). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
18 MSGERR	Message Error Flag Indicates an error caused by: • Trying to write to or read from the MWMSG_SDR register when in a DDR message. • Trying to write to or read from the MWMSG_DDR register when in an SDR message. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
17 OWRITE	Overwrite Error Flag Indicates an error caused by trying to write to Controller Write Data Byte (MWDATAB) when the FIFO is full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
16 OREAD	Overread Error Flag Indicates an error caused by: • Trying to read from Controller Read Data Byte (MRDATAB) when the FIFO is empty. • Trying to read from the MRMSG_SDR register or the MRMSG_DDR register when no message has yet started. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Error When writing 0b - No effect 1b - Clear the flag
15-13 —	Reserved
12 —	Reserved
11 —	Reserved
10 HCRC	High Data Rate CRC Error Flag Indicates that a cyclic redundancy check (CRC) error occurred from a DDR read. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
9 HPAR	High Data Rate Parity Flag Indicates a parity error from a DDR read, including a bad preamble on a read. This does not stop the read because it is not safe to terminate; the read data may become misframed. Ends on a run of 1 second. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
8-5 —	Reserved
4 —	Reserved
3 WRABT	Write Abort Error Flag Indicates an error caused by the I2C target NACKing the write data, terminating the message. For example, the controller is writing in I2C and the target NACKed the write. If you write to the MCTRL register, this field automatically becomes 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
2 NACK	Not Acknowledge Error Flag Indicates an error caused by the target or targets NACKing (not acknowledging) the last address. If 7Eh is the address, then it indicates all targets NACKed the last address. If you write to the MCTRL register, this field automatically becomes 0. **NOTE** In HDR mode, this error occurs when an address is not accepted (as opposed to NACKed). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag

65.8.34 Controller DMA Control (MDMACTRL)

Offset

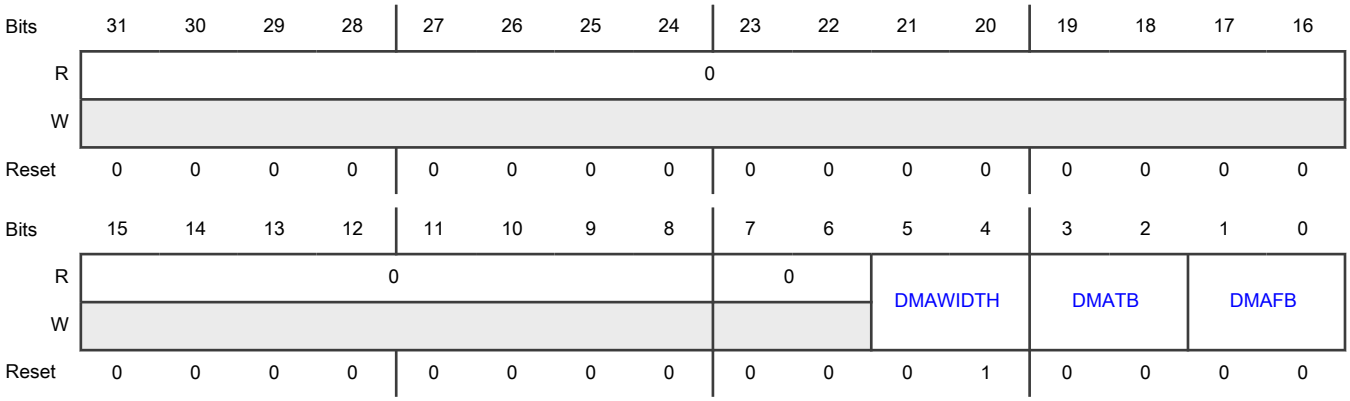
Register	Offset
MDMACTRL	A0h

Function

DMA can be used with a controller in these ways:

- Push or pull data for MCTRL[REQUEST] = 1 (EmitStartAddr) request written by the processor.
- Implementing message mode, completely controlled by DMA.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-6 —	Reserved
5-4 DMAWIDTH	DMA Width Specifies the data width of DMA operations.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The halfword (16 bits) setting ensures that two bytes are free or available in FIFO. 00b,01b - Byte 10b - Halfword (16 bits) 11b - Reserved
3-2 DMATB	DMA to Bus Represents the DMA write (to-bus) trigger. When DMAFB = 1 or DMAFB = 2, I3C requests DMA when a transmit trigger occurs (see Controller Data Control (MDATACTRL)). I3C requests until full, unless the DMA is set up as a trigger. DMAFB becomes 0 when MSTATUS[ERRWARN] = 1. If this field is 1b, STOP or START causes DMATB to become 0 (see SCONFIG[MATCHSS]). Normally, DMA enable must be used only in Controller Message mode. 00b - DMA not used 01b - Enable DMA for one frame (ended by DMA or terminated) 10b - Enable DMA until DMA is turned off 11b - Reserved
1-0 DMAFB	DMA from Bus Represents the DMA read (from-bus) trigger. When DMAFB = 1 or DMAFB = 2, I3C requests DMA when a receive trigger occurs (see Controller Data Control (MDATACTRL)). I3C requests until empty unless the DMA is set up as a trigger. DMAFB becomes 0 when MSTATUS[ERRWARN] = 1. If this field is 1b, STOP or Repeated START causes DMAFB to automatically become 0 (see SCONFIG[MATCHSS]). **NOTE** Do not enable DMA after a transaction starts. It must be enabled only when enabling the controller and interrupts to avoid any kind of RX FIFO overrun. 00b - DMA not used 01b - Enable DMA for one frame 10b - Enable DMA until DMA is turned off 11b - Reserved

65.8.35 Controller Data Control (MDATACTRL)

Offset

Register	Offset
MDATACTRL	ACh

Function

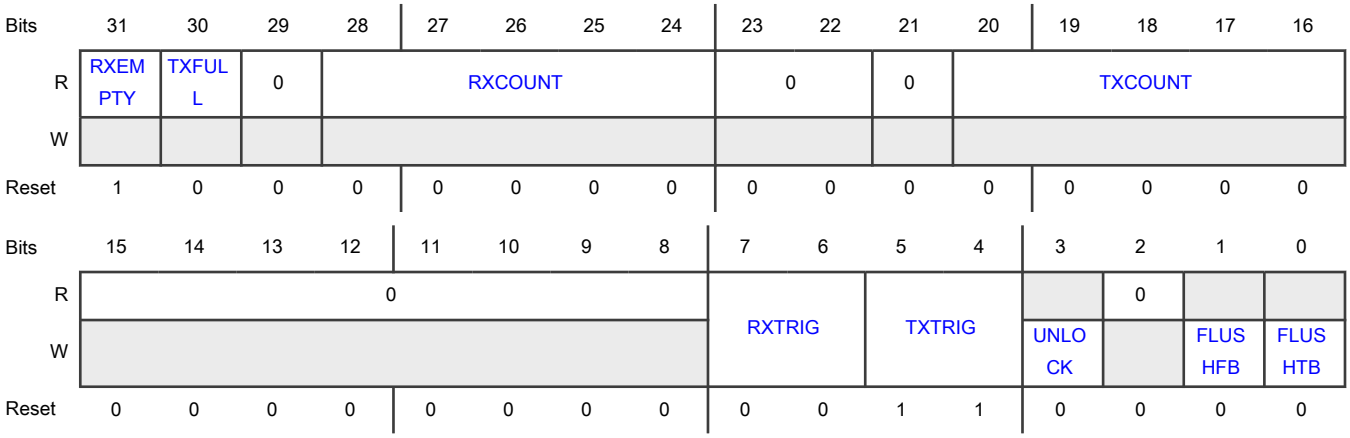
Assists in data control when there is no FIFO. This register also assists the FIFO when FIFO is available (regardless of size), and this assistance allows some control over the FIFO behavior. In particular, the register provides control over when to interrupt when a particular state of fullness or emptiness is reached. It also controls behavior related to width, when the width is not 1 byte wide.

This register acts as an alias of Target Data Control (SDATACTRL).

NOTE

When flushing a FIFO if DMA is in use, disable the DMA channel first. You must not use FIFO flush when a message (in that direction) is in flight.

Diagram



Fields

Field	Function
31 RXEMPTY	Receive is Empty Indicates whether the receive FIFO or buffer is empty. 0b - Not empty 1b - Empty
30 TXFULL	Transmit is Full Indicates whether the transmit FIFO or buffer is full. 0b - Not full 1b - Full
29 —	Reserved
28-24 RXCOUNT	Receive Byte Count Contains the count of bytes in the receive FIFO or buffer.
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21 —	Reserved
20-16 TXCOUNT	Transmit Byte Count Contains the count of bytes waiting in the TXFIFO. This count is the number of bytes that the application has written to the transmit FIFO that have not yet gone onto the bus.
15-8 —	Reserved
7-6 RXTRIG	Receive Trigger Level Indicates the trigger level for receive fullness when using a FIFO. This field affects the RXPEND interrupt. 00b - Trigger when not empty 01b - Trigger when 1/4 full or more 10b - Trigger when 1/2 full or more 11b - Trigger when 3/4 full or more
5-4 TXTRIG	Transmit Trigger Level Indicates the trigger level for transmit emptiness when using a FIFO. This field affects the TXNOTFULL interrupt. 00b - Trigger when empty 01b - Trigger when 1/4 full or less 10b - Trigger when 1/2 full or less 11b - Trigger when 1 less than full or less (default)
3 UNLOCK	Unlock Unlocks the functionality so that the RXTRIG and TXTRIG fields can be changed on a write. This field must be 1 (unlocked) in the same cycle when writing to TXTRIG or RXTRIG. If this field is 0 (locked), RXTRIG and TXTRIG fields cannot be changed on a write. 0b - Locked 1b - Unlocked
2 —	Reserved
1 FLUSHFB	Flush From-Bus Buffer or FIFO Flushes from-bus buffer or FIFO. You normally do not use this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No action 1b - Flush the buffer
0 FLUSHTB	Flush To-Bus Buffer or FIFO Flushes to-bus buffer or FIFO. This field is used when the controller terminates a to-bus message (read) prematurely. 0b - No action 1b - Flush the buffer

65.8.36 Controller Write Data Byte (MWDATAB)

Offset

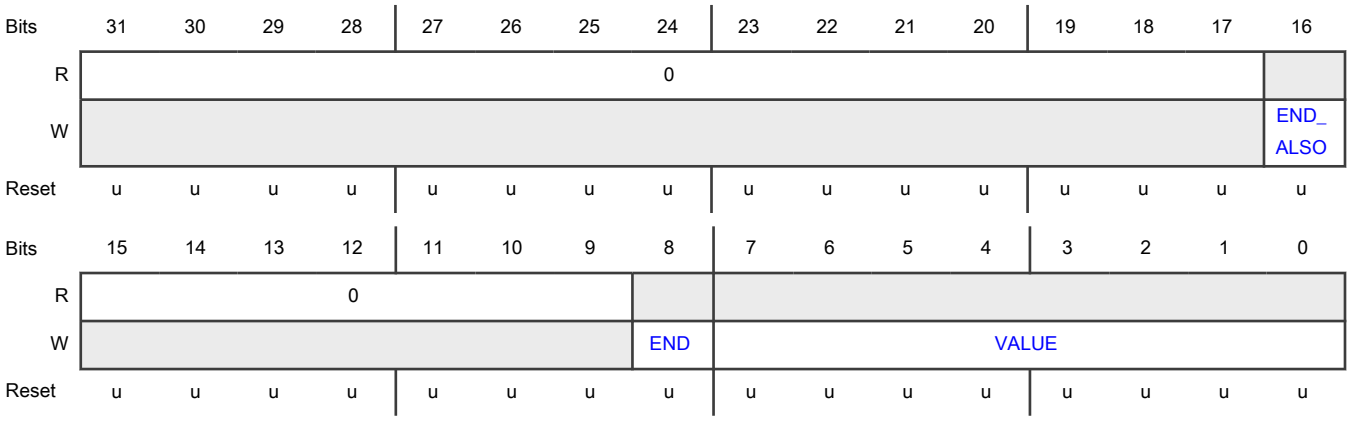
Register	Offset
MWDATAB	B0h

Function

Allows writing bytes to send onto the bus. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Write Data Byte (SWDATAB).

Diagram



Fields

Field	Function
31-17	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
16 END_ALSO	End of Message ALSO Indicates end of message, used to end an outbound message normally. Every message must indicate when it is the last message to be sent. This method can be used with the MDATABE register. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with END_ALSO must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
15-9 —	Reserved
8 END	End of Message Indicates the end of a message. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
7-0 VALUE	Data Byte Represents the byte written to the target (stored in transmit FIFO): • I3C computes the parity. • I2C manages the ACK or NACK.

65.8.37 Controller Write Data Byte End (MWDATABE)

Offset

Register	Offset
MWDATABE	B4h

Function

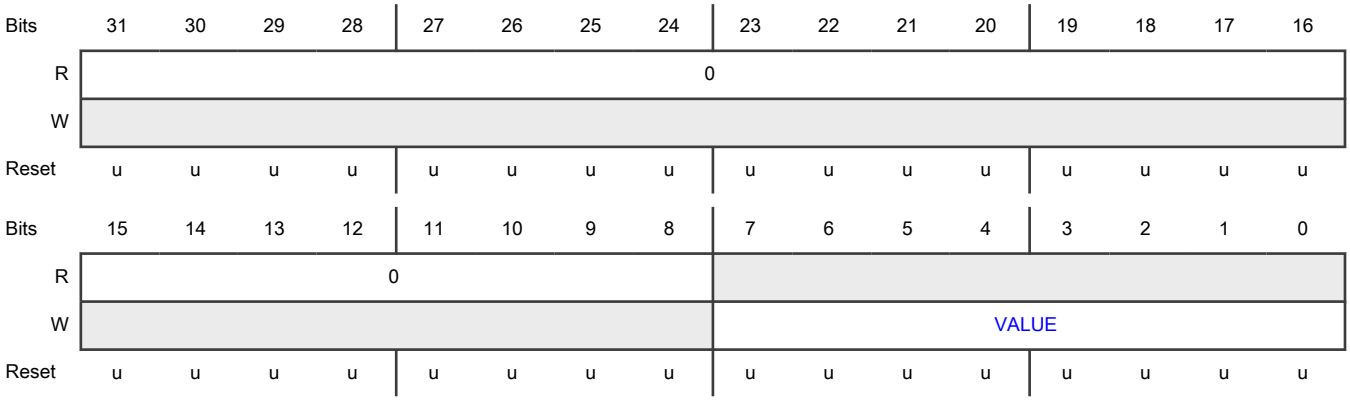
Allows writing the last byte to send onto the bus. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Write Data Byte End (SWDATABE).

NOTE

MWDATABE can also indicate END using bit 8.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Data Represents the last byte written to the target (stored in transmit FIFO): • I3C computes the parity. • I2C manages the ACK or NACK.

65.8.38 Controller Write Data Halfword (MWDATAH)

Offset

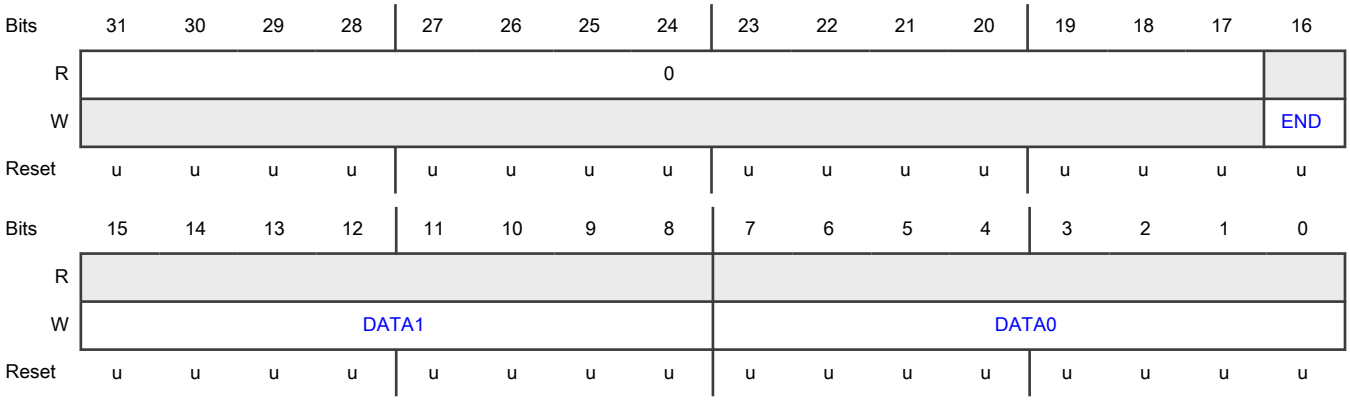
Register	Offset
MWDATAH	B8h

Function

Allows writing a halfword (pair of bytes) to the bus unless an external FIFO is used, sending the low byte followed by the high byte. An end-of-data (last) marker bit is allowed (or must be 0). A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or MDATACTRL[TXCOUNT].

This register acts as an alias of Target Write Data Halfword (SWDATAH).

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of Message Indicates the end of a message. For this register, this field always marks DATA1 as the end. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
15-8 DATA1	Data Byte 1 Represents the second byte that is sent to the target (written to transmit FIFO).
7-0 DATA0	Data Byte 0 Represents the first byte that is sent to the target (written to transmit FIFO).

65.8.39 Controller Write Data Halfword End (MWDATAHE)

Offset

Register	Offset
MWDATAHE	BCh

Function

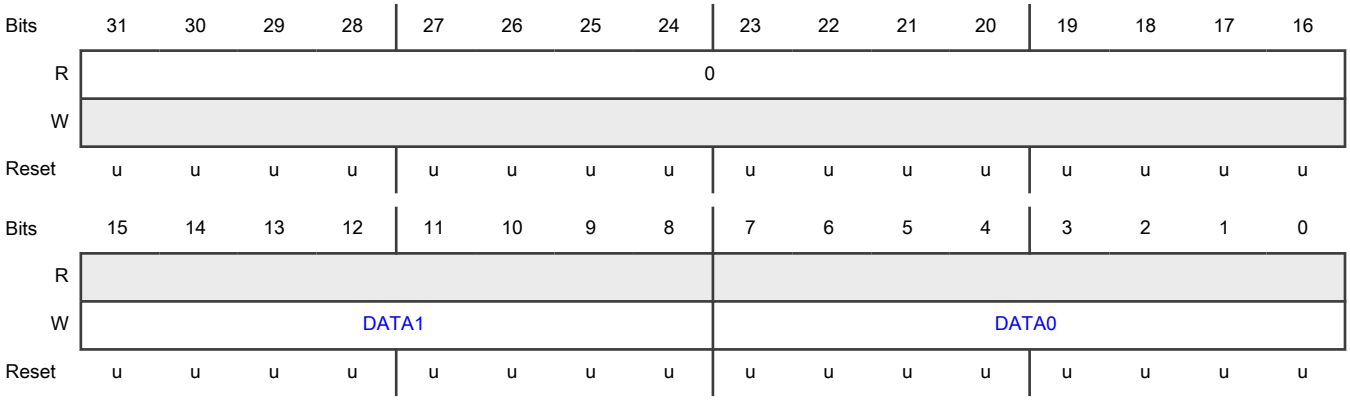
Allows writing a halfword of data, which is the end (the last byte of the halfword is the end). The target writes the halfword (byte pair) in the same way as it does to Controller Write Data Halfword (MWDATAH), but marks the second byte as end-of-data (last byte).

For HDR-DDR, the byte with the END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs.

You must not write a halfword unless there is room for both, as indicated by the use of transmit FIFO level trigger or MDATACTRL[TXCOUNT].

This register acts as an alias of Target Write Data Halfword End (SWDATAHE).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data Byte 1 Represents the second byte that is sent to the target (written to transmit FIFO).
7-0 DATA0	Data Byte 0 Represents the first byte that is sent to the target (written to transmit FIFO).

65.8.40 Controller Read Data Byte (MRDATAB)

Offset

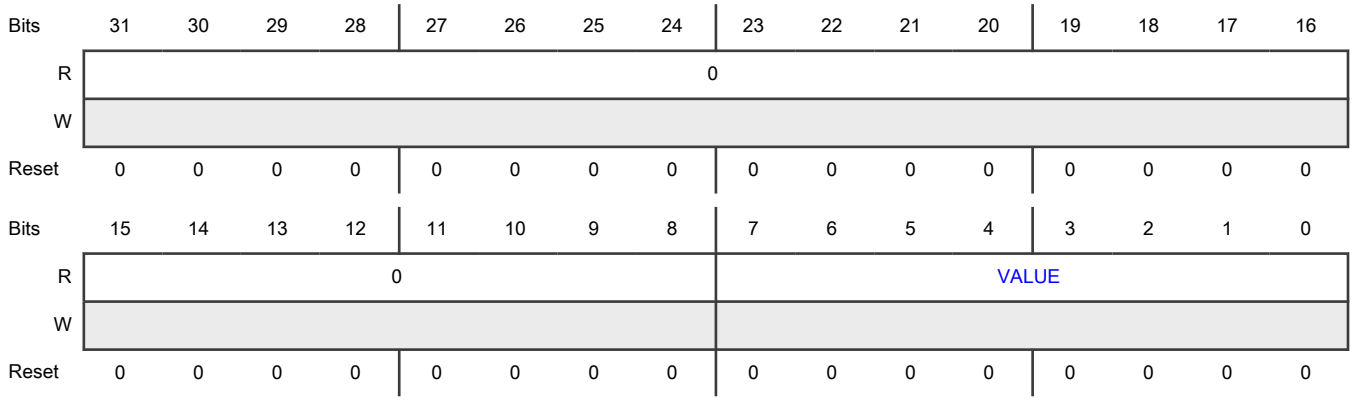
Register	Offset
MRDATAB	C0h

Function

Allows reading bytes written by the target after an SDR read, or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Read Data Byte (SRDATAB).

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value Represents the byte read from the controller (and written by the target).

65.8.41 Controller Read Data Halfword (MRDATAH)

Offset

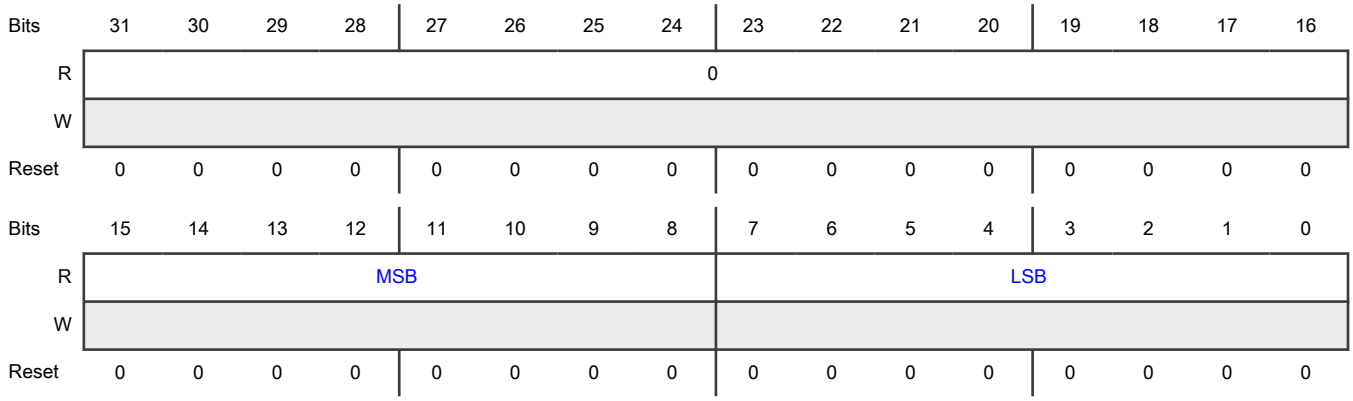
Register	Offset
MRDATAH	C8h

Function

Allows reading a halfword (byte pair) written by the target after an SDR read or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

A halfword must not be read unless there are at least two bytes of data waiting, as indicated by the receive FIFO level trigger or MDATACTRL[RXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	High Byte Represents the second byte read from the controller (and written by the target).
7-0 LSB	Low Byte Represents the first byte read from the controller (and written by the target).

65.8.42 Controller Write Byte Data 1 (to Bus) (MWDATAB1)

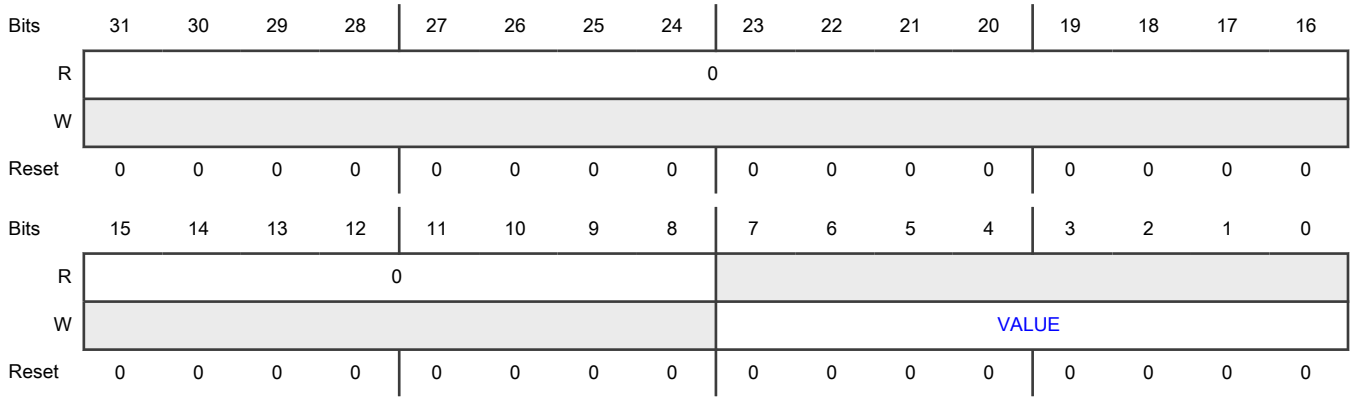
Offset

Register	Offset
MWDATAB1	CCh

Function

Allows writing bytes to send onto the bus, and is intended for DMAs that do not clear the upper bits of the word. This register does not have the END bits and is only used when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value Represents the byte to write out. The I3C module computes the parity for I3C, or manages the ACK or NACK for I2C.

65.8.43 Controller Write Message Control in SDR mode (MWMSG_SDR_CONTROL)

Offset

Register	Offset
MWMSG_SDR_CONTROL	D0h

Function

Allows setting up and writing 16-bit words in Single Data Rate (SDR) mode. The MWMSG_SDR_ register is modal and has two modes—control and data:

- For the first write to set up a new message, this register functions as the MWSMSG_SDR_CONTROL register.
- For subsequent writes, this register functions as MWMSG_SDR_DATA.
- The control information is not pipelined. You must write to control information registers for a start and do not write to them until data is sent.

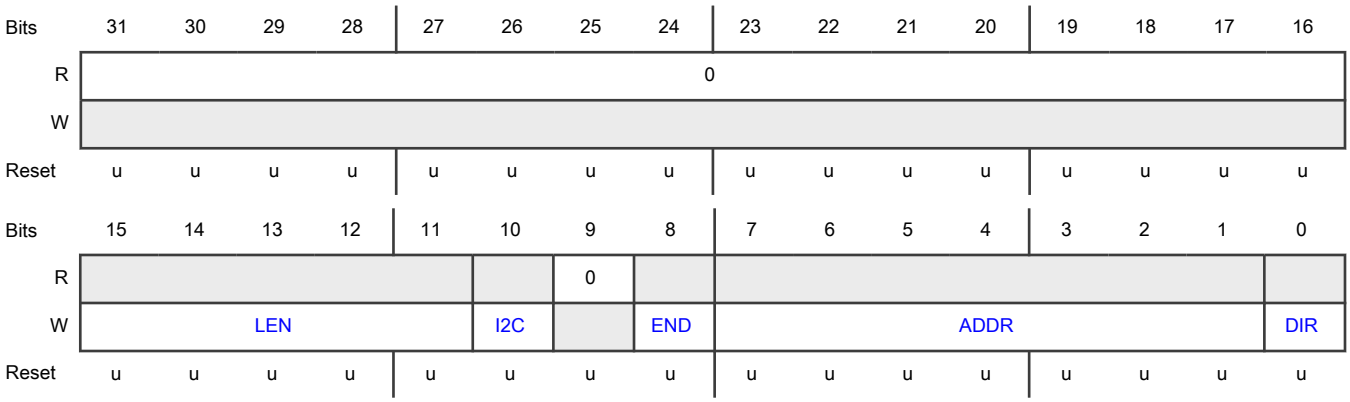
When not in the middle of a message, the MWMSG_SDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_SDR_DATA register is used until the length (see the LEN field) counts down, or until data with END = 1 is used.

The MWMSG_SDR_CONTROL register is written with the 16-bit control word if currently stopped or after the end of the previous message. If MSTATUS[STATE] = 2 (MSGSDR) and MSTATUS[BETWEEN] = 0, the register (at this offset address) functions as the MWMSG_SDR_DATA register. Otherwise, this register (at this offset address) functions as the MWMSG_SDR_CONTRL register, as long as MSTATUS[STATE] is not in another mode.

The control word contains the byte length (6-bit), address, direction, and how it ends (stop, ready for next, continuation with more length). If the command is START and an event (IBI, CR, HJ) occurs, MCTRL[IBIRESP] is used to determine action, and the corresponding interrupt occurs. In that case, the message is restarted.

The MWMSG_SDR_CONTROL and MWMSG_SDR_DATA registers are only targeted for DMA operations, but the processor can also write to the MWMSG_SDR_CONTROL register (instead of using MCTRL and MxDATAB).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-11 LEN	Length Indicates the byte length of the message. If LEN = 0, then only END is used (and it does not use the address if stopped). LEN = 1 must not be used. The minimal LEN size is 2 bytes (LEN = 2).
10 I2C	I2C Specifies whether the message is I2C or I3C. 0b - I3C message 1b - I2C message
9 —	Reserved
8 END	End of SDR Message Indicates the end of SDR message. MSTATUS[COMPLETE] = 1 when done. The end can happen: • Before LEN bytes are read in I3C mode, if a target ends sooner. • Before LEN bytes are written in I2C mode, if a target NACKs. If this field is 0, the SDR message ends waiting for a new SDR message (issues a Repeated START for a new message). If this field is 1, the SDR message ends at the STOP.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not the end 1b - End
7-1 ADDR	Address Contains the address to be written.
0 DIR	Direction 0b - Write 1b - Read

65.8.44 Controller Write Message Data in SDR mode (MWMSG_SDR_DATA)

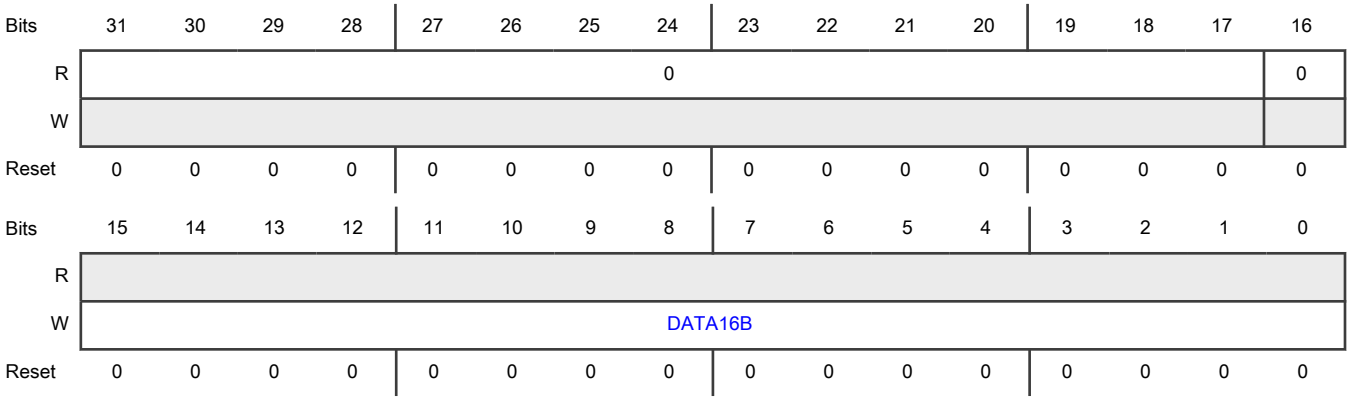
Offset

Register	Offset
MWMSG_SDR_DATA	D0h

Function

Contains the 16-bit word to be written in Single Data Rate (SDR) mode. This register functions in a way similar to MWMSG_SDR_CONTROL.

Diagram



Fields

Field	Function
31-17 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 —	Reserved
15-0 DATA16B	Data

65.8.45 Controller Read Message in SDR mode (MRMSG_SDR)

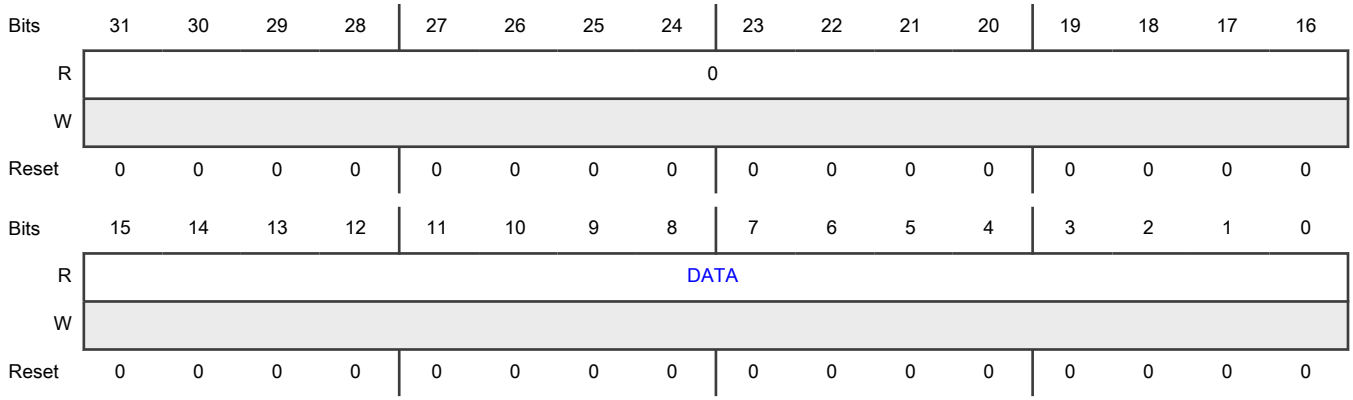
Offset

Register	Offset
MRMSG_SDR	D4h

Function

Allows reading 16-bit words from a target in SDR Message mode. The MRMSG_SDR register is used to read 16-bit words from an active message started with MWMSG_SDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Contains the 16-bit word read from the target: • If the length (LEN) is an odd number, the upper byte is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If the target ends before LEN is finished, the module treats the read as completed. • If the target is not done before LEN is finished and END is not a continuation, the read is terminated.

65.8.46 Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL)

Offset

Register	Offset
MWMSG_DDR_CONTROL	D8h

Function

Allows setting up and writing 16-bit words in DDR mode. The register has three modes:

- The first write to set up a new message functions as the MWSMSG_DDR_CONTROL register.
- The second write contains the functions as shown in the MWMSG_DDR_CONTROL2 register.
- For subsequent writes, this register functions in a way similar to Controller Write Message Data in DDR mode (MWMSG_DDR_DATA).
- The control information is not pipelined. You must write to control information registers for a start and do not write to them until data is sent.

When not in the middle of a message, the MWMSG_DDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_DDR_DATA register is used until the length (see LEN field) counts down or until data with END = 1 is used.

The MWMSG_DDR_CONTROL register is written with the 16-bit control word if currently stopped or after the end of the previous message. If MSTATUS[STATE] = 4 (MSGDDR) and MSTATUS[BETWEEN] = 0, then the register (at this offset address) functions as the MWMSG_DDR_DATA register. Otherwise, this register (at this offset address) functions as the MWMSG_DDR_CONTROL register, as long as MSTATUS[STATE] is not in another mode.

The main control word contains the 16-bit word length and how it ends (stop, ready for next, continuation with more length). Then the command word contains the command and address for read or write. If the command is START and an event (IBI, CR, HJ) occurs, MCTRL[IBIRESP] is used to determine action, and the corresponding interrupt occurs. In that case, the message is restarted.

The MWMSG_DDR_CONTROL, MWMSG_DDR_CONTROL2, and MWMSG_DDR_DATA registers are only targeted for DMA operations, but the processor can also write to the MWMSG_DDR_CONTROL register (instead of using MCTRL and MxDATAB).

NOTE

The module handles preamble, parity, and CRC.

Field	Function
31-16 —	Reserved
15-0 ADDRCMD	Address Command Indicates the first data write after control write, with LEN ≠ 0. This is formatted as: • Bits 15:9: target address to read or write • Bit 8: reserved, must be 0 • Bit 7: 1 if read, 0 if write • Bits 6:0: CMD as 7-bit value, always for controller

65.8.47 Controller Write Message in DDR Mode Control 2 (MWMSG_DDR_CONTROL2)

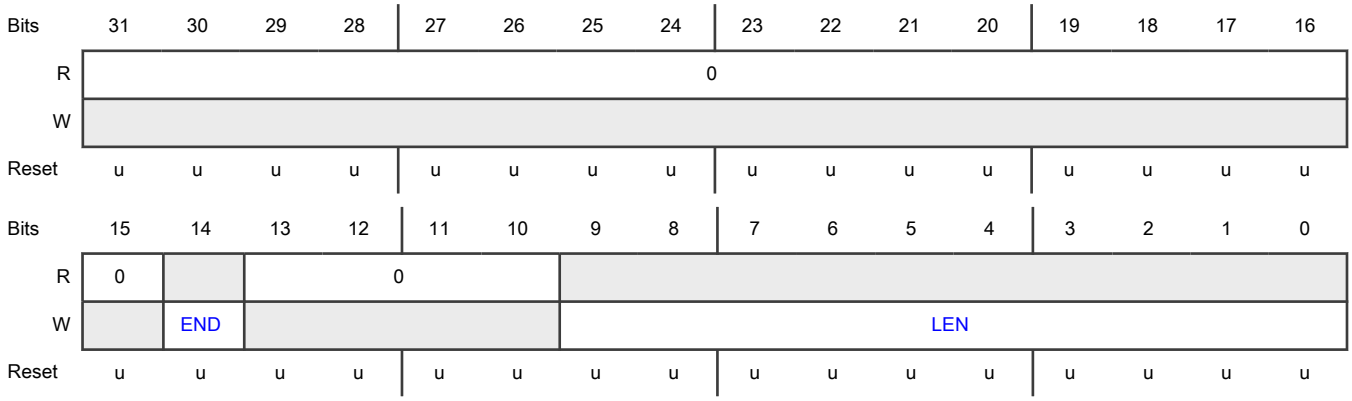
Offset

Register	Offset
MWMSG_DDR_CONTROL2	D8h

Function

Contains the second control word instructions with the length of message and end.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14 END	End of Message Indicates the end of DDR message. MSTATUS[COMPLETE] becomes 1 when done. The end can happen before LEN bytes are read if the target ends sooner. If this field is 0, DDR message ends waiting for a new DDR message (issues an HDR restart for the new message). If this field is 1, DDR message ends on HDR exit. 0b - Not the end 1b - End
13-10 —	Reserved
9-0 LEN	Length of Message Contains the length of the message (including the command) in halfwords, up to 2046 bytes. If LEN = 0, then only END is applied: • For reads, + 1 for the CRC. For example, to read 4 bytes (2 halfwords), use 1 + 2 + 1 for CMD + 2 halfwords + CRC. • For writes, LEN is the number of halves of data bytes + 1 (for command).

65.8.48 Controller Write Message Data in DDR mode (MWMSG_DDR_DATA)

Offset

Register	Offset
MWMSG_DDR_DATA	D8h

Function

Contains the 16-bit word to be written in DDR mode. This register functions in a way similar to Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL).

Diagram

65.8.49 Controller Read Message in DDR mode (MRMSG_DDR)

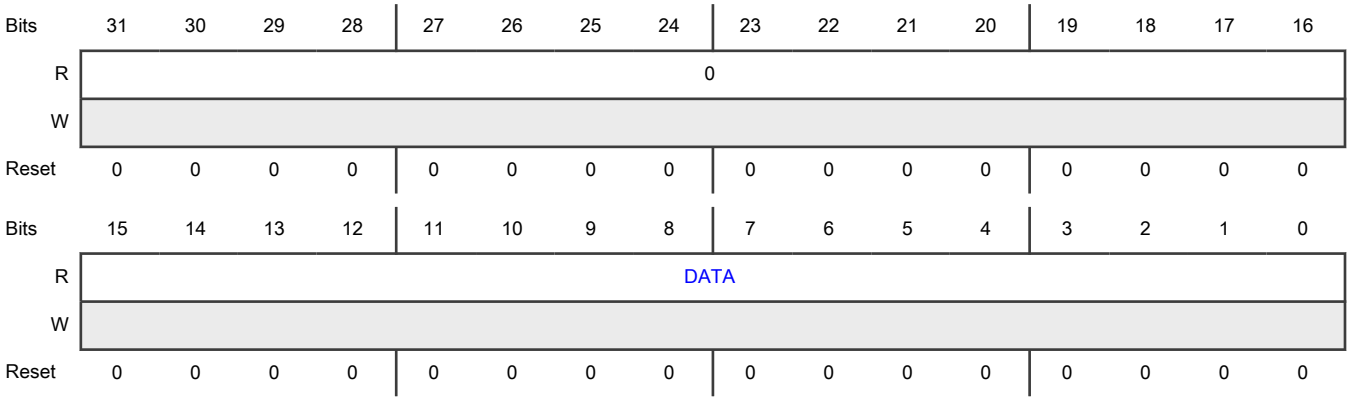
Offset

Register	Offset
MRMSG_DDR	DCh

Function

Allows reading 16-bit words from a target in DDR Message mode from an active message started with MWMSG_DDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Contains the 16-bit word read from a target. The first byte is the LSB, and is in DATA[7:0]. The second byte is the MSB, and is in DATA[15:8]: • If the target ends before the entire length of the message (MWMSG_DDR[LEN]) is read, the module considers the DATA read as completed. In I3C mode, the target can indicate the end of message (the last byte). Otherwise, the controller terminates the message if the message is more than the controller can accept. • If the target has not yet finished sending DATA before the entire length of the message (MWMSG_DDR[LEN]) is read and END is not a continuation, the DATA read is terminated.

65.8.50 Controller Dynamic Address (MDYNADDR)

Offset

Register	Offset
MDYNADDR	E4h

Function

Allows the I3C module to write its own dynamic address (DA) when the module changes from Controller mode to Target mode.

If this device is the main controller (the controller during bus initialization), then the device may use this mechanism to assign itself its DA. When the device hands off control to a secondary controller, it becomes a target itself. This DA must be written before switching to Target mode and must not be changed once in Target mode (it is not clock-safe to do so). It must be written with a valid address value in DADDR if DAVALID = 1.

NOTE

The main controller also uses DEFSLVS CCC to define the target addresses, including itself. This mechanism is how secondary controllers know this address. If the controller is not the main controller, then this mechanism must not be used.

0 DAVALID	Dynamic Address Valid 0b - No valid DA assigned 1b - Valid DA assigned

65.8.51 Timing Rules for Target Reset Recovery (SRSTACTTIME)

Offset

Register	Offset
SRSTACTTIME	100h

Function

Indicates the timing rules for a recovery following a TargetReset.

When the controller issues a TargetReset, some part of the device may be reset, such as a peripheral, the whole device, or some subset of the device. The controller must know how long the device takes to recover and be ready for new I3C messages. This behavior may be hard-coded or configured using this register.

This register is used if the device is enabled for MMR.

0 BASE	Base Determines whether any unhandled CCC commands in the range of 0h to 1Fh and 80h to 8Fh are passed to the application or suppressed. 0b - Suppressed 1b - Passed to application

65.8.53 Target Errors and Warnings Mask (SERRWARNMASK)

Offset

Register	Offset
SERRWARNMASK	110h

Function

Allows masking of target errors and warnings.

Target Errors and Warnings (SERRWARN) contains I3C protocol errors and issues detected on the line. If any are 1, SSTATUS[ERRWARN] becomes 1. The corresponding interrupt field also becomes 1, if enabled. SERRWARNMASK allows masking them, so only some form the status bit.

65.8.54 Map Feature Control 0 (SMAPCTRL0)

Offset

Register	Offset
SMAPCTRL0	11Ch

Function

Provides map feature control.

The SMAPCTRL*n* registers are named SMAPCTRL0, SMAPCTRL1, and so on based on the number of mapped addresses. MAPCTRL0 represents the primary DA or SA with SMAPCTRL1 onwards being the mapped addresses.

The features of the SMAPCTRL*n* registers depend on configuration. SMAPCTRL0 acts differently, as described in this chapter.

In general, this mechanism is intended to replace the DYNADDR register for all MAP-related uses.

When using the Auto-MAP and DASA or AASA, the slot is changed from SA to DA. If the controller then issues RSTDAA, the application must rewrite the static addresses and enable them because they are marked disabled.

Diagram

Chapter 66
Timers Overview

66.1 Overview

The following timers are supported in this chip:

- General Purpose Timer (GPT): A 32-bit up-counter with 12-bit pre-scaler
- Low Power Periodic Interrupt Timer (LPIT): A 32-bit counter timer that features programmable count modulus, clock division features etc.
- Quad Timer (TMR): It provides four timer channels with variety of controls for individual and multi-channel features
- Quadrature Decoder (eQDC): It provides interfacing capability to position/speed sensors
- Enhanced FlexPWM: It contains PWM submodules each of which is set up to control a single half bridge power stage
- Watchdog timers (WDOG1-WDOG5): It is a high reliability independent timer that is available for system use
- External Watchdog Monitor (EWM): It is designed to monitor external circuits, as well as the MCU software flow

66.1.1 General Purpose Timer (GPT)

The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT also features output compare event generation, when the timer matches a preset value, GPT can generate an interrupt for software and a compare event signal on output pins for external hardware.

The GPT has a 12-bit pre-scaler, which provides a programmable clock frequency derived from multiple clock sources.

66.1.2 Low Power Periodic Interrupt Timer (LPIT)

The LPIT is a basic 32-bit counter timer. It features 32-bit counter timer, programmable count modulus, clock division features, interrupt generation, and ability to chain adjacent timers to achieve longer interval.

66.1.3 Quad Timer (TMR)

The quad-timer provides four timer channels. Specific features include up/down count, cascading of counters, programmable modulo, count once/repeated, counter preload, compare registers with preload, shared use of input signals, prescaler controls, independent capture/compare, fault input control, programmable input filters, and multi-channel synchronization.

As shown in diagram below, input of QTimer can be sourced from PADs or XBAR1:

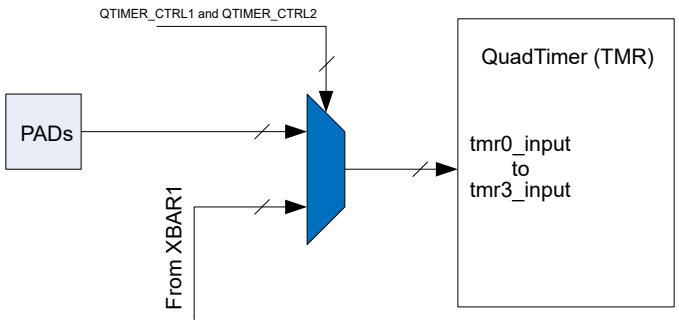

Figure 481. QTimer inputs

66.1.4 Enhanced Flex Pulse Width Modulator (eFlexPWM)

This module can generate various switching patterns, including highly sophisticated waveforms. Each module shall be configured with 4 channels supporting A, B, and X PWM output. All channels are configured for standard edge placement and have their capture function enabled.

66.1.5 Quadrature Decoder (eQDC)

The enhanced Quadrature Decoder module provides interfacing capability to position speed sensors used in industrial motor control applications, and capability of compare output as well as input capture. The Enhanced Quadrature Decoder module interfaces to position/speed sensors that are used in industrial motor control applications and decodes shaft position, revolution count, and speed. The quadrature decoder gets 8 input signals: PHASEA, PHASEB, INDEX/PRESET, TRIGGER, HOME/ENABLE and ICAP[3:1] from those position/speed sensors, and outputs 11 signals: POS_MATCH[3:0], COMP_FLG[3:0], DIR, CNT_DN, and CNT_UP for system use.

66.1.6 Watchdog Timer (WDOG)

The WDOG module is an high reliability independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the CPU.

There are 5 watch dog timers. One for the Cortex-M33 non-secure world, one for the Cortex-M33 secure world, and one for the Cortex-M7. Two additional for customer usage

Main features of the WDOG module are:

- Configurable independent clock source input from bus clock
- Programmable time-out period
- Robust write sequence for counter refresh
- Windowed refresh option
- Optional timeout interrupt to allow post-processing diagnostics
- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered
- Robust write sequence for unlocking write-once control/configuration bits

The WDOG clocks can be sourced from:

- Fixed 24MHz (ext_clk)
- Fixed 32KHz (lpo_clk)

66.1.7 External Watchdog Monitor (EWM)

The External Watchdog Monitor provides a back-up mechanism to the internal WDOG that can reset the system. The EWM differs from the internal WDOG in that it does not reset the system.

The EWM, if allowed to time-out, provides an independent trigger pin that when asserted resets or places an external circuit into a safe mode.

Fault functionality

eFlexPWM fault may work abnormally when the fault signal is very narrow. If the fault signal pulse width is narrower than a certain threshold, the protected PWM channels may generate a glitch, which occurs after the PWM channel outputs become inactive.

The following workaround can be used to mitigate this abnormal functioning.

- When FCTRL2[NOCOMB] = 0, FFILT [GSTR]= 0, and FFILT[FILT_PER]=0, pulse width of fault signals must be larger than 6 PWM clock periods, otherwise a glitch may be generated on the protected PWM channels.
- When FCTRL2[NOCOMB] = 0, FFILT [GSTR]= 1, and FFILT[FILT_PER]=0, pulse width of fault signals must be larger than 3 PWM clock periods, otherwise a glitch may be generated on the protected PWM channels.
- When FCTRL2[NOCOMB] = 0, FFILT [GSTR]= 1, and FFILT[FILT_PER] has non-zero values, pulse width of fault signals must be larger than FILT_PER*(FILT_CNT+3)+6 PWM clock periods, otherwise a glitch may be generated on the protected PWM channels.
- When FCTRL2[NOCOMB] = 0, FFILT [GSTR]= 0, and FFILT[FILT_PER] has non-zero values, pulse width of fault signals must be larger than FILT_PER*(FILT_CNT+3)+9 PWM clock periods, otherwise a glitch may be generated on the protected PWM channels.

67.2 Overview

The Pulse Width Modulator (PWM) module contains PWM submodules, each of which can be used to control a single half-bridge power stage. Fault channel support is provided.

This module generates various switching patterns, including highly sophisticated waveforms. It can be used to control all known motor types and is ideal for controlling different Switched Mode Power Supplies (SMPS) topologies.

67.2.1 Block diagram

The following figure shows the PWM block diagram.

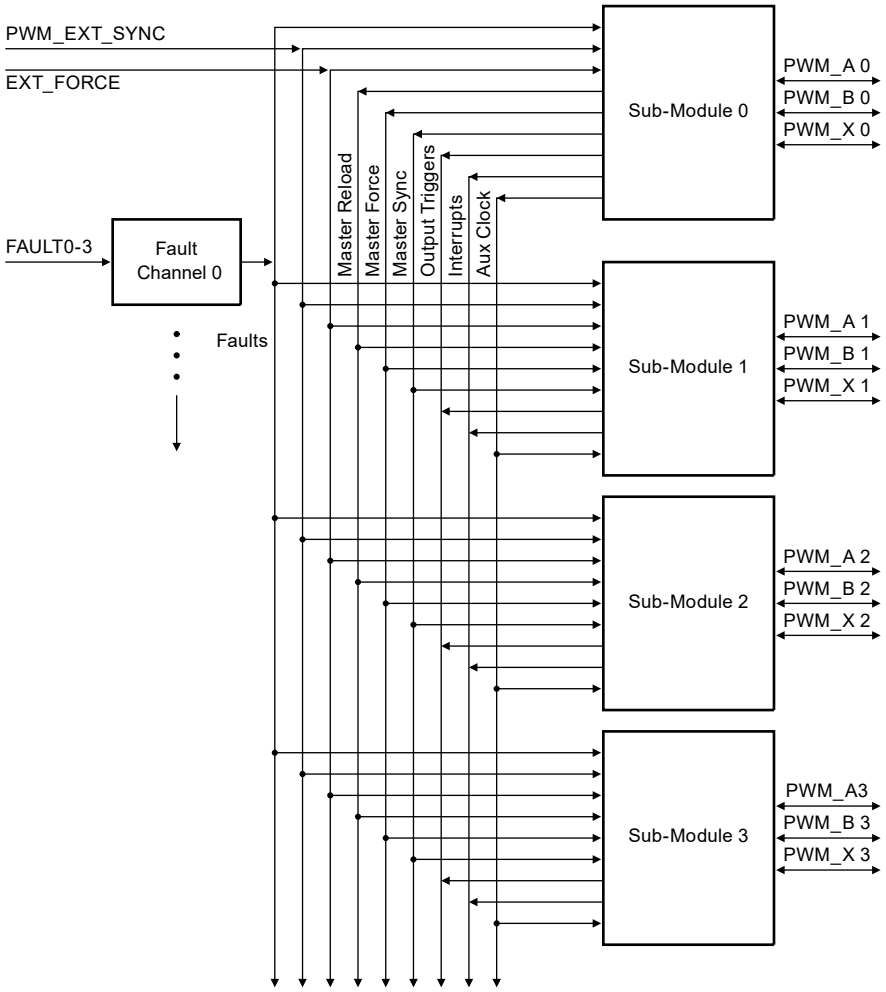

Figure 482. PWM block diagram

67.2.2 Features

Following are the features of PWM:

- 16-bit resolution for center, edge-aligned, and asymmetrical PWMs
- Dithering to simulate enhanced resolution when fine edge placement is not available
- PWM outputs that can operate as complementary pairs or independent channels
- Ability to accept signed numbers for PWM generation
- Independent control of both edges of each PWM output
- Support for synchronization to external hardware or other PWM
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware

- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs
- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- All outputs can be programmed to change simultaneously via a FORCE_OUT event
- PWM_X pin can optionally output a third PWM signal from each submodule
- Channels not used for PWM generation can be used for buffered output compare functions and for input capture functions
- Enhanced dual edge capture functionality

67.3 Functional description

67.3.1 PWM submodule

The following figure shows the PWM Submodule Block Diagram.

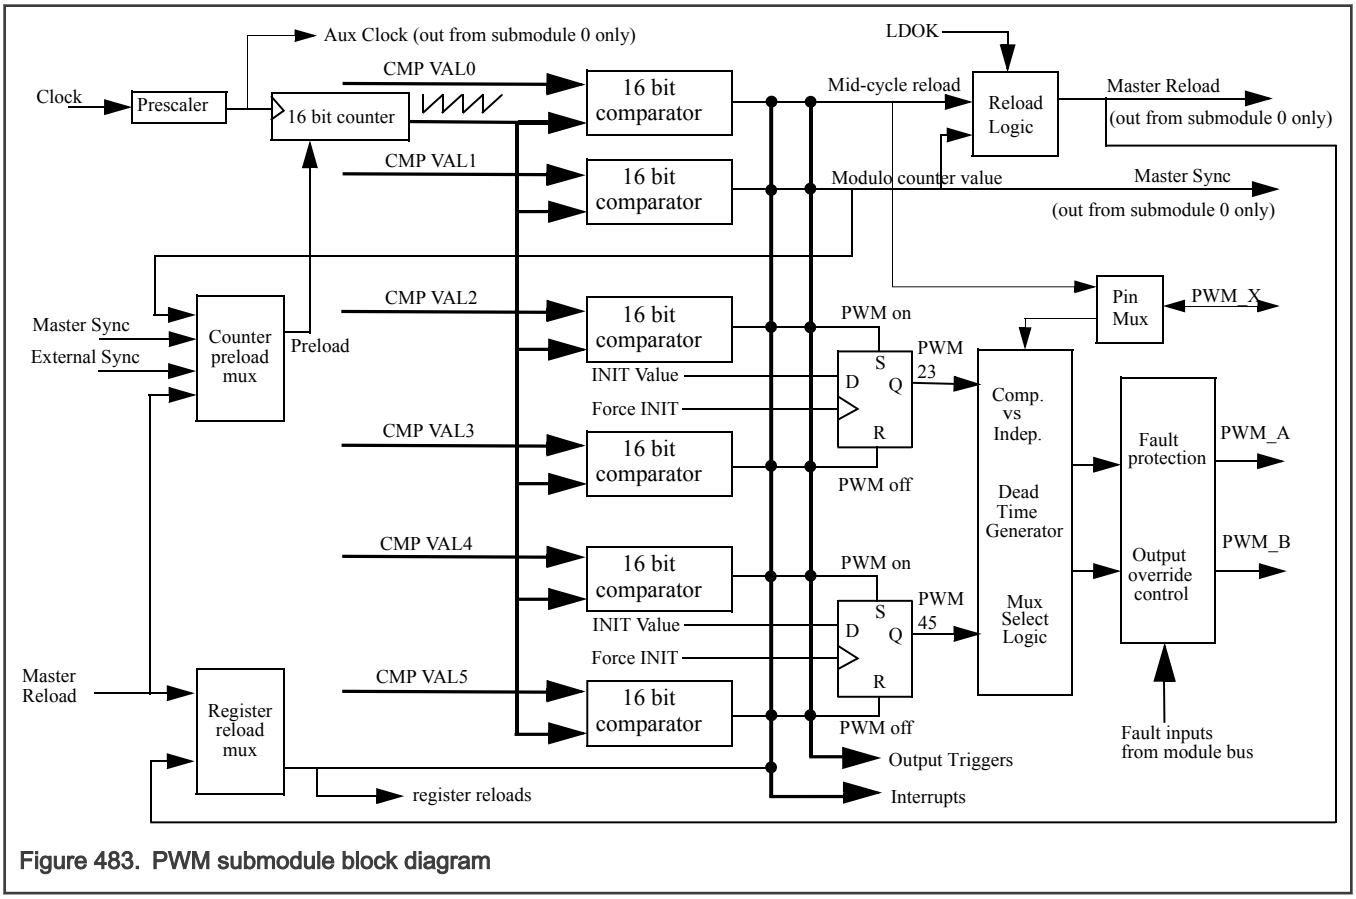

Figure 483. PWM submodule block diagram

67.3.2 PWM capabilities

This section describes some capabilities of the PWM module.

67.3.2.1 Center aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in Figure 484.

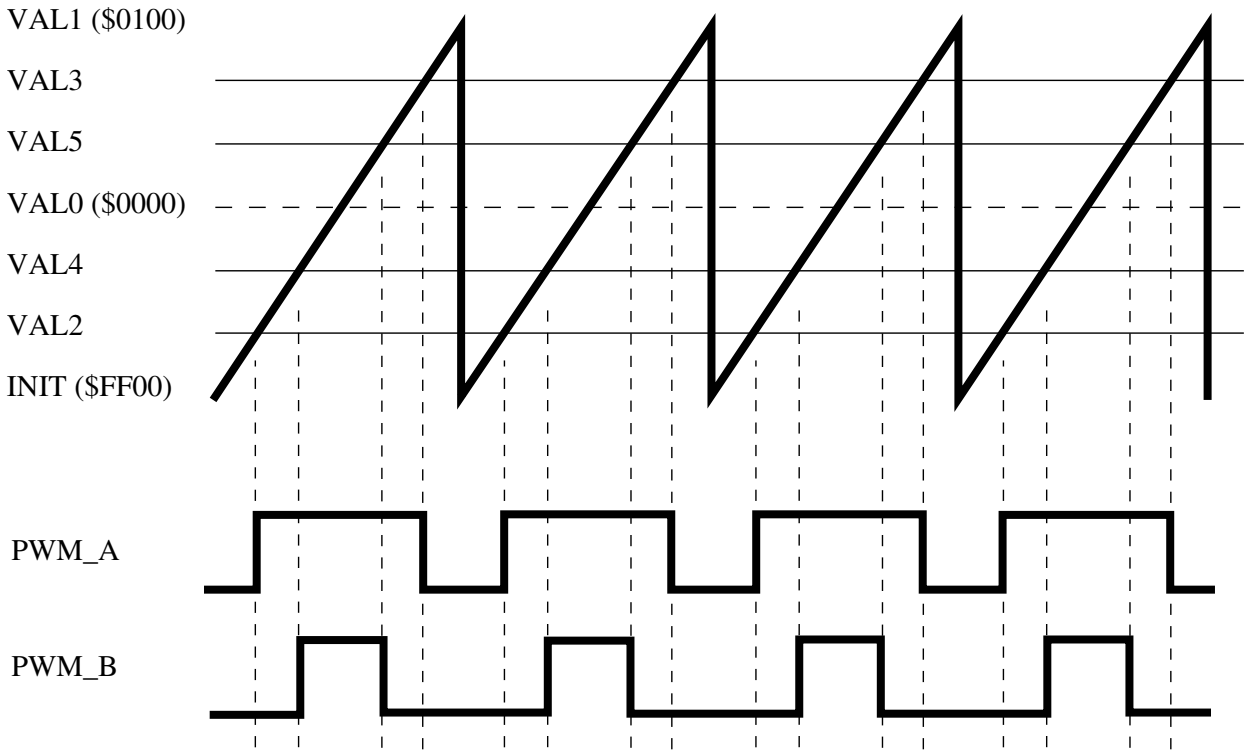

Figure 484. Center aligned PWM example

The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn-on edge and the turn-off edge. This double-action edge generation provides the user control over the pulse width and also the relative alignment of the signal. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn-on and turn-off edge values.

Figure 484 also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user-specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then the PWM generator operates in "signed" mode. This means if each PWM's turn-on and turn-off edge values are same in numbers but different in their sign, the "on" portion of the output signal is centered around a count value of zero. Therefore, only one PWM value is calculated in software and then this value and its negative are provided to the submodule as the turn-off and turn-on edges respectively. This technique results in a pulse width consists of an odd number of timer counts. If all PWM signal edge calculations follow this convention, then the signals will be center aligned with each other, which is the goal. The center alignment between the signals is not restricted to symmetry around the zero count value, as any other number would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

67.3.2.2 Edge aligned PWMs

Figure 485 shows the results of edge aligned operation when the turn-on edge for each pulse is specified to be the INIT value. Therefore, only the turn-off edge value needs to be periodically updated to change the pulse width.

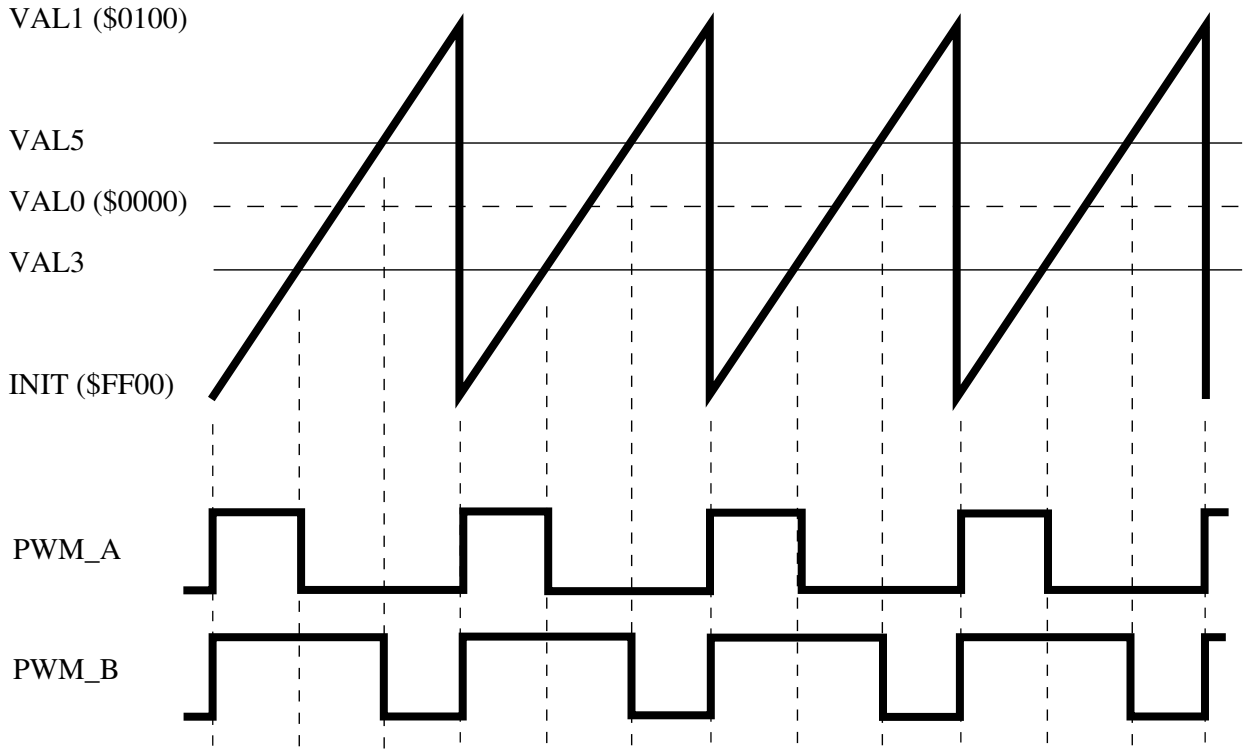

Figure 485. Edge aligned example (INIT=VAL2=VAL4)

With edge aligned PWMs, another example of the benefits of signed mode can be seen. Use "bipolar" PWMs to drive an H-bridge, where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% generate negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn-off edge value and the motor inverter voltage, including the sign. Therefore, signed mode of operation simplifies the software interface to the PWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.

67.3.2.3 Phase shifted PWMs

In the previous sections, the benefits of the signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases are applied to the turn-on and turn-off edges of different PWM signals, the signals will be phase shifted to each other, as shown in Figure 486. This results in certain advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at the same time. This can be troublesome from a noise standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does not affect the duty cycle so average load voltage is not affected.

If the outputs of submodules 1 - 3 need to be delayed from the output of submodule 0 (and from each other), instead of just creating a phase delay by adding an offset to the turn on and turn off times of the different submodules, another method is to use the PHASEDLY registers for submodules 1 - 3 to indicate their delay from the submodule 0 timing. This method can be used when the master sync signal from submodule 0 is selected as the initialization source (CTRL2[INIT_SEL]==b10). This method allows all of the submodules to be programmed with the same turn on and turn off time but submodules 1 - 3 can still be delayed the time from submodule 0.

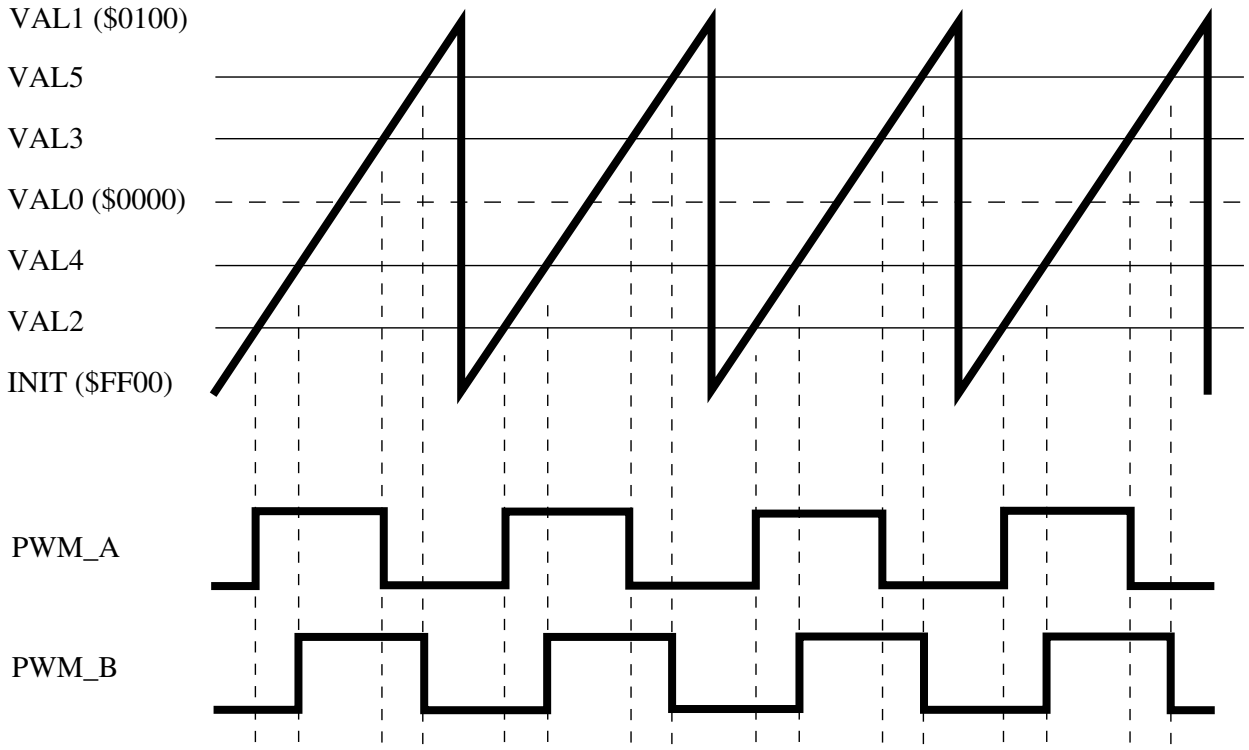

Figure 486. Phase shifted outputs - example for 1 submodule

An additional benefit of phase shifted PWMs is shown in Figure 487. In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to generate a square wave with 50% duty cycle. This works for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching requirements of the transistors. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% suitable for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

NOTE

The square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals.

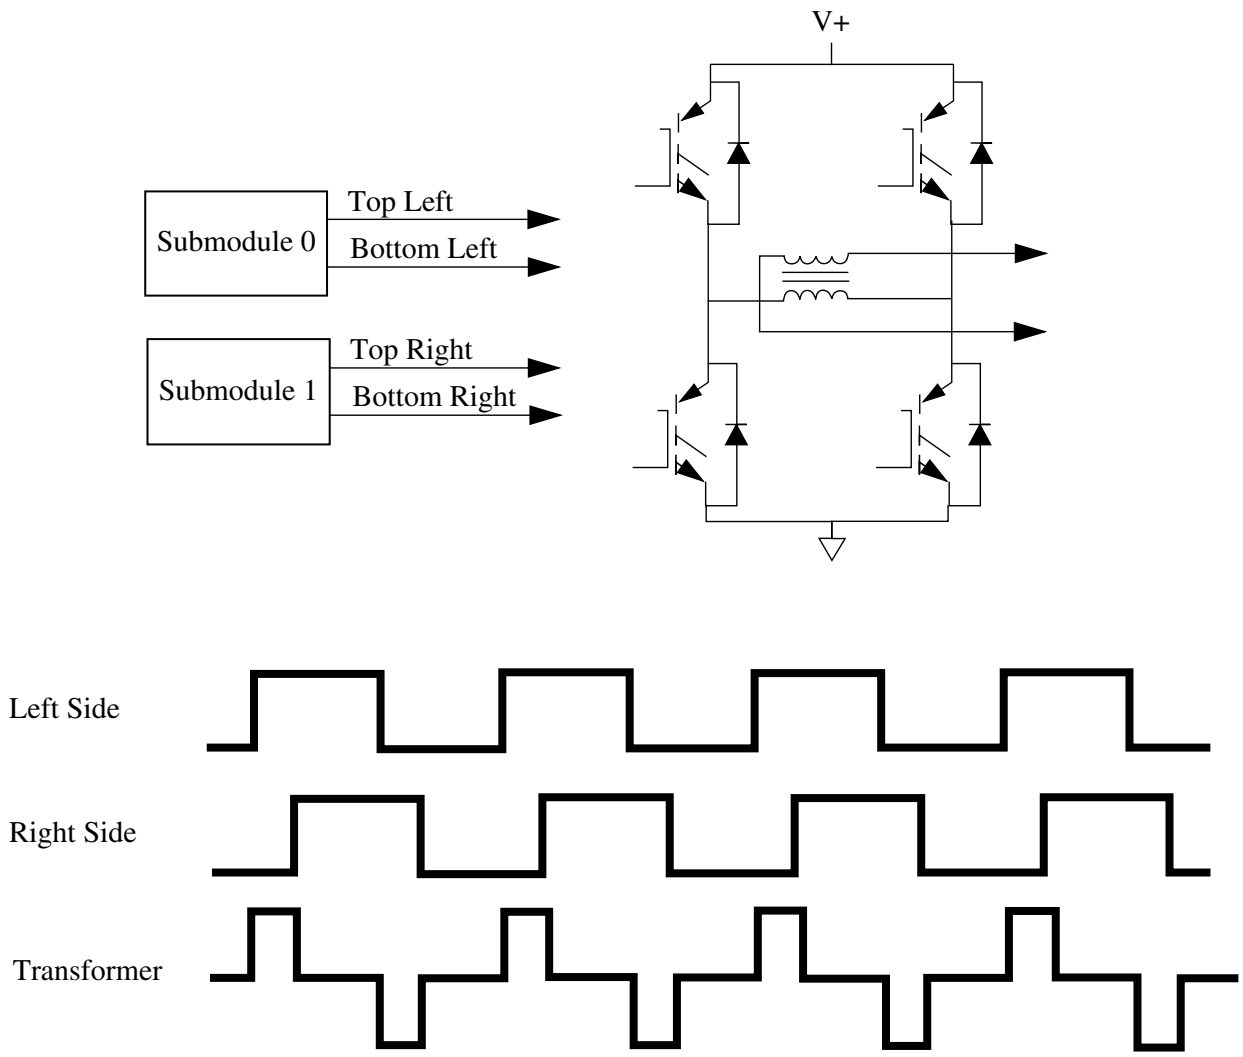

Figure 487. Phase Shifted PWMs Applied to a Transformer Primary

67.3.2.4 Double switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three-phase reconstruction. This method supports two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labeled as PWM_A in Figure 488) while VAL4 and VAL5 are used to generate the odd channel. The two channels (PWM23 or PWM_A and PWM45 or PWM_B from force out logic) are combined using XOR logic (force out logic) as the following figure shows. The DBLPWM signal can be run through the deadtime insertion logic.

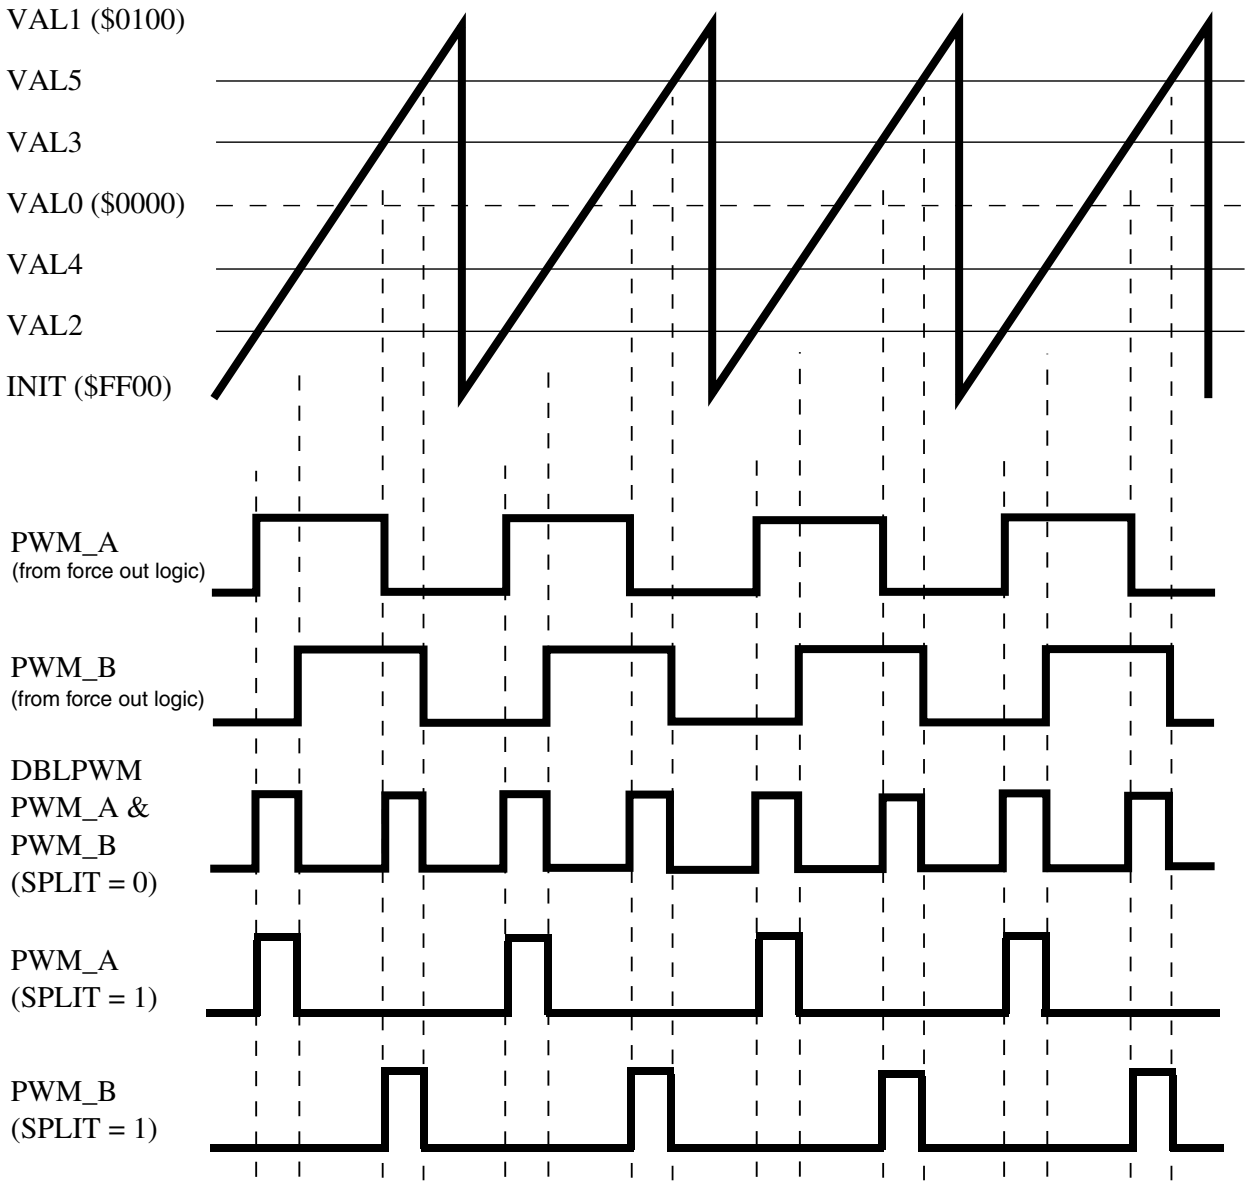

Figure 488. Double switching output example

67.3.2.5 ADC triggering

In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this PWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. Figure 489 shows how this is accomplished. When specifying a complementary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means the other comparators are free to perform other functions. In this example, the software does not need to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

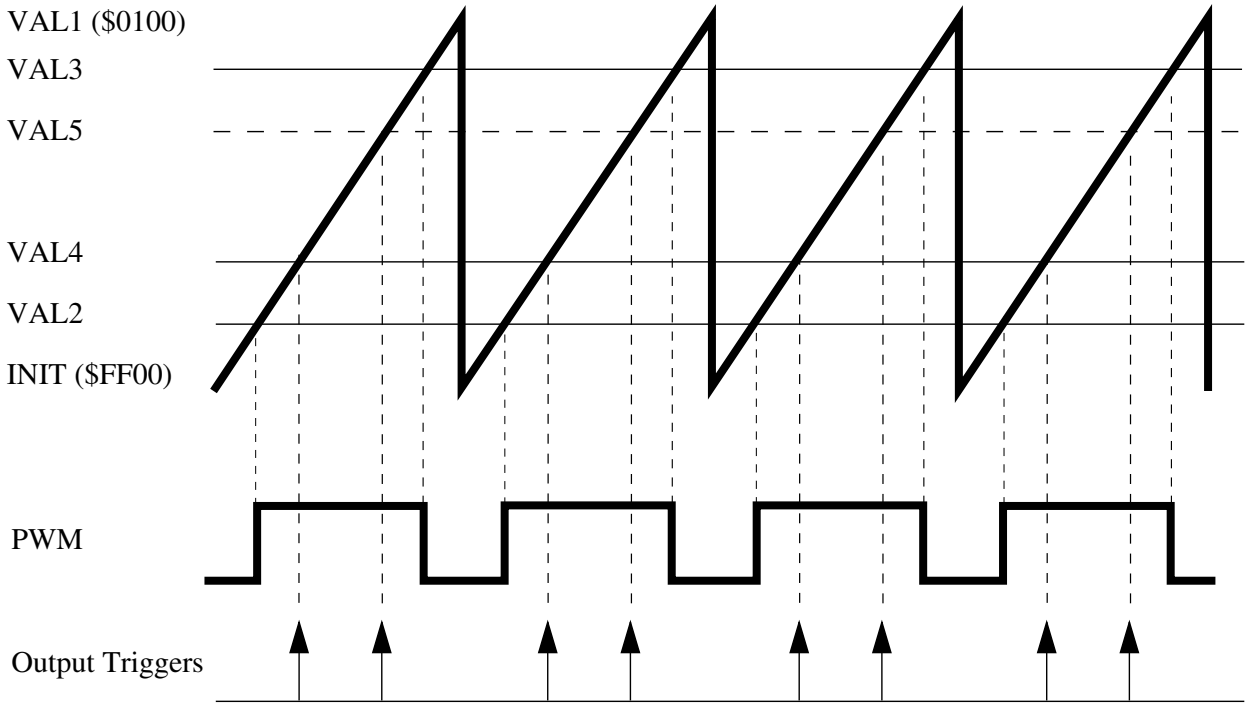

Figure 489. Multiple output trigger generation in hardware

Because each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this PWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. Figure 490 shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. You can use the lower-frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In Figure 490, *all* submodule comparators are shown being used for ADC trigger generation.

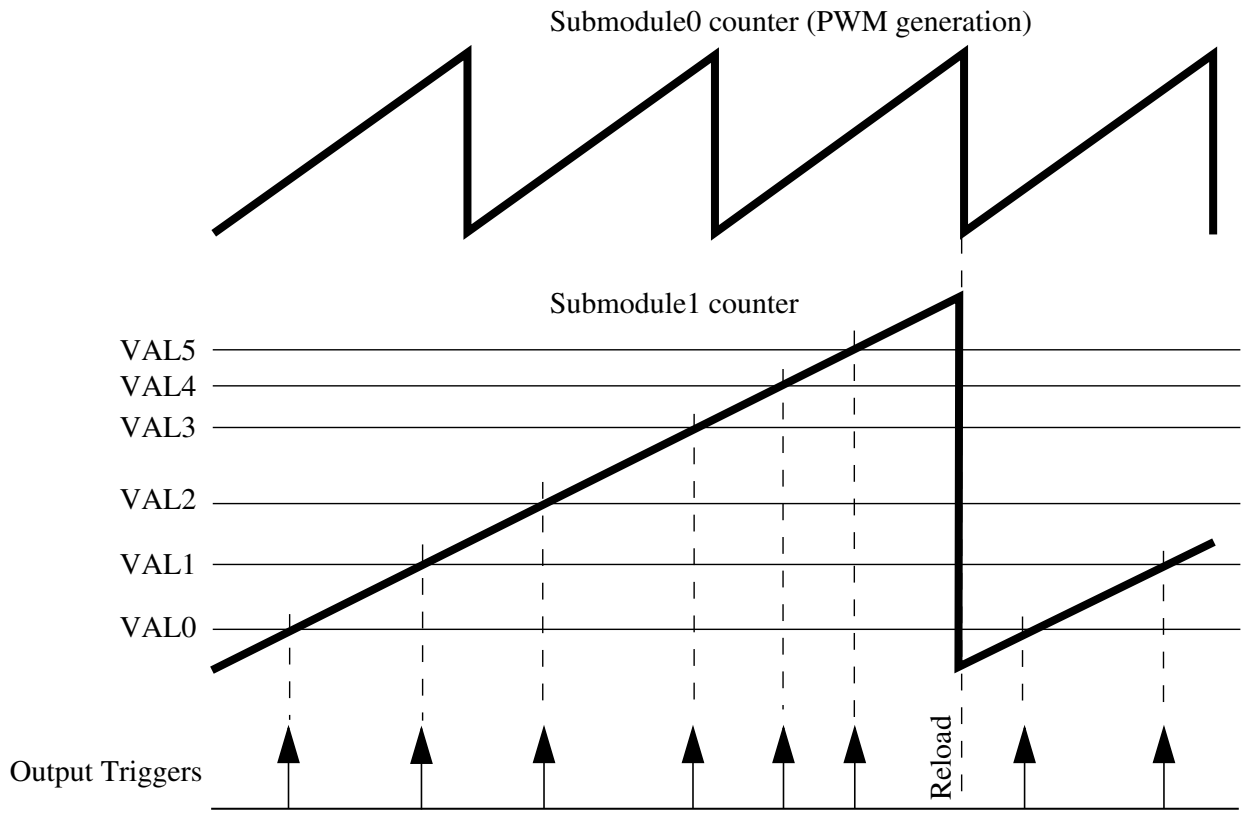

Figure 490. Multiple output triggers over several PWM cycles

67.3.2.6 Enhanced capture capabilities (E-Capture)

When a PWM pin is not used for PWM generation, it can be used to perform input captures. For PWM generation, both edges of the PWM signals are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. Programming the desired edge of each capture circuit, period, and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8-bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature counts a specified number of edge events and then performs a capture and interrupt. The following figure illustrates some of the functionality of the E-Capture circuit.

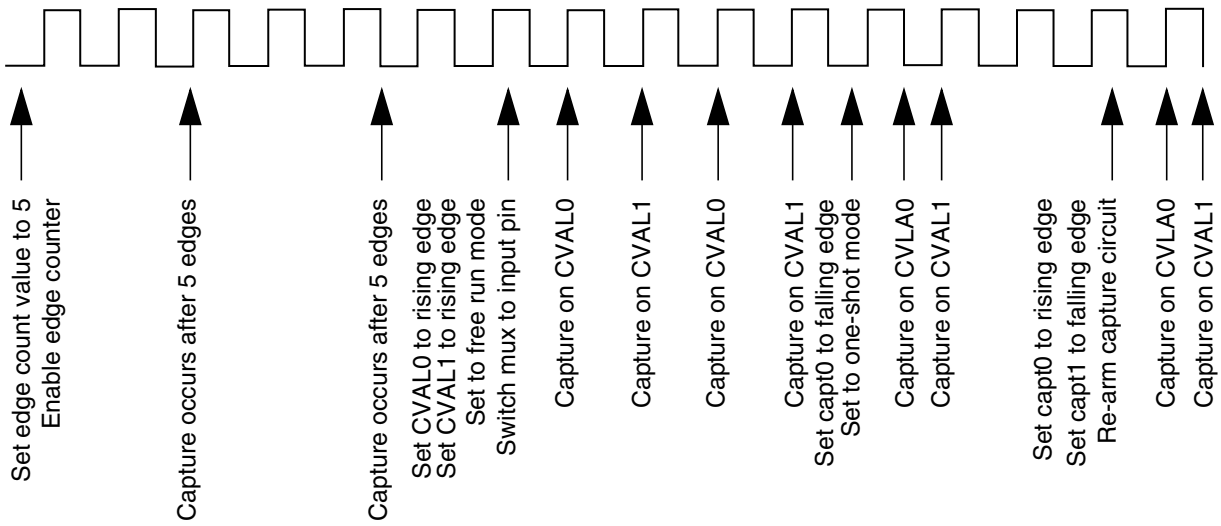

Figure 491. Capture capabilities of the E-Capture circuit

When a submodule is used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (for example, PWM_X) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16-bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is suited for the application. As shown in Figure 492, the output of a PWM power stage is connected to the PWM_X pin that is configured for free running input captures. Specifically, the CVAL0 capture circuitry is programmed for rising edges and the CVAL1 capture circuitry is set for falling edges. This results in new load pulse width data acquired every PWM cycle. To calculate the pulse width, subtract the CVAL0 register value from the CVAL1 register value. This measurement is beneficial when performing deadtime distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays. For details, refer to the separate discussion of deadtime distortion correction.

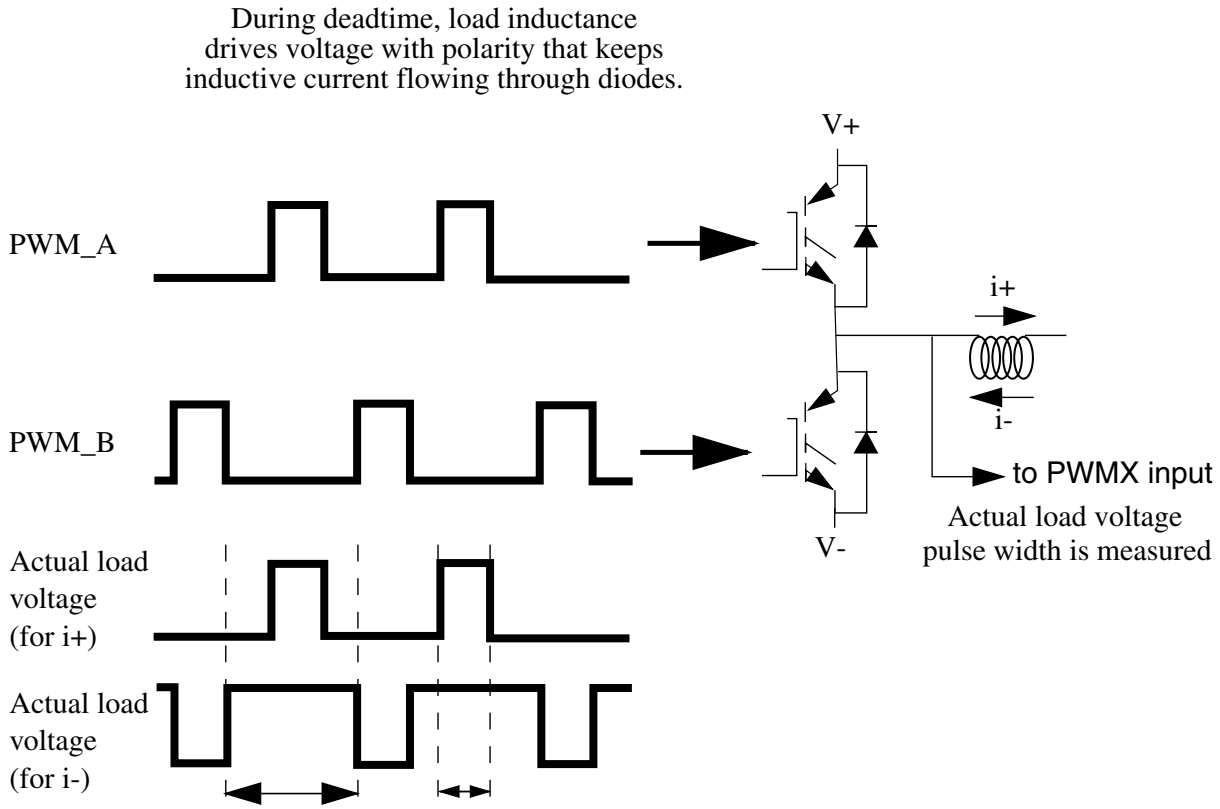

Figure 492. Output pulse width measurement possible with the E-capture circuit

67.3.2.7 Synchronous switching of multiple outputs

Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. This feature is useful in commutated motor applications where the next commutation state can be laid in ahead of time and then immediately switched to the outputs when the appropriate condition or time is reached. All the changes occur immediately after the trigger event occurs eliminating any interrupt latency and also the changes occurs synchronously on all submodule outputs.

The synchronous output switching is accomplished via a signal called FORCE_OUT. This signal originates from the local FORCE bit within the submodule, from submodule0, or from external to the PWM module, and in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next FORCE_OUT event. This selection lays dormant until the FORCE_OUT signal transitions and then all outputs are switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that occur do not violate deadtime on the power stage when in complementary mode.

Figure 493 shows an application that can benefit from this feature. On a brushless DC motor in many cases, it is required to spin the motor without need of hall-effect sensor feedback. Instead, the back EMF of the motor phases is monitored and this information is used to schedule the next commutation event. The top waveforms of Figure 493 represent these back EMF signals. Timer compare events (represented by the long vertical lines in the diagram) are scheduled based on the zero crossings of the back-EMF waveforms. The PWM module is configured via software ahead of time with the next state of the PWM pins in anticipation of the compare event. When it happens, the output compare of the timer drives the FORCE_OUT signal which immediately changes the state of the PWM pins to the next commutation state with no software latency.

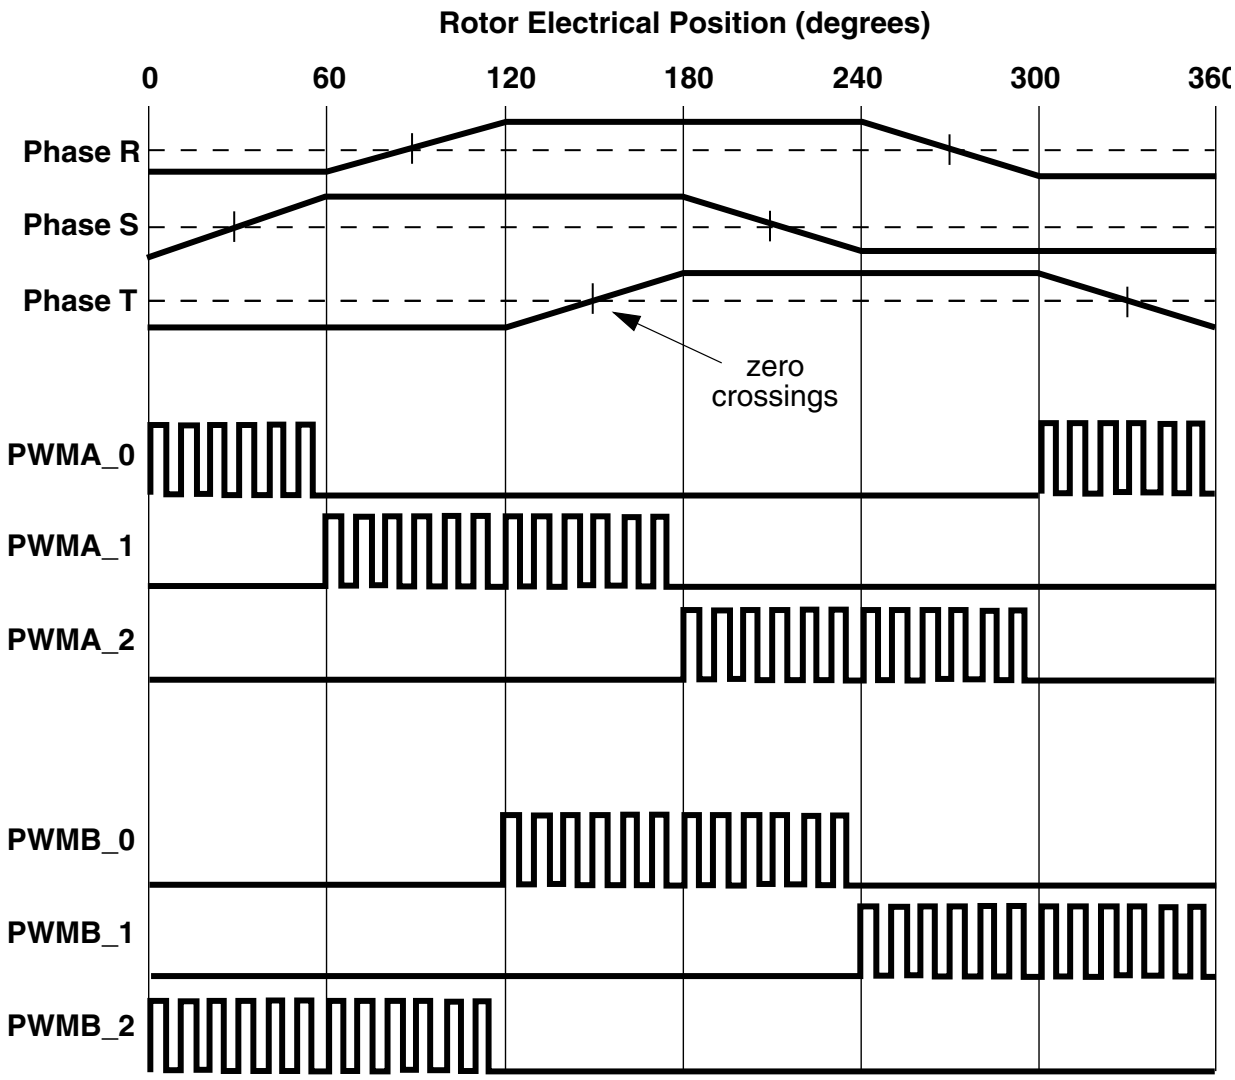

Figure 493. Sensorless BLDC commutation using the force out function

67.3.3 Operation

This section describes the implementation of various sections of the PWM in detail.

The following figure is a high-level block diagram of output PWM generation.

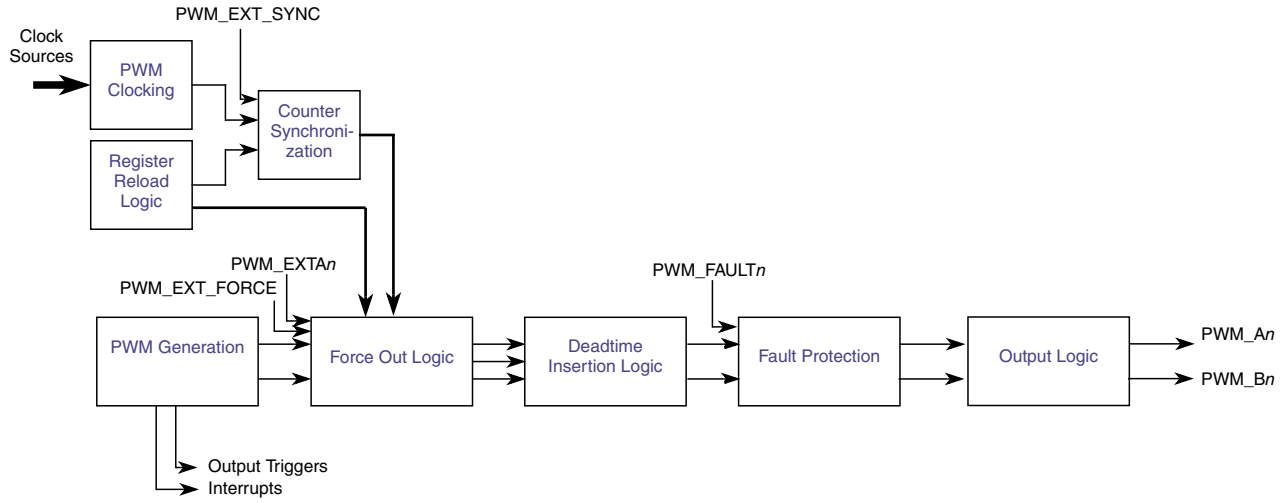

Figure 494. High-level output PWM generation block diagram

67.3.3.1 Register reload logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using CTRL[LDFQ] and CTRL[FULL], which is defined by VAL1 register. A half cycle reload option is also supported (CTRL[HALF]) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the VAL0 register and does not have to be exactly in the middle of the PWM cycle.

As shown in Figure 495 the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

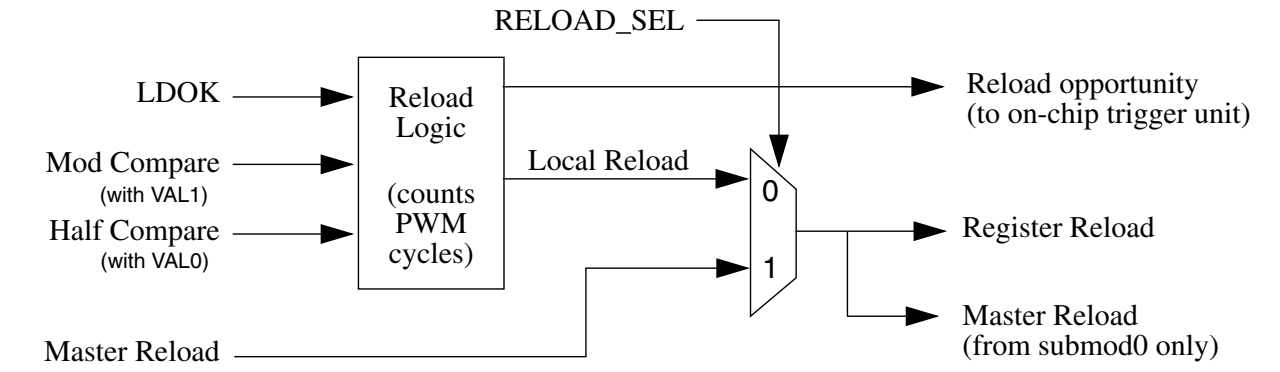

Figure 495. Register reload logic of each submodule

67.3.3.2 Counter synchronization

As shown in Figure 496, the 16-bit counter counts up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Synchronization signal which is one of four possible sources used to cause the 16-bit counter to be initialized with INIT. If Local Synchronization is selected as the counter initialization signal, VAL1 within the submodule effectively controls the timer period (and then the PWM frequency generated by that submodule), and everything operates or functions at a local level.

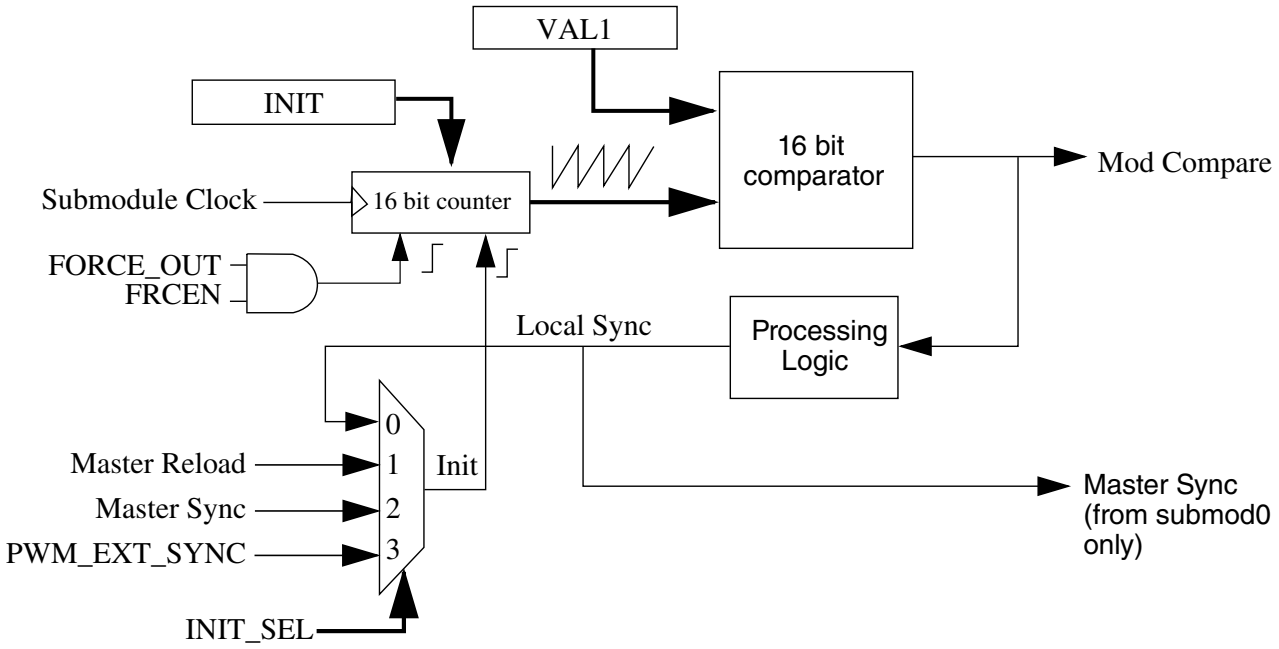

Figure 496. Counter synchronization for each submodule

The Master Synchronization signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0.

The PWM_EXT_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.

If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is commensurate to the sampling frequency of the software control algorithm, the submodule counter period is equal the sampling period. As a result, this timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE_OUT signal assuming that CTRL2[FRCEN] is set. As shown in Figure 496, this constitutes a second initialization input into the counter, which causes the counter to initialize regardless of which signal is selected as the counter initialization signal. A forced initialization causes a register reload if MCTRL[LDOK] is set.

The counter can be initialized by FORCE_OUT signal only when MCTRL[RUN] = 1 or CTLR2[CLK_SEL] = 2 which chooses auxiliary clock from SM0.

The FORCE_OUT signal is provided mainly for commutated applications. When PWM signals are commutated on an inverter controlling a brushless DC motor, it is necessary to restart the PWM cycle at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor winding integrated over the entire commutation interval will be a function of the timing between the asynchronous commutation event for the PWM cycle. The effect is more critical at higher motor speeds where each commutation interval may consist of only a few PWM cycles. If the counter is not initialized at the start of each commutation interval, the result is an oscillation caused by the beating between the PWM frequency and the commutation frequency.

67.3.3.3 PWM generation

Figure 497 illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated VALx registers are utilized for each PWM output signal. One comparator and VALx register are used to control the turn-on edge, while a second comparator and VALx register control the turn-off edge.

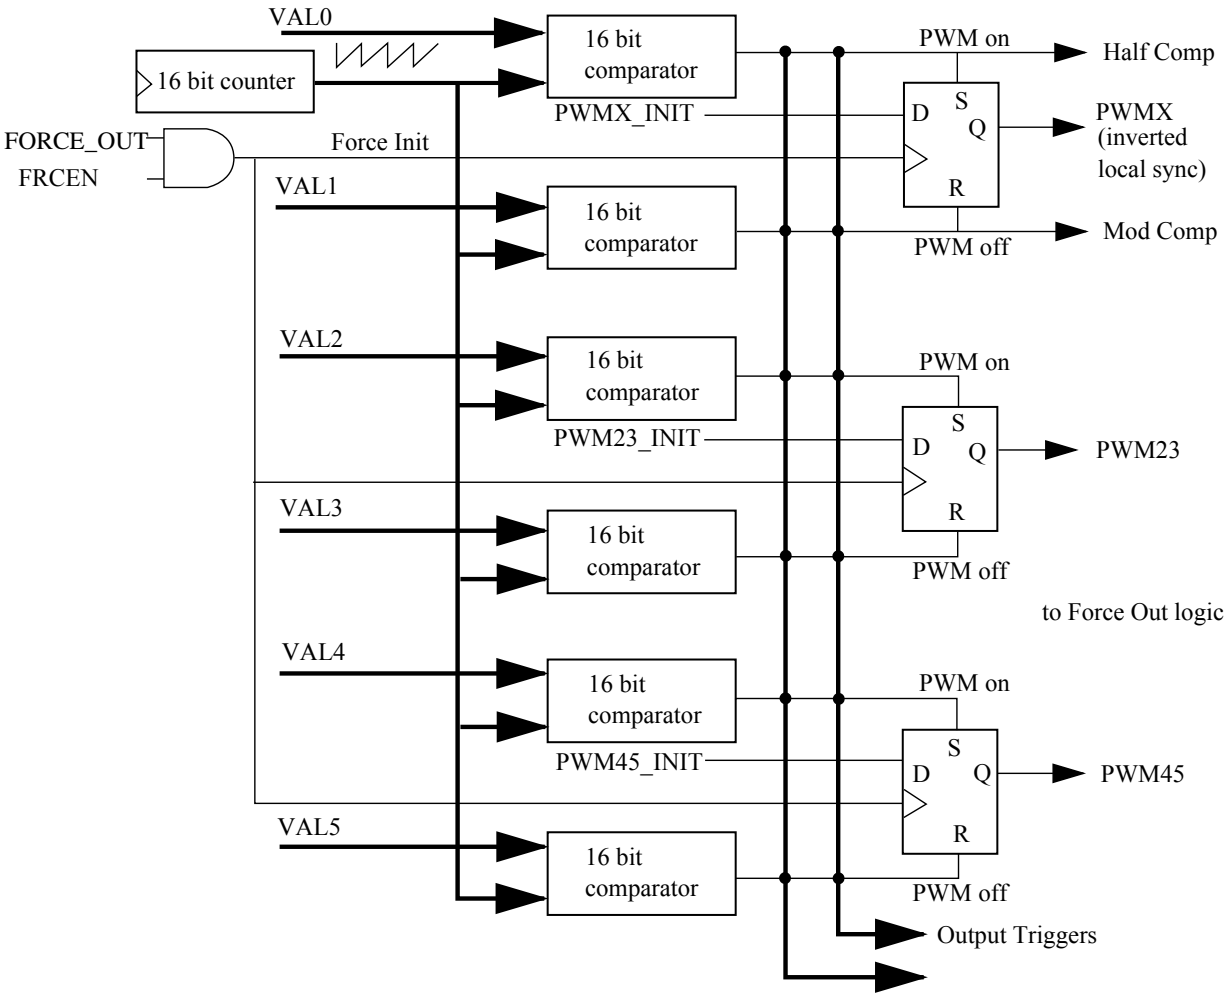

Figure 497. PWM Generation Hardware of each submodule

The generation of the Local Synchronization signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a falling edge of the Local Synchronization signal, comparator 1 generates a rising edge. Comparator 1 is also hardwired to the reload logic to generate the full cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the VAL1 register minus the INIT value, then the half cycle reload pulse occurs exactly half way through the timer count period and the Local Synchronization will have a 50% duty cycle. On the other hand, if the VAL1 and VAL0 registers are not required for register reloading or counter initialization, they can be used to modulate the duty cycle of the Local Synchronization signal, effectively turning it into an auxiliary PWM signal (PWM_X) assuming that the PWM_X pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Synchronization signal, each submodule is capable of generating three PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

The 16-bit comparators shown in Figure 497 are "equal to" comparators. In addition, if both the set and reset of the flip-flop are asserted, then the flop output goes to 0.

67.3.3.4 Output compare capabilities

By using the VALx registers in conjunction with the submodule timer and 16-bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high
- An output compare sets the output low
- An output compare generates an interrupt
- An output compare generates an output trigger

In PWM generation, an output compare is initiated by programming a VALx register for a timer compare, which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWM_A signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset again after the compare has occurred, the VAL3 register must be programmed to a value out of the modulus range of the counter. Therefore, a comparison that would result in resetting the D flip-flop output would never occur. Conversely, if an output compare is desired on the PWM_A signal that sets it low, the VAL3 register is programmed with the appropriate count value and the VAL2 register is programmed with a value out of the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt, or output trigger can be generated when the compare event occurs.

67.3.3.5 Force out logic

For each submodule, the software can select between eight signal sources for the FORCE_OUT signal depending on the chip architecture:

1. Local CTRL2[FORCE]
2. Master Force signal from submodule0
3. Local Reload signal
4. Master Reload signal from submodule0
5. Local Synchronization signal
6. Master Synchronization signal from submodule0
7. EXT_SYNC signal from on or off chip
8. EXT_FORCE signal from on or off chip

The local signals are used to change the signals on the output pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master, EXT_SYNC, or EXT_FORCE signals must be selected.

Figure 498 illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the PWM_EXTA alternate external control signals. The selection can be determined ahead of time, and when a FORCE_OUT event occurs, these values are presented to the signal selection mux that immediately switches the requested signal to the output of the mux for further processing downstream.

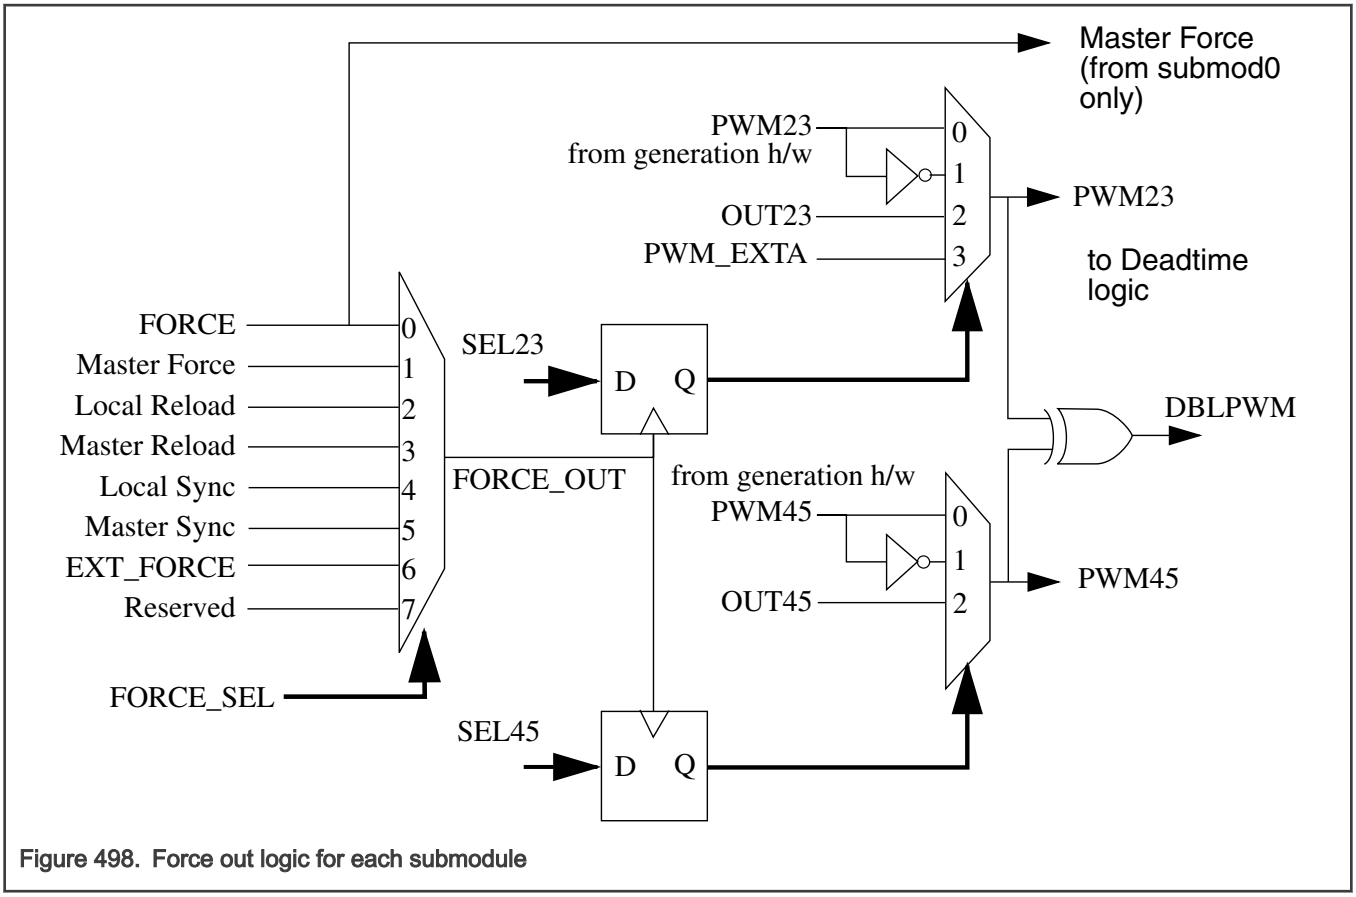

Figure 498. Force out logic for each submodule

The local CTRL2[FORCE] signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the CTRL2[FORCE] of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT_FORCE signal originates from outside the PWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

67.3.3.6 Independent or complementary channel operation

Writing a logic one to CTRL2[INDEP] configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

Writing a logic zero to CTRL2[INDEP] configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in Figure 3-16 in complementary channel operation. The signal that is connected to the output pin (PWM23 or PWM45) is determined by MCTRL[IPOL].

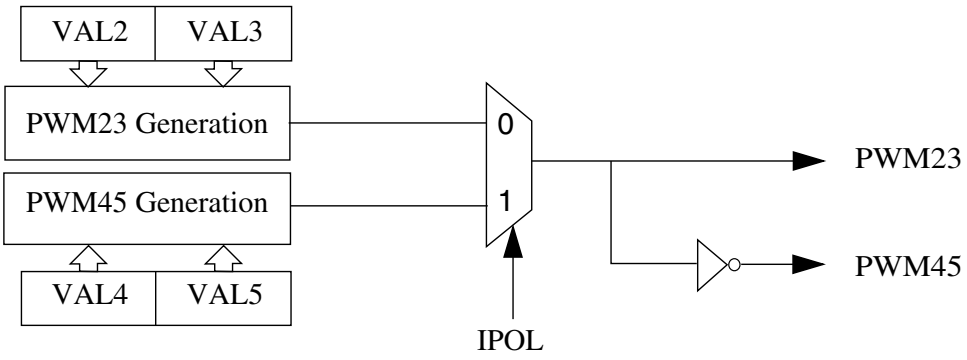

Figure 499. Complementary channel pair for each submodule

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, as shown in Figure 500.

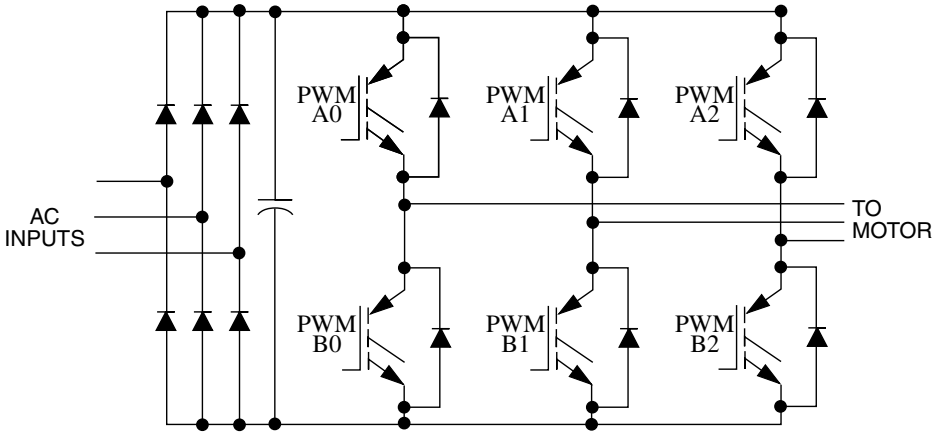

Figure 500. Typical 3 phase AC motor drive

The complementary operation allows the use of the deadtime insertion feature.

67.3.3.7 Deadtime insertion logic

The following figure shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.

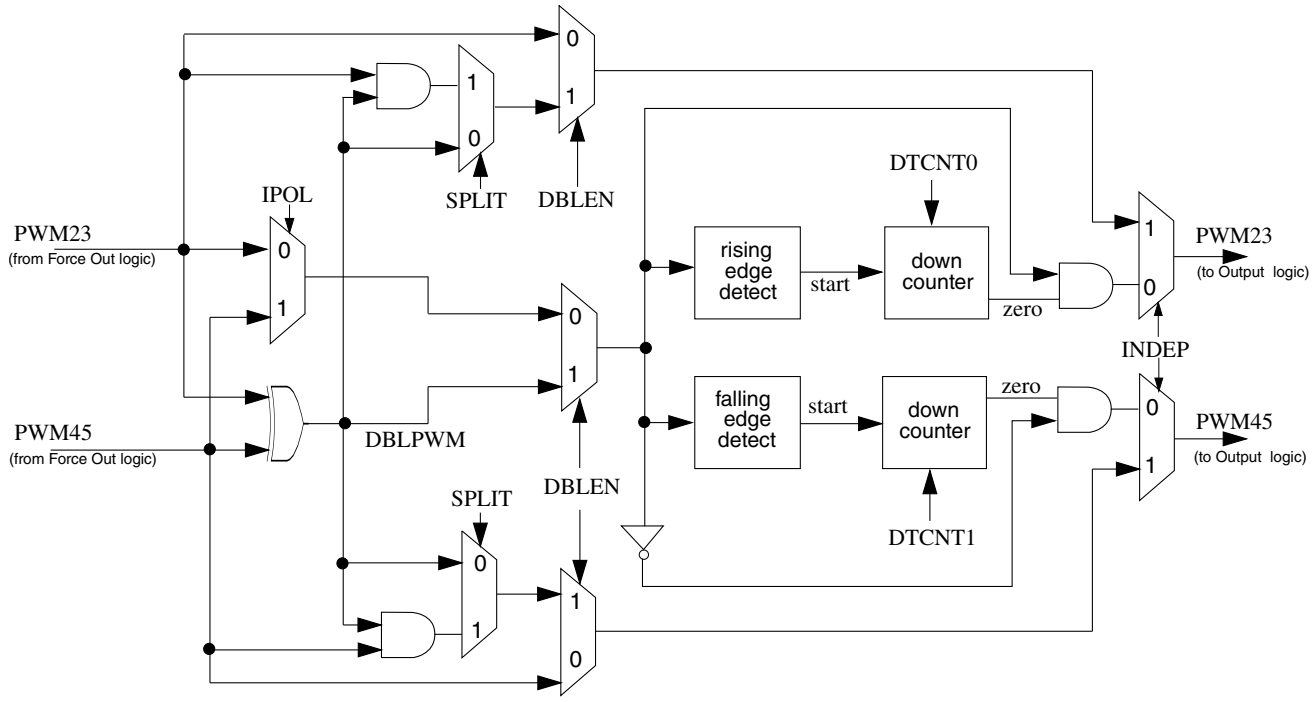

Figure 501. Deadtime Insertion Logic for each submodule

While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in the figure. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

NOTE

To avoid short-circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between the top and bottom transistors. But the transistor's characteristics make its switching-off time longer than switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as shown in Figure 502.

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of IPBus clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the PWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

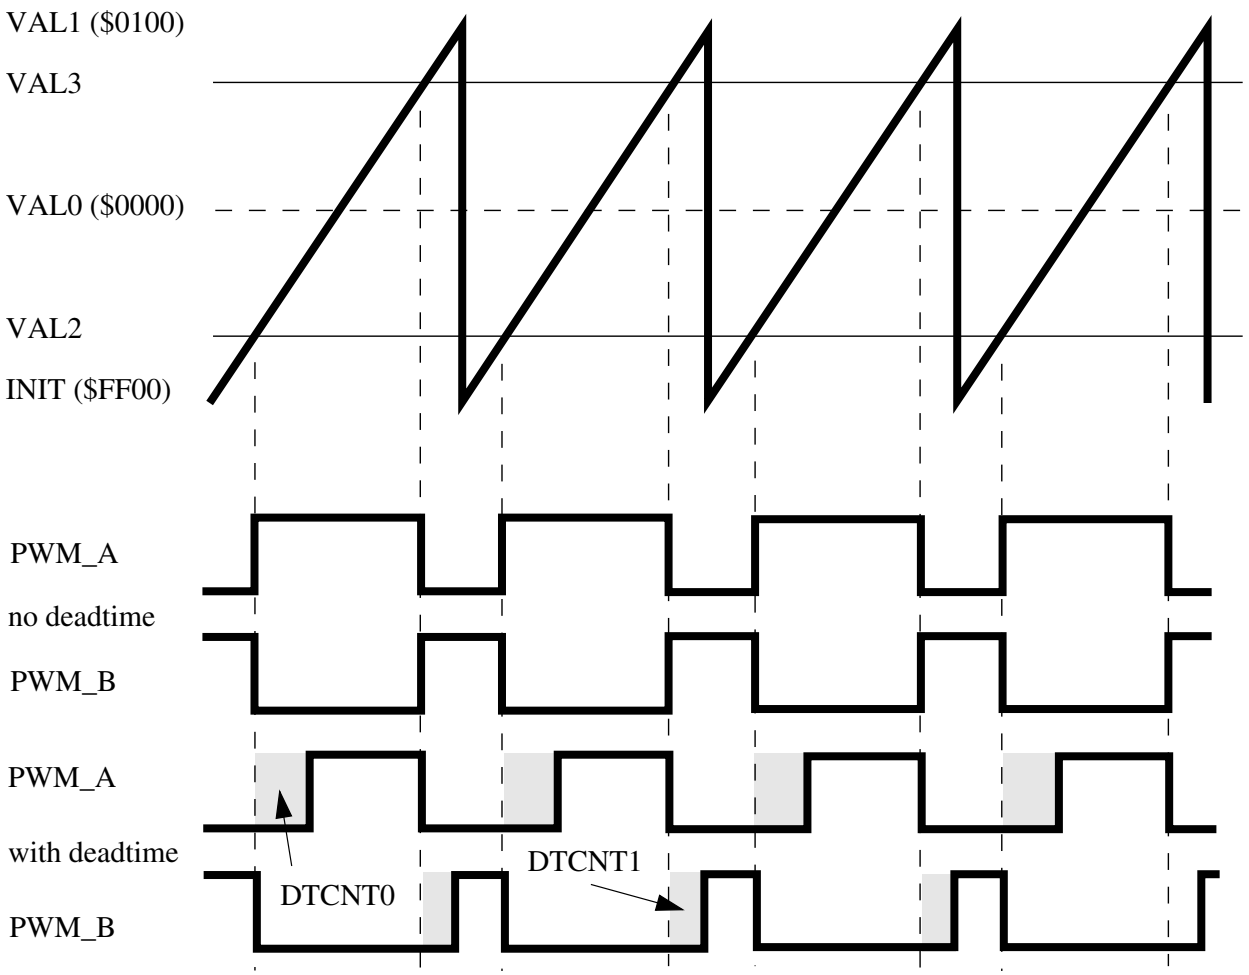

Figure 502. Deadtime insertion

67.3.3.7.1 Top/Bottom correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introducing distortion in the output voltage, as shown in Figure 503. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

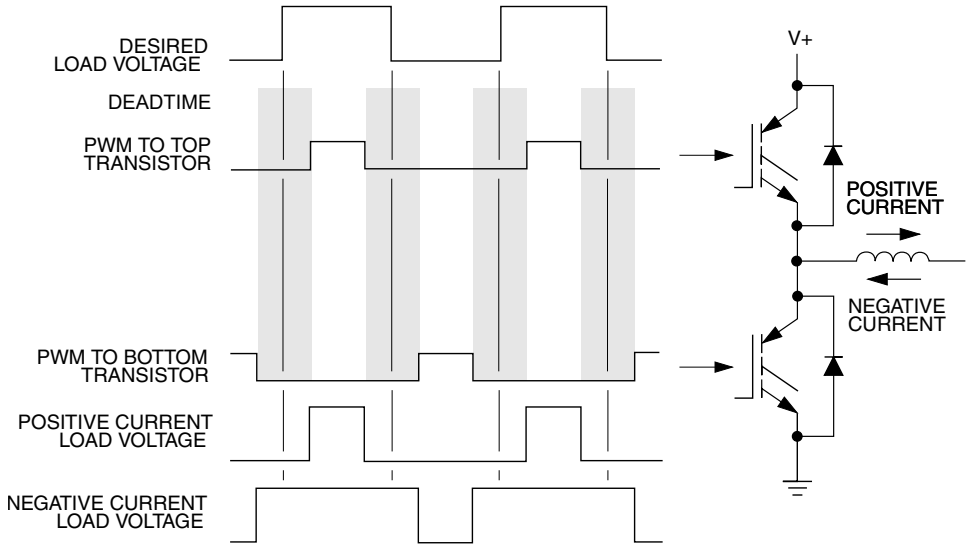

Figure 503. Deadtime distortion

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with the current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths were shortened by deadtime insertion, the averaged sinusoidal output is less than the desired value. However, when deadtime is inserted, it distorts in the motor current waveform inverter outputs. This distortion is aggravated by different turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors is effective in controlling the output voltage at any given time. This depends on the direction of the motor inverter current for that pair, as shown in Figure 503. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the VALx registers. Either the VAL2/VAL3 or the VAL4/VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the VAL2/VAL3 or VAL4/VAL5 pair is active depends on either:

- The state of the current status pin, PWMX, for that driver
- The state of the odd/even correction bit, MCTRL[IPOL], for that driver

To correct deadtime distortion, the software can decrease or increase the value in the appropriate VALx register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

67.3.3.7.2 Manual correction

To detect the current status, the voltage on each PWMX pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in CTRL[DT]. CTRL[DT] is a timing marker indicating when to toggle between PWM value registers. The software can then set MCTRL[IPOL] to switch between VAL2/VAL3 and VAL4/VAL5 register pairs according to CTRL[DT] values.

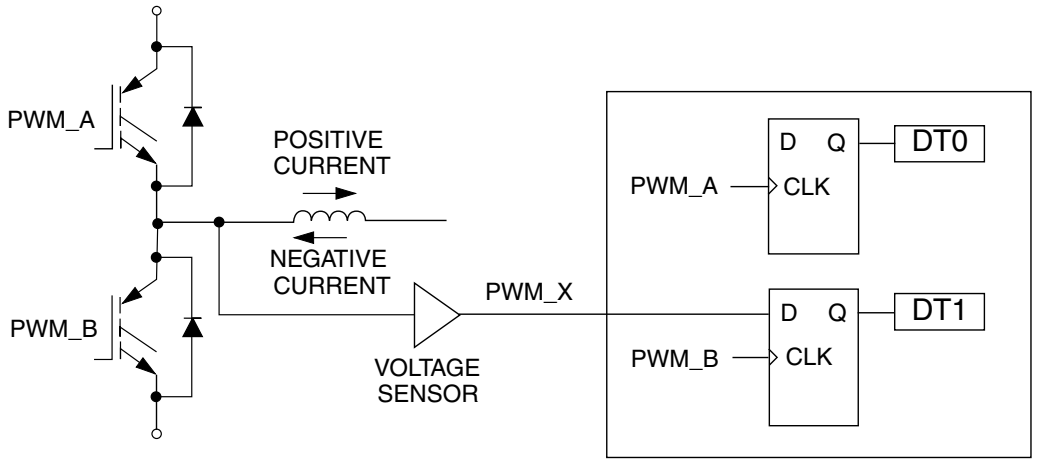

Figure 504. Current-status sense scheme for deadtime correction

Both D flip-flops latch low, CTRL[DT] = 00, during deadtime periods if the current is large and flowing out of the complementary circuit. See the preceding figure. Both D flip-flops latch the high, CTRL[DT] = 11, during deadtime periods if the current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. Sampled results are CTRL[DT] = b10. Thus, the best time to change one PWM value register to another is just before the current zero crossing.

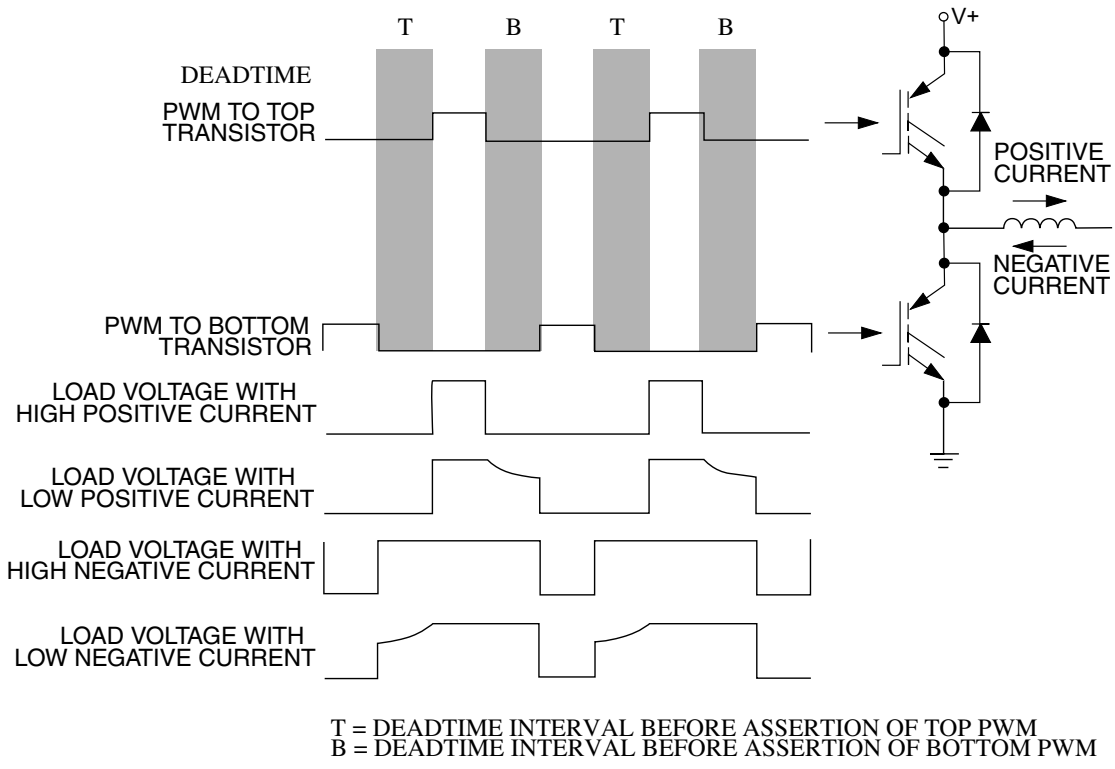

Figure 505. Output voltage waveforms

67.3.3.8 Fractional delay logic

For applications where more resolution than a single IPBus clock period is needed, the fractional delay logic can be used to achieve fine resolution on the rising and falling edges of the PWM_A and PWM_B outputs. Enable the use of the fractional delay logic by setting FRCTRL[FRACx_EN]. The FRACVALx registers act as a fractional clock cycle addition to the turn-on and turn-off count specified by the VAL2, VAL3, VAL4, or VAL5 registers. The FRACVAL1 register acts as a fractional increase in the PWM period as defined by VAL1. If FRACVAL1 is programmed to a non-zero value, then the largest value for the VAL1 register is 0xFFFE for unsigned usage or 0x7FFE for signed usage. This limit is required to avoid counter rollovers when accumulating the fractional additional period.

Both the fractional enables (1, 23, 45) and the fractional values (1-5) are double buffered and reloaded at the same time as the value registers.

Each PWM cycle, the value compare point is increased by 1 when there is overflow on the double buffered value of the fractional register plus the 5-bit accumulated fractional value. The accumulated fractional value starts at zero, so it is impossible to overflow the first PWM cycle.

At the end of each PWM cycle, if the corresponding fractional enable is set then the accumulated fractional value increments by the fractional value (double buffered value). The accumulated fractional value is 5-bits, so in the case of overflow only the remainder is kept. If the corresponding fractional enable is clear, then the accumulated fractional value is reset. This is the only way to reset the accumulated fractional value.

The accumulated fractional values are not accessible to software.

To fine-tune the PWM period using the FRACVAL1 register, if you want a period of 100.25 clock cycles, program VAL1 with 0x0064 and FRACVAL1 with 0x4000. The fractional value will accumulate so that every 4 PWM cycles will be 1 clock cycle longer (101 instead of 100). The rising and falling edges of the PWM outputs will also use the accumulated fraction to delay their edges and maintain a consistent 100.25 cycles spacing between corresponding edges from one cycle to the next.

The results of the fractional delay logic depend on whether or not the PWM submodule has an analog NanoEdge placer block available. With fractional delay enabled, PWM works in digital dithering mode: the value of FRACVALx is accumulated in each PWM period; when the accumulated value of FRACVALx overflows, VALx increments one in the next PWM period.

67.3.3.8.1 Fractional delay logic without NanoEdge placement block

For submodules that are not supported by the NanoEdge placer, the PWM can use dithering to simulate fine edge control. Enable this feature by setting the FRCTRL[FRAC1_EN], FRCTRL[FRAC23_EN], and FRCTRL[FRAC45_EN] bits. The PWM period or the PWM edges will dither from the nearest whole number values to achieve an average value that is equivalent to the programmed fractional value. The added cycles are based on the accumulation of the fractional component. For example, if you want the PWM period to be 50.25 clock cycles, then program VAL1 with 0x0032 and FRACVAL1 with 0x4000. The PWM period will be 50 cycles long most of the time, but will occasionally be 51 cycles long to achieve a long-term average of 50.25 cycles.

In submodules that are not supported by a NanoEdge placer, the clock frequency is not required to be any specific value to achieve proper operation.

67.3.3.9 Output logic

The following figure shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing with the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic (as shown in Figure 506) are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic between the pin and the transistor. Therefore, it is imperative that the user program OCTRL[POLA] and OCTRL[POLB] before enabling the output pins. A fault condition can result in the PWM output being put in a high-impedance state, forced to a logic 1 state, or forced to a logic 0 state, depending on the values programmed into the OCTRL[PWMxFS] fields.

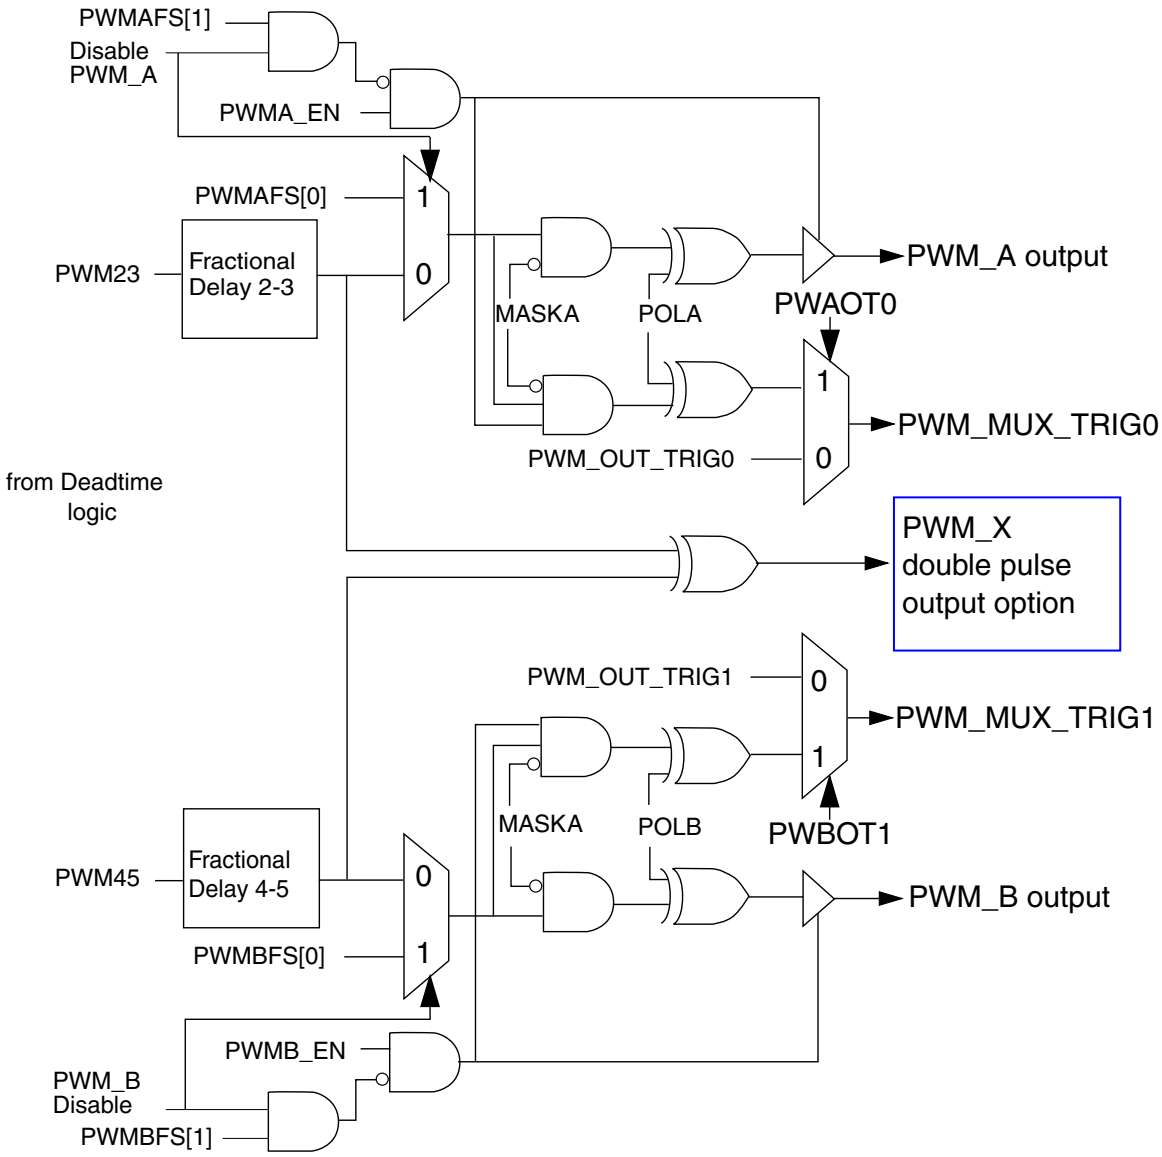

Figure 506. Output logic for each submodule

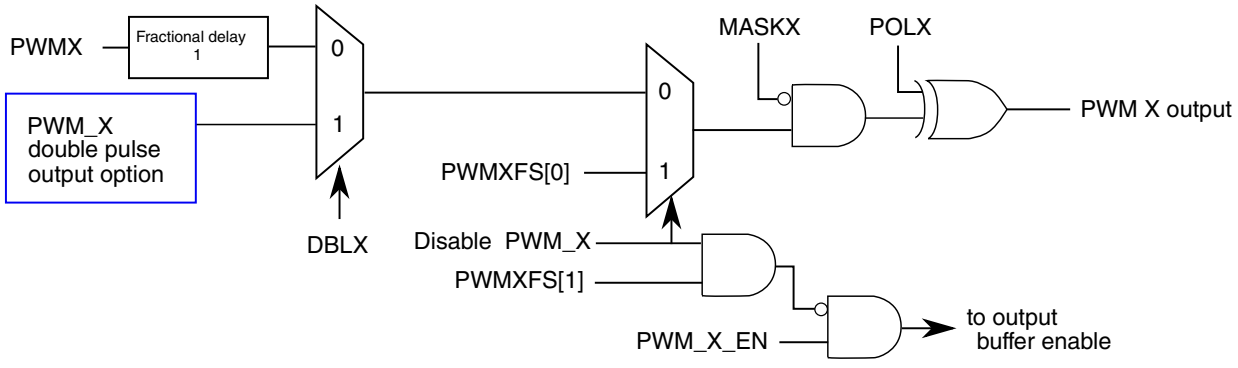

Figure 507. Output logic continued

67.3.3.10 E-Capture

The Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

The following figure shows block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8-bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8-bit value that is specified by the user (EDGCMPx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. This feature is useful for dividing down high frequency signals for capture processing so that capture interrupts do not overwhelm the CPU. Also, this feature can be used to generate an interrupt after "n" events have been counted.

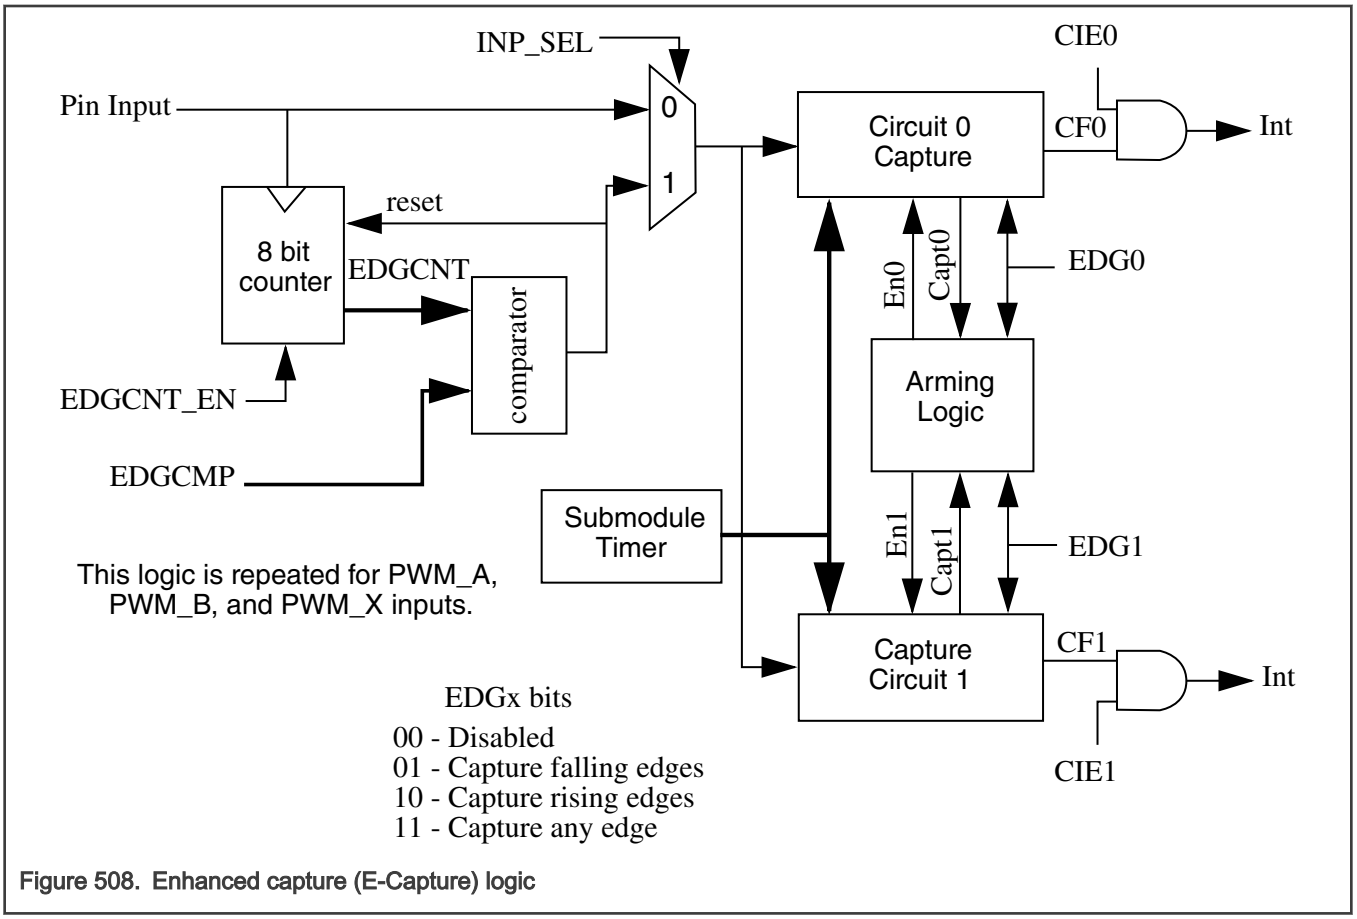

Figure 508. Enhanced capture (E-Capture) logic

Based on the mode selection, the mux selects either the pin input or the compare output from the count/compare circuit to be processed by the capture logic. The selected signal is routed to two separate capture circuits which work in tandem to capture sequential edges of the signal. The type of edge to be captured by each circuit is determined by CAPTCTRLx[EDGx1] and CAPTCTRLx[EDGx0], whose functionality is listed in the above figure. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot mode. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

67.3.3.11 Fault protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via FCTRL[FLVL]. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or high impedance depending on the values of OCTRL[PWMxFS].

The fault decoder disables PWM pins selected by the fault logic and the disable mapping (DISMAPn) registers. The following figure shows an example of the fault disable logic. Each bank of bits in DISMAPn control the mapping for a single PWM pin. See the following table.

The fault protection is enabled even when the PWM module is not enabled. Therefore, a fault is latched in and must be cleared to prevent an interrupt when the PWM is enabled.

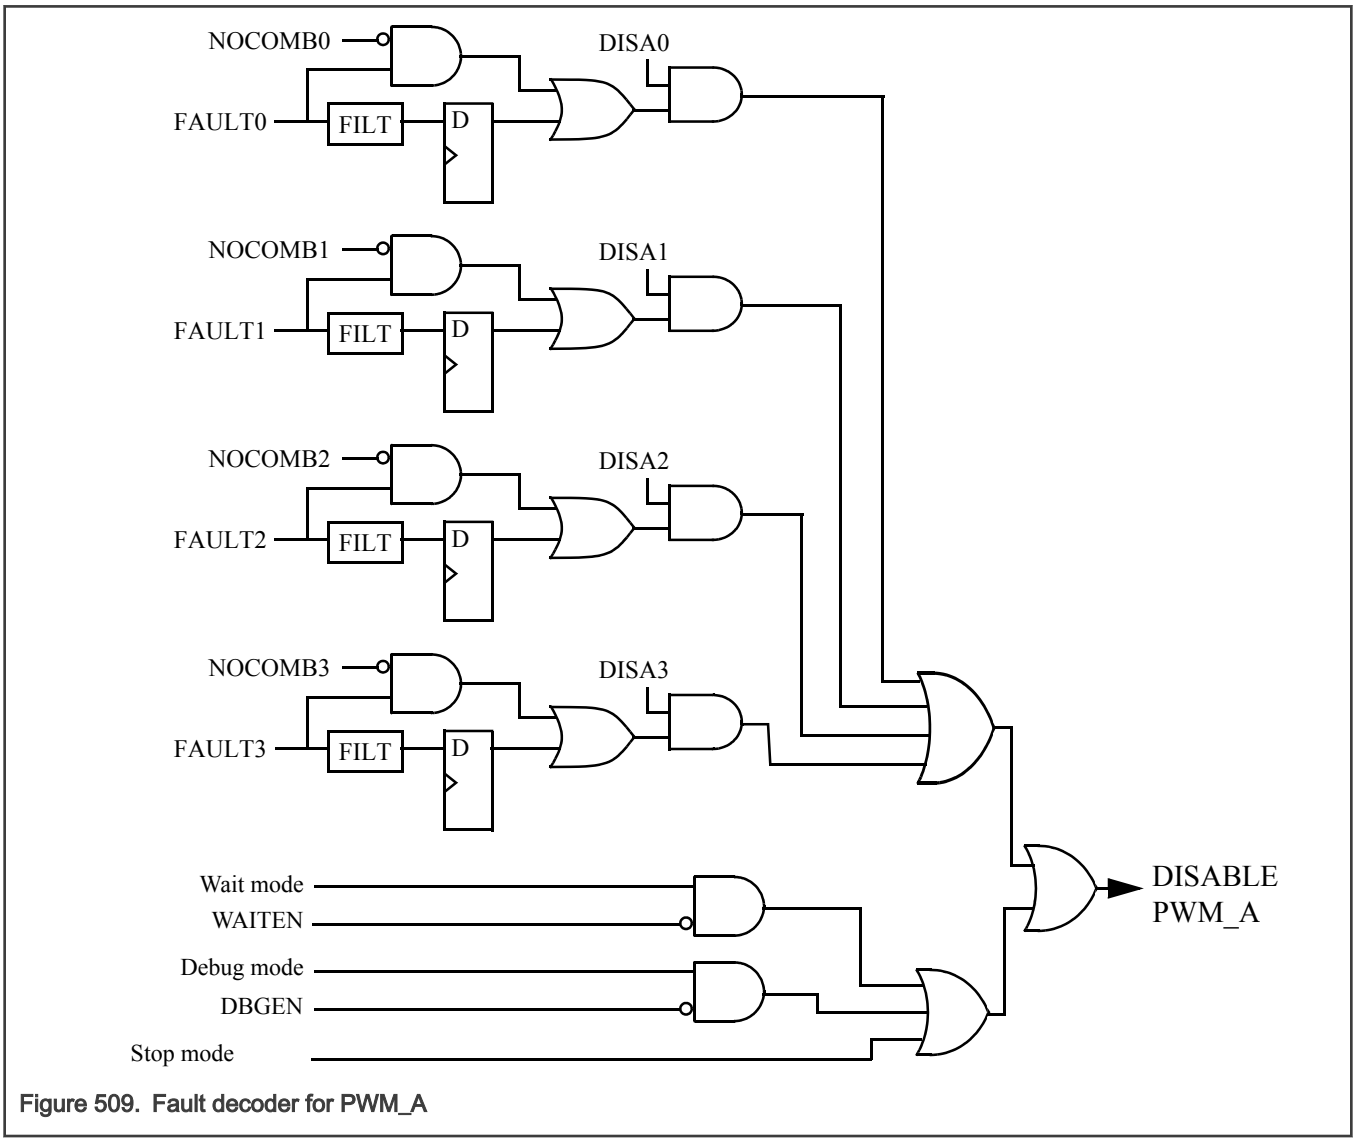

Figure 509. Fault decoder for PWM_A

Table 1053. Fault Mapping

PWM Pin for 1 submodule	Controlling Register Bits
PWM_A	DISMAP0[DIS0A]

Table continues on the next page...

Table 1053. Fault Mapping (continued)

PWM Pin for 1 submodule	Controlling Register Bits
PWM_B	DISMAP0[DIS0B]
PWM_X	DISMAP0[DIS0X]

67.3.3.11.1 Fault pin filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with FFILT[FILT_PER]. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using FFILT[FILT_CNT]. Setting FFILT[FILT_PER] to all 0 disables the input filter for a given FAULTx pin.

Upon detecting a logic 0 on the filtered FAULTx pin (or a logic 1 if FCTRL[FLVLx] is set), the corresponding FSTS[FFPINx] and FSTS[FFLAGx] bits are set. FSTS[FFPINx] remains set as long as the filtered FAULTx pin is zero. Clear FSTS[FFLAGx] by writing a logic 1 to FSTS[FFLAGx].

If the FIEx, FAULTx pin interrupt enable bit is set, FSTS[FFLAGx] generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears FSTS[FFLAGx] by writing a logic one to the bit
- Software clears the FIEx bit by writing a logic zero to it
- A reset occurs

Even with the filter enabled, there is a combinational path from the FAULTx inputs to the PWM pins, which in turn bypasses the filter when FCTRL20[NOCOMBx] = 0. This logic is also capable of holding a fault condition in the event of loss of clock to the PWM module.

67.3.3.11.2 Automatic fault clearing

Setting an automatic clearing mode bit, FCTRL[FAUTOx] configures faults from the FAULTx pin for automatic clearing.

When FCTRL[FAUTOx] is set, disabled PWM pins are enabled when the FAULTx pin returns to logic one and a new PWM full or half cycle begins. See the following figure. If FSTS[FFULLx] is set and the fault condition on FAULTx disappears, then the disabled PWM pins are enabled at the start of next full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle. Clearing FSTS[FFLAGx] does not affect disabled PWM pins when FCTRL[FAUTOx] is set.

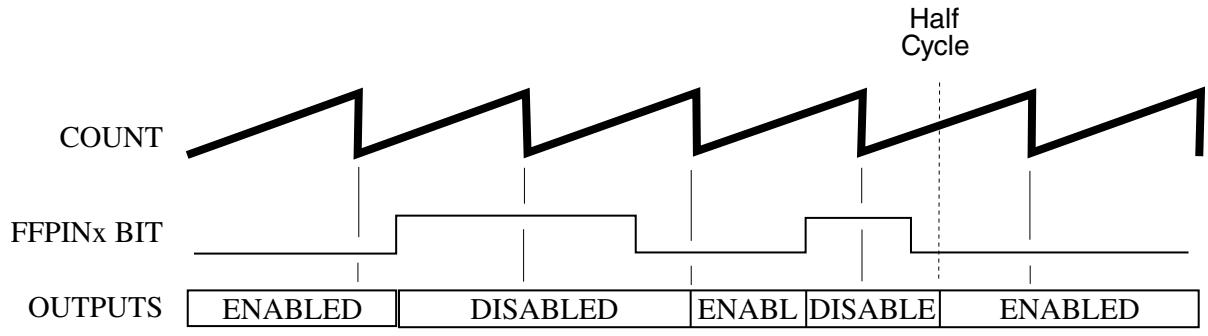

Figure 510. Automatic fault clearing

67.3.3.11.3 Manual fault clearing

Clearing the automatic clearing mode bit, FCTRL[FAUTOx], configures faults from the FAULTx pin for manual clearing:

- If the fault safety mode bits FCTRL[FSAFEx] are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag

— The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin, as shown in Figure 511. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.

- If the fault safety mode bits FCTRL[FSAFEx] are set, then PWM pins disabled by the FAULTx pins are enabled when:
  — Software clears the corresponding FSTS[FFLAGx] flag
  — The filter detects a logic zero on the FAULTx pin at the start of the next PWM full or half cycle boundary, as shown in Figure 512. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.

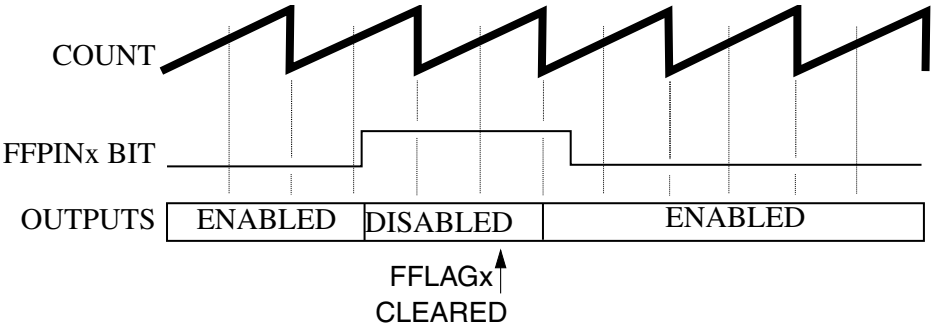

Figure 511. Manual fault clearing (FCTRL[FSAFEx] = 0, FSTS[FFULLx] = 1)

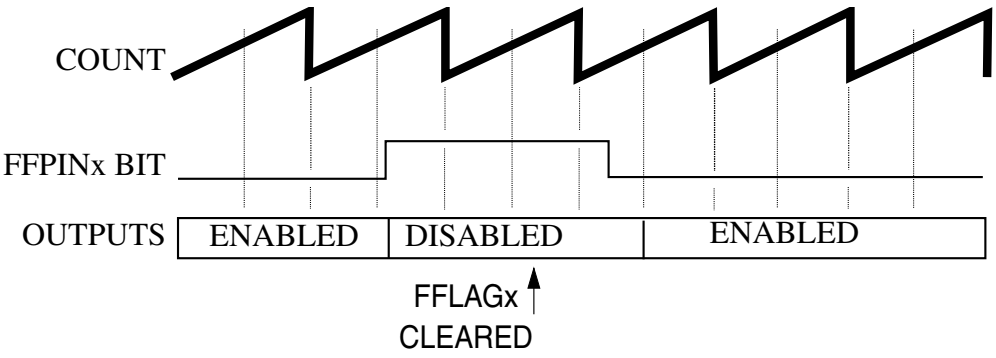

Figure 512. Manual fault clearing (FCTRL[FSAFEx] = 1, FSTS[FHALFx] = 1)

NOTE

Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or PWM_EXTA. Fault clearing still occurs at half or full PWM cycle boundaries while the PWM generator is engaged, MCTRL[RUN] equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, MCTRL[RUN] equals zero. Thus, fault clearing occurs at IPBus cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

67.3.3.11.4 Fault testing

FTST[FTEST] is used to simulate a fault condition on each of the fault inputs within that fault channel.

67.3.3.12 PWM generator loading

67.3.3.12.1 Load enable

MCTRL[LDOK] enables loading of the following PWM generator parameters.

- The prescaler divisor: from CTRL[PRSC]

- The PWM period and pulse width: from the INIT, FRACVALx, and VALx registers

MCTRL[LDOK] allows the software to finish calculating all of these PWM parameters so they can be synchronously updated. The CTRL[PRSC], INIT, and VALx registers are loaded by software into a set of outer buffers. When MCTRL[LDOK] is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator when CTRL[LDMOD] is cleared. These values can be transferred to the inner set of registers immediately upon setting MCTRL[LDOK] if CTRL[LDMOD] is set. Set MCTRL[LDOK] by reading it when it is a logic zero and then writing a logic one to it. After loading, MCTRL[LDOK] is automatically cleared.

67.3.3.12.2 Load frequency

CTRL[LDFQ] selects an integral loading frequency of one to 16 PWM reload opportunities. CTRL[LDFQ] takes effect at every PWM reload opportunity, regardless of the state of MCTRL[LDOK]. CTRL[HALF] and CTRL[FULL] control reload timing. If CTRL[FULL] is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If CTRL[HALF] is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both CTRL[HALF] and CTRL[FULL] are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

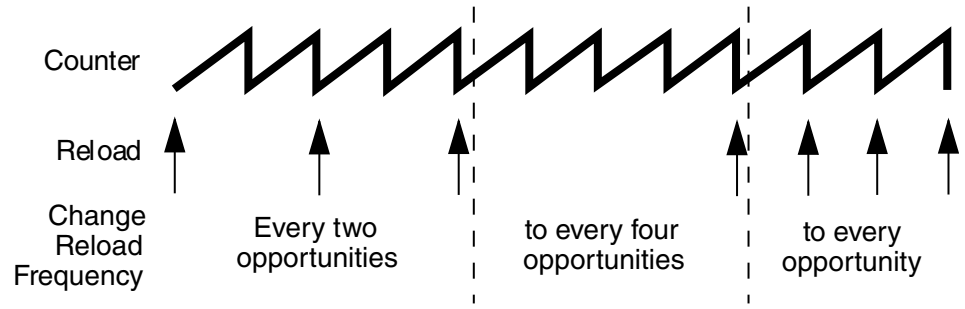

Figure 513. Full cycle reload frequency change

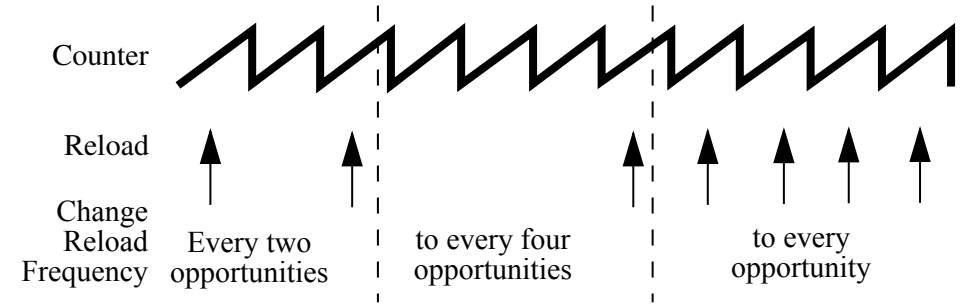

Figure 514. Half cycle reload frequency change

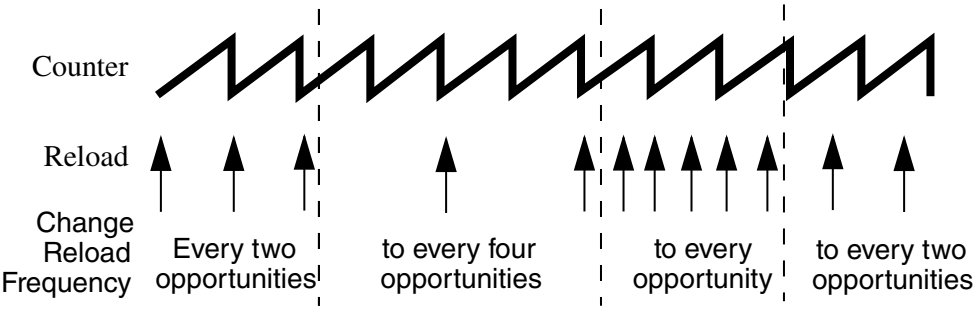

Figure 515. Full and half cycle reload frequency change

67.3.3.12.3 Reload flag

At every reload opportunity the PWM Reload Flag (STS[RF]) is set. Setting STS[RF] happens even if an actual reload is prevented by MCTRL[LDOK]. If the PWM reload interrupt enable bit INTEN[RIE] is set, the STS[RF] flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When INTEN[RIE] is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

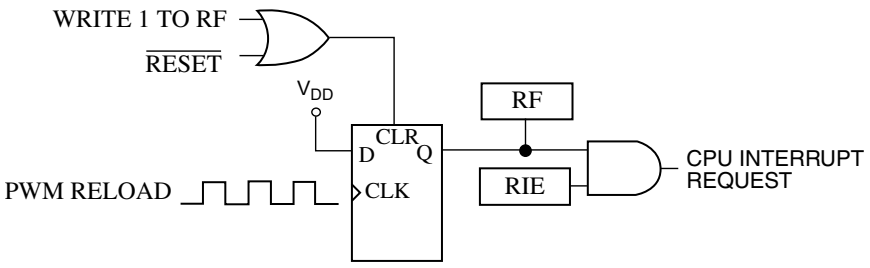

Figure 516. PWMF reload interrupt request

67.3.3.12.4 Reload errors

When one of the INIT, VALx, FRACVALx, or CTRL[PRSC] registers is updated (written by software), the STS[RUF] flag is set to indicate the data in the set of double buffered registers is not coherent. STS[RUF] is cleared by a successful reload which consists of the reload signal while MCTRL[LDOK] is set. If STS[RUF] is set and MCTRL[LDOK] is clear when the reload signal occurs, a reload error takes place and STS[REF] is set. If STS[RUF] is clear when a reload signal asserts, then the data is coherent and no error is flagged.

67.3.3.12.5 Initialization

Initialize all registers and then set MCTRL[LDOK] before setting MCTRL[RUN].

NOTE

If MCTRL[LDOK] is not set, setting MCTRL[RUN] also sets the STS[RF] flag. To prevent a CPU interrupt request, clear INTEN[RIE] before setting MCTRL[RUN].

The PWM generator uses the last values loaded if MCTRL[RUN] is cleared and then set while MCTRL[LDOK] equals zero.

When MCTRL[RUN] is cleared:

- The STS[RF] flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active
- Software/external output control remains active
- Deadtime insertion continues during software/external output control

67.3.4 Power modes

Be careful when using this module in Stop, Wait, and Debug operating modes.

CAUTION

Some applications (such as three-phase AC motors) require regular software updates for proper operation. Failure to provide regular software updates could result in destroying the hardware setup.

To accommodate this situation, PWM outputs are placed in their inactive states in Stop mode, and they can optionally be placed in inactive states in Wait and Debug modes. PWM outputs are reactivated (assuming they were active beforehand) when these modes are exited.

Table 1054. Modes when PWM operation is restricted

Mode	Description
Stop	PWM outputs are inactive.
Wait	PWM outputs are driven or inactive as a function of CTRL2[WAITEN].
Debug	PWM outputs are driven or inactive as a function of CTRL2[DBGEN].

67.3.5 Clocking

Figure 517 shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the IPBus clock, EXT_CLK, and AUX_CLK. The EXT_CLK goes to all of the submodules. The AUX_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 8-bit prescaler and MCTRL[RUN] from submodule0 can control all of the submodules.

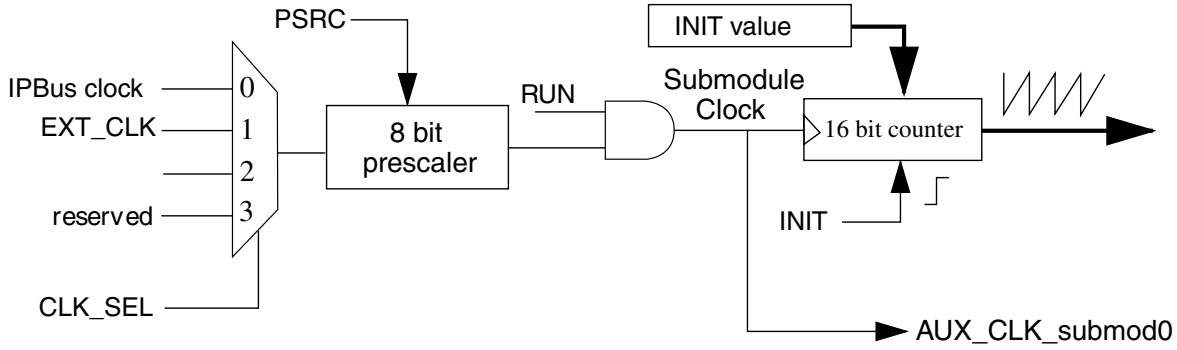

Figure 517. Clocking Block Diagram for PWM Submodule 0

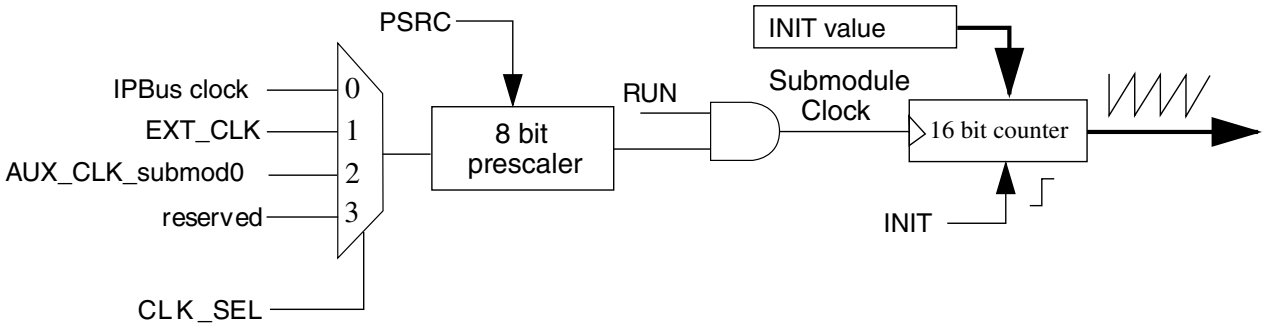

Figure 518. Clocking Block Diagram for all other PWM Submodules

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the IPBus clock frequency by 1-128. The prescaler bits, CTRL[PRSC], select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until MCTRL[LDOK] is set and a new PWM reload cycle begins or CTRL[LDMOD] is set.

67.3.6 Resets

All PWM registers are reset to their default values upon any system reset.

The reset forces all registers to their reset states and tristates the PWM outputs.

67.3.7 Interrupts

Each of the submodules within the eFlexPWM module can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 1055. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
PWM_CMP0	SM0STS[CMPF]	SM0INTEN[CMPIE]	Submodule 0 compare interrupt	Compare event has occurred
PWM_CAP0	SM0STS[CFA1], SM0STS[CFA0], SM0STS[CFB1], SM0STS[CFB0], SM0STS[CFX1], SM0STS[CFX0]	SM0INTEN[CFA1IE], SM0INTEN[CFA0IE], SM0INTEN[CFB1IE], SM0INTEN[CFB0IE], SM0INTEN[CFX1IE], SM0INTEN[CFX0IE]	Submodule 0 input capture interrupt	Input capture event has occurred
PWM_RELOAD0	SM0STS[RF]	SM0INTEN[RIE]	Submodule 0 reload interrupt	Reload event has occurred
PWM_CMP1	SM1STS[CMPF]	SM1INTEN[CMPIE]	Submodule 1 compare interrupt	Compare event has occurred
PWM_CAP1	SM1STS[CFA1], SM1STS[CFA0], SM1STS[CFB1], SM1STS[CFB0], SM1STS[CFX1], SM1STS[CFX0]	SM1INTEN[CFA1IE], SM1INTEN[CFA0IE], SM1INTEN[CFB1IE], SM1INTEN[CFB0IE], SM1INTEN[CFX1IE], SM1INTEN[CFX0IE]	Submodule 1 input capture interrupt	Input capture event has occurred
PWM_RELOAD1	SM1STS[RF]	SM1INTEN[RIE]	Submodule 1 reload interrupt	Reload event has occurred
PWM_CMP2	SM2STS[CMPF]	SM2INTEN[CMPIE]	Submodule 2 compare interrupt	Compare event has occurred
PWM_CAP2	SM2STS[CFA1], SM2STS[CFA0], SM2STS[CFB1], SM2STS[CFB0], SM2STS[CFX1], SM2STS[CFX0]	SM2INTEN[CFA1IE], SM2INTEN[CFA0IE], SM2INTEN[CFB1IE], SM2INTEN[CFB0IE], SM2INTEN[CFX1IE], SM2INTEN[CFX0IE	Submodule 2 input capture interrupt	Input capture event has occurred
PWM_RELOAD2	SM2STS[RF]	SM2INTEN[RIE]	Submodule 2 reload interrupt	Reload event has occurred

Table continues on the next page...

Table 1055. Interrupt Summary (continued)

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
PWM_CMP3	SM3STS[CMPF]	SM3INTEN[CMPIE]	Submodule 3 compare interrupt	Compare event has occurred
PWM_CAP3	SM3STS[CFA1], SM3STS[CFA0], SM3STS[CFB1], SM3STS[CFB0], SM3STS[CFX1], SM3STS[CFX0]	SM3INTEN[CFA1IE], SM3INTEN[CFA0IE], SM3INTEN[CFB1IE], SM3INTEN[CFB0IE], SM3INTEN[CFX1IE], SM3INTEN[CFX0IE	Submodule 3 input capture interrupt	Input capture event has occurred
PWM_RELOAD3	SM3STS[RF]	SM3INTEN[RIE]	Submodule 3 reload interrupt	Reload event has occurred
PWM_RERR	SM0STS[REF]	SM0INTEN[REIE]	Submodule 0 reload error interrupt	Reload error has occurred
	SM1STS[REF]	SM1INTEN[REIE]	Submodule 1 reload error interrupt	
	SM2STS[REF]	SM2INTEN[REIE]	Submodule 2 reload error interrupt	
	SM3STS[REF]	SM3INTEN[REIE]	Submodule 3 reload error interrupt	
PWM_FAULT	FSTS[FFLAG]	FCTRL[FIE]	Fault input interrupt	Fault condition has been detected

67.3.8 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered registers.

Table 1056. DMA summary

DMA request	DMA enable	Name	Description
Submodule 0 read request	SM0DMAEN[CX0DE]	SM0 Capture FIFO X0 read request	SM0CVAL0 contains a value to be read
Submodule 0 read request	SM0DMAEN[CX1DE]	SM0 Capture FIFO X1 read request	SM0CVAL1 contains a value to be read
Submodule 0 read request	SM0DMAEN[CA0DE]	SM0 Capture FIFO A0 read request	SM0CVAL2 contains a value to be read
Submodule 0 read request	SM0DMAEN[CA1DE]	SM0 Capture FIFO A1 read request	SM0CVAL3 contains a value to be read

Table continues on the next page...

Table 1056. DMA summary (continued)

DMA request	DMA enable	Name	Description
Submodule 0 read request	SM0DMAEN[CB0DE]	SM0 Capture FIFO B0 read request	SM0CVAL4 contains a value to be read
Submodule 0 read request	SM0DMAEN[CB1DE]	SM0 Capture FIFO B1 read request	SM0CVAL5 contains a value to be read
Submodule 0 read request	SM0DMAEN[CAPTDE]	SM0 Capture FIFO read request source select	Selects source of submodule0 read DMA request
Submodule 0 write request	SM0DMAEN[VALDE]	SM0VALx write request	SM0VALx and SM0FRACVALx registers need to be updated
Submodule 1 read request	SM1DMAEN[CX0DE]	SM1 Capture FIFO X0 read request	SM1CVAL0 contains a value to be read
Submodule 1 read request	SM1DMAEN[CX1DE]	SM1 Capture FIFO X1 read request	SM1CVAL1 contains a value to be read
Submodule 1 read request	SM1DMAEN[CA0DE]	SM1Capture FIFO A0 read request	SM1CVAL2 contains a value to be read
Submodule 1 read request	SM1DMAEN[CA1DE]	SM1 Capture FIFO A1 read request	SM1CVAL3 contains a value to be read
Submodule 1 read request	SM1DMAEN[CB0DE]	SM1 Capture FIFO B0 read request	SM1CVAL4 contains a value to be read
Submodule 1 read request	SM1DMAEN[CB1DE]	SM1 Capture FIFO B1 read request	SM1CVAL5 contains a value to be read
Submodule 1 read request	SM1DMAEN[CAPTDE]	SM1 Capture FIFO read request source select	Selects source of submodule1 read DMA request
Submodule 1 write request	SM1DMAEN[VALDE]	SM1VALx write request	SM1VALx and SM1FRACVALx registers need to be updated
Submodule 2 read request	SM2DMAEN[CX0DE]	SM2 Capture FIFO X0 read request	SM2CVAL0 contains a value to be read
Submodule 2 read request	SM2DMAEN[CX1DE]	SM2 Capture FIFO X1 read request	SM2CVAL1 contains a value to be read
Submodule 2 read request	SM2DMAEN[CA0DE]	SM2 Capture FIFO A0 read request	SM2CVAL2 contains a value to be read
Submodule 2 read request	SM2DMAEN[CA1DE]	SM2 Capture FIFO A1 read request	SM2CVAL3 contains a value to be read

Submodule 3 write request	SM3DMAEN[VALDE]	SM3VALx write request	SM3VALx and SM3FRACVALx registers need to be updated

67.4 External signals

The PWM has pins named PWM_An, PWM_Bn, PWM_Xn, FAULTn, EXT_SYNC, EXT_FORCE, and PWMn_EXTA. The PWM also has an on-chip input called EXT_CLK and output signals called PWMn_OUT_TRIGx and PWMn_MUX_TRIGx.

67.4.1 PWM_An and PWM_Bn - External PWM output pair

These pins are the output pins of the PWM channels. These pins can be independent PWM signals or a complementary pair. When not needed as an output, they can be used as inputs to the input capture circuitry.

67.4.2 PWM_Xn - Auxiliary PWM output signal

These pins are the auxiliary output pins of the PWM channels. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or used to detect the polarity of the current flowing through the complementary circuit at deadtime correction.

67.4.3 FAULTn - Fault Inputs

These are input pins for disabling selected PWM outputs.

67.4.4 EXT_SYNC - External synchronization signal

These input signals allow a source external to the PWM to initialize the PWM counter. Therefore, the PWM can be synchronized to external circuitry.

67.4.5 EXT_FORCE - External output force signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. Therefore, the PWM can be synchronized to external circuitry.

67.4.6 PWMn_EXTA - Alternate PWM control signals

These pins allow an alternate source to control the PWM_An and PWM_Bn outputs. Typically, the PWMn_EXTA input (depending on the state of MCTRL[IPOL]) is used for the generation of a complementary pair. Typical control signals include ADC conversion high/low limits, TMR outputs, GPIO inputs, and comparator outputs.

For pin input details, see chip-specific eFlexPWM information.

67.4.7 PWMn_OUT_TRIG0 and PWMn_OUT_TRIG1 - Output triggers

These outputs allow the PWM submodules to control timing of ADC conversions. See the description of the SMnTCTRL[OUT_TRIG_EN] for information about how to enable these outputs and how the compare registers match up to the output triggers.

67.4.8 PWM[n]_MUX_TRIG0 and PWM[n]_MUX_TRIG1 - Output triggers

These outputs can be either PWMn_OUT_TRIG0/PWMn_OUT_TRIG1 signals or PWM_A/PWM_B signals from output logic. See the description of the PWAOT0 and PWBOT1 bits in the Output Trigger Control Register for information about how to enable these outputs.

67.4.9 EXT_CLK - External clock signal

This signal allows a source external to the PWM (typically a timer or an off-chip source) to control the PWM clocking. Therefore, the PWM can be synchronized to the timer, or multiple chips can be synchronized to each other.

67.5 PWM register descriptions

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level, and the address offset is defined at the module level. The PWM module has a set of registers for each PWM submodule, for the configuration logic, and for each fault channel.

NOTE

While the registers are 16-bit wide, they can be accessed in pairs as 32-bit registers, if the pairs are word-aligned.

Submodule registers are repeated for each PWM submodule. To designate which submodule that they are in, register names are prefixed with SMx(x=0,1...). The base address of submodule 0 is the same as the base address for the PWM module as a whole. The base address of submodule 1 is offset 0x60 from the base address for the PWM module as a whole. This 0x60 offset is based on the number of registers in a submodule. The base address of submodule 2 is equal to the base address of submodule 1 plus this same 0x60 offset. The pattern repeats for the base address of submodule 3.

The base address of the configuration registers is equal to the base address of the PWM module as a whole plus an offset of 0x180.

67.5.1 PWM memory map

PWM1 base address: 4265_0000h

PWM2 base address: 4266_0000h

PWM3 base address: 4267_0000h

PWM4 base address: 4268_0000h

67.5.3 Initial Count Register (SM0INIT - SM3INIT)

Offset

Register	Offset
SM0INIT	2h
SM1INIT	62h
SM2INIT	C2h
SM3INIT	122h

Function

The 16-bit signed value in this buffered register defines the initial count value for the PWM in PWM clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of CTRL2[INIT_SEL]) or when CTRL2[FORCE] is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle. This register is not byte accessible.

NOTE

The INIT register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. This register cannot be written when MCTRL[LDOK] is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

W										FORCE						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 DBGEN	Debug Enable When set to one, the PWM continues to run while the chip is in Debug mode. If the device enters Debug mode and this bit is zero, then the PWM outputs are disabled until Debug mode is exited. At that point, the PWM pins resume operation as programmed in the PWM registers. For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in Debug mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in Debug mode. The key point is PWM parameter updates will not occur in Debug mode. Any motors requiring such updates should be disabled during Debug mode. If in doubt, leave this bit set to zero.
14 WAITEN	Wait Enable When set to one, the PWM continues to run while the chip is in Wait mode. In this mode, the peripheral clock continues to run but the CPU clock does not. If the device enters Wait mode and this bit is zero, then the PWM outputs are disabled until Wait mode is exited. At that point the PWM pins resume operation as programmed in the PWM registers. For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in Wait mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in Wait mode. The key point is PWM parameter updates will not occur in this mode. Any motors requiring such updates should be disabled during Wait mode. If in doubt, leave this bit set to zero.
13 INDEP	Independent or Complementary Pair Operation This bit determines if the PWM_A and PWM_B channels are independent PWMs or a complementary PWM pair. 0b - PWM_A and PWM_B form a complementary PWM pair. 1b - PWM_A and PWM_B outputs are independent PWMs.

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 PWM23_INIT	PWM23 Initial Value This bit determines the initial value for PWM23 and the value to which it is forced when FORCE_INIT is asserted.
11 PWM45_INIT	PWM45 Initial Value This bit determines the initial value for PWM45 and the value to which it is forced when FORCE_INIT is asserted.
10 PWMX_INIT	PWM_X Initial Value This bit determines the initial value for PWM_X and the value to which it is forced when FORCE_INIT is asserted.
9-8 INIT_SEL	Initialization Control Select These bits control the source of the INIT signal which goes to the counter. 00b - Local sync (PWM_X) causes initialization. 01b - Master reload from submodule 0 causes initialization. This setting should not be used in submodule 0 as it forces the INIT signal to logic 0. The submodule counter will only re-initialize when a master reload occurs. 10b - Master sync from submodule 0 causes initialization. This setting should not be used in submodule 0 as it forces the INIT signal to logic 0. 11b - EXT_SYNC causes initialization.
7 FRCEN	Force Enable This bit allows the CTRL2[FORCE] signal to initialize the counter without regard to the signal selected by CTRL2[INIT_SEL]. This is a software controlled initialization. A forced initialization will also assert the register reload if MCTRL[LDOK] is set. 0b - Initialization from a FORCE_OUT is disabled. 1b - Initialization from a FORCE_OUT is enabled.
6 FORCE	Force Initialization If CTRL2[FORCE_SEL] is set to 000, writing a 1 to this bit results in a FORCE_OUT event. This causes the following actions to be taken: • The PWM_A and PWM_B output pins assume values based on DTSRCSEL[SMxSEL23] and DTSRCSEL[SMxSEL45]. • If CTRL2[FRCEN] is set, the counter value is initialized with the INIT register value only when the submodule MCTRL[RUN] = 1 or CTRL2[CLK_SEL] = 2.
5-3 FORCE_SEL	Force Select This bit determines the source of the FORCE OUTPUT signal for this submodule. 000b - The local force signal, CTRL2[FORCE], from this submodule is used to force updates.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	001b - The master force signal from submodule 0 is used to force updates. This setting should not be used in submodule 0 as it holds the FORCE OUTPUT signal to logic 0. 010b - The local reload signal from this submodule is used to force updates without regard to the state of LDOK. 011b - The master reload signal from submodule0 is used to force updates if LDOK is set. This setting should not be used in submodule0 as it holds the FORCE OUTPUT signal to logic 0. 100b - The local sync signal from this submodule is used to force updates. 101b - The master sync signal from submodule0 is used to force updates. This setting should not be used in submodule0 as it holds the FORCE OUTPUT signal to logic 0. 110b - The external force signal, EXT_FORCE, from outside the PWM module causes updates. 111b - The external sync signal, EXT_SYNC, from outside the PWM module causes updates.
2 RELOAD_SEL	Reload Source Select This bit determines the source of the RELOAD signal for this submodule. When this bit is set, MCTRL[LDOK[0]] for submodule 0 should be used since the local MCTRL[LDOK] will be ignored. 0b - The local RELOAD signal is used to reload registers. 1b - The master RELOAD signal (from submodule 0) is used to reload registers. This setting should not be used in submodule 0 as it forces the RELOAD signal to logic 0.
1-0 CLK_SEL	Clock Source Select These bits determine the source of the clock signal for this submodule. 00b - The IPBus clock is used as the clock for the local prescaler and counter. 01b - EXT_CLK is used as the clock for the local prescaler and counter. 10b - Submodule 0’s clock (AUX_CLK) is used as the source clock for the local prescaler and counter. This setting should not be used in submodule 0 as it forces the clock to logic 0. 11b - Reserved

67.5.5 Control Register (SM0CTRL - SM3CTRL)

Offset

Register	Offset
SM0CTRL	6h
SM1CTRL	66h
SM2CTRL	C6h
SM3CTRL	126h

Function

Includes control settings for timing, loading, and buffering.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LDFQ				HALF	FULL	DT		COMP MODE	PRSC			SPLIT	LDMOD	DBLX	DBLEN
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 LDFQ	Load Frequency These buffered bits select the PWM load frequency. Reset clears LDFQ, selecting loading every PWM opportunity. A PWM opportunity is determined by HALF and FULL. **NOTE** LDFQ takes effect when the current load cycle is complete, regardless of the state of MCTRL[LDOK]. Reading LDFQ reads the buffered values and not necessarily the values currently in effect. 0000b - Every PWM opportunity 0001b - Every 2 PWM opportunities 0010b - Every 3 PWM opportunities 0011b - Every 4 PWM opportunities 0100b - Every 5 PWM opportunities 0101b - Every 6 PWM opportunities 0110b - Every 7 PWM opportunities 0111b - Every 8 PWM opportunities 1000b - Every 9 PWM opportunities 1001b - Every 10 PWM opportunities 1010b - Every 11 PWM opportunities 1011b - Every 12 PWM opportunities 1100b - Every 13 PWM opportunities 1101b - Every 14 PWM opportunities 1110b - Every 15 PWM opportunities 1111b - Every 16 PWM opportunities
11 HALF	Half Cycle Reload This bit enables half-cycle reloads. A half cycle is defined by when the submodule counter matches the VAL0 register and does not have to be halfway through the PWM cycle. 0b - Half-cycle reloads disabled. 1b - Half-cycle reloads enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 FULL	Full Cycle Reload This bit enables full-cycle reloads. A full cycle is defined by when the submodule counter matches the VAL1 register. Either CTRL[HALF] or CTRL[FULL] must be set to move the buffered data into the registers used by the PWM generators or CTRL[LDMOD] must be set. If both CTRL[HALF] and CTRL[FULL] are set, then reloads can occur twice per cycle. 0b - Full-cycle reloads disabled. 1b - Full-cycle reloads enabled.
9-8 DT	Deadtime These bits reflect the sampled values of the PWM_X input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits.
7 COMPMODE	Compare Mode This bit controls how comparisons are made between the VAL* registers and the PWM submodule counter. This bit can be written one time after which it requires a reset to release the bit for writing again. 0b - The VAL* registers and the PWM counter are compared using an "equal to" method. This means that PWM edges are only produced when the counter is equal to one of the VAL* register values. This implies that a PWM_A output that is high at the end of a period maintains this state until a match with VAL3 clears the output in the following period. 1b - The VAL* registers and the PWM counter are compared using an "equal to or greater than" method. This means that PWM edges are produced when the counter is equal to or greater than one of the VAL* register values. This implies that a PWM_A output that is high at the end of a period could go low at the start of the next period if the starting counter value is greater than (but not necessarily equal to) the new VAL3 value.
6-4 PRSC	Prescaler These buffered bits select the divide ratio of the PWM clock frequency selected by CTRL2[CLK_SEL]. **NOTE** Reading CTRL[PRSC] reads the buffered values and not necessarily the values currently in effect. CTRL[PRSC] takes effect at the beginning of the next PWM cycle and only when the load okay bit MCTRL[LDOK] is set, or CTRL[LDMOD] is set. This field cannot be written when MCTRL[LDOK] is set. 000b - Prescaler 1. PWM clock frequency = f_{clk} 001b - Prescaler 2. PWM clock frequency = f_{clk} /2 010b - Prescaler 4. PWM clock frequency = f_{clk} /4 011b - Prescaler 8. PWM clock frequency = f_{clk} /8 100b - Prescaler 16. PWM clock frequency = f_{clk} /16 101b - Prescaler 32. PWM clock frequency = f_{clk} /32 110b - Prescaler 64. PWM clock frequency = f_{clk} /64 111b - Prescaler 128. PWM clock frequency = f_{clk} /128

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 SPLIT	Split the DBLPWM signal to PWM_A and PWM_B This bit is used in independent mode when DBLEN is set. This bit allows the two PWM pulses generated by DBLEN to be split with one pulse on PWM_A and one on PWM_B. The two pulses within the same PWM period are created by an XOR function of the PWM_A and PWM_B sources. The splitting function causes PWM_A to output the pulse that occurs when the PWM_A source is 1 and the PWM_B source is 0. The PWM_B output occurs when the PWM_B source is 1 and the PWM_A source is 0. (See Double switching PWMs .) 0b - DBLPWM is not split. PWM_A and PWM_B each have double pulses. 1b - DBLPWM is split to PWM_A and PWM_B.
2 LDMOD	Load Mode Select This bit selects the timing of loading the buffered registers for this submodule. 0b - Buffered registers of this submodule are loaded and take effect at the next PWM reload if MCTRL[LDOK] is set. 1b - Buffered registers of this submodule are loaded and take effect immediately upon MCTRL[LDOK] being set. In this case, it is not necessary to set CTRL[FULL] or CTRL[HALF].
1 DBLX	PWM_X Double Switching Enable This bit enables the double switching behavior on PWM_X. When this bit is set, the PWM_X output shall be the exclusive OR combination of PWM_A and PWM_B prior to polarity and masking considerations. 0b - PWM_X double pulse disabled. 1b - PWM_X double pulse enabled.
0 DBLEN	Double Switching Enable This bit enables the double switching PWM behavior (See Double switching PWMs). 0b - Double switching disabled. 1b - Double switching enabled.

67.5.6 Value Register 0 (SM0VAL0 - SM3VAL0)

Offset

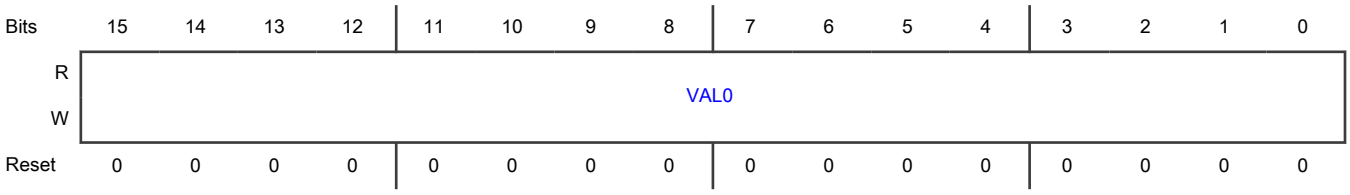
Register	Offset
SM0VAL0	Ah
SM1VAL0	6Ah
SM2VAL0	CAh
SM3VAL0	12Ah

Function

NOTE

The VAL0 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL0 cannot be written when MCTRL[LDOK] is set. Reading VAL0 reads the value in a buffer. It is not necessarily the value that the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 VAL0	Value 0 The 16-bit signed value in this buffered register defines the mid-cycle reload point for the PWM in PWM clock periods. This value also defines when the PWM_X signal is set and the local sync signal is reset. This register is not byte accessible. **NOTE** The actual behavior takes effect when counter equal VAL0+1.

67.5.7 Fractional Value Register 1 (SM0FRACVAL1 - SM3FRACVAL1)

Offset

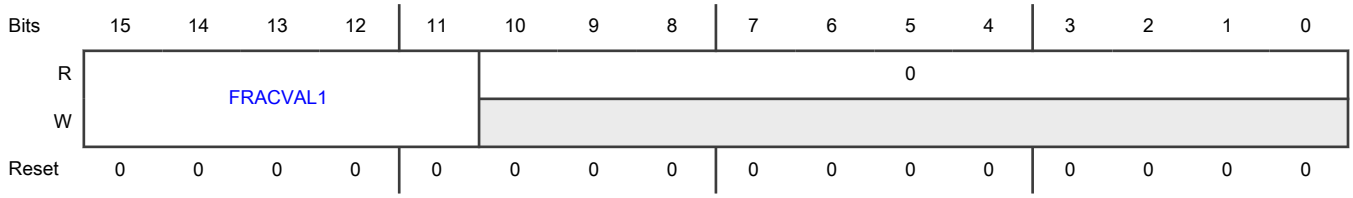
Register	Offset
SM0FRACVAL1	Ch
SM1FRACVAL1	6Ch
SM2FRACVAL1	CCh
SM3FRACVAL1	12Ch

Function

NOTE

The FRACVAL1 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL1 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL1 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Diagram



Fields

Field	Function
15-11 FRACVAL1	Fractional Value 1 These bits act as a fractional addition to the value in the VAL1 register which controls the PWM period. With fractional delay enabled, PWM works in digital dithering mode. The PWM period is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL1 is temporarily incremented, and the PWM period is extended by one clock to compensate for the accumulated fractional values.
10-0 —	Reserved

67.5.8 Value Register 1 (SM0VAL1 - SM3VAL1)

Offset

Register	Offset
SM0VAL1	Eh
SM1VAL1	6Eh
SM2VAL1	CEh
SM3VAL1	12Eh

Function

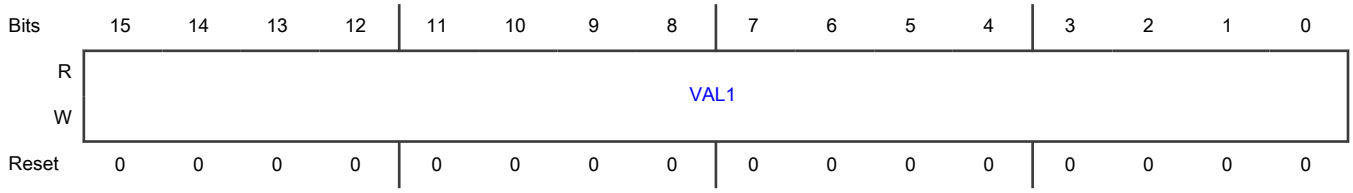
NOTE

The VAL1 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL1 cannot be written when MCTRL[LDOK] is set. Reading VAL1 reads the value in a buffer. It is not necessarily the value that the PWM generator is currently using.

When using FRACVAL1, limit the maximum value of VAL1 to 0xFFFE for unsigned applications or to 0x7FFE for signed applications, to avoid counter rollovers caused by accumulating the fractional period defined by FRACVAL1.

If the VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWM_X output. After the count reaches VAL1, the PWM_X output is low for a minimum of one count every cycle. When the Master Sync signal (only originated by the Local Sync from submodule 0) is used to control the timer period, the VAL1 register can be free for other functions such as PWM generation without the duty cycle limitation.

Diagram



Fields

Field	Function
15-0 VAL1	Value 1 The 16-bit signed value written to this buffered register defines the modulo count value (maximum count) for the submodule counter. When reaching this count value, the counter reloads itself with the contents of the INIT register and asserts the local sync signal while resetting PWM_X. This register is not byte accessible. **NOTE** The actual behavior takes effect when the counter equals VAL1+1.

67.5.9 Fractional Value Register 2 (SM0FRACVAL2 - SM3FRACVAL2)

Offset

Register	Offset
SM0FRACVAL2	10h
SM1FRACVAL2	70h
SM2FRACVAL2	D0h
SM3FRACVAL2	130h

Function

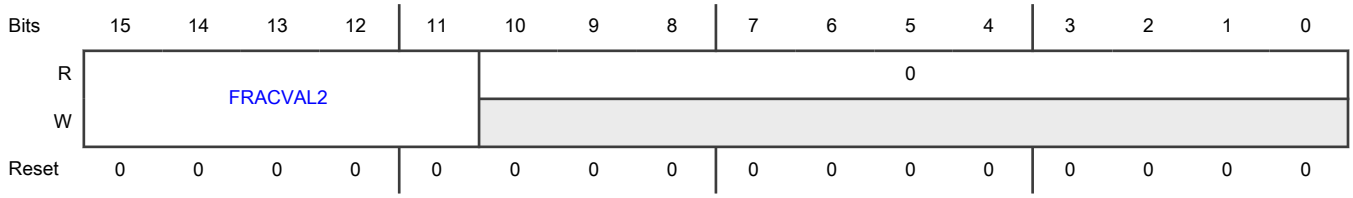
NOTE

The FRACVAL2 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL2 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL2 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

NOTE

FRCTRL[FRAC23_EN] should be set to 0 when the values of VAL2 and VAL3 cause the high or low time of the PWM output to be 3 cycles or less.

Diagram



Fields

Field	Function
15-11 FRACVAL2	Fractional Value 2 These bits act as a fractional addition to the value in the VAL2 register which controls the PWM_A turn on timing. It is also used to control the fractional addition to the turn off delay of PWM_B when MCTRL[IPOLx]=0 in complementary mode, CTRL2[INDEP]=0. With fractional delay enabled, PWM works in digital dithering mode. The PWM_A turn on delay is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL2 is temporarily incremented, and the PWM_A turn on delay is extended by one clock to compensate for the accumulated fractional values.
10-0 —	Reserved

67.5.10 Value Register 2 (SM0VAL2 - SM3VAL2)

Offset

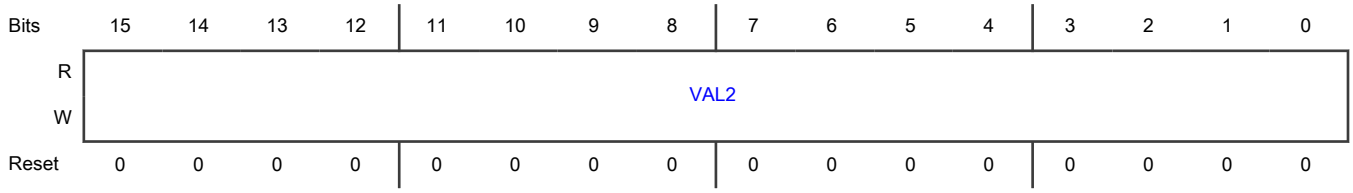
Register	Offset
SM0VAL2	12h
SM1VAL2	72h
SM2VAL2	D2h
SM3VAL2	132h

Function

NOTE

The VAL2 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL2 cannot be written when MCTRL[LDOK] is set. Reading VAL2 reads the value in a buffer and not necessarily the value that the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 VAL2	Value 2 The 16-bit signed value in this buffered register defines the count value to set PWM23 high. This register is not byte accessible. **NOTE** The actual behavior takes effect when the counter equals VAL2+1.

Fields

Field	Function
15 —	Reserved
14 RUF	Registers Updated Flag This bit is set when one of the INIT, VALx, FRACVALx, or CTRL[PRSC] registers has been written, which indicates potentially non-coherent data in the set of double buffered registers. Clear this bit by a proper reload sequence consisting of a reload signal while MCTRL[LDOK] = 1. Reset clears this bit. 0b - No register update has occurred since last reload. 1b - At least one of the double buffered registers has been updated since the last reload.
13 REF	Reload Error Flag This bit is set when a reload cycle occurs while MCTRL[LDOK] is 0 and the double buffered registers are in a non-coherent state (STS[RUF] = 1). Clear this bit by writing a logic one to this location. Reset clears this bit. 0b - No reload error occurred. 1b - Reload signal occurred with non-coherent data and MCTRL[LDOK] = 0.
12 RF	Reload Flag This bit is set at the beginning of every reload cycle regardless of the state of MCTRL[LDOK]. Clear this bit by writing a logic one to this location when DMAEN[VALDE] is clear (non-DMA mode). This bit can also be cleared by the DMA done signal when DMAEN[VALDE] is set (DMA mode) . Reset clears this bit. 0b - No new reload cycle since last STS[RF] clearing 1b - New reload cycle since last STS[RF] clearing
11 CFA1	Capture Flag A1 This bit is set when a capture event occurs on the Capture A1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CA1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA1DE] is set (DMA mode) . Reset clears this bit.
10 CFA0	Capture Flag A0 This bit is set when a capture event occurs on the Capture A0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CA0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA0DE] is set (DMA mode) . Reset clears this bit.
9	Capture Flag B1

Table continues on the next page...

Table continued from the previous page...

Field	Function
CFB1	This bit is set when a capture event occurs on the Capture B1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CB1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB1DE] is set (DMA mode) . Reset clears this bit.
8 CFB0	Capture Flag B0 This bit is set when a capture event occurs on the Capture B0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CB0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB0DE] is set (DMA mode) . Reset clears this bit.
7 CFX1	Capture Flag X1 This bit is set when a capture event occurs on the Capture X1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CX1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX1DE] is set (DMA mode) . Reset clears this bit.
6 CFX0	Capture Flag X0 This bit is set when a capture event occurs on the Capture X0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CX0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX0DE] is set (DMA mode) . Reset clears this bit.
5-0 CMPF	Compare Flags These bits are set when the submodule counter value matches the value of one of the VALx registers. Clear these bits by writing a 1 to a bit position. 00_0000b - No compare event has occurred for a particular VALx value. 00_0001b - A compare event has occurred for a particular VALx value.

67.5.20 Interrupt Enable Register (SM0INTEN - SM3INTEN)

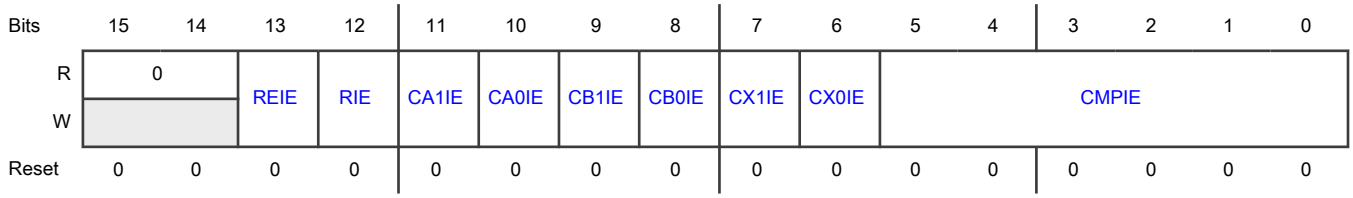
Offset

Register	Offset
SM0INTEN	26h
SM1INTEN	86h
SM2INTEN	E6h
SM3INTEN	146h

Function

Contains Compare and Capture interrupt enables.

Diagram



Fields

Field	Function
15-14 —	Reserved
13 REIE	Reload Error Interrupt Enable This bit enables the reload error flag, STS[REF], to generate CPU interrupt requests. Reset clears this bit. 0b - STS[REF] CPU interrupt requests disabled 1b - STS[REF] CPU interrupt requests enabled
12 RIE	Reload Interrupt Enable This bit enables the reload flag, STS[RF], to generate CPU interrupt requests. Reset clears this bit. 0b - STS[RF] CPU interrupt requests disabled 1b - STS[RF] CPU interrupt requests enabled
11 CA1IE	Capture A 1 Interrupt Enable This bit allows the STS[CFA1] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CA1DE]. 0b - Interrupt request disabled for STS[CFA1] 1b - Interrupt request enabled for STS[CFA1]
10 CA0IE	Capture A 0 Interrupt Enable This bit allows the STS[CFA0] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CA0DE]. 0b - Interrupt request disabled for STS[CFA0]. 1b - Interrupt request enabled for STS[CFA0].
9 CB1IE	Capture B 1 Interrupt Enable This bit allows the STS[CFB1] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CB1DE]. 0b - Interrupt request disabled for STS[CFB1]. 1b - Interrupt request enabled for STS[CFB1].
8	Capture B 0 Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
CB0IE	This bit allows the STS[CFB0] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CB0DE]. 0b - Interrupt request disabled for STS[CFB0]. 1b - Interrupt request enabled for STS[CFB0].
7 CX1IE	Capture X 1 Interrupt Enable This bit allows the STS[CFX1] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CX1DE]. 0b - Interrupt request disabled for STS[CFX1]. 1b - Interrupt request enabled for STS[CFX1].
6 CX0IE	Capture X 0 Interrupt Enable This bit allows the STS[CFX0] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CX0DE]. 0b - Interrupt request disabled for STS[CFX0]. 1b - Interrupt request enabled for STS[CFX0].
5-0 CMPIE	Compare Interrupt Enables These bits enable the STS[CMPF] flags to cause a compare interrupt request to the CPU. 00_0000b - The corresponding STS[CMPF] bit will not cause an interrupt request. 00_0001b - The corresponding STS[CMPF] bit will cause an interrupt request.

67.5.21 DMA Enable Register (SM0DMAEN - SM3DMAEN)

Offset

Register	Offset
SM0DMAEN	28h
SM1DMAEN	88h
SM2DMAEN	E8h
SM3DMAEN	148h

Function

Contains controls for DMA.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						VALDE	FAND	CAPTDE		CA1DE	CA0DE	CB1DE	CB0DE	CX1DE	CX0DE

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-10 —	Reserved
9 VALDE	Value Registers DMA Enable This bit enables DMA write requests for the VALx and FRACVALx registers when STS[RF] is set. Reset clears this bit. 0b - DMA write requests disabled 1b - Enabled. DMA write requests for the VALx and FRACVALx registers enabled
8 FAND	FIFO Watermark AND Control This bit works in conjunction with the DMAEN[CAPTDE] field when it is set to watermark mode (DMAEN[CAPTDE] = 01). While DMAEN[CAxDE], DMAEN[CBxDE], and DMAEN[CXxDE] determine which FIFO watermarks the DMA read request is sensitive to. This bit determines if the selected watermarks are AND'ed together or OR'ed together to create the request. 0b - Selected FIFO watermarks are OR'ed together. 1b - Selected FIFO watermarks are AND'ed together.
7-6 CAPTDE	Capture DMA Enable Source Select These bits select the source of enabling the DMA read requests for the capture FIFOs. Reset clears these bits. 00b - Read DMA requests disabled. 01b - Exceeding a FIFO watermark sets the DMA read request. This requires at least one of DMAEN[CA1DE], DMAEN[CA0DE], DMAEN[CB1DE], DMAEN[CB0DE], DMAEN[CX1DE], or DMAEN[CX0DE] to be set to determine which watermark(s) the DMA request is sensitive. 10b - A local synchronization (VAL1 matches counter) sets the read DMA request. 11b - A local reload (STS[RF] being set) sets the read DMA request.
5 CA1DE	Capture A1 FIFO DMA Enable This bit enables DMA read requests for the Capture A1 FIFO data when STS[CFA1] is set. Reset clears this bit. Do not set this bit and INTEN[CA1IE].
4 CA0DE	Capture A0 FIFO DMA Enable This bit enables DMA read requests for the Capture A0 FIFO data when STS[CFA0] is set. Reset clears this bit. Do not set both this bit and INTEN[CA0IE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 CB1DE	Capture B1 FIFO DMA Enable This bit enables DMA read requests for the Capture B1 FIFO data when STS[CFB1] is set. Reset clears this bit. Do not set both this bit and INTEN[CB1IE].
2 CB0DE	Capture B0 FIFO DMA Enable This bit enables DMA read requests for the Capture B0 FIFO data when STS[CFB0] is set. Reset clears this bit. Do not set both this bit and INTEN[CB0IE].
1 CX1DE	Capture X1 FIFO DMA Enable This bit enables DMA read requests for the Capture X1 FIFO data when STS[CFX1] is set. Reset clears this bit. Do not set both this bit and INTEN[CX1IE].
0 CX0DE	Capture X0 FIFO DMA Enable This bit enables DMA read requests for the Capture X0 FIFO data when STS[CFX0] is set. Reset clears this bit. Do not set both this bit and INTEN[CX0IE].

67.5.22 Output Trigger Control Register (SM0TCTRL - SM3TCTRL)

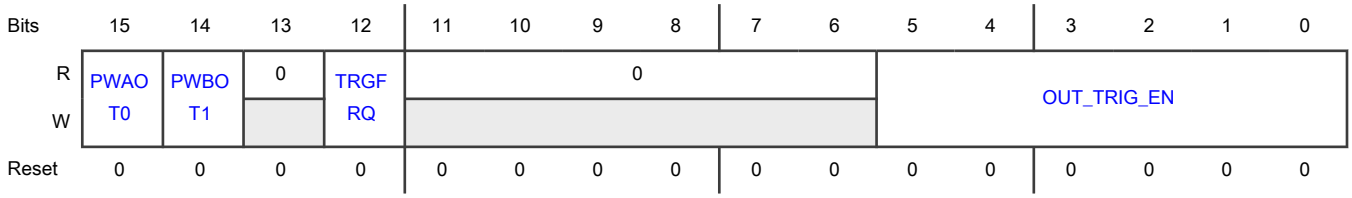
Offset

Register	Offset
SM0TCTRL	2Ah
SM1TCTRL	8Ah
SM2TCTRL	EAh
SM3TCTRL	14Ah

Function

Contains trigger controls.

Diagram



Fields

Field	Function
15 PWAOT0	Mux Output Trigger 0 Source Select This bit selects which signal to bring out on the PWM's PWM_MUX_TRIG0 port. 0b - Route the PWM_OUT_TRIG0 signal to PWM_MUX_TRIG0 port. 1b - Route the PWM_A output to the PWM_MUX_TRIG0 port.
14 PWBOT1	Mux Output Trigger 1 Source Select This bit selects which signal to bring out on the PWM's PWM_MUX_TRIG1 port. 0b - Route the PWM_OUT_TRIG1 signal to PWM_MUX_TRIG1 port. 1b - Route the PWM_B output to the PWM_MUX_TRIG1 port.
13 —	Reserved
12 TRGFRQ	Trigger Frequency This bit allows control over the frequency of the trigger outputs when using non-zero values of CTRL[LDFQ]. 0b - Trigger outputs are generated during every PWM period even if the PWM is not reloaded every period due to CTRL[LDFQ] being non-zero. 1b - Trigger outputs are generated only during the final PWM period prior to a reload opportunity when the PWM is not reloaded every period due to CTRL[LDFQ] being non-zero.
11-6 —	Reserved
5-0 OUT_TRIG_EN	Output Trigger Enables These bits enable the generation of PWM_OUT_TRIG0 and PWM_OUT_TRIG1 outputs based on the counter value matching the value in one or more of the VAL0-5 registers. **NOTE** Due to delays in creating the PWM outputs, the output trigger signals lead the PWM output edges by 2-3 clock cycles depending on the fractional cycle value being used. 1x_xxxxb - PWM_OUT_TRIG1 will set when the counter value matches the VAL5 value. x1_xxxxb - PWM_OUT_TRIG0 will set when the counter value matches the VAL4 value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	xx_1xxxb - PWM_OUT_TRIG1 will set when the counter value matches the VAL3 value. xx_x1xxb - PWM_OUT_TRIG0 will set when the counter value matches the VAL2 value. xx_xx1xb - PWM_OUT_TRIG1 will set when the counter value matches the VAL1 value. xx_xxx1b - PWM_OUT_TRIG0 will set when the counter value matches the VAL0 value.

67.5.23 Fault Disable Mapping Register 0 (SM0DISMAP0 - SM3DISMAP0)

Offset

Register	Offset
SM0DISMAP0	2Ch
SM1DISMAP0	8Ch
SM2DISMAP0	ECh
SM3DISMAP0	14Ch

Function

This register determines which PWM pins are disabled by the fault protection inputs. Reset sets all of the bits in the fault disable mapping register.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Function
	A reset sets all bits in this field.
7-4 DIS0B	PWM_B Fault Disable Mask 0 Each of the four bits of this field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_B output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. DIS0B[0] is associated with FAULT0. DIS0B[1] is associated with FAULT1. DIS0B[2] is associated with FAULT2. DIS0B[3] is associated with FAULT3. A reset sets all bits in this field.
3-0 DIS0A	PWM_A Fault Disable Mask 0 Each of the four bits of this field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_A output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. DIS0A[0] is associated with FAULT0. DIS0A[1] is associated with FAULT1. DIS0A[2] is associated with FAULT2. DIS0A[3] is associated with FAULT3. A reset sets all bits in this field.

67.5.24 Deadtime Count Register 0 (SM0DTCNT0 - SM3DTCNT0)

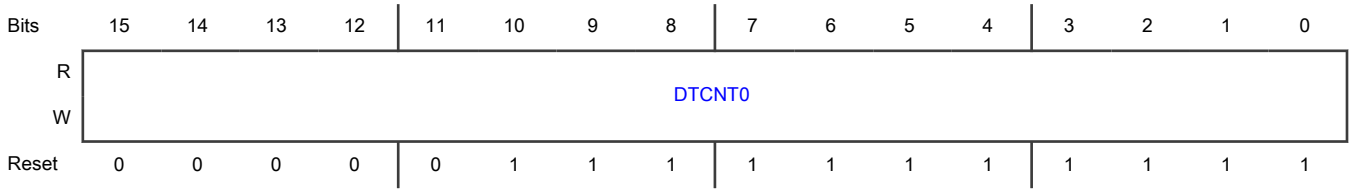
Offset

Register	Offset
SM0DTCNT0	30h
SM1DTCNT0	90h
SM2DTCNT0	F0h
SM3DTCNT0	150h

Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles, when fractional delay is not enabled. The DTCNTx registers are not byte accessible.

Diagram



Fields

Field	Function
15-0 DTCNT0	DTCNT0 The DTCNT0 field is used to control the deadtime during 0 to 1 transitions of the PWM_A output (assuming normal polarity). The DTCNT0 field is interpreted differently depending on whether the fractional delays are enabled or not. • If the fractional delays are disabled (FRCTRL[FRAC23_EN] cleared to 0 when MCTRL[IPOL]=0, or FRCTRL[FRAC45_EN] cleared to 0 when MCTRL[IPOL]=1), then the upper 5 bits of DTCNT0 are ignored and the remaining 11 bits are used to specify the number of PWM clock cycles of deadtime, i.e. the number cycles of deadtime = DTCNT0[10:0] . In this case, the maximum value is 0x07FF which indicates 2047 cycles of deadtime. • If the fractional delays are enabled (FRCTRL[FRAC23_EN] set to 1 when MCTRL[IPOL]=0, or FRCTRL[FRAC45_EN] set to 1 when MCTRL[IPOL]=1), then the upper 11 bits of DTCNT0 represent the number of PWM clock cycles of deadtime, while the lower 5 bits of each register represent the fractional number of cycle. With fractional delay enabled, PWM works in digital dithering mode. When the accumulation of fractional cycles exceeds 1, the whole number specified in DTCNT0[15:5] increments one additional cycle, and the reminder is used for the next fractional cycle accumulation. **NOTE** It is highly recommended to clear DTCNT0[4:0], to prevent unexpected deadtime increase, when the fractional digital dithering delays are adopted. Then the number of cycles of deadtime = DTCNT0[15:5].

67.5.25 Deadtime Count Register 1 (SM0DTCNT1 - SM3DTCNT1)

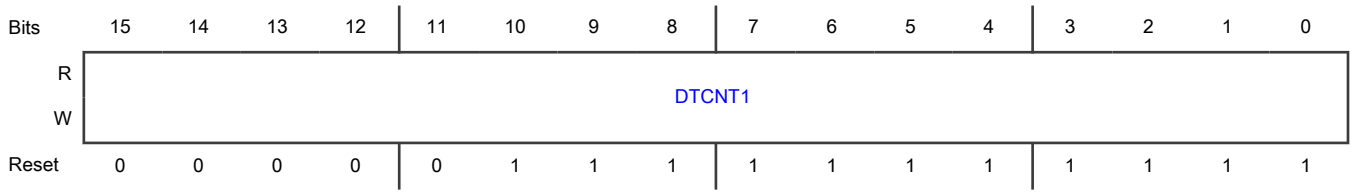
Offset

Register	Offset
SM0DTCNT1	32h
SM1DTCNT1	92h
SM2DTCNT1	F2h
SM3DTCNT1	152h

Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles, when fractional delay is not enabled. The DTCNTx registers are not byte accessible.

Diagram



Fields

Field	Function
15-0 DTCNT1	DTCNT1 The DTCNT1 field is used to control the deadtime during 0 to 1 transitions of the PWM_B output (assuming normal polarity). The DTCNT1 field is interpreted differently depending on whether the fractional delays are enabled or not. • If the fractional delays are disabled (FRCTRL[FRAC23_EN] cleared to 0 when MCTRL[IPOL]=0, or FRCTRL[FRAC45_EN] cleared to 0 when MCTRL[IPOL]=1), then the upper 5 bits of DTCNT1 are ignored and the remaining 11 bits are used to specify the number of PWM clock cycles of deadtime, i.e. the number cycles of deadtime = DTCNT1[10:0] . In this case, the maximum value is 0x07FF which indicates 2047 cycles of deadtime. • If the fractional delays are enabled (FRCTRL[FRAC23_EN] set to 1 when MCTRL[IPOL]=0, or FRCTRL[FRAC45_EN] set to 1 when MCTRL[IPOL]=1), then the upper 11 bits of DTCNT1 represent the number of PWM clock cycles of deadtime, while the lower 5 bits of each register represent the fractional number of cycle. In this case, the maximum value is 0xFFFF which represents 2047 + 31/32 cycles of deadtime. With fractional delay enabled, PWM works in digital dithering mode. When the accumulation of fractional cycles exceeds 1, the whole number specified in DTCNT1[15:5] increments one additional cycle, and the reminder is used for the next fractional cycle accumulation. **NOTE** It is highly recommended to clear DTCNT1[4:0], to prevent unexpected deadtime increase, when the fractional digital dithering delays are adopted. Then the number of cycles of deadtime = DTCNT1[15:5].

67.5.26 Capture Control A Register (SM0CAPTCTRLA)

Offset

Register	Offset
SM0CAPTCTRLA	34h

Function

Contains capture controls for mode A.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Fields

Field	Function
15-13 CA1CNT	Capture A1 FIFO Word Count This field reflects the number of words in the Capture A1 FIFO. (FIFO depth is 1.)
12-10 CA0CNT	Capture A0 FIFO Word Count This field reflects the number of words in the Capture A0 FIFO. (FIFO depth is 1.)
9-8 CFAWM	Capture A FIFOs Water Mark This field represents the water mark level for capture A FIFOs. The capture flags, STS[CFA1] and STS[CFA0], are not set until the word count of the corresponding FIFO is greater than this water mark level. (FIFO depth is 1.)
7 EDGCNTA_EN	Edge Counter A Enable This field enables the edge counter which counts rising and falling edges on the PWM_A input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELA	Input Select A This field selects between the raw PWM_A input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_A input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLA[EDGA0] and CAPTCTRLA[EDGA1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRA[EDGA0] and/or CAPTCTRLA[EDGA1] fields to enable one or both of the capture registers.
5-4 EDGA1	Edge A 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Capture rising edges 11b - Capture any edge
3-2 EDGA0	Edge A 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTA	One Shot Mode A This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLA[ARMA] is cleared. No further captures are performed until CAPTCTRLA[ARMA] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLA[ARMA] is then cleared.
0 ARMA	Arm A Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLA[EDGAx] is enabled.

67.5.44 Capture PWM_A Input Filter Register (SM0CAPTFILTA - SM3CAPTFILTA)

Offset

Register	Offset
SM0CAPTFILTA	5Ah
SM1CAPTFILTA	BAh
SM2CAPTFILTA	11Ah
SM3CAPTFILTA	17Ah

Function

Input filter considerations include:

- The CAPTA_FILT_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The CAPTA_FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the CAPTA_FILT_CNT+3 power.

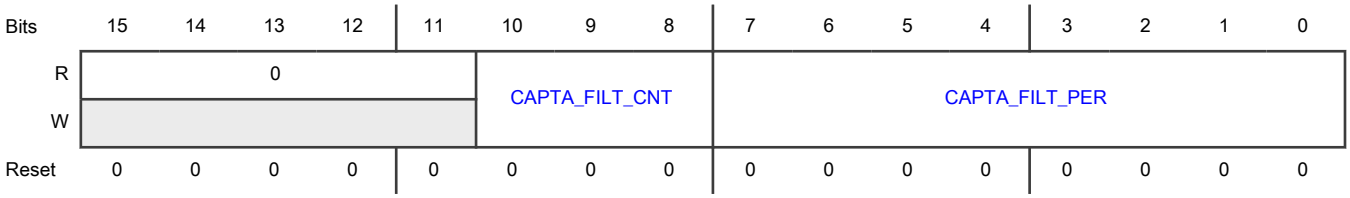
- The values of CAPTA_FILT_PER and CAPTA_FILT_CNT must be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting CAPTA_FILT_PER to a non-zero value) introduces a latency of ((CAPTA_FILT_CNT+4) x CAPTA_FILT_PER x IPBus clock period).

NOTE

When the filter is enabled, there is a combinational path to disable the PWM outputs to ensure rapid response to input capture conditions if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set FSTS[FFLAG] and FSTS[FFPIN].

This register is not byte accessible

Diagram



Fields

Field	Function
15-11 —	Reserved
10-8 CAPTA_FILT_CNT	Input Capture Filter Count This field represents the number of consecutive samples that must agree prior to the input filter accepting an input transition. The number of samples is the decimal value of this field plus three: the bit field value of 0-7 represents 3-10 samples, respectively. The value of CAPTA_FILT_CNT affects the input latency.
7-0 CAPTA_FILT_PER	Input Capture Filter Period This field applies universally to all capture inputs. These bits represent the sampling period (in IPBus clock cycles) of the input capture pin input filter. Each input is sampled multiple times at the rate specified by this field. If CAPTA_FILT_PER is 0x00 (default), then the input filter is bypassed. The value of CAPTA_FILT_PER affects the input latency. **NOTE** When changing values for CAPTA_FILT_PER from one non-zero value to another non-zero value, first write a value of zero to clear the filter.

SM3CAPTFILTB	17Ch

Function

Input filter considerations include:

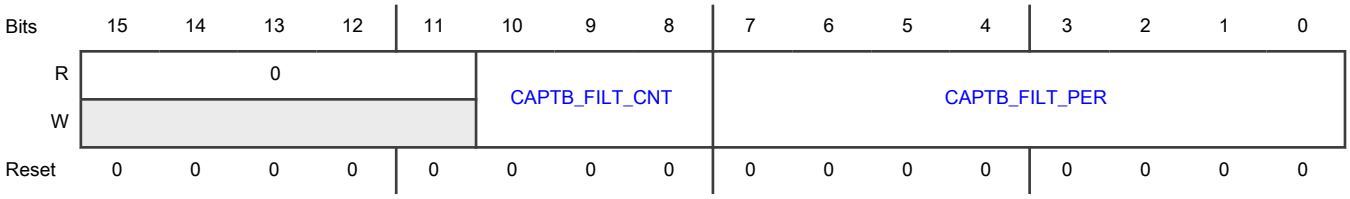
- The CAPTB_FILT_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The CAPTB_FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the CAPTB_FILT_CNT+3 power.
- The values of CAPTB_FILT_PER and CAPTB_FILT_CNT must be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting CAPTB_FILT_PER to a non-zero value) introduces a latency of ((CAPTB_FILT_CNT+4) x CAPTB_FILT_PER x IPBus clock period).

NOTE

When the filter is enabled, there is a combinational path to disable the PWM outputs to ensure rapid response to input capture conditions if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set FSTS[FFLAG] and FSTS[FFPIN].

This register is not byte accessible

Diagram



Fields

Field	Function
15-11 —	Reserved
10-8 CAPTB_FILT_CNT	Input Capture Filter Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. The number of samples is the decimal value of this field plus three: the bit field value of 0-7 represents 3-10 samples, respectively. The value of CAPTB_FILT_CNT affects the input latency.
7-0	Input Capture Filter Period This field applies universally to all capture inputs.

Table continues on the next page...

Table continued from the previous page...

Field	Function
CAPTB_FILT_PER	These bits represent the sampling period (in IPBus clock cycles) of the input capture pin input filter. Each input is sampled multiple times at the rate specified by this field. If CAPTB_FILT_PER is 0x00 (default), then the input filter is bypassed. The value of CAPTB_FILT_PER affects the input latency. **NOTE** When changing values for CAPTB_FILT_PER from one non-zero value to another non-zero value, first write a value of zero to clear the filter.

67.5.46 Capture PWM_X Input Filter Register (SM0CAPTFILTX - SM3CAPTFILTX)

Offset

Register	Offset
SM0CAPTFILTX	5Eh
SM1CAPTFILTX	BEh
SM2CAPTFILTX	11Eh
SM3CAPTFILTX	17Eh

Function

Input filter considerations include:

- The CAPTX_FILT_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The CAPTX_FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the CAPTX_FILT_CNT+3 power.
- The values of FILT_PER and CAPTX_FILT_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting CAPTX_FILT_PER to a non-zero value) introduces a latency of ((CAPTX_FILT_CNT+4) x CAPTX_FILT_PER x IPBus clock period).

NOTE

When the filter is enabled, there is a combinational path to disable the PWM outputs to ensure rapid response to input capture conditions if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set FSTS[FFLAG] and FSTS[FFPIN].

67.5.65 Phase Delay Register (SM1PHASEDLY - SM3PHASEDLY)

Offset

Register	Offset
SM1PHASEDLY	B8h
SM2PHASEDLY	118h
SM3PHASEDLY	178h

Function

The 16-bit unsigned value in this buffered register defines the delay from the master sync signal of submodule 0 to the time that this submodule recognizes the master sync in PWM clock periods. CTRL2[INIT_SEL] must be set to 10b to select the master sync signal as the source for initialization when using this register. Setting this register with a non-zero value and using the master sync signal as the initialization source, allows the output of this submodule to be a fixed number of cycles delayed from submodule 0. For PWM operation, the buffered contents of this register are updated at the start of every PWM cycle. This field is not byte accessible.

NOTE

The PHASEDLY register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. This register cannot be written when MCTRL[LDOK] is set. Reading PHASEDLY reads the value in a buffer and not necessarily the value that the PWM generator is currently using. Also, the value of this register should not be set to a value larger than the period defined in submodule 0.

67.5.106 Master Control Register (MCTRL)

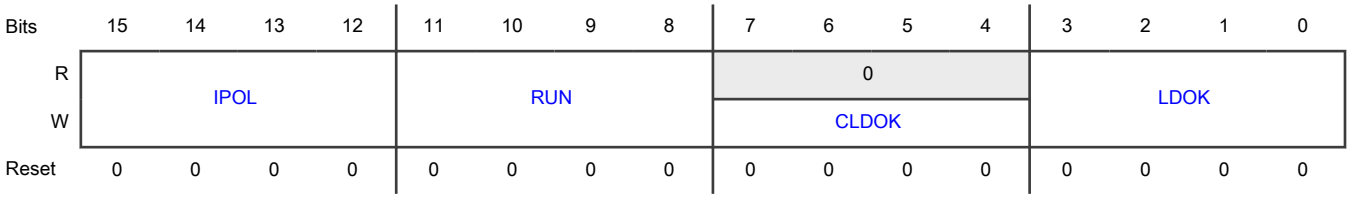
Offset

Register	Offset
MCTRL	188h

Function

In every 4-bit field in this register, each bit acts on a separate submodule. Accordingly, the description of every bit field refers to the effect of an individual bit.

Diagram



Fields

Field	Function
15-12 IPOL	Current Polarity This field corresponds to submodules 3 - 0, respectively. Each bit selects between PWM23 and PWM45 as the source for the generation of the complementary PWM pair output for the corresponding submodule. MCTRL[IPOL] is ignored in independent mode. MCTRL[IPOL] does not take effect until a FORCE_OUT event takes place in the appropriate submodule. Reading MCTRL[IPOL] reads the buffered value and not necessarily the value currently in effect. 0000b - PWM23 is used to generate complementary PWM pair in the corresponding submodule. 0001b - PWM45 is used to generate complementary PWM pair in the corresponding submodule.
11-8 RUN	Run This field enables the clocks to the PWM generator of submodules 3 - 0, respectively. The corresponding MCTRL[RUN] bit must be set for each submodule that is using its input capture functions or is using the local reload as its reload source. When this bit equals zero, the submodule counter is reset, and PWM outputs are held. A reset clears this field. 0000b - PWM counter is stopped, but PWM outputs hold the current state. 0001b - PWM counter is started in the corresponding submodule.
7-4 CLDOK	Clear Load Okay This field corresponds to submodules 3 - 0, respectively. Each write-only bit is used to clear the corresponding bit of MCTRL[LDOK]. Write a 1 to CLDOK to clear the corresponding MCTRL[LDOK] bit. If a reload occurs within a submodule with the corresponding MCTRL[LDOK] bit set at the same time that

Table continues on the next page...

Table continued from the previous page...

Field	Function
	MCTRL[CLDOK] is written, then the reload in that submodule will not be performed and MCTRL[LDOK] will be cleared. CLDOK bit is self-clearing and always reads as a 0.
3-0 LDOK	Load Okay This field corresponds to submodules 3 - 0, respectively. Each read/set bit loads CTRL[PRSC] and the INIT, FRACVALx, and VALx registers of the corresponding submodule into a set of buffers. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if CTRL[LDMOD] is clear or if CTRL[LDMOD] is set. Set the corresponding MCTRL[LDOK] bit by reading it when it is logic zero and then writing a logic one to it. The VALx, FRACVALx, INIT, and CTRL[PRSC] registers of the corresponding submodule cannot be written while the corresponding MCTRL[LDOK] bit is set. In Master Reload Mode (CTRL2[RELOAD_SEL]=1), it is necessary to set the LDOK bit corresponding to submodule0; however, it is recommended to also set the LDOK bit of the slave submodules, to prevent unwanted writes to the registers in the slave submodules. The MCTRL[LDOK] bit is automatically cleared after the new values are loaded, or it can be manually cleared before a reload by writing a logic 1 to the appropriate MCTRL[CLDOK] bit. LDOK bits cannot be written with a zero. MCTRL[LDOK] can be set in DMA mode when the DMA indicates that it has completed the update of all CTRL[PRSC], INIT, FRACVALx, and VALx registers in the corresponding submodule. Reset clears LDOK field. 0000b - Do not load new values. 0001b - Load prescaler, modulus, and PWM values of the corresponding submodule.

67.5.107 Master Control 2 Register (MCTRL2)

Offset

Register	Offset
MCTRL2	18Ah

Function

Includes control for monitoring the PLL state and write protection of some configuration registers.

Diagram

67.5.108 Fault Control Register (FCTRL0)

Offset

Register	Offset
FCTRL0	18Ch

Function

For every 4-bit field in this register, the bits act on the fault inputs in order. For example, FLVL bits 15-12 act on faults 3-0, respectively.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	FLVL				FAUTO				FSAFE				FIE			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 FLVL	Fault Level This field selects the active logic level of the individual fault inputs 3-0, respectively. A reset clears this field. 0000b - A logic 0 on the fault input indicates a fault condition. 0001b - A logic 1 on the fault input indicates a fault condition.
11-8 FAUTO	Automatic Fault Clearing This field selects automatic or manual clearing of faults 3-0, respectively. A reset clears this field. 0000b - Manual fault clearing. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL]. If neither FFULL nor FHALF is set, then the fault condition cannot be cleared. This is further controlled by FCTRL[FSAFE]. 0001b - Automatic fault clearing. PWM outputs disabled by this fault are enabled when FSTS[FFPINx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL] without regard to the state of FSTS[FFLAGx]. If neither FFULL nor FHALF is set, then the fault condition cannot be cleared.
7-4 FSAFE	Fault Safety Mode This field selects the safety mode during manual fault clearing. A reset clears this field. FSTS[FFPINx] may indicate that a fault condition still exists even though the actual fault signal at the FAULTx pin is clear due to the fault filter latency. 0000b - Normal mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL] without regard to the state of FSTS[FFPINx]. If neither FHALF nor FFULL is set, then the fault condition cannot be cleared. The PWM outputs disabled by this fault input will not be re-enabled until the actual FAULTx input signal de-asserts since the fault input will combinationally disable the PWM outputs (as programmed in DISMAPn). 0001b - Safe mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear and FSTS[FFPINx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL]. If neither FHLAF nor FFULL is set, then the fault condition cannot be cleared.
3-0 FIE	Fault Interrupt Enables This field enables CPU interrupt requests generated by the FAULTx pins. A reset clears this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The fault protection circuit is independent of the FIEx bit and is always active. If a fault is detected, the PWM outputs are disabled according to the disable mapping register. 0000b - FAULTx CPU interrupt requests disabled. 0001b - FAULTx CPU interrupt requests enabled.

67.5.109 Fault Status Register (FSTS0)

Offset

Register	Offset
FSTS0	18Eh

Function

Includes controls related to fault conditions.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FHALF				FFPIN				FFULL				FFLAG			
W																
Reset	0	0	0	0	u	u	u	u	0	0	0	0	u	u	u	u

Fields

Field	Function
15-12 FHALF	Half Cycle Fault Recovery This field is used to control the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition. **NOTE** Both FHALF and FFULL can be set so that the fault recovery occurs at the start of a full cycle and at the start of a half cycle (as defined by VAL0). If neither FHALF nor FFULL is set, then no fault recovery is possible. 0000b - PWM outputs are not re-enabled at the start of a half cycle. 0001b - PWM outputs are re-enabled at the start of a half cycle (as defined by VAL0).
11-8 FFPIN	Filtered Fault Pins

Table continues on the next page...

Table continued from the previous page...

Field	Function
	These read-only bits reflect the current state of the filtered FAULTx pins converted to high polarity. A logic 1 indicates that a fault condition exists on the filtered FAULTx pin. A reset has no effect on this field. After the system reset de-asserts, these are the possible values of FFPIN: If FCTRL[FLVL] = 0 and FAULTx = 0, then FFPIN is set to 1. If FCTRL[FLVL] = 0 and FAULTx = 1, then FFPIN is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 0, then FFPIN is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 1, then FFPIN is set to 1.
7-4 FFULL	Full Cycle This field is used to control the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition. **NOTE** Both FHALF and FFULL can be set so that the fault recovery occurs at the start of a full cycle and at the start of a half cycle (as defined by VAL0). If neither FHALF nor FFULL is set, then no fault recovery is possible. 0000b - PWM outputs are not re-enabled at the start of a full cycle 0001b - PWM outputs are re-enabled at the start of a full cycle
3-0 FFLAG	Fault Flags These read-only flags are set within two CPU cycles after a transition to active on the FAULTx pin. Clear this bit by writing a logic one to it. A reset clears this field. While the reset value is 0, these bits may be set to 1 by the time they can be read depending on the state of the fault input signals. After the system reset de-asserts, these are the possible values of FFLAG: If FCTRL[FLVL] = 0 and FAULTx = 0, then FFLAG is set to 1. If FCTRL[FLVL] = 0 and FAULTx = 1, then FFLAG is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 0, then FFLAG is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 1, then FFLAG is set to 1. 0000b - No fault on the FAULTx pin. 0001b - Fault on the FAULTx pin.

67.5.110 Fault Filter Register (FFILT0)

Offset

Register	Offset
FFILT0	190h

Function

The settings in this register are shared among each of the fault input filters within the fault channel.

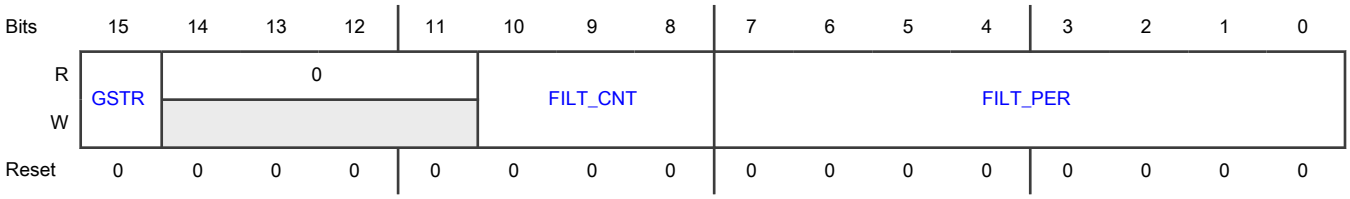
Input filter considerations include:

- Set the FILT_PER value such that the sampling period is larger than the period of the expected noise. This way a noise spike corrupts one sample. Select the FILT_CNT value to reduce and recognize the probability of noisy samples causing an incorrect transition. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT+3 power.
- The values of FILT_PER and FILT_CNT must be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of ((FILT_CNT+4) x FILT_PER x IPBus clock period).

NOTE

When the filter is enabled, there is a combinational path to disable the PWM outputs to ensure rapid response to fault conditions, and fault response if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set FSTS[FFLAG] and FSTS[FFPIN].

Diagram



Fields

Field	Function
15 GSTR	Fault Glitch Stretch Enable This field is used to enable the fault glitch-stretching logic. This logic ensures that narrow fault glitches are stretched to be at least 2 IPBus clock cycles wide. In some cases, a narrow fault input can cause problems due to the short PWM output shutdown/re-activation time. The stretching logic ensures that a glitch on the fault input, when the fault filter is disabled, will be registered in the fault flags. 0b - Fault input glitch stretching is disabled. 1b - Input fault signals are stretched to at least 2 IPBus clock cycles.
14-11 —	Reserved
10-8 FILT_CNT	Fault Filter Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. The number of samples is the decimal value of this field plus three: the bit field value of 0-7 represents 3-10 samples, respectively. The value of FILT_CNT affects the input latency.
7-0 FILT_PER	Fault Filter Period This 8-bit field applies universally to all fault inputs. These bits represent the sampling period (in IPBus clock cycles) of the fault pin input filter. Each input is sampled multiple times at the rate specified by this field. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When changing values for FILT_PER from one non-zero value to another non-zero value, first write a value of zero to clear the filter.

67.5.111 Fault Test Register (FTST0)

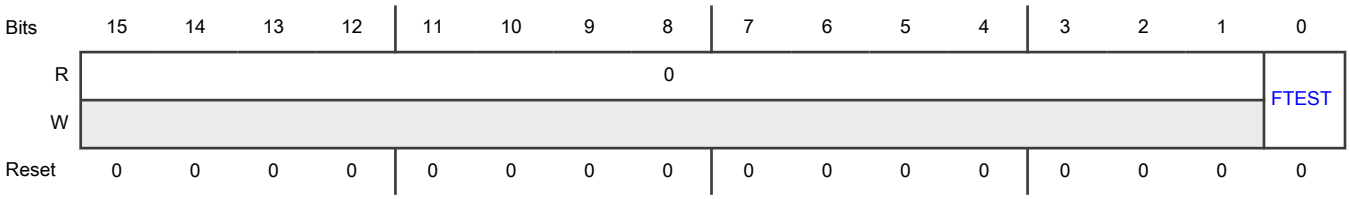
Offset

Register	Offset
FTST0	192h

Function

Contains FTEST field for fault simulation.

Diagram



Fields

Field	Function
15-1 —	Reserved
0 FTEST	Fault Test This field is used to simulate a fault condition. Setting this bit causes a simulated fault to be sent into all of the fault filters. The condition propagates to the fault flags and possibly the PWM outputs depending on the DISMAPn settings. Clearing this bit removes the simulated fault condition. 0b - No fault 1b - Cause a simulated fault

67.5.112 Fault Control 2 Register (FCTRL20)

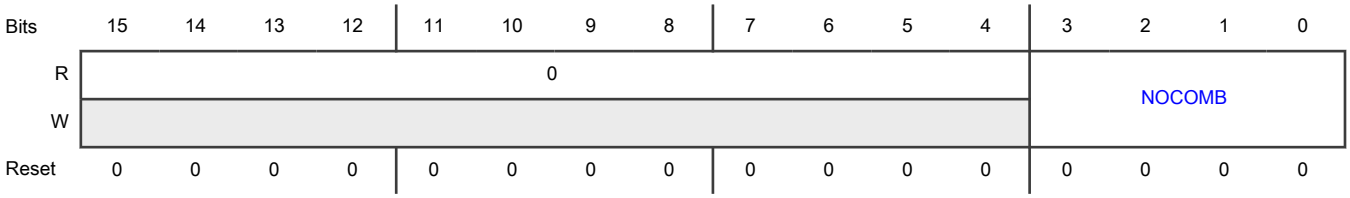
Offset

Register	Offset
FCTRL20	194h

Function

Controls combinational link from fault inputs to PWM outputs.

Diagram



Fields

Field	Function
15-4 —	Reserved
3-0 NOCOMB	No Combinational Path From Fault Input To PWM Output This field is used to control the combinational path from the fault inputs to the PWM outputs. When these bits are low (default), the corresponding fault inputs have a combinational path to the PWM outputs that are sensitive to these fault inputs (as defined by DISMAP0). This combinational path is a safety feature that ensures the output is disabled even if the SOC has a failure of its clocking system. The combinational path also means that a pulse on the fault input can cause a brief disable of the PWM output even if the fault pulse is not wide enough to get through the input filter and be latched in the fault logic. Setting these bits removes the combinational path and uses the filtered and latched fault signals as the fault source to disable the PWM outputs. This eliminates fault glitches from creating PWM output glitches but also increases the latency to respond to a real fault. 0000b - There is a combinational link from the fault inputs to the PWM outputs. The fault inputs are combined with the filtered and latched fault signals to disable the PWM outputs. 0001b - The direct combinational path from the fault inputs to the PWM outputs is disabled and the filtered and latched fault signals are used to disable the PWM outputs.

68.2 Overview

GPT is a 32-bit, up-counter with clock source and frequency scaling options that provide a wide range of timing rates for various system applications. External hardware can send GPT a Capture Event signal on an input pin to load the current timer value into a register for software to read. This Capture Event signal can be configured to trigger GPT on a rising edge, a falling edge, or both. When the timer matches a preset value, GPT can generate an interrupt for software and a Compare Event signal on output pins for external hardware.

68.2.1 Block diagram

Figure 519 is a functional block diagram of GPT.

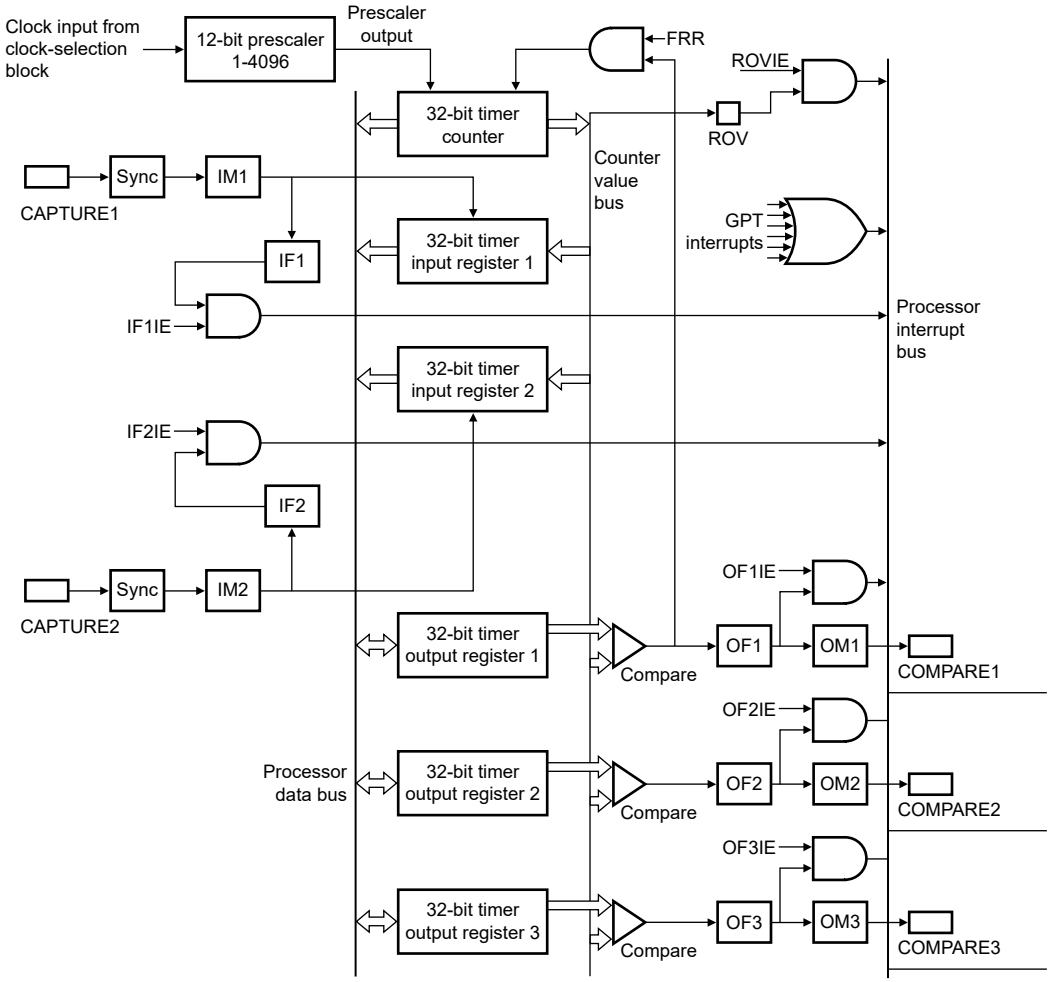

Figure 519. GPT block diagram

68.2.2 Features

- One 32-bit up-counter with clock source selection, including external clock.
- Two input capture channels with a programmable trigger edge.
- Three output compare channels with a programmable output mode. A forced-compare feature is also available.
- Programmable active option in Low Power and Debug modes.
- Interrupt generation at capture, compare, and rollover events.
- Restart or Free-Run modes for counter operations.

68.3 Functional description

68.3.1 Operating modes

You can program the GPT counter to work in one of two modes: Restart or Free-Run.

68.3.1.1 Restart mode

In Restart mode (selectable through the Control (CR)), the counter resets and starts again from 0000_0000h when the counter reaches the compared value. The restart feature is only associated with Compare Channel 1.

Any write access to the Channel 1 compare register resets the GPT counter. This is done to avoid missing a compare event when the compare value is changed from a higher value to a lower value while counting is already in process.

For the other two compare channels, the counter is not reset when the compare event occurs.

68.3.1.2 Free-Run mode

In Free-Run mode, the counter is mot reset when compare events occur for all three channels. Instead, the counter continues to count until FFFF_FFFFh, and then rolls over to 0000_0000h.

68.3.2 Operation

GPT has a single counter (GPT_CNT) which is a 32-bit free-running up-counter. It starts counting after it is enabled by writing 1 to CR[EN]. The clock source of the counter is the output of the prescaler labeled "Prescaler output" in Figure 519.

If the GPT timer is disabled (EN=0), then both the Main Counter and Prescaler Counter freeze their current count values. Use the CR[ENMOD] field to determine the value of the GPT counter when the CR[EN] field is programmed and the Counter is enabled again.

- If you write 1 to CR[ENMOD], then the Main Counter and Prescaler Counter values are reset to 0 when GPT is enabled (EN=1).
- If you write 0 to CR[ENMOD], then the Main Counter and Prescaler Counter restart counting from their frozen values when GPT is enabled again (EN=1).

If you program GPT to be disabled in a low-power mode (that is, Stop or Wait mode), then the Main Counter and Prescaler Counter freeze at their current count values when GPT enters Low Power mode. When GPT exits a low-power mode, the Main Counter and Prescaler Counter start counting from their frozen values regardless of the CR[ENMOD] field value.

NOTE

Both Input Capture Channels use the same counter (GPT_CNT). The processor can read GPT_CNT at any time.

A hardware reset resets all the GPT registers to their respective reset values. All registers, except the Output Compare (OCR1 - OCR3) registers (OCR1, OCR2, and OCR3), obtain a value of 0h. The Compare registers are reset to FFFF_FFFFh.

Writing to CR[SWR] resets all of the register fields except for the CR[EN], CR[ENMOD], CR[STOPEN], CR[WAITEN], and CR[DBGEN] fields. The state of these fields is not affected by a software reset.

NOTE

You can perform a software reset while GPT is disabled.

68.3.2.1 Input capture

There are two input capture channels and each channel has a dedicated capture signal, capture register, and input edge detection and selection logic. Each input capture function has an associated status flag and can cause the processor to make an interrupt service request.

When a selected edge transition occurs on an input capture signal, the contents of Counter (CNT) are captured on the corresponding capture register and the appropriate interrupt status flag is set. You can generate an interrupt request when the transition is detected by writing to its corresponding enable field in Interrupt (IR). You can program the capture to occur on the input signal's rising edge, falling edge, on both the rising and falling edges, or you can disable the capture. The events are synchronized with the clock you selected to run the counter. Only those transitions that occur at least one clock cycle after the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in the latching of the input transition.

NOTE

The Input Capture registers can be read at any time without affecting their values.

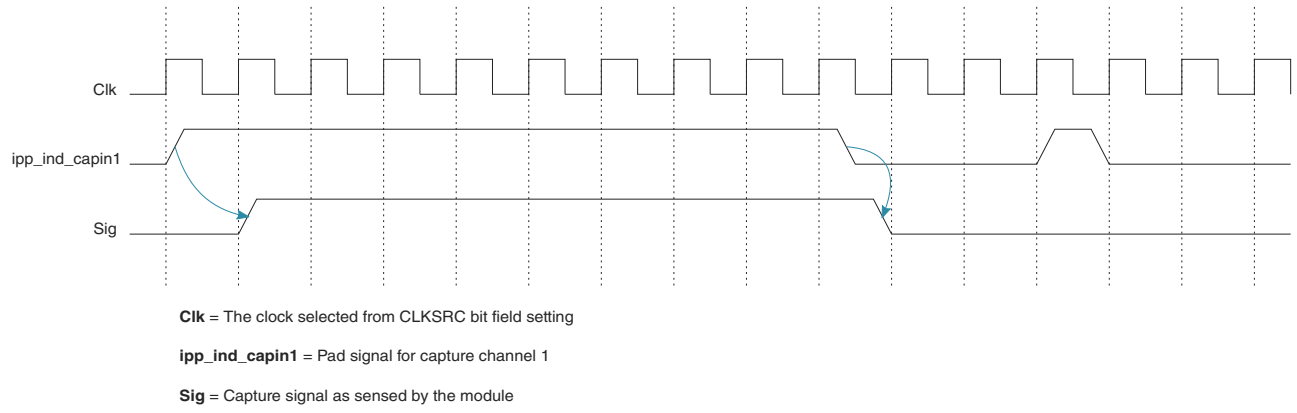

Figure 520. Input capture event timing

68.3.2.2 Output compare

The three Output Compare Channels use the same counter (GPT_CNT) as the Input Capture Channels. When the programmed content of an Output Compare (OCR1 - OCR3) register matches the value in GPT_CNT, an output compare status flag is set. An interrupt is also generated, if the corresponding field is 1 in Interrupt (IR). Consequently, the Output Compare signal either sets, clears, toggles, is not affected at all, or provides an active-low pulse for one input clock period, according to the CR[OM*n*] field setting.

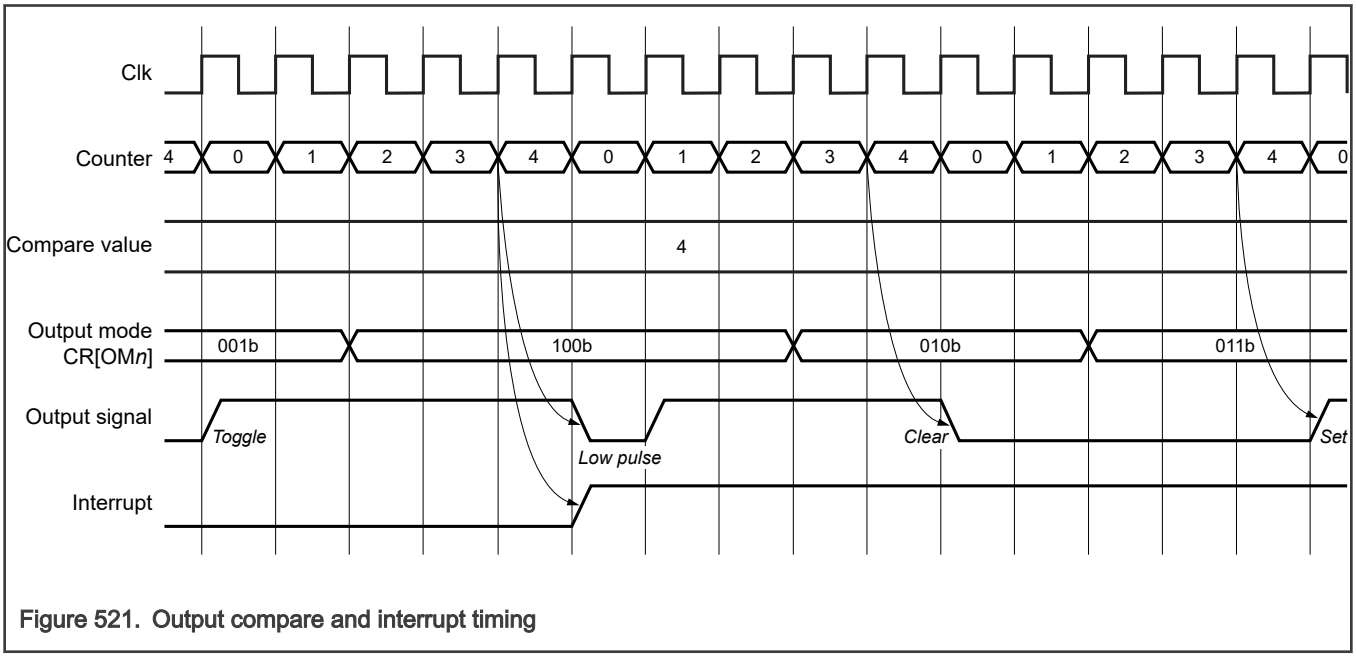

Figure 521. Output compare and interrupt timing

There is also a forced-compare feature that allows you to generate a compare event when needed, without requiring the counter value to be equal to the compare value. The action taken as a result of a forced compare is the same as when an output compare match occurs, except that the status flags are not set and no interrupt is generated. Forced channels take programmed action immediately after you write to the force-compare fields. These fields are self-negating and always read as zeroes.

68.3.2.3 Low Power mode behavior

If the clock from the selected clock source is available in low-power modes, the counter continues to run depending on how you program the control field for that mode. You can only use the external clock (GPT_CLK) as the clock source if the peripheral clock (MODULE_CLK) is available. If the clock is not present or if the corresponding low-power field in Control (CR) is 0, the Main Counter and the Prescaler Counter freeze at their current values and resume counting (from their frozen values) when the chip exits Low Power mode.

68.3.2.4 Debug mode behavior

In Debug mode, the modules in the chip can either continue to run or halt. Use CR[DBGEN] to enable or disable the GPT timer in Debug mode.

68.3.3 Clocking

You can select the clock input to the prescaler from multiple clock sources, as shown in Figure 522. See the Clock Controller Module (CCM) for the chip-specific GPT clock source connection, configuration, and gating information.

NOTE

All clocking options may not be supported.

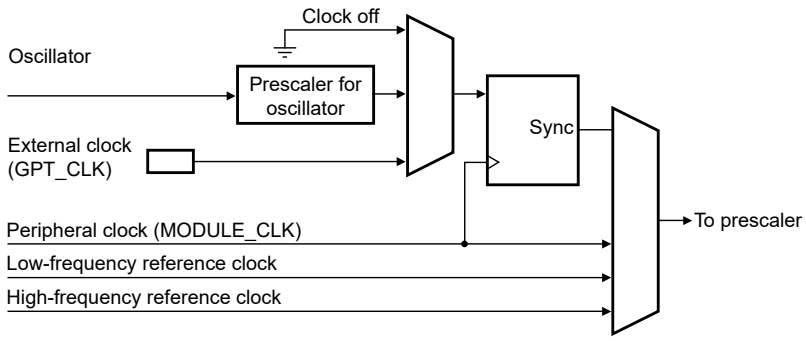

Figure 522. GPT counter clocks diagram

Table 1058 describes the clock sources for GPT.

Table 1058. GPT clocks

Clock name	Description
Peripheral clock (MODULE_CLK)	This is the internal clock used to access the module registers. If you select the peripheral clock or external clock (GPT_CLK) as the clock source (by writing 001 or 011 to CR[CLKSRC]), then the peripheral clock will be on in normal GPT operations. If you program GPT to be disabled in low-power modes (when STOPEN, WAITEN, or DOZEN equals zero), then the peripheral clock can be switched off.
Low-frequency reference clock (ipg_clk_32k)	This low-frequency, 32 kHz reference clock (provided by CCM) is intended to be on in Low Power mode when the peripheral clock is turned off. This enables GPT to operate in Low Power mode using the low-frequency reference clock.
High-frequency reference clock (ipg_clk_highfreq)	This high-frequency reference clock (provided by CCM) is intended to be on in Normal Power mode when the peripheral clock is turned off. This enables GPT to operate in Normal Power mode using the high-frequency reference clock.

Table continues on the next page...

Table 1058. GPT clocks (continued)

Clock name	Description
Oscillator clock (ipg_clk_24M)	This 24-MHz oscillator reference clock is intended to be used against frequency changes of the peripheral clock and to provide a more accurate timer clock for system operation. The 24 MHz oscillator clock is provided without synchronization to the system bus clock (ahb_clk) in Normal functional mode. Synchronization is done in GPT. Before synchronization, the 24 MHz oscillator clock is divided by a dedicated prescaler to ensure the clock frequency is less than half of the system bus clock.
External clock (GPT_CLK)	The external clock comes from outside the chip and can be selected to run the GPT counter. The external clock frequency is limited to less than 1/4 frequency of the peripheral clock (MODULE_CLK) for proper GPT operations. **NOTE** If the peripheral clock is not available in low-power modes, then you cannot use the external clock to run the counter.

Use CR[CLKSRC] to configure the clock input source. You can disable the clock input to the prescaler by writing 000 to the CLKSRC field. Only change the CLKSRC field value after disabling GPT (using the CR[EN] field).

Use the PR[PRESCALER] field to select the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value from 1 to 4096 and can be changed at any time. Changing the value of the PR[PRESCALER] field immediately affects the output clock frequency.

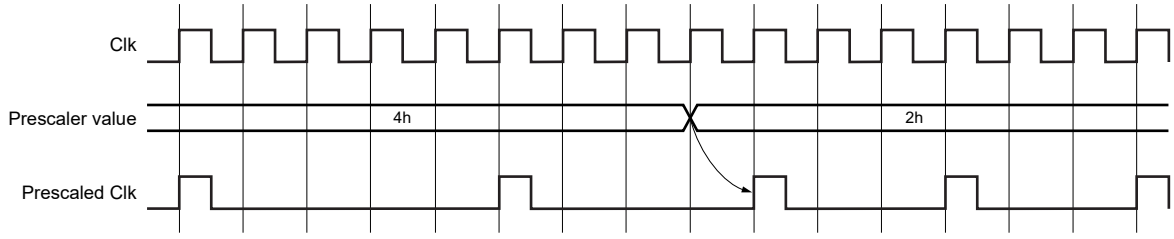

Figure 523. Prescaler value change timing diagram

68.3.4 Interrupts

GPT generates six different interrupts. If the selected clock for running the counter is available, then GPT can generate all interrupts in Low Power and Debug modes.

Table 1059. Interrupts

Interrupt	Description
Rollover Interrupt	GPT generates the Rollover Interrupt when the GPT counter reaches FFFF_FFFFh, then resets to 0000_0000h and continues counting. Use IR[ROVIE] to enable the Rollover Interrupt. SR[ROV] indicates the rollover status.
Input Capture Interrupt 1, 2	After a capture event occurs, the associated Input Capture Channel generates an interrupt. Use the IF2IE and IF1IE fields of the Interrupt (IR) to enable the capture-event interrupts. The IF2 and IF1 fields of the Status (SR) indicate their statuses.

Table continues on the next page...

Table 1059. Interrupts (continued)

Interrupt	Description
	A pending capture interrupt does not affect the counter value captured because of a capture event. The Control (CR) is updated with a new counter value when a capture event occurs, regardless of whether the interrupt of that capture channel has been serviced or not.
Output Compare Interrupt 1, 2, 3	After a compare event occurs, the associated Output Compare Channel generates an interrupt. Use OF3IE, OF2IE, and OF1IE fields of the Interrupt (IR) to enable compare-event interrupts. The OF3, OF2, and OF1 fields of the Status (SR) indicate their statuses. A forced compare does not generate an interrupt.

NOTE

A cumulative interrupt line is also present. It asserts whenever any of the above interrupts post. The cumulative interrupt line has no associated enable or status bits.

68.4 External signals

GPT follows the IP Bus protocol for interfacing with the processor core. The only interface signals GPT has with other modules inside the chip are the clock and reset inputs (from the clock and reset controller module) and the interrupt signals to the processor interrupt handler. There are also functional and clock inputs and functional output signals going outside the chip boundary.

Table 1060 describes all block signals that connect off-chip. See the IOMUX Controller for GPT pin mux assignments.

Table 1060. Off-chip module signals

Name	Direction	Function	Reset state	Pullup
GPT_CLK	I	Input for an external clock that the counter can be operated at.	–	Passive hysteresis
CAPTURE1	I	Input for a capture event for Input Capture Channel 1.	–	Passive
CAPTURE2	I	Input for a capture event for Input Capture Channel 2.	–	Passive
COMPARE1	O	Output that indicates a compare event occurrence in Output Compare Channel 1.	0	Passive
COMPARE2	O	Output that indicates a compare event occurrence in Output Compare Channel 2.	0	Passive
COMPARE3	O	Output that indicates a compare event occurrence in Output Compare Channel 3.	0	Passive

68.4.1 External clock input

You can operate the GPT counter using an external clock from outside the chip. The external clock input (GPT_CLK) is the input used for that purpose.

The external clock input is treated as asynchronous to the peripheral clock (MODULE_CLK). To ensure proper GPT operations, the external clock input frequency must be less than 1/4 of the frequency of the peripheral clock. Because GPT_CLK is a clock input, hysteresis characteristics on this pad are required.

68.4.2 Input capture trigger signals

The GPT counter value can be stored in a register, triggered by an event from outside the chip. A positive or negative edge on the CAPTURE*n* signals can trigger this capture event. These signals are treated as asynchronous to the peripheral clock (MODULE_CLK). Only those transitions which occur at least a single clock cycle (for the clock you select to run the counter) after the previous recorded transition are guaranteed to trigger a capture event.

68.4.3 Output compare signals

The COMPARE*n* signals indicate that an output compare event has occurred on the corresponding Output Compare Channel *n*. See Output compare for more information.

68.5 Initialization and application information

68.5.1 Selecting the clock source

To select the clock source, use the clock source field in the Control Register (CR[CLKSRC]). Only change the clock source field after disabling GPT, using CR[EN].

Use this sequence to change the clock source:

1. Write 0 to CR[EN] to disable GPT.
2. Clear Interrupt (IR) to disable GPT interrupts.
3. Write 0 to CR[OM*n*] to disable the Output mode for all channels.
4. Write 0 to CR[IM*n*] to disable the input capture modes.
5. Change the clock source (CR[CLKSRC]) to the desired value.
6. Write 1 to CR[SWR] to assert a GPT software reset.
7. Clear the flags in the Status (SR) register.
8. Write 1 to CR[ENMOD] to reset the GPT counter to zero.
9. Write 1 to CR[EN] to enable GPT.
10. Write 1 to the desired interrupt enable fields in Interrupt (IR) to enable GPT interrupts.

68.6 Memory map and register definitions

68.6.1 GPT register descriptions

GPT has 10 user-accessible, 32-bit registers used to configure, operate, and monitor the GPT module.

Writing to the GPT Status Registers (read-only registers ICR1, ICR2, and CNT) generates a bus exception.

68.6.1.1 GPT memory map

GPT1 base address: 446C_0000h

GPT2 base address: 42EC_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (CR)	32	RW	0000_0000h
4h	Prescaler (PR)	32	RW	0000_0000h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
8h	Status (SR)	32	RW	0000_0000h
Ch	Interrupt (IR)	32	RW	0000_0000h
10h - 18h	Output Compare (OCR1 - OCR3)	32	RW	FFFF_FFFFh
1Ch - 20h	Input Capture (ICR1 - ICR2)	32	R	0000_0000h
24h	Counter (CNT)	32	R	0000_0000h

68.6.1.2 Control (CR)

Offset

Register	Offset
CR	0h

Function

Contains configuration options for GPT operations, such as selecting the clock source for the counter and selecting the output response for a channel when a compare event occurs. The GPT Control Register also includes the control bit used to trigger a software reset (CR[SWR]).

NOTE

Writing 1 to SWR resets all of the GPT registers to their default reset values, except for the EN, ENMOD, STOPEN, DOZEEN, WAITEN, and DBGEN fields in this register.

For applications where precise timing is critical, note that writes to CR take effect after one cycle of the GPT register bus clock (1 wait state of latency). Reads to the register occur immediately (0 wait states).

Fields

Field	Function
31-29 FOn	Force Output Compare for Channel n Forces the Output Compare *n* signal to respond according to the action programmed in the OM*n* field (in this register). This field is self-clearing and always reads as zero. **NOTE** The OF*n* flag in the Status register (SR) is not set. 0b - No effect 1b - Trigger the programmed response on the output signal
28-26: OM3 25-23: OM2 22-20: OM1	Output Compare Operating Mode for Channel n Selects the response on the output signal when a compare event occurs. 000b - Output disabled. No response on the signal. 001b - Toggle output 010b - Clear output 011b - Set output 1xxb - Generate a low pulse that is one input clock cycle wide on the output signal. When OMn is first programmed as 1xx, the output is set to one immediately on the next input clock (if it was not already). The input clock here refers to the clock selected by the CLKSRC field of this register.
19-18: IM2 17-16: IM1	Input Capture Operating Mode for Channel n Selects which input transition triggers a capture event. 00b - Capture disabled 01b - Capture on rising edge only 10b - Capture on falling edge only 11b - Capture on both edges
15 SWR	Software Reset Resets all of the registers to their default reset values, except for the DOZEEN, EN, ENMOD, STOPEN, WAITEN, and DBGEN fields in the GPT Control register. The SWR field remains set while the module is resetting. It automatically clears when the reset procedure finishes. 0b - GPT is not in software reset state 1b - GPT is in software reset state
14-11 —	Reserved Write zeros to these reserved bits. These bits always read as zero.
10 EN_24M	Enable Oscillator Clock Input Enables the 24-MHz clock input from an oscillator.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
9 FRR	Free-Run or Restart Mode Selects the behavior of GPT when a compare event in channel 1 occurs. 0b - Restart mode. After a compare event, the counter resets to 0000_0000h and resumes counting. 1b - Free-Run mode. After a compare event, the counter continues counting until FFFF_FFFFh and then rolls over to 0.
8-6 CLKSRC	Clock Source Select Selects which clock goes to the prescaler and then runs the GPT counter. **NOTE** Only change the CLKSRC field value after disabling GPT (EN=0). For other programming requirements when changing the clock source, see Selecting the clock source. 000b - No clock 001b - Peripheral clock (MODULE_CLK) 010b - High-frequency reference clock (ipg_clk_highfreq) 011b - External clock 100b - Low-frequency reference clock (ipg_clk_32k)
5 STOPEN	GPT Stop Mode Enable Enables GPT operation during Stop mode. 0b - Disable in Stop mode 1b - Enable in Stop mode
4 DOZEEN	GPT Doze Mode Enable Enables GPT operation during Doze mode. 0b - Disable in Doze mode 1b - Enable in Doze mode
3 WAITEN	GPT Wait Mode Enable Enables GPT operation during Wait mode. 0b - Disable in Wait mode 1b - Enable in Wait mode
2 DBGEN	GPT Debug Mode Enable Enables GPT operation during Debug mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable in Debug mode 1b - Enable in Debug mode
1 ENMOD	GPT Enable Mode When GPT is disabled (EN=0), both the Main and Prescaler counters freeze their current count values. The ENMOD field selects the value of the Main Counter and Prescaler Counter when GPT is enabled again (EN=1). If you program GPT to be disabled in low-power modes (STOP or WAIT), the Main Counter and Prescaler Counter freeze at their current count values when the GPT enters Low Power mode. When GPT exits Low Power mode, the Main Counter and Prescaler Counter start counting from their frozen values, regardless of the ENMOD value. A software reset (SWR=1) clears the Main Counter and Prescaler Counter values, regardless of the value of the EN or ENMOD fields. 0b - Restart counting from frozen values after GPT is enabled (EN=1). 1b - Reset counting from 0 after GPT is enabled (EN=1).
0 EN	GPT Enable Enables the GPT module. **NOTE** Program all registers before writing 1 to the EN field. 0b - Disable 1b - Enable

68.6.1.3 Prescaler (PR)

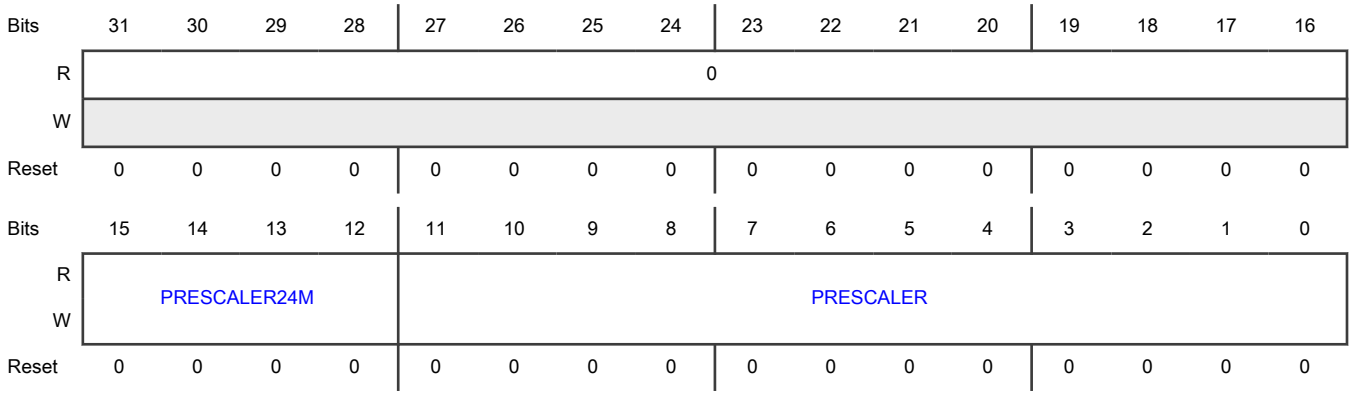
Offset

Register	Offset
PR	4h

Function

Contains the divide value of the clock that runs the counter.

Diagram



Fields

Field	Function
31-16 —	Reserved Write zero to this field. These bits always read as zero.
15-12 PRESCALER24M	Prescaler Divide Value for the Oscillator Clock The 24-MHz oscillator clock is divided by [PRESCALER24M + 1] before it is selected by the CLKSRC field. If the 24-MHz oscillator clock is not selected, this field does not take effect. 0000b - Divide by 1 0001b - Divide by 2 1111b - Divide by 16
11-0 PRESCALER	Prescaler Divide Value The clock selected by the CLKSRC field is divided by [PRESCALER + 1], and then used to run the counter. **NOTE** Changing the value of PRESCALER causes the Prescaler counter to reset and a new count period to start immediately. See Clocking for an example timing diagram. 0000_0000_0000b - Divide by 1 0000_0000_0001b - Divide by 2 1111_1111_1111b - Divide by 4096

68.6.1.4 Status (SR)

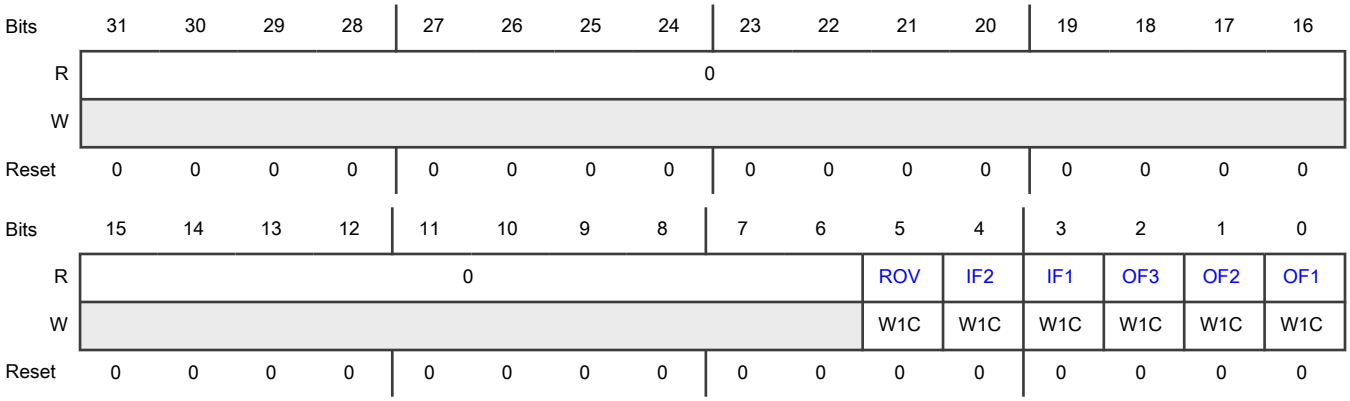
Offset

Register	Offset
SR	8h

Function

Contains flags to indicate that a counter has rolled over and if any event has occurred on the Input Capture and Output Compare channels. Write 1 to clear the flags.

Diagram



Fields

Field	Function
31-6 —	Reserved Write zero to this field. These bits always read as zero.
5 ROV	Rollover Flag Indicates that the counter has reached its maximum possible value and rolled over to 0 (from which the counter continues counting). ROV is set only when the counter has reached FFFF_FFFFh in both Restart and Free-Run modes. 0b - Rollover has not occurred. 1b - Rollover has occurred.
4-3 IFn	Input Capture Flag for Channel n Indicates that a capture event has occurred on Input Capture channel *n*. 0b - Capture event has not occurred. 1b - Capture event has occurred.
2-0 OFn	Output Compare Flag for Channel n Indicates that a compare event has occurred on Output Compare channel *n*. 0b - Compare event has not occurred. 1b - Compare event has occurred.

68.6.1.5 Interrupt (IR)

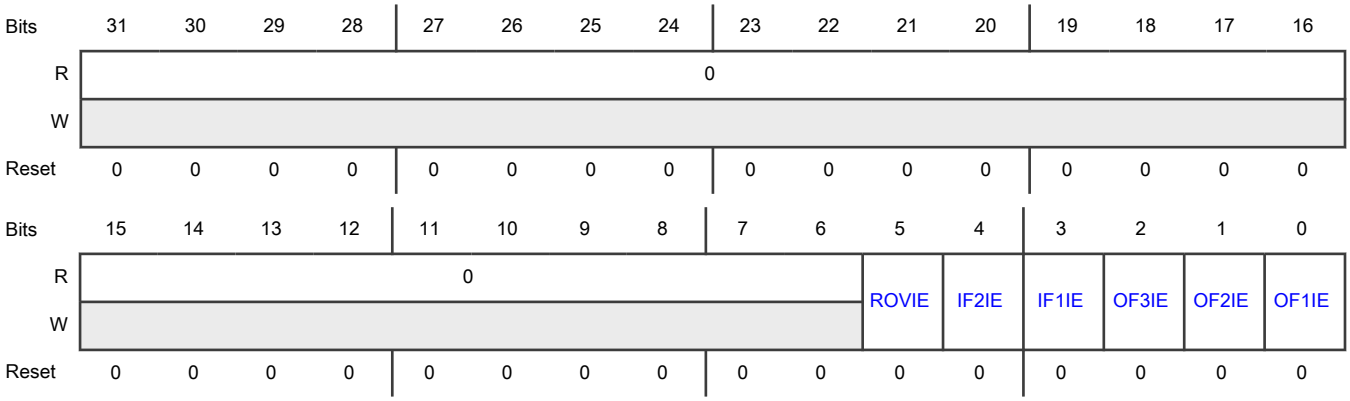
Offset

Register	Offset
IR	Ch

Function

Contains enable bits that control whether interrupts are generated after rollover, input capture, and output compare events.

Diagram



Fields

Field	Function
31-6 —	Reserved Writing a value to this field does not affect GPT operations. These reserved bits always read as zero.
5 ROVIE	Rollover Interrupt Enable Enables the Rollover interrupt. 0b - Disable 1b - Enable
4-3 IFnIE	Input Capture Flag for Channel n Interrupt Enable Enables the Input Capture Flag for Channel *n* interrupt. 0b - Disable 1b - Enable
2-0 OFnIE	Output Compare Flag for Channel n Interrupt Enable Enables the Output Compare Flag for Channel *n* interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable

68.6.1.6 Output Compare (OCR1 - OCR3)

Offset

Register	Offset
OCR1	10h
OCR2	14h
OCR3	18h

Function

Holds the value that determines when a compare event is generated on the corresponding Output Compare Channel *n*.

NOTE

The behavior of OCR1 is different from OCR2 and OCR3:

- A write access to OCR1 while in Restart mode (CR[FRR]=0) resets the GPT counter.
- Writes to OCR1 take effect after one cycle of the module's register bus clock (1 wait state of latency). Reads to the register occur immediately (0 wait states).

Diagram

69.2 LPTMR clocks

The prescaler and glitch filter of the LPTMR module (the module functional clock) can be clocked from one of four sources determined by LPTMRn_PSR[PCS]. The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes. The following table shows the clock assignments for this field.

Table 1062. LPTMR1*n* prescaler/glitch filter clocking options

LPTMR*n*_PSR[PCS]	Prescaler/glitch filter clock number	Chip clock
00	0	ipg_clk_irclk: The frequency depends on configuration of lptmr1_clk_root.
01	1	ipg_clk_1kHz: Tied to the fixed 32 kHz clock
10	2	ipg_clk_32kHz: It is fixed at 32 kHz.
11	3	ipg_clk_erclk: Tied to the fixed 32 kHz clock.

69.3 Overview

You can configure LPTMR to operate as a time counter with an optional prescaler, or as a pulse counter with an optional glitch filter, across all power modes, including low-power modes. It is reset only on Power on Reset (POR) or Low Voltage Detect (LVD), allowing it to be used as a time-of-day counter.

69.3.1 Block diagram

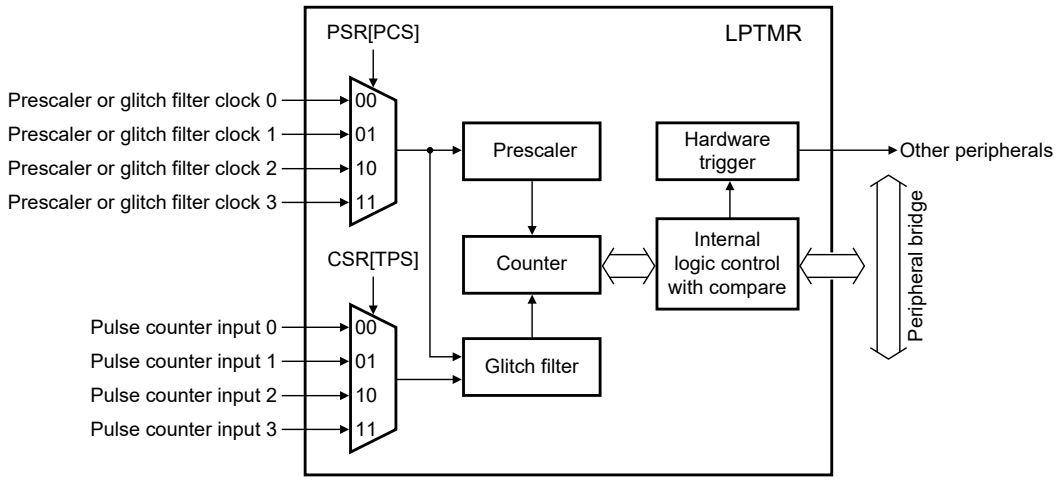

Figure 524. Block diagram

69.3.2 Features

- 32-bit time counter or pulse counter with compare:
  - Optional interrupt that can generate an asynchronous wake-up from any low-power mode
  - Hardware trigger output
  - Counter that supports a free-running mode or reset on compare
- Configurable clock source for prescaler and glitch filter
- Configurable input source for pulse counter (rising-edge or falling-edge)

69.4 Functional description

69.4.1 Low-power modes

In low-power modes, LPTMR continues to operate normally. You can configure LPTMR to exit a low-power mode by generating either an interrupt or a DMA request.

69.4.2 Clocks

The LPTMR prescaler and glitch filter can be clocked by one of the clocks that you configure by using PSR[PCS]. You must enable the clock source before you enable LPTMR.

In Pulse Counter mode, with the glitch filter bypassed, the selected input source directly clocks Counter (CNR), and no other clock source is required. To minimize power in this case, configure the glitch filter clock source for a clock that is disabled.

NOTE

- You may need to configure the clock source that you select in PSR[PCS] for it to remain enabled in low-power modes. Otherwise, LPTMR does not operate in low-power modes.
- The clock source or pulse input source selected for LPTMR must not exceed the maximum frequency of f_{LPTMR} defined in the chip data sheet.

69.4.3 Reset

LPTMR is reset only on Power on Reset (POR) or Low Voltage Detect (LVD). When configuring LPTMR registers, you must initially write to Control Status (CSR) with LPTMR disabled, before configuring Prescaler and Glitch Filter (PSR) and Compare (CMR). Then, you must write 1 to CSR[TEN] as the last step in the initialization. Doing so ensures that LPTMR is configured correctly and the LPTMR counter is reset to zero following a Power on Reset (POR) or Low Voltage Detect (LVD).

69.4.4 Prescaler and glitch filter

The LPTMR prescaler and glitch filter share the same logic, which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

NOTE

You must not alter the prescaler and glitch filter configuration when LPTMR is enabled.

69.4.4.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks Counter (CNR). When LPTMR is enabled, CNR increments every 2^1 to 2^{16} prescaler clock cycles. After LPTMR is enabled, the first increment of CNR takes an additional one or two prescaler clock cycles because of the synchronization logic.

69.4.4.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments Counter (CNR) on every clock cycle. When LPTMR is enabled, the first increment takes an additional one or two prescaler clock cycles because of the synchronization logic.

69.4.4.3 Glitch filter enabled

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks Counter (CNR). When LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

Table 1063. Glitch filter output with the selected input source

If	Then
The selected input source remains deasserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output also deasserts.
The selected input source remains asserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output also asserts.

NOTE

The input is sampled only on the rising clock edge.

The value of CNR increments each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which CNR can increment is once every 2^2 to 2^{16} glitch filter clock edges. When first enabled, the glitch filter waits for an additional one or two glitch filter clock edges because of the synchronization logic.

69.4.4.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the value of Counter (CNR) every time it asserts. Before LPTMR is first enabled, the selected input source is forced to be asserted. This prevents CNR from incrementing if the selected input source is already asserted when LPTMR is first enabled.

69.4.5 Counter

The value of Counter (CNR) increments by 1 on every:

- Prescaler clock in Time Counter mode, with prescaler bypassed.
- Prescaler output in Time Counter mode, with prescaler enabled.
- Input source assertion in Pulse Counter mode, with glitch filter bypassed.
- Glitch filter output in Pulse Counter mode, with glitch filter enabled.

CNR is reset when LPTMR is disabled or if the counter register overflows. If CSR[TFC] = 0, then CNR is also reset whenever CSR[TCF] = 1.

When the core is halted in Debug mode:

- CNR continues incrementing if configured for Pulse Counter mode.
- CNR stops incrementing if configured for Time Counter mode.

You cannot initialize CNR but can read it at any time. On each read of CNR, you must first write a value to it. This synchronizes and registers the current value of CNR into a temporary register. The contents of the temporary register are returned on each read of CNR.

When reading CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing; otherwise, incorrect data may be returned.

69.4.6 Compare

After the next Counter (CNR) increment (when its value is equal to that of Compare (CMR)), the following events occur:

- CSR[TCF] is read as 1b.
- LPTMR generates an interrupt if CSR[TIE] is 1 as well.
- LPTMR generates a hardware trigger.
- LPTMR writes 0 to CNR if CSR[TFC] is 0.

When LPTMR is enabled, you can modify the value of CMR only when CSR[TCF] is 1. When updating CMR, you must write to it and clear CSR[TCF] before the LPTMR counter increments past the new LPTMR compare value.

NOTE

When LPTMR is enabled in Time Counter mode, the first increment takes an additional one or two clock cycles because of the synchronization logic. This results in the first compare (and therefore interrupt and hardware trigger) occurring slightly later. A faster prescaler clock or larger prescaler value minimizes this impact.

69.4.7 Interrupt

LPTMR generates an interrupt whenever CSR[TIE] and CSR[TCF] are 1. CSR[TCF] is cleared by disabling LPTMR or writing a logic 1 to it.

You can modify the value of CSR[TIE] and write 1 to CSR[TCF] when LPTMR is enabled.

LPTMR generates an interrupt asynchronously to the system clock. The interrupt can be used to generate a wake-up from any low-power mode, provided LPTMR is enabled as a wake-up source.

69.4.8 Hardware trigger

The LPTMR hardware trigger asserts at the same time CSR[TCF] is set and can be used to trigger hardware events in other peripherals without your intervention. The hardware trigger is always enabled.

Table 1064. Hardware trigger

When	Then
CMR[COMPARE] and CSR[TFC] are 0	The LPTMR hardware trigger asserts on the first compare and does not deassert.
CMR[COMPARE] is set to a nonzero value, or if CSR[TFC] = 1	The LPTMR hardware trigger asserts on each compare and deasserts on the following increment of Counter (CNR).

69.5 External signals

Table 1065. External signals

Signal	Description		Direction
LPTMR_ALT*n*	Pulse Counter Input LPTMR can select one of the input pins to be used in Pulse Counter mode.		Input
	State meaning	Assertion—If configured for Pulse Counter mode with an active-high input, assertion causes Counter (CNR) to increment. Deassertion—If configured for Pulse Counter mode with an active-low input, deassertion causes CNR to increment.	
	Timing	Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.	

69.6 Initialization

Perform the following procedure to initialize LPTMR:

1. Configure Control Status (CSR) for the selected mode and pin configuration, when CSR[TEN] is 0. This resets the counter and clears the flag.
2. Configure Prescaler and Glitch Filter (PSR) with the selected clock source and prescaler or glitch filter configuration.
3. Configure Compare (CMR) with the selected compare point.
4. Write 1 to CSR[TEN] to enable LPTMR.

69.7 Application information

69.7.1 Application 1: Generate an interrupt every 100 ms using 32.768 kHz clock source

1. Disable LPTMR by writing 0 to CSR[TEN].
2. Select a 32.768 kHz clock source by configuring PSR[PCS].
3. Bypass the prescaler and glitch filter by writing 1 to PSR[PBYP].
4. Assert an interrupt every 3277 cycles by configuring CMR[COMPARE] = 0CCCh.
5. Enable LPTMR by writing 1 to CSR[TEN].
6. Enable the LPTMR interrupt by writing 1 to CSR[TIE].

NOTE

This is just an example. See the chip-specific SPC information for the clocks supported on a given chip.

69.7.2 Application 2: Generate an interrupt once a minute using 32.768 kHz clock source

1. Disable LPTMR by writing 0 to CSR[TEN].
2. Select a 32.768 kHz clock source by configuring PSR[PCS].
3. Select the prescaler to divide the prescaler clock by 32768 to increment the counter once a second by configuring PSR[PRESCALE] = 00h.
4. Assert an interrupt every 60 seconds by configuring CMR[COMPARE] = 003Bh.
5. Enable LPTMR by writing 1 to CSR[TEN].
6. Enable the LPTMR interrupt by writing 1 to CSR[TIE].

NOTE

This is just an example. See the chip-specific SPC information for the clocks supported on a given chip.

69.8 Memory map and register definition

NOTE

The LPTMR registers are reset only on Power on Reset (POR) or Low Voltage Detect (LVD). See Reset for more information.

70.2 Overview

TPM is a 4-channel timer that controls electric motor and power management applications by supporting:

- Input capture
- Output comparison
- Generation of PWM signals

An asynchronous clock that can remain enabled in low-power modes clocks the counter, compare, and capture registers.

70.2.1 Block diagram

TPM uses one input/output (I/O) pin per channel: CH*n* (TPM channel *n*) where *n* is the channel number.

The central component of TPM is a 32-bit counter with a programmable final value. Its counting can be up or up-down.

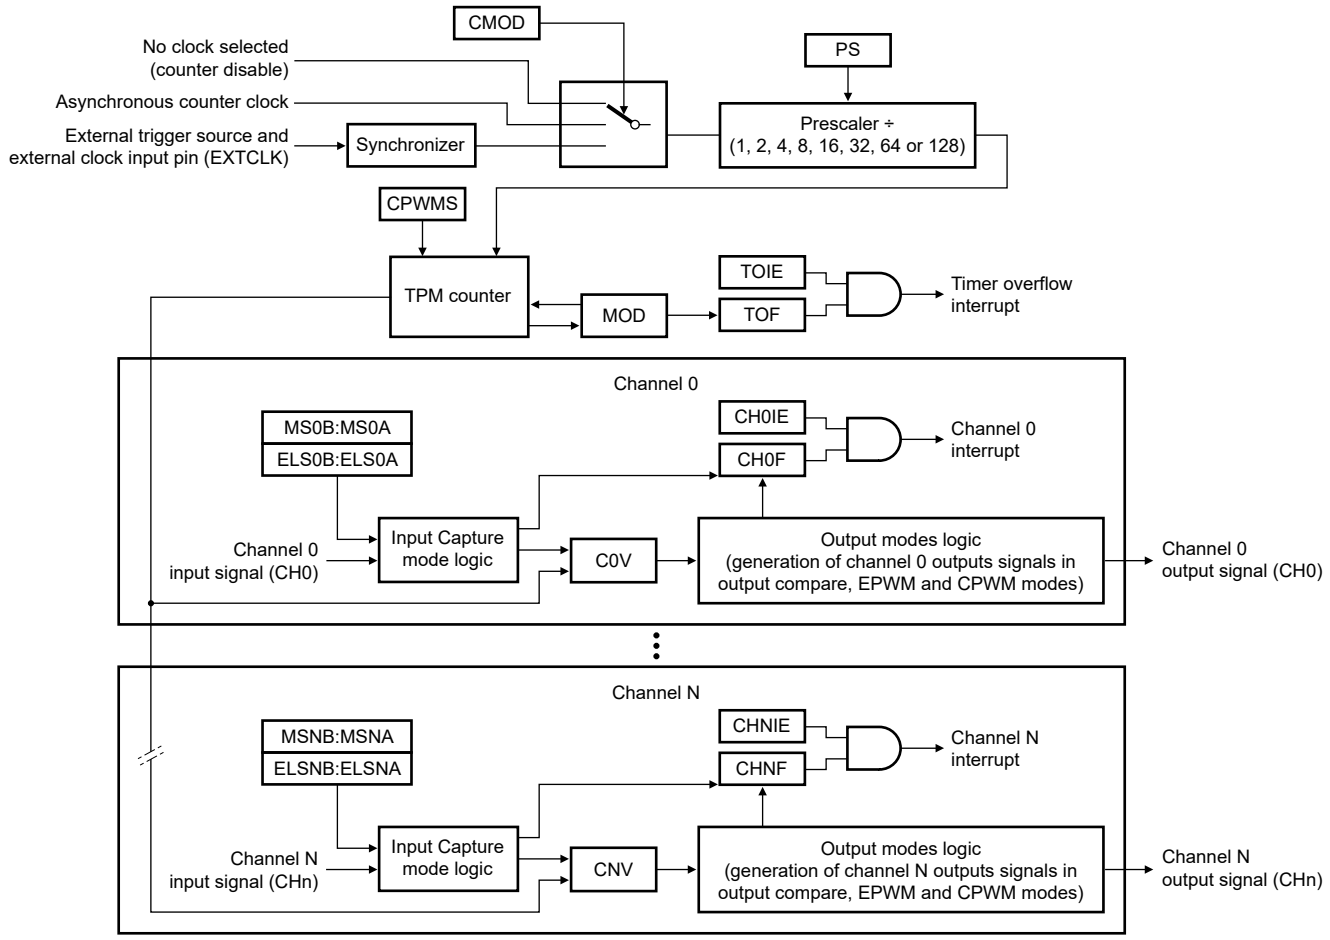

Figure 525. Block diagram

70.2.2 Features

- Supports selectable clock modes:
  - Can increment on every edge of the asynchronous counter clock
  - Can increment on the rising edge of an external clock input that is synchronized to the asynchronous counter clock
- Includes a prescaler divided by 1, 2, 4, 8, 16, 32, 64, or 128
- Includes a 32-bit TPM counter:
  - Can be a free-running counter or a modulo counter
  - The counting can be up or up-down
- Includes 4 channels that can be configured as follows:
  - Input Capture mode: the capture can occur on rising edges, falling edges, or both edges.
  - Output Compare mode: the output signal can be set, cleared, pulsed, or toggled on the match.
  - Edge-Aligned or Center-Aligned PWM mode for all channels.
- Supports the generation of an interrupt and DMA request per channel
- Supports the generation of an interrupt and DMA request when the counter overflows

- Supports selectable trigger input to either reset the counter to 0 or else cause the counter to start incrementing
  - The counter can also optionally stop incrementing on counter overflow.
- Supports the generation of hardware triggers when the counter overflows and per channel

70.3 Functional description

70.3.1 Counter

TPM has a 32-bit counter that the channels use for either input or output modes. The counter updates from the selected clock after it has been divided by the prescaler. The TPM counter has these modes of operation:

- Up counting
- Up-down counting

70.3.1.1 Counter Clock mode

SC[CMOD] either disables the TPM counter or enables one of the three possible clock sources for the TPM counter. After any reset, SC[CMOD] becomes 0, which disables the TPM counter. You can configure SC[CMOD] for one of the following counter clock sources:

- Asynchronous counter clock
- External clock input pin
- External trigger source

You can read or write to SC[CMOD] at any time. Disabling the TPM counter by writing 0 to SC[CMOD] does not affect the TPM counter value or other registers, but the TPM counter clock domain must acknowledge this disabling action before SC[CMOD] becomes 0.

The external clock input and external trigger source pass through a synchronizer. The TPM counter clock clocks this synchronizer to ensure that counter transitions are properly aligned to counter clock transitions. Therefore, to meet Nyquist criteria, and also considering jitter, the frequency of the external clock source must be less than half of the counter clock frequency.

70.3.1.2 Prescaler

The counter clock source that you select passes through a prescaler that is a 7-bit counter. SC[PS] defines the value of the prescaler. The following figure shows an example of the prescaler counter and TPM counter.

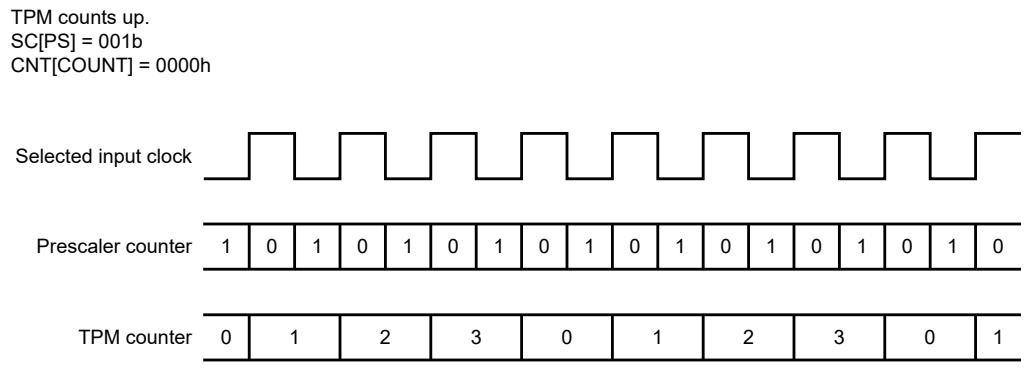

Figure 526. Example of the prescaler counter

70.3.1.3 Up counting

Up counting is enabled when you write 0 to SC[CPWMS].

In this mode, the TPM counter loads with value 0 and increments until it reaches the value defined in MOD[MOD], then the counter reloads with 0.

The TPM period when using up counting is (MOD[MOD] + 0001h) × period of the TPM counter clock.

SC[TOF] becomes 1 when the TPM counter changes from the value defined in MOD[MOD] to 0.

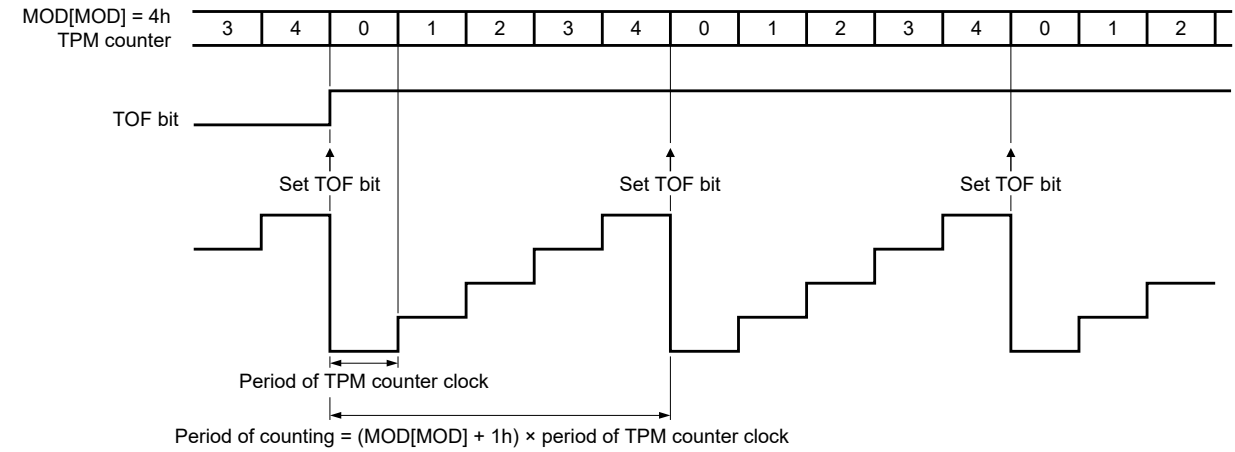

Figure 527. Example of TPM up counting

NOTE

- Configuring MOD[MOD] = 0 is a redundant condition. In this case, the TPM counter is always equal to the value of MOD[MOD], and SC[TOF] remains 1 for each rising edge of the TPM counter clock.
- Configuring MOD[MOD] = 1 and SC[PS] = 0 causes TPM to attempt to set SC[TOF] every second TPM counter clock. Because of synchronization delays between the TPM counter clock and the bus clock, you must write 1 to SC[TOF] to clear it two counter clock cycles before SC[TOF] can become 1 again.

70.3.1.4 Up-down counting

You enable up-down counting when you write 1 to SC[CPWMS]. This mode does not support configuring the value of Modulo (MOD) to be less than 2.

In this mode, the TPM counter loads with value 0 and increments until it reaches the value defined in MOD[MOD]. Then the counter starts decrementing until it returns to 0 and the up-down counting restarts.

The TPM period when using up-down counting is 2 × MOD[MOD] × period of the TPM counter clock.

TPM writes 1 to SC[TOF] when the TPM counter changes from the value defined in MOD[MOD] to (MOD[MOD] – 1).

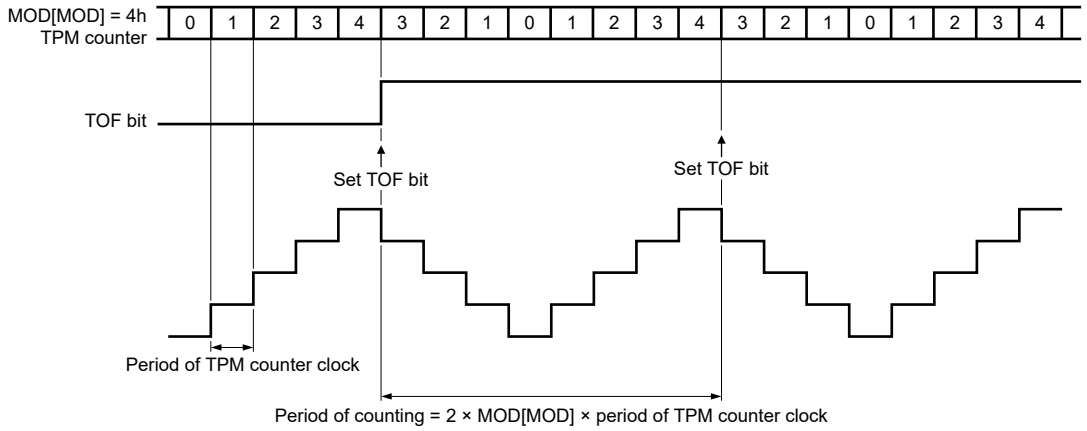

Figure 528. Example of up-down counting

70.3.1.5 Counter reset

Any write to CNT[COUNT] resets the TPM counter and forces the channel outputs to their initial values (except for channels in Output Compare mode).

70.3.1.6 Counter trigger

You can configure the TPM counter to start, stop, or reset in response to a hardware trigger input. The trigger input synchronizes with the asynchronous counter clock, so there is a three-counter-clock delay between the trigger assertion and counter response.

- When CONF[CSOT] = 1, the counter does not start incrementing until the trigger input detects a rising edge.
- When CONF[CSOO] = 1, the counter stops incrementing whenever SC[TOF] = 1. The counter does not increment again unless:
  - It is disabled.
  - CONF[CSOT] = 1 and the trigger input detects a rising edge.
- When CONF[CROT] = 1, the counter resets to 0, as if an overflow occurred, whenever the trigger input detects a rising edge. Any PWM channels are updated to their reload state.
- When CONF[CPOT] = 1, the counter pauses incrementing whenever you assert the trigger input. The counter continues incrementing when the trigger input negates. PWM output channels are forced to their default state.

You can configure the polarity of the external input trigger with CONF[TRGPOL].

When you enable an internal trigger source, the trigger input is selected from one or more channel input capture events. The input capture filters are used with the internal trigger sources. You can use POL[POL*n*] fields to invert the polarity of the input channels.

The following restrictions apply with input capture channel sources:

- When CONF[CSOT] = 1, the counter starts incrementing only on a rising edge on the channel input, if C*n*SC[ELS*n*A] = 1.
- When CONF[CROT] = 1, the counter resets to 0 on either edge of the channel input, as you configure it using C*n*SC[ELS*n*B] and C*n*SC[ELS*n*A].
- When CONF[CPOT] = 1, the counter pauses incrementing whenever you assert the channel input. PWM output channels are forced to their default state.

70.3.2 Registers updated from write buffers

70.3.2.1 MOD register update

If SC[CMOD] = 0, then Modulo (MOD) updates whenever you write to MOD[MOD].

If SC[CMOD] ≠ 0, then the MOD register updates according to SC[CPWMS]:

- If CPWM mode is disabled (SC[CPWMS] = 0), then the MOD register updates whenever you write to MOD[MOD], and the TPM counter value changes from the value defined in MOD[MOD] to 0.
- If CPWM mode is enabled (SC[CPWMS] = 1), then the MOD register updates whenever you write to MOD[MOD], and the TPM counter value changes from the value defined in MOD[MOD] to (MOD[MOD] – 1).

70.3.2.2 C*n*V register update

If SC[CMOD] = 0, then the C*n*V register updates whenever you write to C*n*V[VAL].

If SC[CMOD] ≠ 0, then the C*n*V register updates according to the selected mode:

- If you select Output Compare mode, then the C*n*V register updates on the next TPM counter increment (end of the prescaler counting) after you write to C*n*V[VAL].
- If you select EPWM mode, then the C*n*V register updates after you write to C*n*V[VAL], and the TPM counter value changes from the value defined in MOD[MOD] to 0.
- If you select CPWM mode, then the C*n*V register updates after you write to C*n*V[VAL], and the TPM counter value changes from the value defined in MOD[MOD] to (MOD[MOD] – 1).

70.3.3 Peripheral triggers

See the chip-specific TPM information for more details.

70.3.3.1 Output triggers

TPM generates output triggers for the counter and for each channel that you can use to trigger events in other peripherals. The counter trigger asserts whenever SC[TOF] is 1 and remains asserted until the next increment.

Each TPM channel generates both a pre-trigger output and a trigger output.

1. The pre-trigger output asserts whenever C*n*SC[CH*n*F] sets.
2. The trigger output asserts on the first counter increment after the pre-trigger asserts.
3. Both the trigger and pre-trigger negate on the first counter increment after the trigger asserts.

When (COMBINE[COMBINE*n*] = 1) in Output Compare mode, the pre-trigger output for both channel *n* and channel *n* + 1 asserts when the CH*n*F flag is set and negates when the CH(*n* + 1)F flag is set. The trigger continues to assert on the first counter increment, after the pre-trigger asserts and negates at the same time as the pre-trigger negation.

70.3.3.2 Input trigger

You can configure the TPM input trigger to perform the following operations with configurable polarity:

- Increment the counter on trigger rising edge
- Start incrementing the counter on trigger rising edge
- Reset or reload the counter on trigger rising edge
- Pause the counter while trigger high

The TPM input trigger is synchronized and must remain asserted for at least two counter clock cycles, so that the input trigger can be detected.

70.3.4 Modes of operations

70.3.4.1 Input Capture mode

Input Capture mode is enabled when:

- (SC[CPWMS] = 0)
- (MS*n*B:MS*n*A = 0:0)
- (ELS*n*B:ELS*n*A ≠ 0:0)

When a selected edge occurs on the channel input:

- The C*n*V register captures the current value of the TPM counter.
- It also writes 1 to C*n*SC[CH*n*F] and generates a channel interrupt if C*n*SC[CH*n*IE] = 1 (see Figure 529).

When you configure a channel for input capture, the CH*n* pin is an edge-sensitive input. ELS*n*B:ELS*n*A control fields determine which edge, falling or rising, triggers the input-capture event. To detect the input signal correctly and to meet Nyquist criteria for signal sampling, the maximum frequency for the channel input signal is the counter clock divided by 4.

Input Capture mode ignores any writes to the C*n*V register.

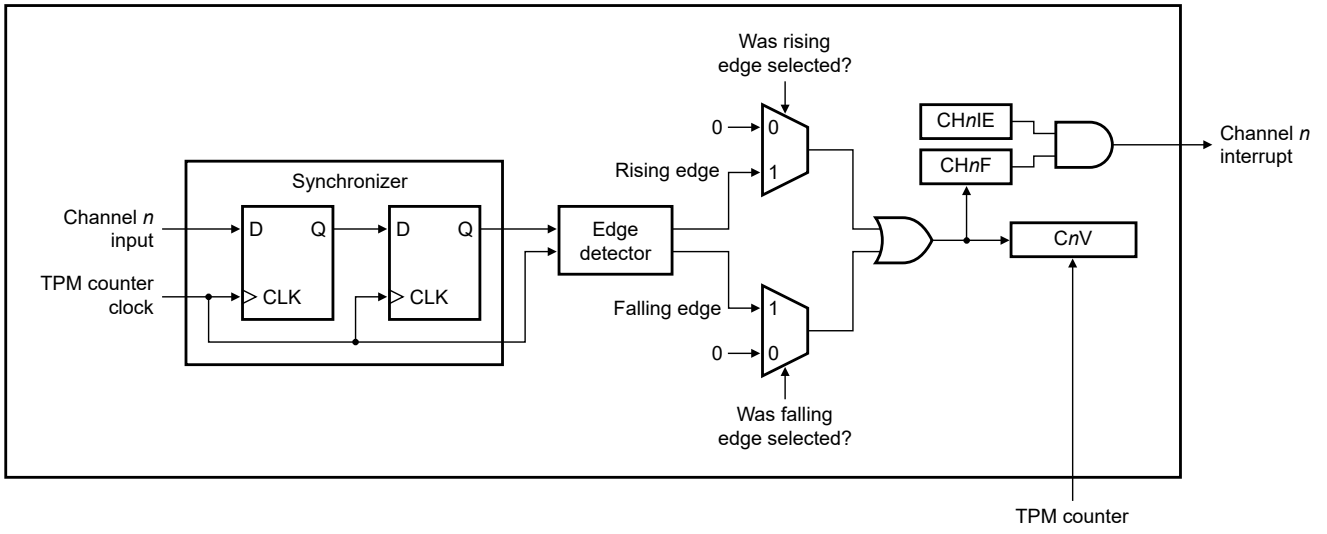

Figure 529. Input Capture mode

The CH*n*F flag is set on the third rising edge of the TPM counter clock after a valid edge occurs on the channel input.

70.3.4.1.1 Input capture filter

The input capture filter function is only available in Input Capture or Software Compare mode when Quadrature Decoder mode is enabled.

First, the TPM counter clock synchronizes the input signal. After synchronization, the input signal enters the filter block (see Figure 530).

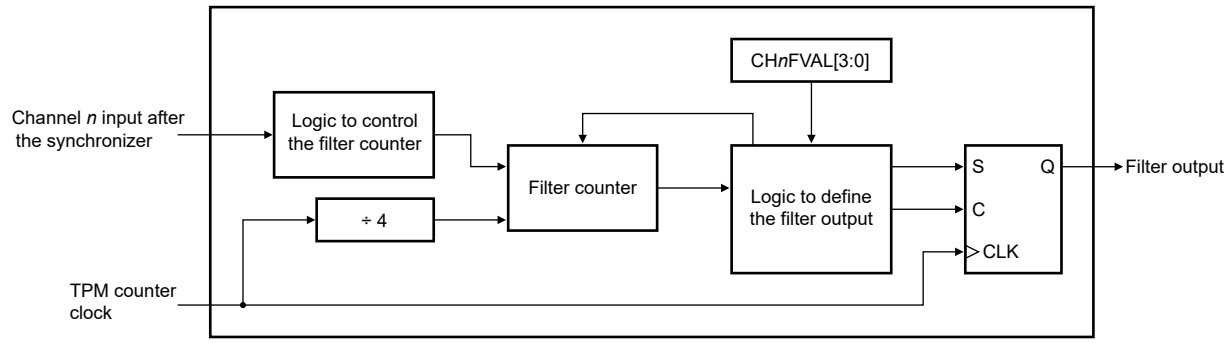

Figure 530. Channel input filter

When there is a state change in the input signal, TPM resets the counter, and it starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to (CH*n*FVAL[3:0] × 4), the state change of the input signal is validated.

TPM resets the counter if the opposite edge appears on the input signal before it is validated. At the next input transition, the counter starts counting again. Any pulse that is less than the minimum value selected by (CH*n*FVAL[3:0] × 4 counter clocks) is considered as a glitch and does not pass through the filter. Figure 531 shows a timing diagram of the input filter.

The filter function is disabled when CH*n*FVAL[3:0] = 0. In this case, the input signal is delayed by 2 rising edges of the counter clock. If CH*n*FVAL[3:0] ≠ 0000, then the input signal is delayed by the minimum pulse width (CH*n*FVAL[3:0] × 4 system clocks) plus a further 3 rising edges of the system clock: two rising edges to the synchronizer, plus one more to the edge detector. In other words, the CH*n*F flag is set for (3 + (4 × CH*n*FVAL[3:0])) counter clock periods after a valid edge occurs on the channel input (see Figure 531).

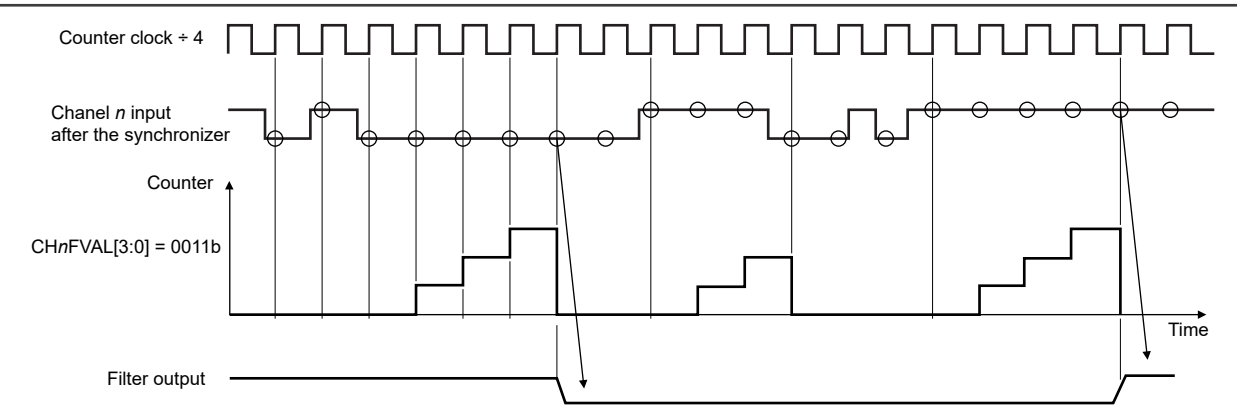

Figure 531. Channel input filter example

70.3.4.2 Output Compare mode

Output Compare mode is enabled when (SC[CPWMS] = 0) and (MS*n*B:MS*n*A = X:1).

In this mode, TPM can generate timed pulses with programmable:

- Position
- Polarity
- Duration
- Frequency

When the TPM counter matches the value defined in C*n*V[VAL] of an output compare channel, then channel *n* output can be set, cleared, or toggled if MS*n*B = 0. If MS*n*B = 1, then channel *n* output is pulsed high or low (as long as the TPM counter matches the value defined in C*n*V[VAL]).

When you initially configure a channel to Output Compare mode, the channel output is updated with its negated value (logic 0 for set/toggle/pulse high and logic 1 for clear/pulse low).

The channel *n* match (TPM counter = C*n*V[VAL]) writes 1 to C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1).

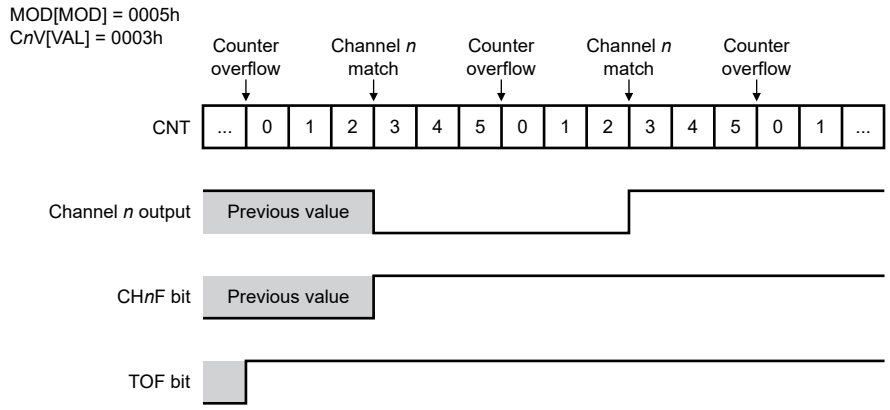

Figure 532. Example of Output Compare mode when a match toggles the channel output

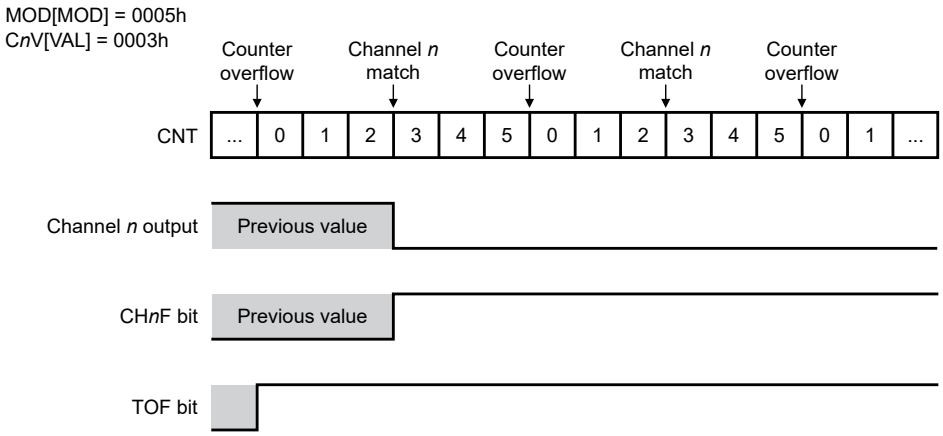

Figure 533. Example of Output Compare mode when a match clears the channel output

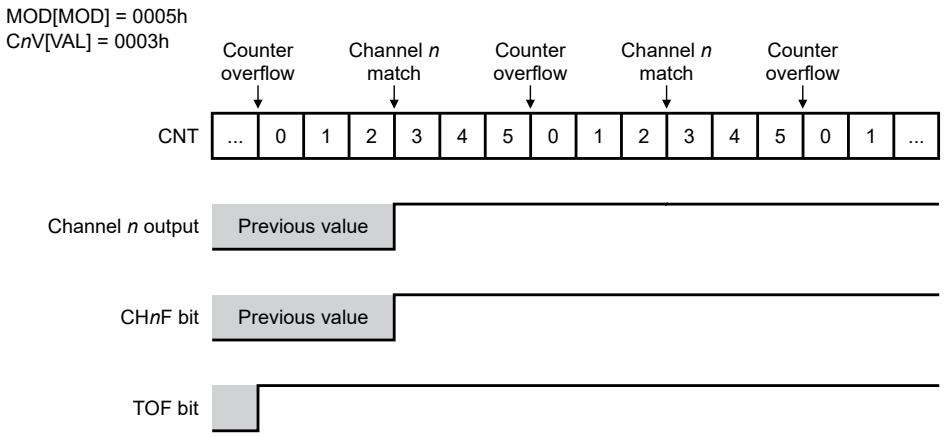

Figure 534. Example of Output Compare mode when a match sets the channel output

You can also use Output Compare mode with:

- (SC[CPWMS] = 0) and (MS*n*B:MS*n*A = 0:1)
- (SC[CPWMS] = 0) and (ELS*n*B:ELS*n*A = 0:0)

This condition is known as Software Compare mode. This mode sets the CH*n*F flag and generates a channel *n* interrupt (if CH*n*IE = 1) when the TPM counter reaches the value defined in the C*n*V register; however, TPM does not modify or control the channel *n* output.

70.3.4.3 Edge-Aligned PWM (EPWM) mode

EPWM mode is enabled when (SC[CPWMS] = 0) and (MS*n*B:MS*n*A = 1:0). The EPWM period is determined by (MOD[MOD] + 0001h) and the pulse width (duty cycle) is determined by C*n*V[VAL].

The channel *n* match (TPM counter = C*n*V[VAL]) writes 1 to C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1) at the end of the pulse width (see Figure 535).

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within TPM.

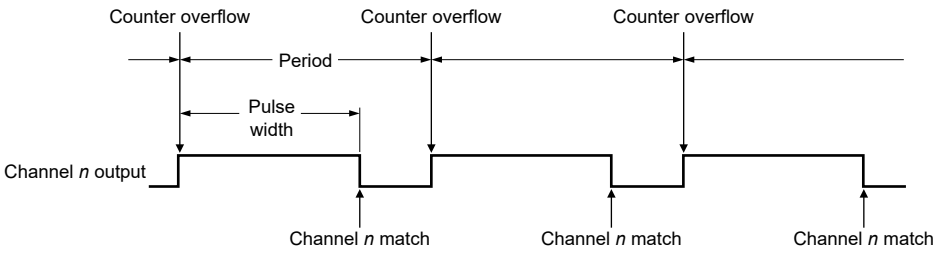

Figure 535. EPWM period and pulse width with ELS*n*B:ELS*n*A = 1:0

If (ELS*n*B:ELS*n*A = 1:0) then the channel *n* output is forced high at the counter overflow or reload (when the TPM counter loads with 0), and it is forced low at the channel *n* match (TPM counter = C*n*V[VAL]). The channel *n* output is forced high when you first enable or whenever you pause the TPM counter (see Figure 536).

If (ELS*n*B:ELS*n*A = 0:0) then the channel *n* output is forced high at the counter overflow or reload (when the TPM counter loads with 0), and it is forced low at the channel *n* match (TPM counter = C*n*V[VAL]). The channel *n* output is forced low when you first enable or whenever you pause the TPM counter.

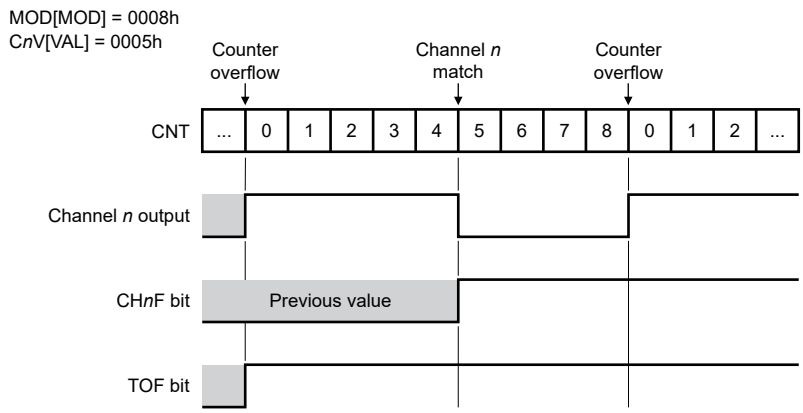

Figure 536. EPWM signal with ELS*n*B:ELS*n*A = 1:0

If (ELS*n*B:ELS*n*A = 0:1) then the channel *n* output is forced low at the counter overflow or reload (when the TPM counter loads with 0), and it is forced high at channel *n* match (TPM counter = C*n*V[VAL]). Channel *n* output is forced low when you first enable or whenever you pause the TPM counter (see Figure 537).

If (ELS*n*B:ELS*n*A = 1:1) then the channel *n* output is forced low at the counter overflow or reload (when the TPM counter loads with 0), and it is forced high at the channel *n* match (TPM counter = C*n*V[VAL]). Channel *n* output is forced high when you first enable or whenever you pause the TPM counter.

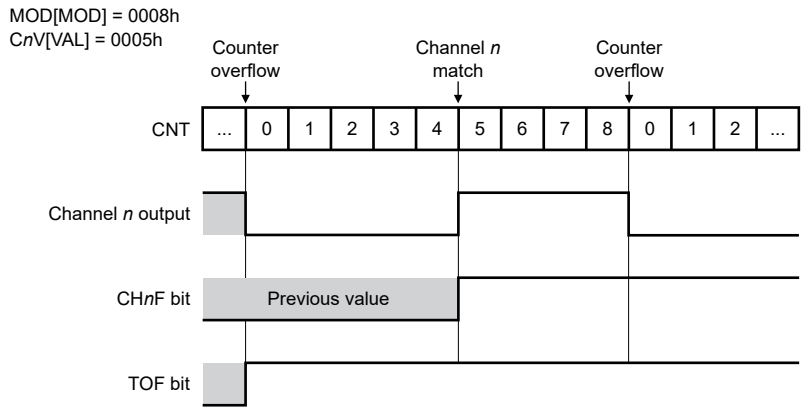

Figure 537. EPWM signal with ELS*n*B:ELS*n*A = 0:1

If (C*n*V[VAL] = 0000h) then the channel *n* output is a 0% duty cycle EPWM signal.

If (C*n*V[VAL] > MOD[MOD]), then the channel *n* output is a 100% duty cycle EPWM signal and the CH*n*F flag is not set because there is never a channel *n* match. Therefore, MOD[MOD] must be less than FFFFFFFFh to get a 100% duty cycle EPWM signal.

70.3.4.4 Center-Aligned PWM (CPWM) mode

CPWM mode is enabled when (SC[CPWMS] = 1) and (MS*n*B:MS*n*A = 1:0).

The CPWM pulse width (duty cycle) is determined by 2 × C*n*V[VAL] and the period is determined by 2 × MOD[MOD] (see Figure 538). You must keep MOD[MOD] in the range of 0001h to 7FFFFFFF because values outside this range can produce ambiguous results.

In CPWM mode, the TPM counter counts up until it reaches the value defined in MOD[MOD], and then counts down until it reaches 0.

The channel *n* match (TPM counter = C*n*V[VAL]) sets C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1) when TPM is counting down (at the begin of the pulse width), and when TPM is counting up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are at the same place when the TPM counter is 0.

The other channel modes are not designed to be used with the up-down counter when SC[CPWMS] = 1. Therefore, you must use all TPM channels in CPWM mode when SC[CPWMS] = 1.

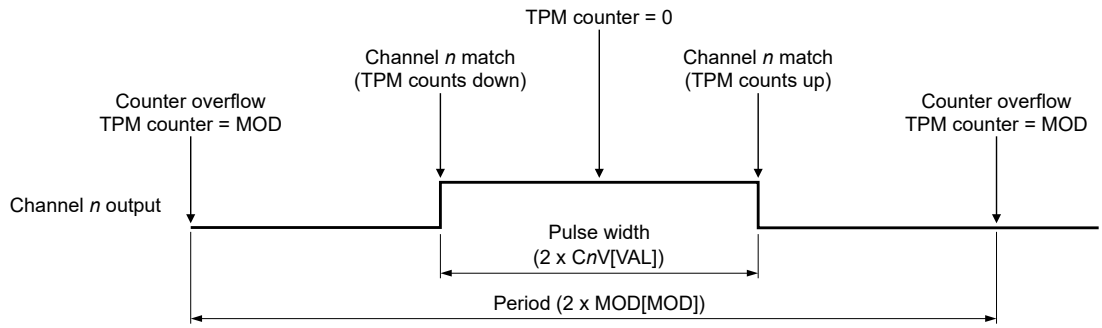

Figure 538. CPWM period and pulse width with ELS*n*B:ELS*n*A = 1:0

If (ELS*n*B:ELS*n*A = 1:0) then the channel *n* output is forced high at the channel *n* match (TPM counter = C*n*V) when counting down, and it is forced low at the channel *n* match when counting up. The channel *n* output is forced high when you first enable or reload the TPM counter, or whenever you pause it (see Figure 539).

If (ELS*n*B:ELS*n*A = 0:0) then the channel *n* output is forced high at the channel *n* match (TPM counter = C*n*V) when counting down, and it is forced low at the channel *n* match when counting up. The channel *n* output is forced low when you first enable or reload the TPM counter, or whenever you pause it.

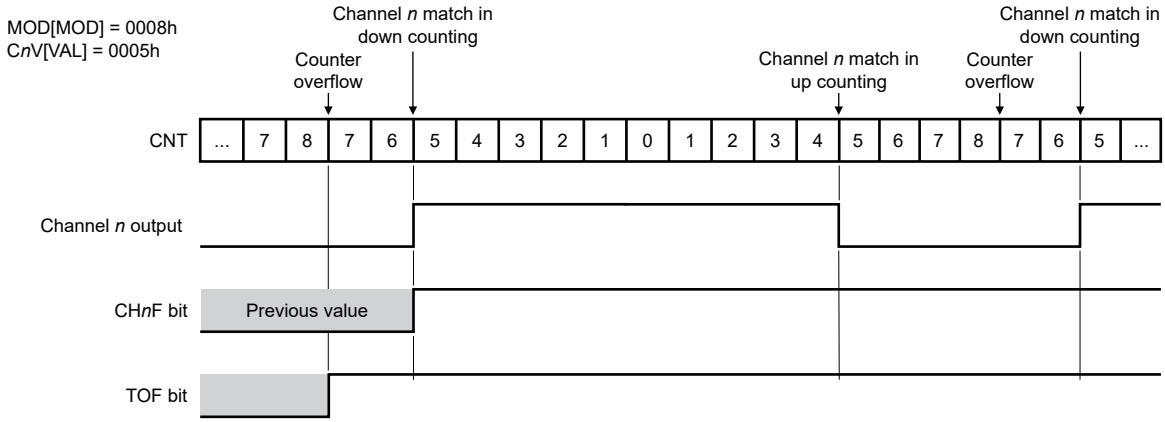

Figure 539. CPWM signal with ELS*n*B:ELS*n*A = 1:0

If (ELS*n*B:ELS*n*A = 0:1) then the channel *n* output is forced low at the channel *n* match (TPM counter = C*n*V) when counting down, and it is forced high at the channel *n* match when counting up. The channel *n* output is forced low when you first enable or reload the TPM counter, or whenever you pause it (see Figure 540).

If (ELS*n*B:ELS*n*A = 1:1) then the channel *n* output is forced low at the channel *n* match (TPM counter = C*n*V) when counting down, and it is forced high at the channel *n* match when counting up. The channel *n* output is forced high when you first enable or reload the TPM counter, or whenever you pause it.

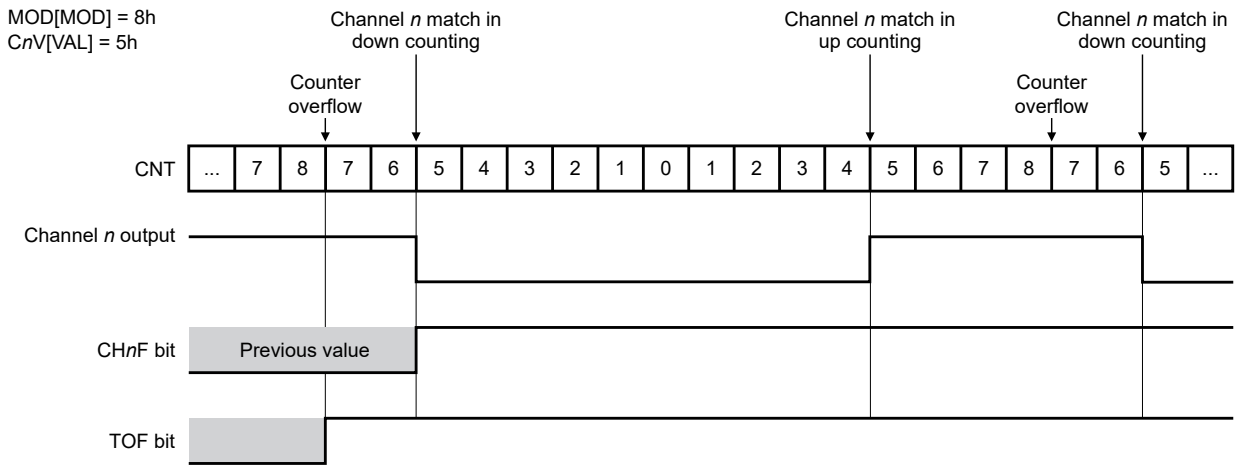

Figure 540. CPWM signal with ELS*n*B:ELS*n*A = 0:1

If (C*n*V[VAL] = 0000h) then the channel *n* output is a 0% duty cycle CPWM signal.

If (C*n*V[VAL] > MOD[MOD]) then the channel *n* output is a 100% duty cycle CPWM signal, although the CH*n*F flag is set when the counter changes from incrementing to decrementing. Therefore, MOD[MOD] must be less than 7FFFFFFF in order to get a 100% duty cycle CPWM signal.

70.3.4.5 Combine PWM mode

Combine PWM mode is enabled when:

- MS*n*B:MS*n*A = 1:0
- COMBINE[COMBINE*n*] = 1
- QDCTRL[QUADEN] = 0
- SC[CPWMS] = 0

In Combine PWM mode, an even channel *n* and adjacent odd channel *n* + 1 are combined to generate a PWM signal in the channel *n* output.

Determine the PWM period and pulse width according to Equation 34.

```
PWM period = MOD[MOD] + 0001h
PWM pulse width (duty cycle) = |C(n + 1)V[VAL] - CnV[VAL]|
```

Equation 34. PWM period and pulse width

- If (C*n*V[VAL] = C(*n* + 1)V[VAL] = 0000h), then the channel *n* output has a 0% duty cycle.
- If (C*n*V[VAL] = C(*n* + 1)V[VAL] > MOD[MOD]), then the channel *n* output has a 100% duty cycle. CH*n*F flag is not set because there is never a channel *n* match.

Therefore, MOD[MOD] must be less than FFFFh in order to get a 100% duty cycle signal.

The channel *n* match (TPM counter = C*n*V[VAL]) writes 1 to C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1). The channel *n* + 1 match (TPM counter = C(*n* + 1)V[VAL]), sets the CH(*n* + 1)F flag and generates a channel *n* + 1 interrupt, if CH(*n* + 1)IE = 1.

If channel *n* (ELS*n*B:ELS*n*A = 0:1), then the channel *n* output is forced low at the beginning of the period (TPM counter = 0) and at the channel *n* + 1 match (TPM counter = C(*n* + 1)V[VAL]). It is forced high at the channel *n* match (TPM counter = C*n*V[VAL]).

If channel *n* (ELS*n*B:ELS*n*A = 1:0), then the channel *n* output is forced high at the beginning of the period (TPM counter = 0) and at the channel *n* + 1 match (TPM counter = C(*n* + 1)V[VAL]). It is forced low at the channel *n* match (TPM counter = C*n*V). See Figure 541 for pictorial representation.

When COMBINE[COMSWAP*n*] = 1, then the channel *n* output is forced low or high at the beginning of the period (TPM counter = 0) and at the channel *n* match (TPM counter = C*n*V[VAL]). It is forced high or low at the channel *n* + 1 match (TPM counter = C(*n* + 1)V[VAL]).

Channel *n* + 1 generates the same output as the channel *n* output, but the channel *n* + 1 (ELS*n*B:ELS*n*A) configuration controls the output polarity.

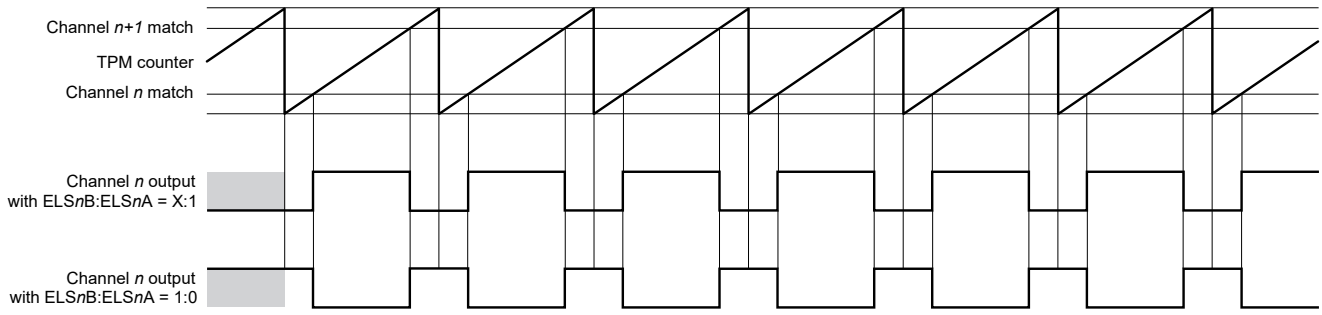

Figure 541. Combine mode

The following figures illustrate generation of PWM signals using the Combine mode.

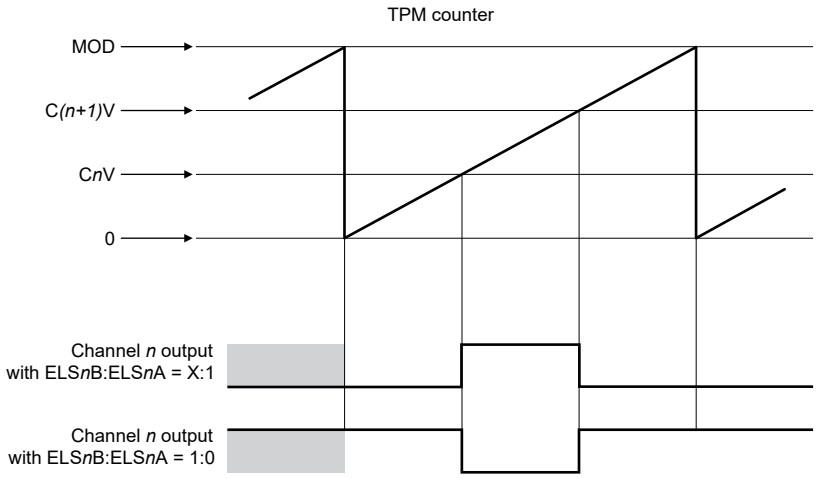

Figure 542. Channel *n* output if (C*n*V < MOD) and (C(*n* + 1)V < MOD) and (C*n*V < C(*n* + 1)V)

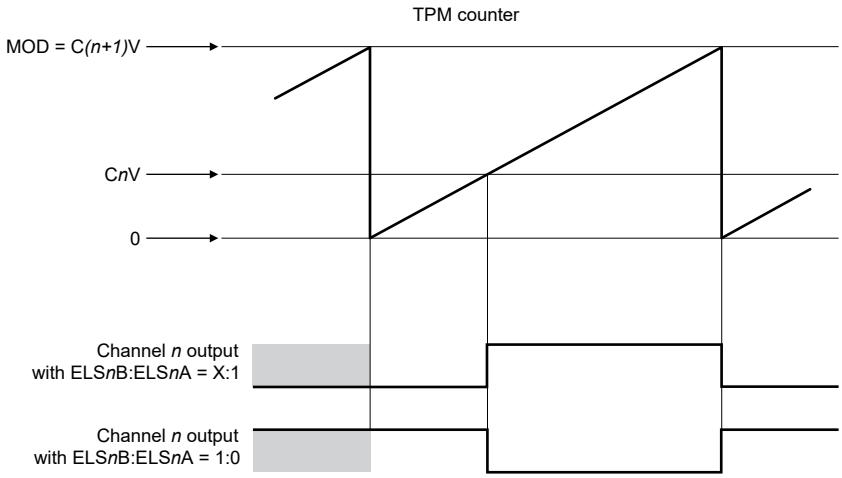

Figure 543. Channel *n* output if (C*n*V < MOD) and (C(*n* + 1)V = MOD)

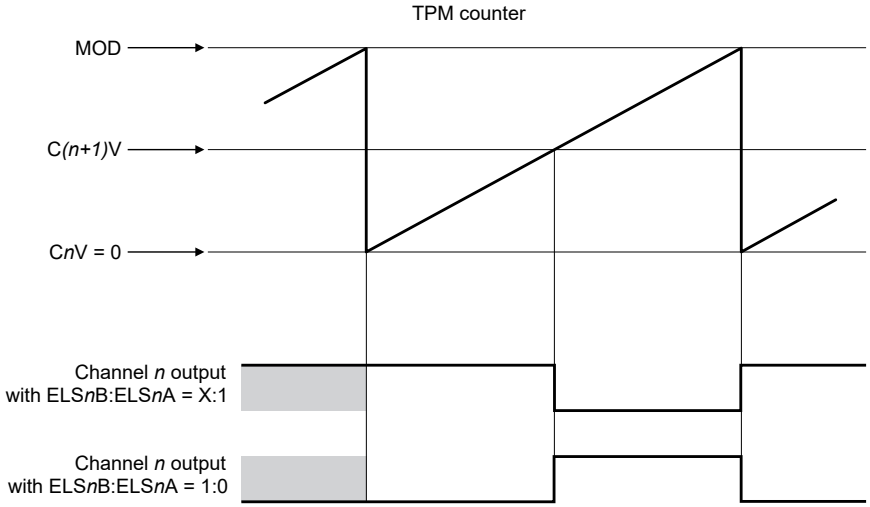

Figure 544. Channel *n* output if (C*n*V = 0) and (C(*n* + 1)V < MOD)

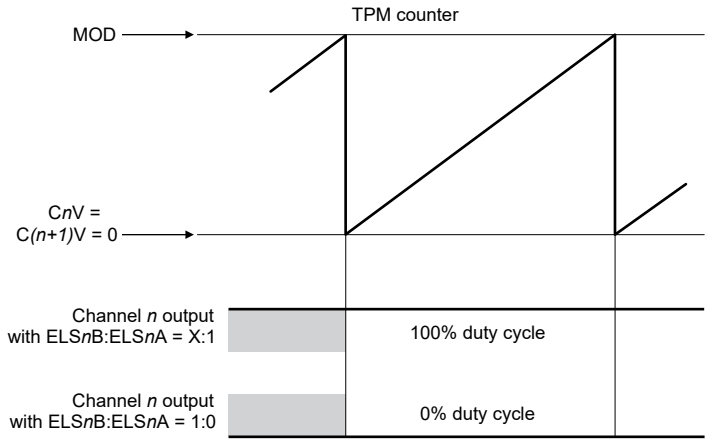

Figure 545. Channel (n) output if (C*n*V = C(*n* + 1)V = 0)

70.3.4.5.1 Dead time insertion

Dead time insertion is enabled in PWM Combine mode for each pair of channels when CH*n*FVAL and CH(*n* + 1)FVAL are non-zero. The dead time delay that is used for each TPM channel is defined as (CH(*n* + 1)FVAL[3:0] × 64) + (CH*n*FVAL[3:0] × 4).

The dead time delay insertion ensures that two complementary signals (even channel *n* and odd channel *n* + 1) do not drive the active state at the same time.

If ELS*n*B:ELS*n*A = 0:1, ELS(*n* + 1)B:ELS(*n* + 1)A = 1:0, COMBINE[COMSWAP*n*] = 0 and dead time is enabled, then:

- When a channel *n* match (TPM counter = C*n*V) occurs, the channel *n* output remains at the low value until the end of the dead time delay, when the channel *n* output is set.
- When a channel *n* + 1 match (TPM counter = C(*n* + 1)V) occurs, the channel *n* + 1 output remains at the low value until the end of the dead time delay, when the channel *n* + 1 output is set (see Figure 546).

If ELS*n*B:ELS*n*A = 1:0, ELS(*n*+1)B:ELS(*n*+1)A = 0:1, COMBINE[COMSWAP*n*] = 1, and dead time is enabled, then:

- When a channel *n* + 1 match (TPM counter = C(*n* + 1)V) occurs, the channel (*n* + 1) output remains at the low value until the end of the dead time delay, when channel *n* + 1 output is set.
- When a channel *n* match (TPM counter = C*n*V) occurs, the channel *n* output remains at the low value until the end of the dead time delay, when channel *n* output is set (see Figure 547).

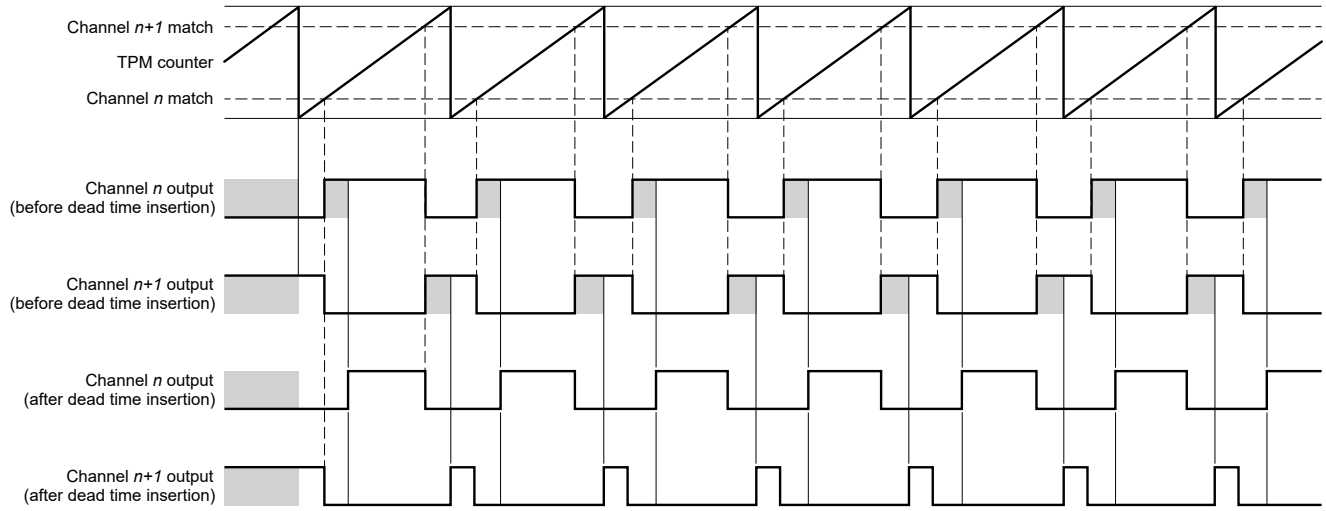

Figure 546. Dead time insertion with ELS*n*B:ELS*n*A = 0:1, ELS(*n* + 1)B:ELS(*n* + 1)A = 1:0, COMBINE[COMSWAP*n*] = 0

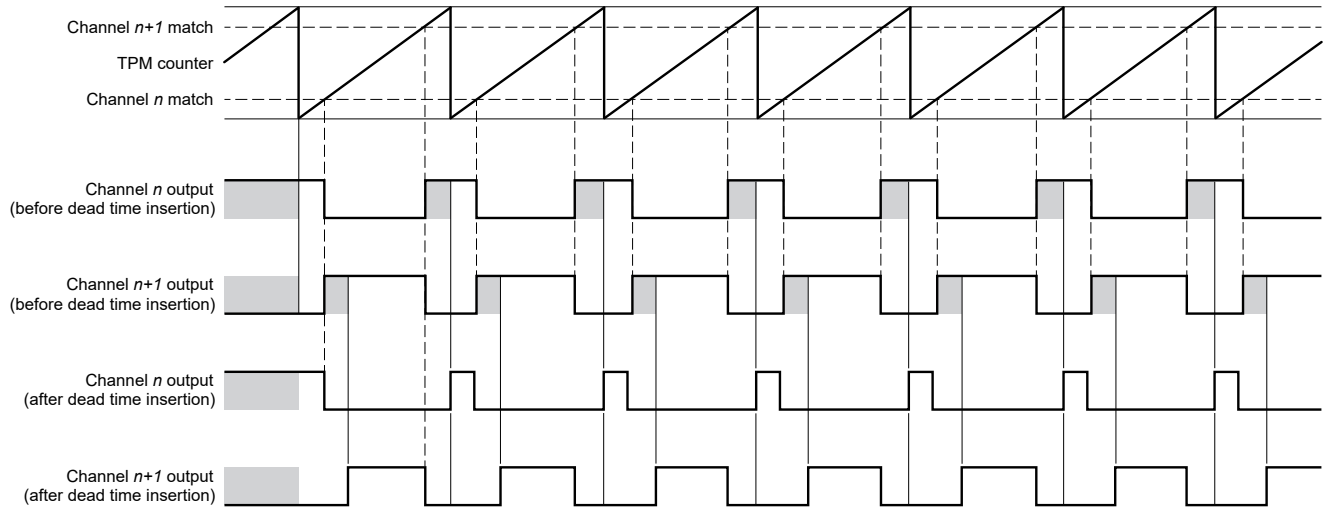

Figure 547. Dead time insertion with ELS*n*B:ELS*n*A = 1:0, ELS(*n* + 1)B:ELS(*n* + 1)A = 0:1, COMBINE[COMSWAP*n*] = 1

70.3.4.6 Combine Input Capture mode

Combine Input Capture mode is enabled if:

- (COMBINE[COMBINE*n*] = 1)
- (MS*n*B:MS*n*A = 0:0)
- (ELS*n*B:ELS*n*A ≠ 0:0)

This mode allows you to measure the pulse width of the signal at the input of channel *n* of a channel pair. The channel *n* filter can be active in this mode.

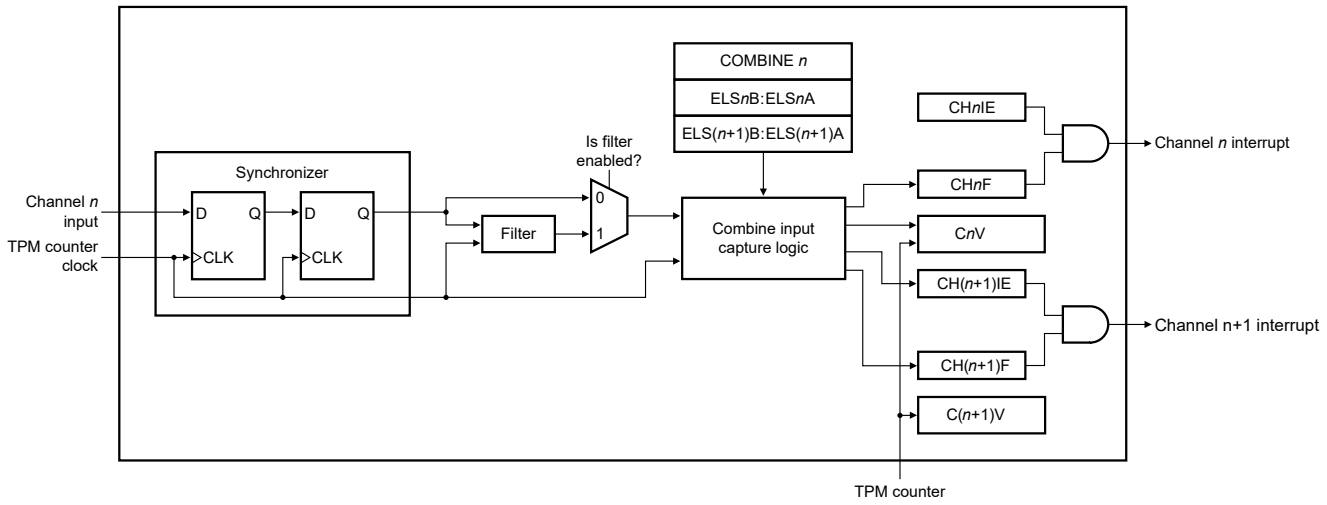

Figure 548. Block diagram

ELS*n*B:ELS*n*A fields select the edge that channel *n* captures. ELS(*n* + 1)B:ELS(*n* + 1)A fields select the edge that channel *n* + 1 captures.

This mode uses only the channel *n* input and ignores the channel *n* + 1 input. If COMBINE[COMSWAP*n*] = 1, then it uses only the channel *n* + 1 input and ignores the channel *n* input.

Detection of the edge selected by channel *n* fields at channel *n* input writes 1 to C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1). Detection of the edge selected by channel *n* + 1 fields at channel *n* input sets the CH(*n* + 1)F flag and generates the channel *n* + 1 interrupt (if CH(*n* + 1)IE = 1).

The C*n*V register stores the value of the TPM counter when the channel *n* input detects the edge selected by channel *n*. The C(*n* + 1)V register stores the value of the TPM counter when a channel *n* input detects the edge selected by channel *n* + 1.

NOTE

- Channel *n* fields are:
  - CH*n*F
  - CH*n*IE
  - MS*n*A
  - ELS*n*B
  - ELS*n*A
- Channel *n* + 1 fields are:
  - CH(*n* + 1)F
  - CH(*n* + 1)IE
  - MS(*n* + 1)A
  - ELS(*n* + 1)B
  - ELS(*n* + 1)A
- Use the Combine Input Capture mode with (ELS*n*B:ELS*n*A = 0:1 or 1:0) and (ELS(*n* + 1)B:ELS(*n* + 1)A = 0:1 or 1:0).

70.3.4.7 Quadrature Decoder mode

Quadrature Decoder mode is enabled if (QDCTRL[QUADEN] = 1). This mode uses channel 0 (phase A) and channel 1 (phase B) input signals to control the TPM counter increment and decrement (see Figure 549).

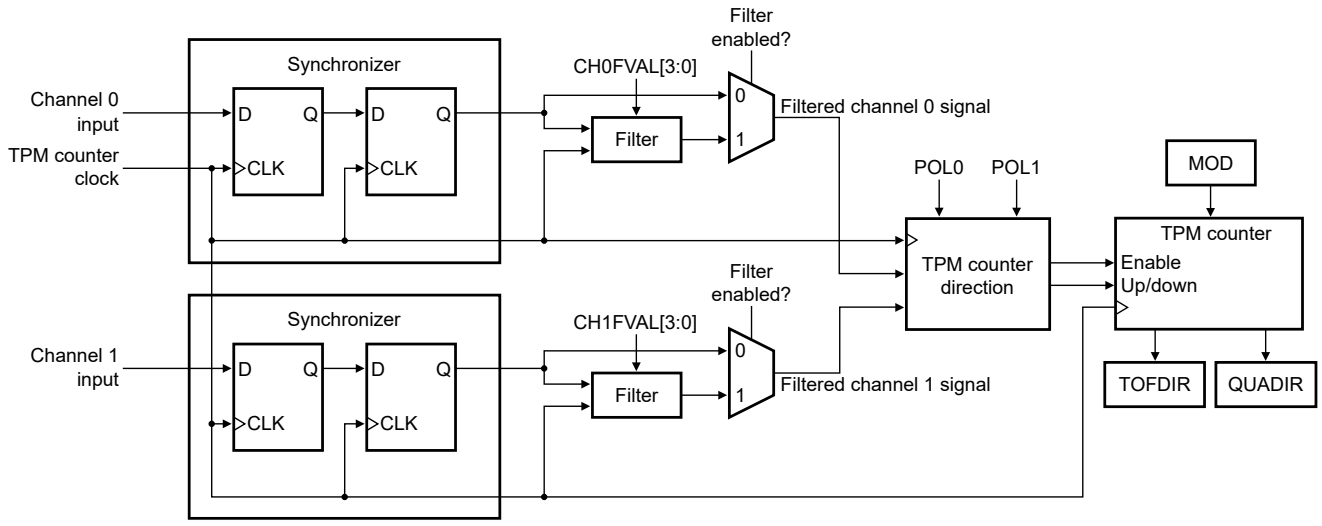

Figure 549. Block diagram

You can configure the input filter and polarity for channel 0 and channel 1 inputs in Quadrature Decode mode using Filter Control (FILTER) and Channel Polarity (POL).

NOTE

When Quadrature Decoder mode is enabled, then channel 0 and channel 1 input signals clock the TPM counter. Therefore, in this mode, you can only use Software Compare mode for channel 0 and channel 1, and you can only use Input Capture or Output Compare mode for other TPM channels.

QDCTRL[QUADMODE] defines the encoding mode that you use in Quadrature Decoder mode.

- If QDCTRL[QUADMODE] = 1, then count and direction encoding mode is enabled.
- If QDCTRL[QUADMODE] = 0, then phase encoding mode is enabled.

In count and direction encoding mode, the channel 1 input value indicates the counting direction, and the channel 0 input value defines the counting rate. A rising edge at the channel 0 input signal updates the TPM counter (see Figure 550).

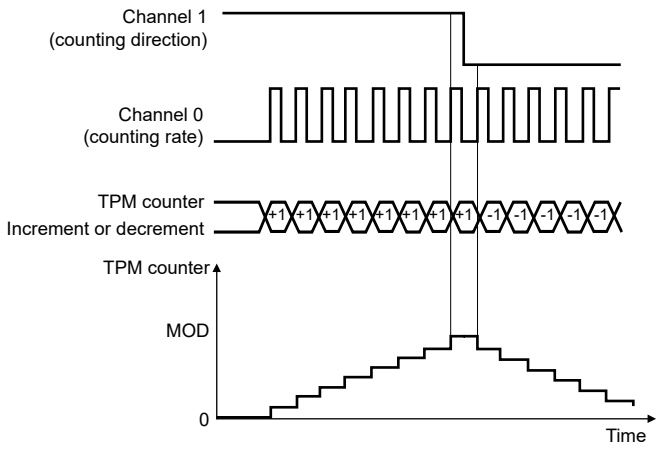

Figure 550. Quadrature Decoder—count and direction encoding mode

In phase encoding mode, the relationship between channel 0 and channel 1 signals indicates the counting direction, and channel 0 and channel 1 signals define the counting rate. An edge at either channel 0 or channel 1 signals updates the TPM counter (see Figure 551).

If POL[POL0] = 0 and POL[POL1] = 0, then:

- The TPM counter increment happens at:
  - A rising edge at channel 0 signal, and channel 1 signal is at logic 0
  - A rising edge at channel 1 signal, and channel 0 signal is at logic 1
  - A falling edge at channel 1 signal, and channel 0 signal is at logic 0
  - A falling edge at channel 0 signal, and channel 1 signal is at logic 1
- The TPM counter decrement happens at:
  - A falling edge at channel 0 signal, and channel 1 signal is at logic 0
  - A falling edge at channel 1 signal, and channel 0 signal is at logic 1
  - A rising edge at channel 1 signal, and channel 0 signal is at logic 0
  - A rising edge at channel 0 signal, and channel 1 signal is at logic 1

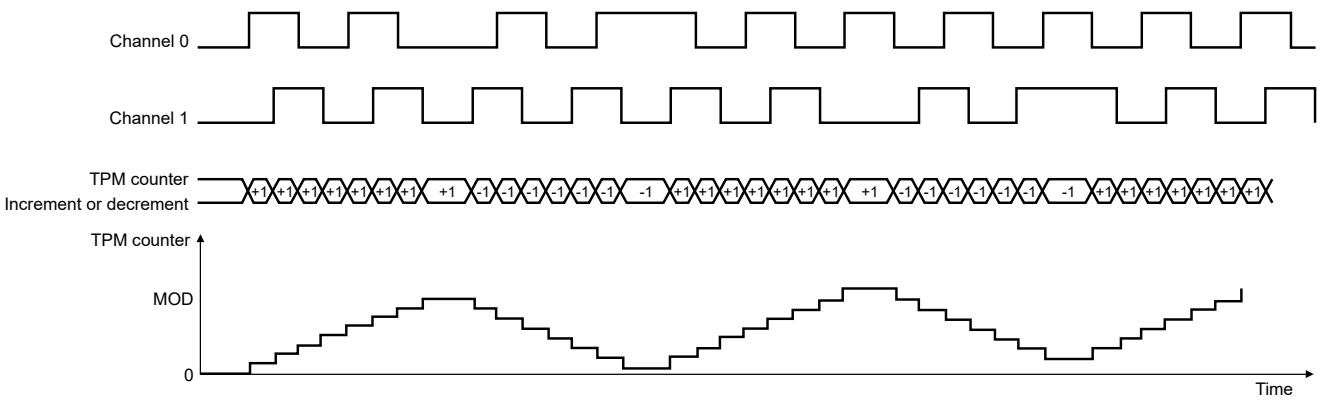

Figure 551. Quadrature Decoder—phase encoding mode

In Figure 552, when the TPM counter changes from the value defined in MOD[MOD] to 0, then SC[TOF] is 1 and QDCTRL[TOFDIR] becomes 1. SC[TOF] indicates that a TPM counter overflow has occurred. QDCTRL[TOFDIR] indicates that TPM was counting up when the TPM counter overflow occurred.

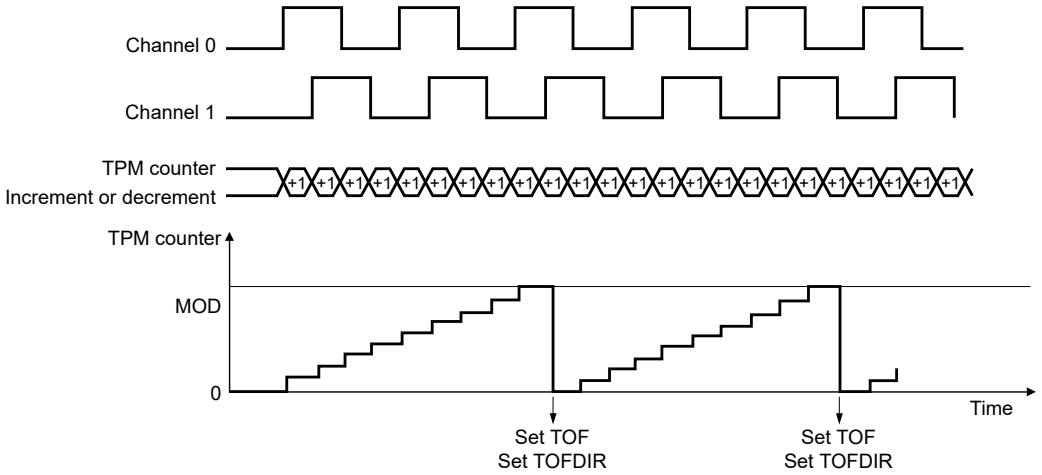

Figure 552. TPM counter overflow in up counting for Quadrature Decoder mode

In Figure 553, when the TPM counter changes from 0 to MOD[MOD], then SC[TOF] is 1 and QDCTRL[TOFDIR] becomes 0. SC[TOF] indicates that a TPM counter overflow has occurred. QDCTRL[TOFDIR] indicates that TPM was counting down when the TPM counter overflow occurred.

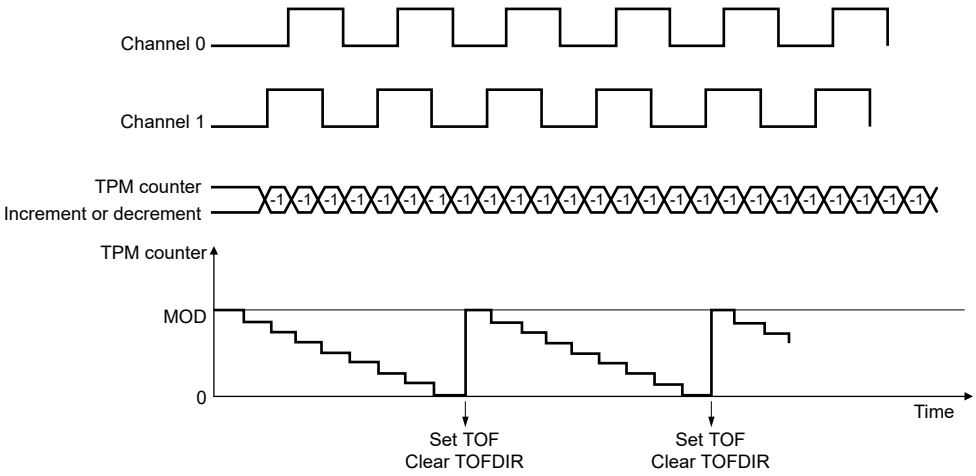

Figure 553. TPM counter overflow in down counting for Quadrature Decoder mode

70.3.5 Low-Power mode

During chip Low-Power mode, you can configure TPM to operate normally or to pause all counting.

Chip mode	TPM operation
Low-Power mode	• When CONF[DOZEEN] = 0, and TPM uses an external or internal clock source that remains functional, then counting continues. TPM can generate an asynchronous interrupt to exit the chip from Low-Power mode. • When CONF[DOZEEN] = 1, then counting pauses during Low-Power mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state.

70.3.6 Debug mode

During chip Debug mode, you can configure TPM to operate normally or to pause all counting temporarily.

Chip mode	TPM operation
Debug (core is in Debug or Halted mode)	• When CONF[DBGMODE] = 00b, then counting pauses until the core returns to normal user operating mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state. • When CONF[DBGMODE] = 11b, then counting continues.

70.3.7 Clocking

TPM supports two clock domains.

The bus clock domain is used by the register interface and for synchronizing interrupts and DMA requests.

The TPM counter clock domain clocks the counter and prescaler along with the output compare and input capture logic. The TPM counter clock is considered asynchronous to the bus clock. It can be a higher or lower frequency than the bus clock. It can optionally remain operational in low-power modes. When the global timebase feature is enabled, you must clock any TPM instance that is sharing the global timebase by the same TPM counter clock.

70.3.8 Reset

TPM resets whenever any chip reset occurs.

When TPM exits from reset:

- The TPM counter and the prescaler counter are 0 and are stopped (SC[CMOD] = 0).
- The timer overflow interrupt is 0.
- The channel interrupts are 0.
- The channels are in Input Capture mode.
- The channel outputs are 0.
- TPM does not control the channel pins (ELS*n*B:ELS*n*A = 0:0).

70.3.9 Interrupts

70.3.9.1 Timer overflow interrupt

TPM generates the timer overflow interrupt when (SC[TOIE] = 1) and (SC[TOF] = 1).

70.3.9.2 Channel *n* interrupt

TPM generates the channel *n* interrupt when (C*n*SC[CH*n*IE] = 1) and (C*n*SC[CH*n*F] = 1).

70.3.10 DMA

The channel and overflow flags generate a DMA transfer request according to SC[DMA] and C*n*SC[CH*n*IE]/SC[TOIE] fields. See the following table for more information.

Table 1067. DMA transfer request

DMA	CH*n*IE/ TOIE	Channel and overflow DMA transfer request	Channel and overflow interrupt
0	0	Not generated	Not generated
0	1	Not generated	Generated if (CH*n*F/TOF = 1)
1	0	Generated if (CH*n*F/TOF = 1)	Not generated
1	1	Generated if (CH*n*F/TOF = 1)	Generated if (CH*n*F/TOF = 1)

If DMA = 1, the CH*n*F/TOF field can be cleared either by completion of the DMA transfer or by writing 1 to CH*n*F/TOF (see Table 1068).

Table 1068. Clear CH*n*F/TOF field

DMA	How to clear CH*n*F/TOF
0	CH*n*F/TOF field is cleared by writing 1 to it.
1	CH*n*F/TOF field is cleared either when the DMA transfer is completed or by writing 1 to it.

70.4 External signals

Table 1069 shows the user-accessible signals for TPM.

Table 1069. TPM signal descriptions

Signal	Description	Direction
EXTCLK	External clock If selected in SC[CMOD], EXTCLK increments the TPM counter on every rising edge synchronized to the TPM counter clock. EXTCLK must be less than half of the TPM counter clock frequency. The TPM counter prescaler selection and settings are also used when EXTCLK is selected.	I
CH*n*	Channel *n* I/O pin (where *n* = 3 to 0) You can configure each CH*n* to operate either as input or output. CH*n* is an output when configured in Output Compare or PWM mode and the TPM counter is enabled; otherwise, CH*n* is an input.	I/O

70.5 Initialization

To initialize TPM:

1. Write to the following registers, in any order, to configure the counter mode of operation:
   - Configuration (CONF)
   - Quadrature Decoder Control and Status (QDCTRL)
   - Modulo (MOD)
2. Write to the following registers, in any order, to configure the mode of operation for each channel:
   - Channel n Value (C0V - C3V)
   - Combine Channel (COMBINE)
   - Channel Trigger (TRIG)
   - Channel Polarity (POL)
   - Filter Control (FILTER)
3. Use Channel n Status and Control (C0SC - C3SC) to configure the mode of operation for each channel and to enable the channel.
4. Use Status and Control (SC) to configure the counter mode of operation and to enable the TPM (TPM is enabled and counting when SC[CMOD] ≠ 00).

70.6 Application information

To configure TPM counter to generate an overflow interrupt every 64,000 cycles:

1. Write any data to CNT to reset the counter.
2. Write MOD[MOD] = F9FFh to configure counter overflow.
3. Write SC = 48h to enable the counter and overflow interrupt.
4. Write STATUS = 100h to clear the flag during the interrupt routine.

To configure TPM channel 0 for input capture on either edge generating an interrupt:

1. Write C0SC = 4Ch to configure channel 0.
2. Optionally, write CONF = 840000h to configure counter to reset on each channel 0 input capture. Write CONF = 850000h to delay starting the counter until the first edge.
3. Write any data to CNT to reset the counter.
4. Write MOD[MOD] = FFFFFFFFh to configure the counter overflow to maximum.
5. Write SC = 48h to enable the counter and overflow interrupt.
6. During the interrupt routine, first check the setting for the STATUS flag:
   - If STATUS[TOF] is set, clear flag by writing STATUS = 100h. Note that software is responsible for tracking number of overflows between consecutive input capture events.
   - If STATUS[CH0F] is set, first read C0V to obtain the input capture value and then clear flag by writing STATUS = 0001h.

To configure TPM channel 0 for output compare to toggle the output pin using an array of counter values:

1. Write C0SC = 54h for interrupt or write C0SC = 15h for DMA.
2. Write C0V = array[0] to configure initial compare value.
3. Write any data to CNT to reset the counter.
4. Write MOD[MOD] = FFFFFFFFh to configure the counter overflow to maximum.
5. Write SC = 08h to enable the counter.
6. Write the next compare value C0V = array[N] during the interrupt routine and then write STATUS = 0001h to clear the flag.

7. Write the next compare value C0V = array[N] during the DMA transfer. DMA transfer will automatically clear the channel flag.

The array is an array of counter values where the first output compare occurs at “array[0]” cycles after the counter is enabled and subsequent output compares occur at “array[N] – array[N-1]” cycles after the last compare. If the output waveform repeats, then MOD can be set to an output compare value where the waveform starts to repeat.

An example of using TPM with the asynchronous DMA is described in AN4631:Using the Asynchronous DMA features of the Kinetis L Series.

70.7 Memory map and register definition

This section provides a detailed description of all TPM registers.

An attempt to access a reserved register location in the TPM memory map generates a bus error.

70.7.1 TPM register descriptions

70.7.1.1 TPM memory map

TPM1 base address: 4431_0000h

TPM2 base address: 4432_0000h

TPM3 base address: 424E_0000h

TPM4 base address: 424F_0000h

TPM5 base address: 4250_0000h

TPM6 base address: 4251_0000h

70.7.1.2 Version ID (VERID)

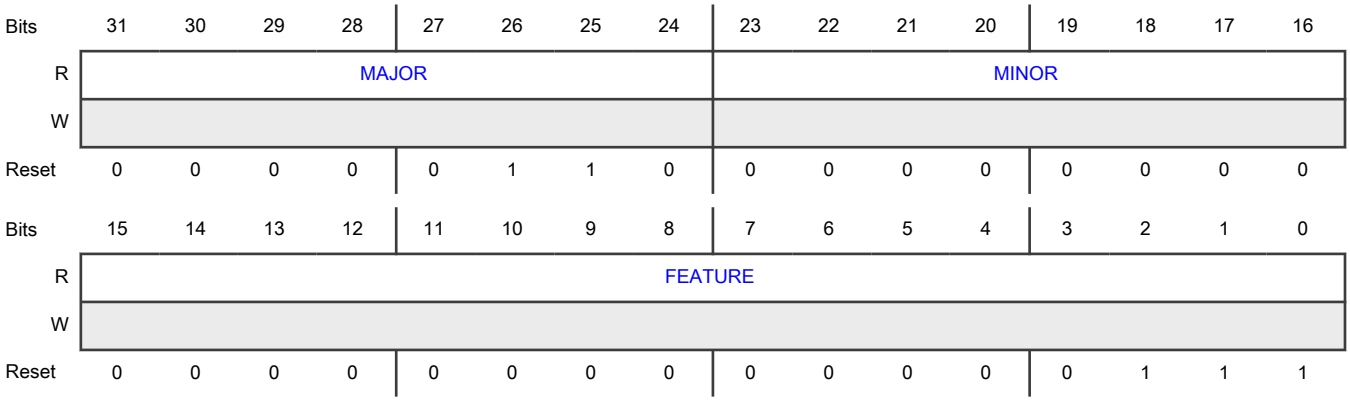
Offset

Register	Offset
VERID	0h

Function

Contains the module version ID and feature information.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Specifies the major version number for the module specification.

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-16 MINOR	Minor Version Number Specifies the minor version number for the module specification.
15-0 FEATURE	Feature Identification Number Configures different feature sets for TPM that implements a standard feature set with Filter Control (FILTER), Combine Channel (COMBINE), and Quadrature Decoder Control and Status (QDCTRL). 0000_0000_0000_0001b - Standard feature set 0000_0000_0000_0011b - Standard feature set with the filter and combine registers implemented 0000_0000_0000_0101b - Standard feature set with the quadrature register implemented 0000_0000_0000_0111b - Standard feature set with the filter, combine, and quadrature registers implemented

70.7.1.3 Parameter (PARAM)

Offset

Register	Offset
PARAM	4h

Function
Contains values of the module parameters.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continued from the previous page...

Field	Function
—	
23-16 WIDTH	Counter Width Specifies the width of the counter and timer channels.
15-8 TRIG	Trigger Count Specifies the number of trigger inputs that TPM implements.
7-0 CHAN	Channel Count Specifies the number of timer channels that TPM implements.

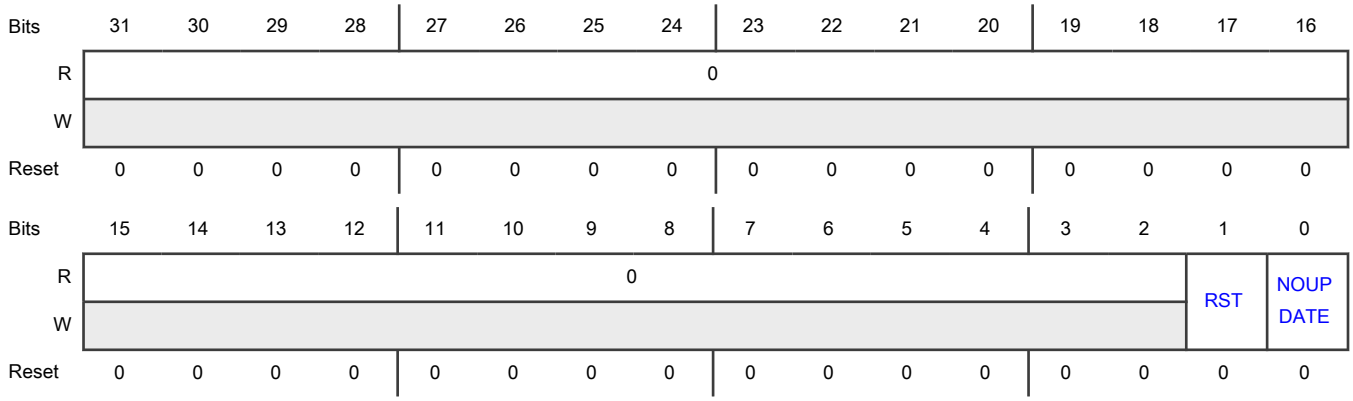
70.7.1.4 TPM Global (GLOBAL)

Offset

Register	Offset
GLOBAL	8h

Function
Includes the software reset control field.

Diagram



Fields

Field	Function
31-2 —	Reserved
1	Software Reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
RST	Resets all internal logic and registers, except TPM Global (GLOBAL). This field remains 1 until you write 0 to it. 0b - Module is not reset 1b - Module is reset
0 NOUPDATE	No Update Blocks updates to all internal double-buffered registers while this field remains 1. You can still update the software visible registers, but changes cannot take effect until you write 0 to this field. At that point they update as normal. 0b - Internal double-buffered registers update as normal 1b - Internal double-buffered registers do not update

70.7.1.5 Status and Control (SC)

Offset

Register	Offset
SC	10h

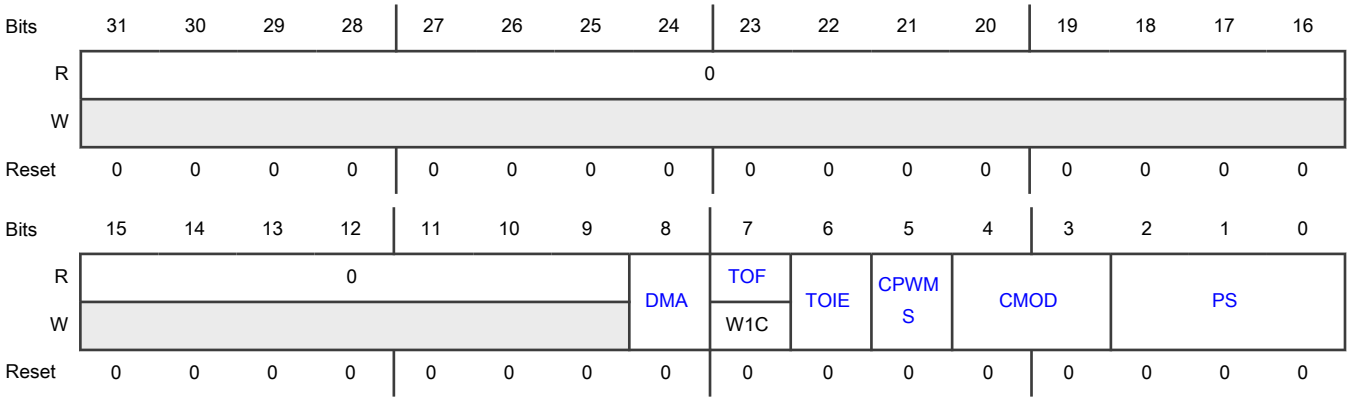
Function

Contains the overflow status flag and control fields that you can use to configure:

- Interrupt enable
- Module configuration
- Prescaler factor

These controls relate to all channels within this module.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 DMA	DMA Enable Enables DMA transfers for the overflow flag. 0b - Disable 1b - Enable
7 TOF	Timer Overflow Flag Indicates whether a TPM overflow has occurred. Hardware sets this flag when the TPM counter value is equal to the value defined in MOD[MOD], and increments after this value. If another TPM overflow occurs between the flag setting and the flag clearing, then the write operation has no effect. Therefore, TOF remains set, which indicates that another overflow has occurred. In this case, a TOF interrupt request is not lost due to a delay in clearing the previous TOF. 0b - No overflow 1b - Overflow
6 TOIE	Timer Overflow Interrupt Enable Enables TPM overflow interrupts. A TOF interrupt is generated when SC[TOF] = 1. If TOIE = 0, use software polling or DMA request. 0b - Disable 1b - Enable
5 CPWMS	Center-Aligned PWM Select Enables CPWM mode. This mode configures TPM to operate in up-down counting mode. This field is write-protected. Disable the TPM counter before you write to this field. 0b - Up counting mode 1b - Up-down counting mode
4-3 CMOD	Clock Mode Selection Selects the TPM counter clock modes. When disabling the counter, this field remains 1 until acknowledged in the TPM clock domain. 00b - TPM counter is disabled 01b - TPM counter increments on every TPM counter clock 10b - TPM counter increments on the rising edge of EXTCLK synchronized to the TPM counter clock 11b - TPM counter increments on the rising edge of the selected external input trigger
2-0	Prescale Factor Selection

Table continues on the next page...

Table continued from the previous page...

Field	Function
PS	Selects one of 8 division factors for the clock mode selected by SC[CMOD]. This field is write-protected. Disable the TPM counter before you write to this field. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

70.7.1.6 Counter (CNT)

Offset

Register	Offset
CNT	14h

Function

Contains the TPM counter value. You can write 0 to this register with reset. Writing any value to CNT[COUNT] triggers a reload of the counter and forces PWM outputs to their reload state.

When debug is active, the TPM counter does not increment unless you configure it otherwise. Reading this register adds two wait states to the register access, because of synchronization delays.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 COUNT	Counter Value Specifies the TPM counter value.

70.7.1.7 Modulo (MOD)

Offset

Register	Offset
MOD	18h

Function

Contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, SC[TOF] sets and the next value of the TPM counter depends on the selected counting method (see Counter).

Writing to the MOD register latches the value into a buffer. This register updates with the value of its write buffer according to MOD register update. Additional writes to the MOD write buffer are ignored until the register has been updated.

To avoid confusion about occurrence of the first counter overflow, initialize the TPM counter (write to CNT[COUNT]) before writing to the MOD register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	MOD															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
31-0 MOD	Modulo Value Specifies the modulo value for the TPM counter. Write a single 16-bit or 32-bit access value to this field.

70.7.1.8 Capture and Compare Status (STATUS)

Offset

Register	Offset
STATUS	1Ch

Function

Contains a copy of the status flag (C*n*SC[CHF]) for each TPM channel, as well as SC[TOF], for software convenience. Each CH*n*F field in STATUS is a mirror of the corresponding C*n*SC[CHF]. You can check all C*n*SC[CHF] fields using only one read of STATUS. Writing all ones to STATUS writes 0 to all C*n*SC[CHF] fields.

Hardware sets the individual channel flags when an event occurs on the channel. If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set, which indicates that another event has occurred. In this case, a CHF interrupt request is not lost because of the clearing sequence for a previous CHF.

Diagram

Field	Function
	Contains a copy of C3SC[CHF]. Sets the flag when an event occurs on the channel (see the register description for more). 0b - Event not occurred 1b - Event occurred
2 CH2F	Channel 2 Flag Contains a copy of C2SC[CHF]. Sets the flag when an event occurs on the channel (see the register description for more). 0b - Event not occurred 1b - Event occurred
1 CH1F	Channel 1 Flag Contains a copy of C1SC[CHF]. Sets the flag when an event occurs on the channel (see the register description for more). 0b - Event not occurred 1b - Event occurred
0 CH0F	Channel 0 Flag Contains a copy of C0SC[CHF]. Sets the flag when an event occurs on the channel (see the register description for more). 0b - Event not occurred 1b - Event occurred

70.7.1.9 Channel n Status and Control (C0SC - C3SC)

Offset

Register	Offset
C0SC	20h
C1SC	28h
C2SC	30h
C3SC	38h

Function

Contains the channel-interrupt-status flag and control fields used to configure:

- Interrupt enable
- Channel configuration
- Pin function

Table 1070. Mode, edge, and level selection

SC[CPWMS]	MS*n*B:MS*n*A	ELS*n*B:ELS*n*A	Mode	Configuration
0	00	00	None	Channel disabled

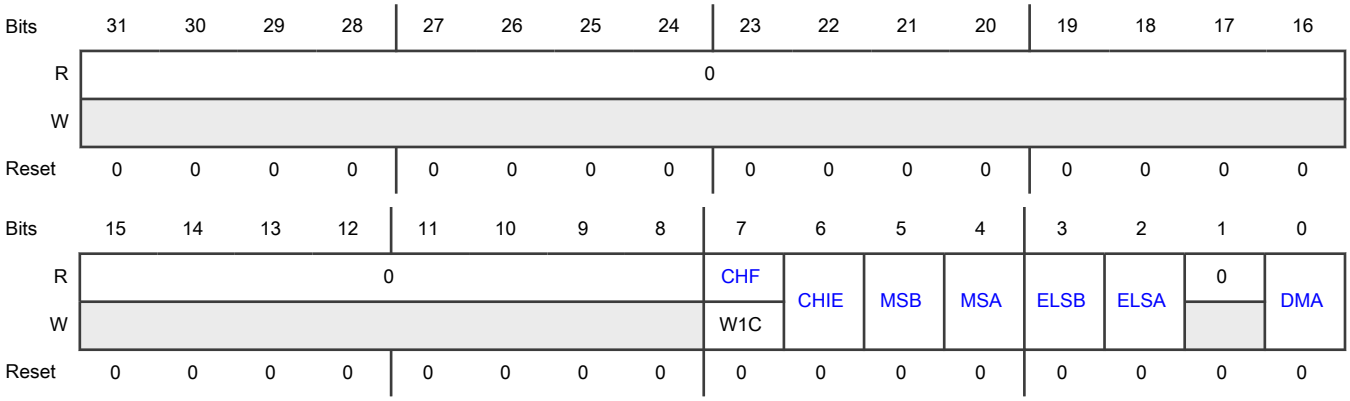
		11		Low-true pulses (set output on match-up, clear output on match-down, set output on counter reload, or when counter first enabled or paused)

Diagram



Fields

Field	Function
31-8 —	Reserved
7 CHF	Channel Flag Indicates whether an event has occurred on the channel. TPM writes 1 to this field when an event occurs on the channel. If another event occurs between the CHF being set and the write operation, the write operation has no effect; therefore, CHF remains set, which indicates that another event has occurred. In this case, a CHF interrupt request is not lost due to the delay in clearing the previous CHF. 0b - Event not occurred 1b - Event occurred
6 CHIE	Channel Interrupt Enable Enables channel interrupts.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
5 MSB	Channel Mode Select B Configures further selections in the channel logic. Its functionality depends on the channel mode (see Table 1070).
4 MSA	Channel Mode Select A Configures further selections in the channel logic. Its functionality depends on the channel mode (see Table 1070).
3 ELSB	Edge or Level Select B Performs the function that depends on the channel mode (see Table 1070).
2 ELSA	Edge or Level Select A Performs the function that depends on the channel mode (see Table 1070).
1 —	Reserved
0 DMA	DMA Enable Enables DMA transfers for the channel. 0b - Disable 1b - Enable

70.7.1.10 Channel n Value (C0V - C3V)

Offset

Register	Offset
C0V	24h
C1V	2Ch
C2V	34h
C3V	3Ch

Function

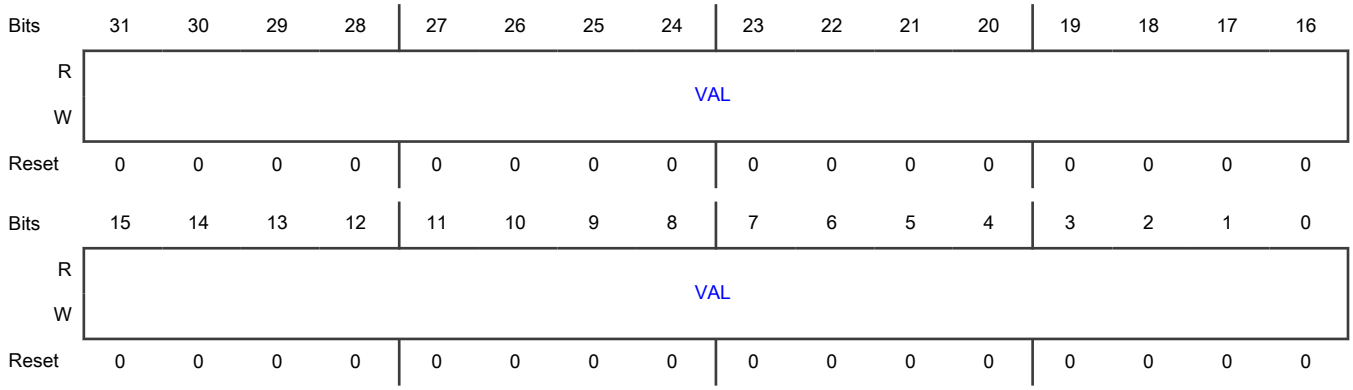
Contains the captured TPM counter value for the input modes or the match value for the output modes.

Input Capture mode ignores any write to a C*n*V register. In compare modes, writing to a C*n*V register latches the value into a buffer. A C*n*V register updates with the value of its write buffer according to C*n*V register update.

NOTE

Additional writes to the C*n*V write buffer are ignored until the register has been updated.

Diagram



Fields

Field	Function
31-0 VAL	Channel Value Contains the captured TPM counter value for the input modes, or the match value for the output modes. Write a single 16-bit or 32-bit access value to this field.

70.7.1.11 Combine Channel (COMBINE)

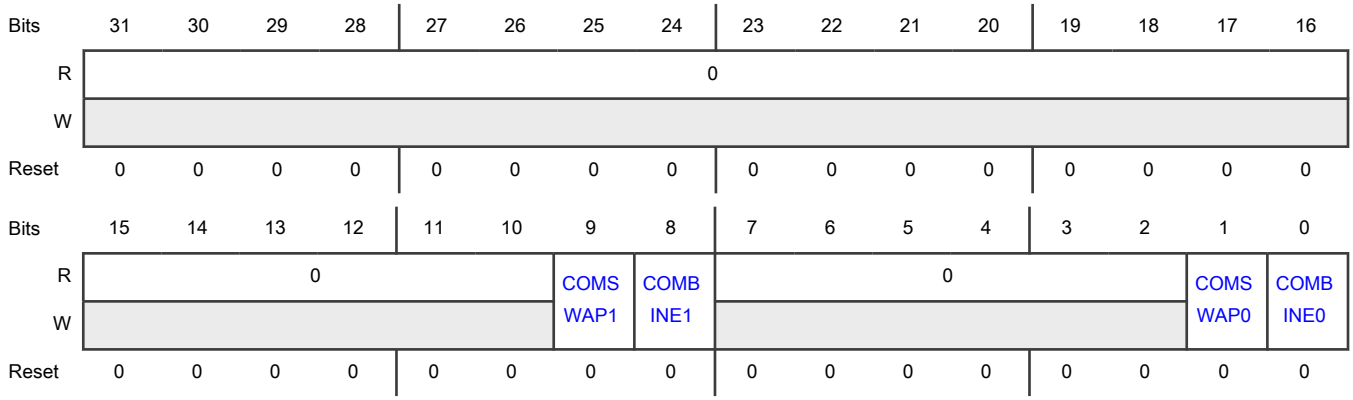
Offset

Register	Offset
COMBINE	64h

Function

Contains the control fields used to configure the combine channel modes for each pair of channels *n* and *n*+1, where n is all the even-numbered channels.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-10 —	Reserved
9 COMSWAP1	Combine Channels 2 and 3 Swap When set in combine modes, the odd channel is used for the input capture and first compare, while the even channel is used for the second compare. 0b - Even channel 1b - Odd channel
8 COMBINE1	Combine Channels 2 and 3 Enables the combine feature for channels 2 and 3. In Input Capture mode, the combined channels use the even channel input. In Software Compare mode, the even channel match asserts the output trigger, and the odd channel match negates the output trigger. In PWM mode, the even channel match is used for the first compare, and odd channel match for the second compare. 0b - Independent 1b - Combined
7-2 —	Reserved
1 COMSWAP0	Combine Channel 0 and 1 Swap When set in combine modes, the odd channel is used for the input capture and first compare, while the even channel is used for the second compare. 0b - Even channel 1b - Odd channel
0 COMBINE0	Combine Channels 0 and 1 Enables the combine feature for channels 0 and 1. In Input Capture mode, the combined channels use the even channel input. In Software Compare mode, the even channel match asserts the output trigger, and the odd channel match negates the output trigger. In PWM mode, the even channel match is used for the first compare and odd channel match for the second compare. 0b - Independent 1b - Combined

70.7.1.12 Channel Trigger (TRIG)

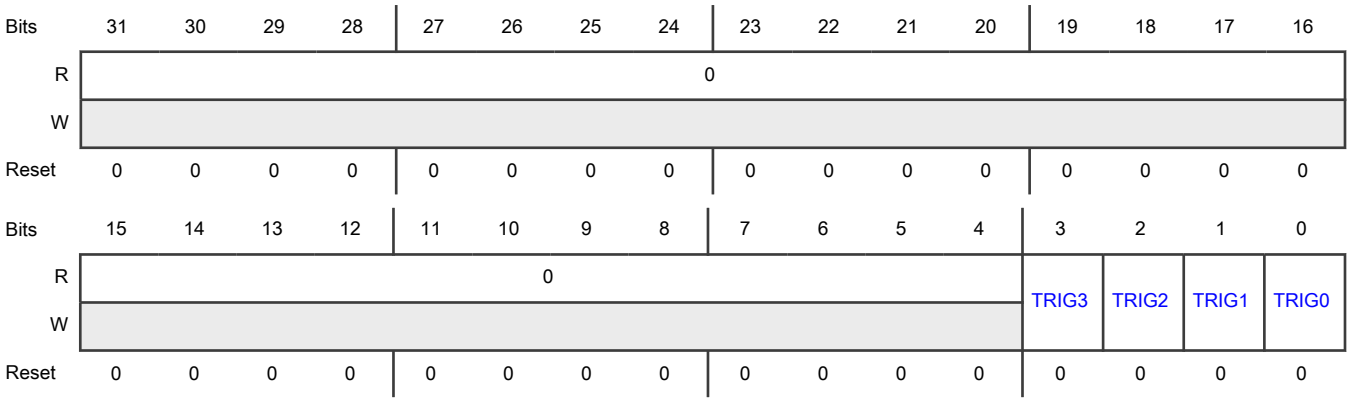
Offset

Register	Offset
TRIG	6Ch

Function

Configures the trigger input that is used by the channel to capture the counter value in Input Capture mode. In Output Compare or PWM mode, configures the trigger input used to modulate the channel output. When modulating the output, the output is forced to the channel initial value whenever the trigger is not asserted. The even-numbered channels share the first input trigger source, and the odd-numbered channels share the second input trigger source.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 TRIG3	Channel 3 Trigger 0b - No effect 1b - Configures trigger input 1 to be used by channel 3
2 TRIG2	Channel 2 Trigger 0b - No effect 1b - Configures trigger input 0 to be used by channel 2
1 TRIG1	Channel 1 Trigger 0b - No effect 1b - Configures trigger input 1 to be used by channel 1
0	Channel 0 Trigger

Table continued from the previous page...

Field	Function
TRIG0	0b - No effect 1b - Configures trigger input 0 to be used by channel 0

70.7.1.13 Channel Polarity (POL)

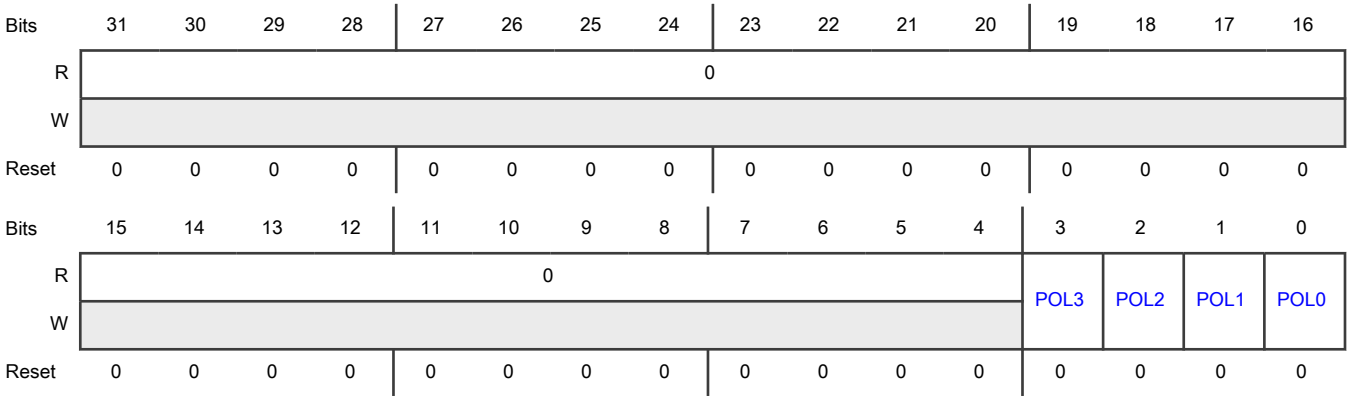
Offset

Register	Offset
POL	70h

Function

Defines the input and output polarity of each of the channels.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 POL3	Channel 3 Polarity 0b - Active high 1b - Active low
2 POL2	Channel 2 Polarity 0b - Active high 1b - Active low

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 POL1	Channel 1 Polarity 0b - Active high 1b - Active low
0 POL0	Channel 0 Polarity 0b - Active high 1b - Active low

70.7.1.14 Filter Control (FILTER)

Offset

Register	Offset
FILTER	78h

Function

Selects the filter value of the channel inputs, and an additional output delay value for the channel outputs. In PWM Combine mode, you can use this field to implement dead-time insertion.

NOTE

To write values to CH*n*FVAL, ensure that the corresponding channel-interrupt status flag and control (C*n*SC[5:2]) fields are set to 0.

Table continued from the previous page...

Field	Function
—	
15-12 CH3FVAL	Channel 3 Filter Value When configured for Input Capture or Software Compare mode, configures the filter value for the channel 3 input. The filter is disabled when the value is zero. Otherwise, the filter is configured as (CH3FVAL×4)clock cycles. Sets the dead-time insertion time for channel 3 in PWM modes. Dead time insertion is disabled when CH3FVAL is zero. Otherwise, dead time insertion for channel 3 is configured as (CH3FVAL×4)clock cycles.
11-8 CH2FVAL	Channel 2 Filter Value When configured for Input Capture or Software Compare mode, configures the filter value for the channel 2 input. The filter is disabled when the value is zero. Otherwise, the filter is configured as (CH2FVAL×4)clock cycles. Sets the dead-time insertion time for channel 2 in PWM modes. Dead time insertion is disabled when CH2FVAL is zero. Otherwise, dead time insertion for channel 2 is configured as (CH2FVAL×4)clock cycles.
7-4 CH1FVAL	Channel 1 Filter Value When configured for Input Capture or Software Compare mode, configures the filter value for the channel 1 input. The filter is disabled when the value is zero. Otherwise, the filter is configured as (CH1FVAL×4)clock cycles. Sets the dead-time insertion time for channel 1 in PWM modes. Dead time insertion is disabled when CH1FVAL is zero. Otherwise, dead time insertion for channel 1 is configured as (CH1FVAL×4)clock cycles.
3-0 CH0FVAL	Channel 0 Filter Value When configured for Input Capture or Software Compare mode, configures the filter value for the channel 0 input. The filter is disabled when the value is zero. Otherwise, the filter is configured as (CH0FVAL×4)clock cycles. Sets the dead time insertion time for channel 0 in PWM modes. Dead time insertion is disabled when CH0FVAL is zero. Otherwise, dead time insertion for channel 0 is configured as (CH0FVAL×4)clock cycles.

70.7.1.15 Quadrature Decoder Control and Status (QDCTRL)

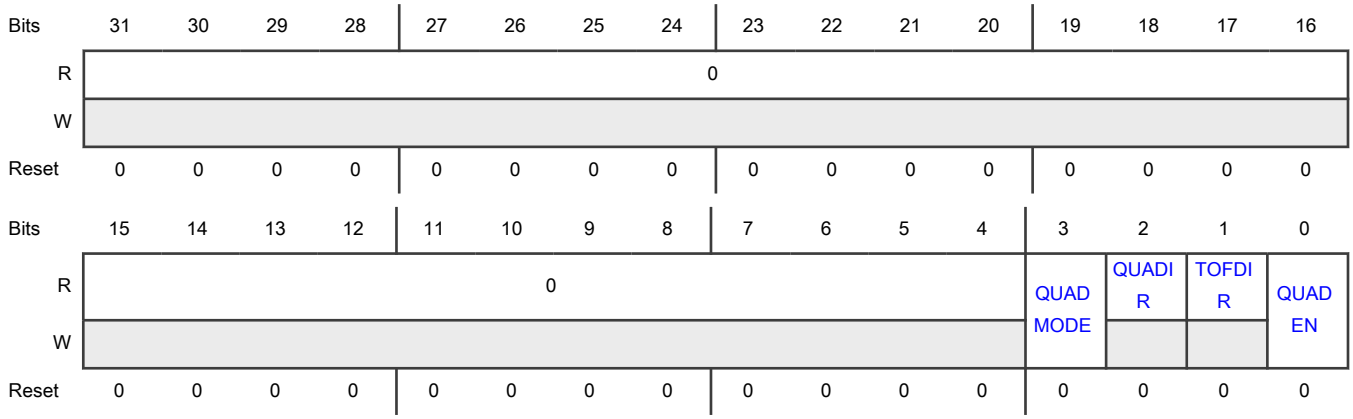
Offset

Register	Offset
QDCTRL	80h

Function

Contains the control and status fields for Quadrature Decoder mode.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 QUADMODE	Quadrature Decoder Mode Selects the encoding mode used in Quadrature Decoder mode. 0b - Phase encoding mode 1b - Count and direction encoding mode
2 QUADIR	Counter Direction in Quadrature Decode Mode Indicates whether the counting direction is decreasing or increasing. 0b - Decreasing (counter decrement) 1b - Increasing (counter increment)
1 TOFDIR	Timer Overflow Direction Indicates if SC[TOF] was set on the top or bottom of counting. • Field value 0 indicates that SC[TOF] was set on the bottom of counting. There was a TPM counter decrement and TPM counter changes from its minimum value (0) to its maximum value (MOD[MOD]). • Field value 1 indicates that SC[TOF] was set on the top of counting. There was a TPM counter increment and TPM counter changes from its maximum value (MOD[MOD]) to its minimum value (0). 0b - Bottom of counting 1b - Top of counting
0 QUADEN	Quadrature Decoder Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables Quadrature Decoder mode. In this mode, the channel 0 and channel 1 inputs control the TPM counter direction and can only be used for Software Compare mode. Quadrature Decoder mode has precedence over the other modes. 0b - Disable 1b - Enable

70.7.1.16 Configuration (CONF)

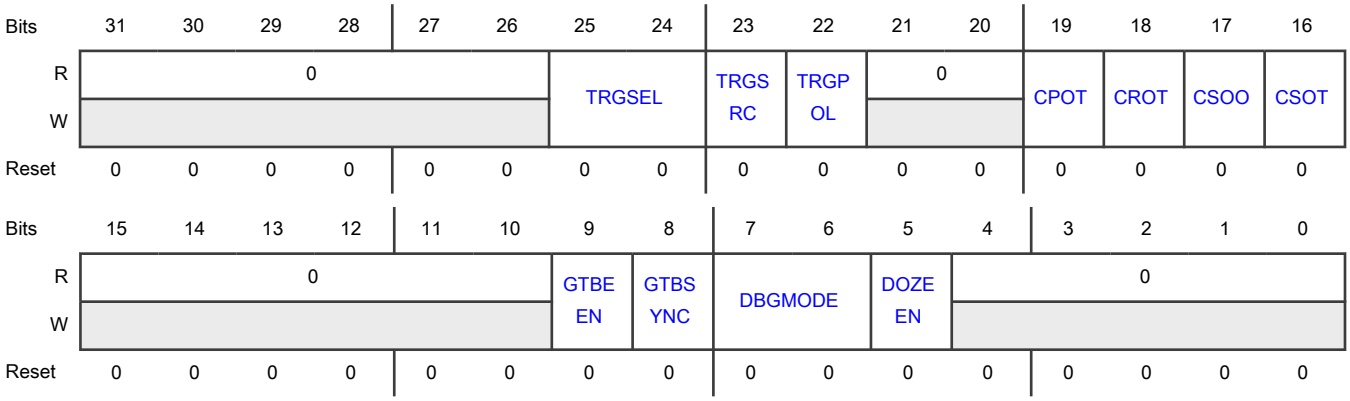
Offset

Register	Offset
CONF	84h

Function

Selects the TPM behavior in Debug mode and Low-Power mode, and the use of an external GTB.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-24 TRGSEL	Trigger Select Selects the input trigger that you use to start, reload, and pause the counter. You can configure the source of the trigger (external or internal to TPM) by CONF[TRGSRC]. Disable the TPM counter before you change this field. See the chip-specific TPM information for available external trigger options.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The below list shows available internal trigger sources. 01b - Channel 0 pin input capture 10b - Channel 1 pin input capture 11b - Channel 0 or channel 1 pin input capture
23 TRGSRC	Trigger Source Selects between internal (channel pin input capture) or external trigger sources. CONF[TRGSEL] selects this trigger source. When selecting an internal trigger, configure the selected channel for input captures as follows: • CONF[CSOT] enables you to start the counter initially using only a rising edge input capture. • CONF[CROT] enables you to reload the counter using either a rising edge or falling edge input capture. • CONF[CPOT] enables you to pause the counter using the state of the channel input pin. You can use Channel Polarity (POL) to invert the polarity of the channel input pins. Disable the TPM counter before you change this field. 0b - External 1b - Internal (channel pin input capture)
22 TRGPOL	Trigger Polarity Selects the polarity of the external trigger source. Disable the TPM counter before you change this field. 0b - Active high 1b - Active low
21-20 —	Reserved
19 CPOT	Counter Pause on Trigger Specifies that while the trigger remains asserted (level sensitive), and this field is 1, the counter pauses incrementing. While being paused, the counter ignores the input capture events and forces PWM outputs to their default state. If the TPM counter pauses during Debug mode or Low-Power mode, then the counter ignores the trigger input. Disable the TPM counter before you change this field. 0b - TPM counter continues 1b - TPM counter pauses
18 CROT	Counter Reload on Trigger Specifies that when you detect a rising edge on the selected trigger input and this field is 1, then the TPM counter reloads with 0 (and sets PWM outputs to their reload state). If the TPM counter pauses during Debug mode or Low-Power mode, then the counter ignores the trigger input. Disable the TPM counter before you change this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No reload 1b - Reload
17 CSOO	Counter Stop on Overflow Specifies that the TPM counter pauses when SC[TOF] = 1 and this field is 1. Reloading the counter with 0 by writing to Counter (CNT), or by a trigger input, does not cause the counter to stop incrementing. When stopped, the counter does not start incrementing unless you first disable and then enable it, or if you detect a rising edge on the selected trigger input when CONF[CSOT] is 1. While the counter is paused, it ignores the input capture events and forces PWM outputs to their default state. Disable the TPM counter before you change this field. 0b - TPM counter continues 1b - TPM counter stops
16 CSOT	Counter Start on Trigger Specifies that until you detect a rising edge on the selected trigger input, and this field is 1, the TPM counter pauses incrementing when it is enabled. If the TPM counter pauses due to an overflow, a rising edge on the selected trigger input also causes the TPM counter to start incrementing again. While being paused, the counter ignores the input capture events, and forces PWM outputs to their default state. If the TPM counter pauses during Debug mode or Low-Power mode, then the counter ignores the trigger input. Disable the TPM counter before you change this field. 0b - Counter starts immediately 1b - Counter starts after detection of a rising edge on the selected input trigger
15-10 —	Reserved
9 GTBEEN	GTB Enable Configures TPM to use an externally generated GTB counter. When you use an externally generated timebase, the channels do not use the internal TPM counter, but you can use the internal TPM counter to generate a periodic interrupt or DMA request using Modulo (MOD) and SC[TOF]. 0b - Internally generated TPM counter 1b - Externally generated GTB counter
8 GTBSYNC	GTB Synchronization Enables the TPM counter to synchronize with GTB. It uses the GTB enable, trigger, paused state and overflow to ensure that the TPM counter starts incrementing, stops incrementing, and resets at the same time as GTB. Disable the TPM counter before you change this field. 0b - Disable 1b - Enable
7-6	Debug Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
DBGMODE	Configures the TPM behavior in Debug mode (see Debug mode). All other configurations are reserved. 00b - TPM counter pauses 11b - TPM counter continues
5 DOZEEN	Doze Enable Configures the TPM behavior in Low-Power mode (see Low-Power mode). 0b - TPM counter continues 1b - TPM counter pauses
4-0 —	Reserved

Chapter 71
Low Power Periodic Interrupt Timer (LPIT)

71.2 Overview

LPIT is a low-power periodic interrupt timer with multiple timer channels. After a timer reaches a programmed count, the respective timer channels generate pre-trigger and trigger output signals, and these outputs can be used to trigger other modules on the chip.

71.2.1 Block diagram

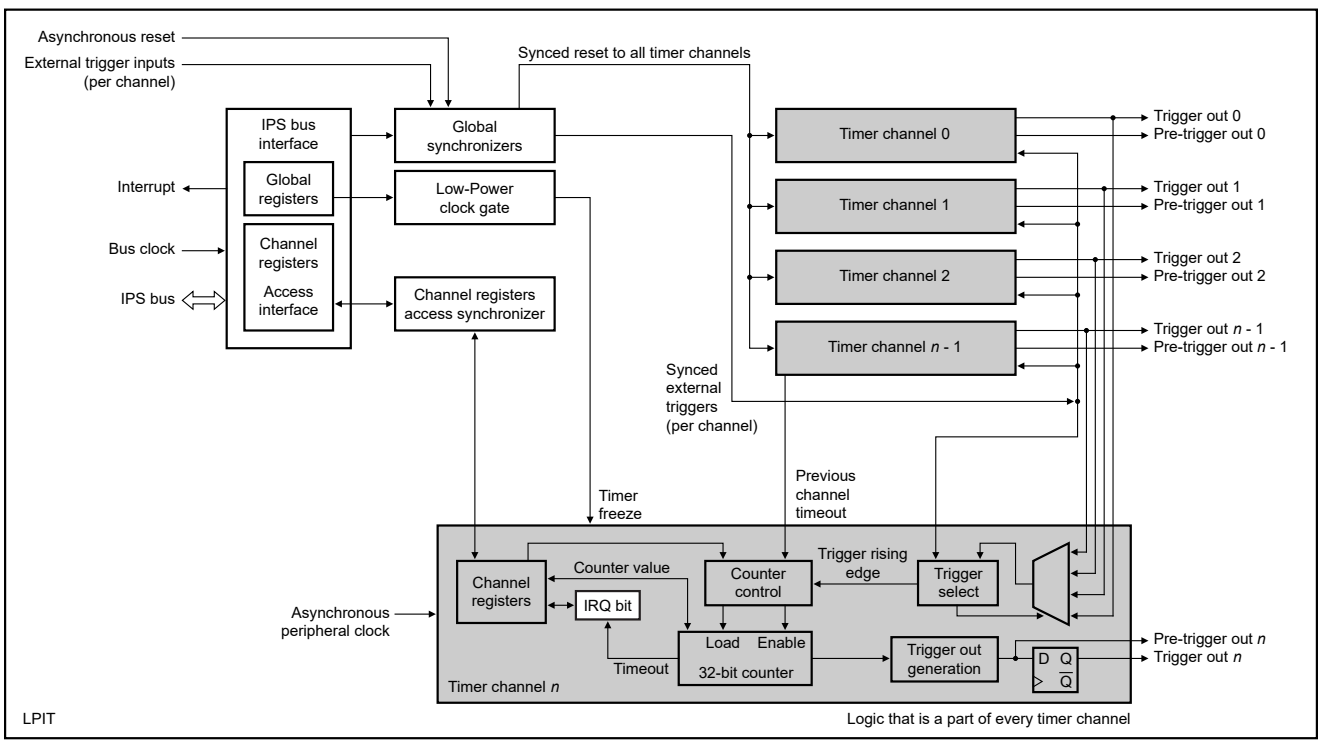

Figure 554. Block diagram

71.2.2 Features

LPIT allows you to configure timer channels in a way that they could be:

- Controlled using external triggers (triggers from outside LPIT).
- Controlled using internal triggers (triggers from other timer channels inside LPIT).
- Chained together, to form a larger width timer.
- Reloaded and counted again, or stopped after reaching the programmed count, depending on the timer modes used.

71.3 Functional description

71.3.1 Programming model

The LPIT programming model (see Figure 555) comprises:

- A global register set (common to all timer channels).
- Registers for each timer channel (that control their respective timer channels).

Access to these registers is synchronized with the asynchronous peripheral clock and then affects the timer channel registers:

- Each timer channel contains a 32-bit counter that loads the starting value and down counts after every peripheral clock's positive edge.
- After reaching a zero value (a channel timer timeout), a trigger output is generated.
- A timer enable register control field, external or internal triggers, or a previous channel timeout (when using timer chaining) control the counter enable.

- After a channel timer timeout, an interrupt flag is also set to tell the CPU about the timer timeout.

You must configure the following global registers only once:

- Module Control (MCR)
- Module Status (MSR)
- Module Interrupt Enable (MIER)
- Set Timer Enable (SETTEN)
- Clear Timer Enable (CLRTEN)

You must configure the following channel registers for each channel:

- Timer Value (TVAL0 - TVAL3)
- Timer Control (TCTRL0 - TCTRL3)

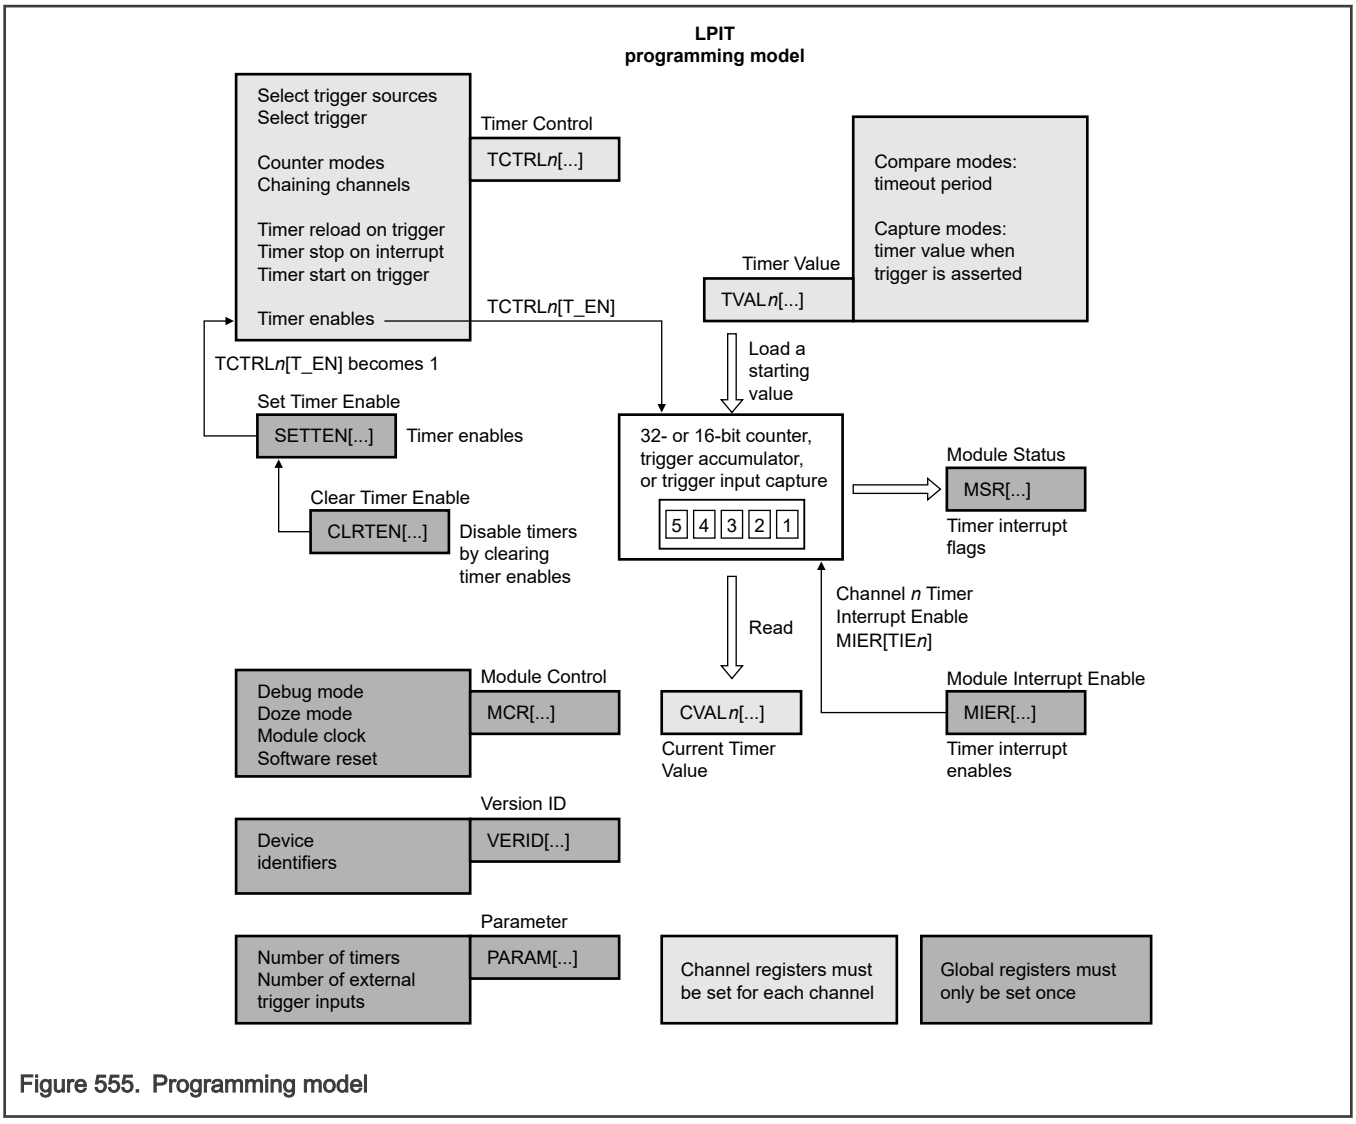

Figure 555. Programming model

71.3.2 Interfacing with other modules

The following figure shows the interface of an LPIT module with other modules on the chip:

- The CPU interface provides the clock, reset, and register read and write bus interface. It handles LPIT interrupts.

- The LPIT trigger output signals may trigger other modules on the chip, such as DMA and ADC.
- Similarly, other timer modules may provide trigger inputs to LPIT to control when an LPIT timer channel must start.

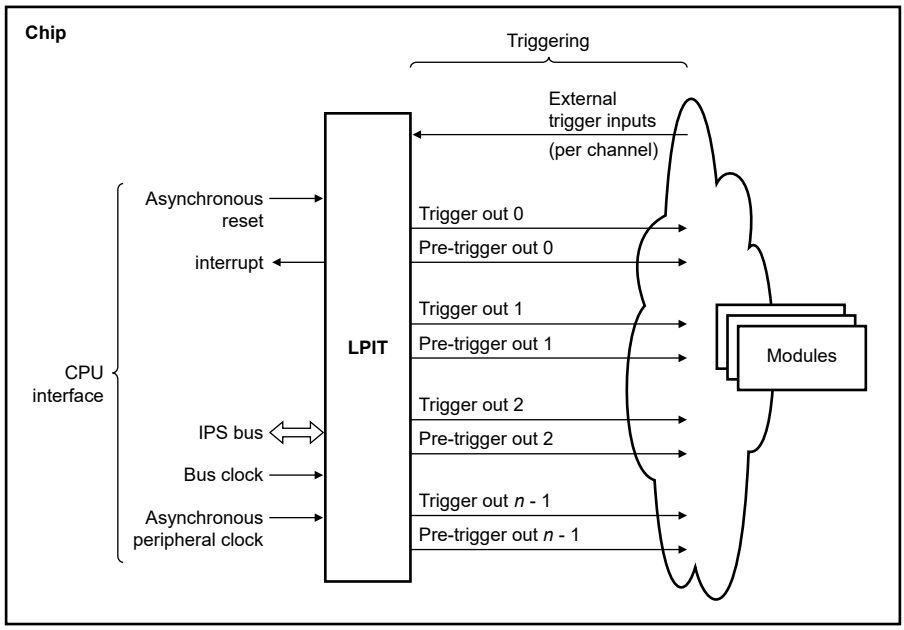

Figure 556. Interfacing with other modules

71.3.3 Chip power modes

LPIT supports the following chip power modes.

Table 1072. Chip power modes

Chip mode	LPIT operation
Run	Normal operation
Stop and Wait	Can continue operating in this mode if MCR[DOZE_EN] = 1 and LPIT is using an external or internal clock source that remains operational during Stop and Wait modes.
Debug	Can continue operating in this mode if MCR[DBG_EN] = 1

71.3.4 Supported timer modes

To configure a timer mode, you must select an appropriate value using TCTRL*n*[MODE].

Table 1073. Supported timer modes

Timer mode	Operation
32-bit periodic counter	The counter loads and decrements down to 0, and this sets the timer interrupt flag and asserts the output pretrigger.

Table continues on the next page...

Table 1073. Supported timer modes (continued)

Timer mode	Operation
Dual 16-bit periodic counter	• The counter loads and then the lower 16 bits decrement down to 0. This asserts the output pretrigger. • The upper 16 bits then decrement down to 0. This sets the timer interrupt flag and negates the output pretrigger.
32-bit trigger accumulator	The counter loads after the first trigger rising edge and then decrements down to 0 after each trigger rising edge. This sets the timer interrupt flag and asserts the output pretrigger.
32-bit trigger input capture	• The counter loads with a value of FFFF_FFFFh and then decrements down to 0. • If a trigger rising edge is detected, it stores the inverse of the current counter value in Timer Value (TVAL0 - TVAL3). This sets the timer interrupt flag and asserts the output pretrigger.

TCTRL*n*[TSOT], TCTRL*n*[TSOI], and TCTRL*n*[TROT] control the timer operation. These fields control the timer load, reload, start, and restart of the timers.

NOTE

- The trigger output is asserted one peripheral timer clock cycle after the pre-trigger output. The trigger and pre-trigger outputs deassert at the same time.
- The pre-trigger output is asserted for two clock cycles and the trigger output is asserted for one clock cycle (except in 16-bit Periodic Counter mode, where both pre-trigger and trigger outputs are asserted for many cycles depending on the value of TVAL*n*[TMR_VAL][31:16]).
- Timer changes (that are based on external triggers) take effect after four peripheral clocks, after the actual external trigger assertion. This is because of clock synchronization, rise edge detection, and timer update.

71.3.5 Timer channel modes

You can configure each timer channel in LPIT to work in either compare modes or capture modes.

The timer channels operate on an asynchronous clock, which is independent of the register read and write access clock. Clock synchronization between clock domains ensures normal operations.

Table 1074. Timer channel modes

Mode	Function
Compare	The timers decrement when enabled and generate an output pretrigger and trigger output. The trigger output is one clock cycle delayed of the pre-trigger pulse. You can configure certain control fields to control each timer channel's start, reload, and restart (see Trigger control for timers for more information). You can also configure the timer to always decrement from a programmed start value, on selected trigger inputs, or previous channel timeout (when channels are chained). By chaining timer channels, applications can achieve larger timeout durations.
Capture	You can use the timer to perform measurements by using Timer Value (TVAL0 - TVAL3), as the timer value is captured when a selected trigger input is asserted. The timer can support once-off or multiple measurements, such as frequency measurements.

71.3.6 Trigger control for timers

You can configure various LPIT register fields to control how trigger inputs and the timer operate:

- TCTRL*n*[TRG_SEL] helps you select the input trigger for the channel from all other channels' trigger outputs.
- TCTRL*n*[TRG_SRC] helps you select between the internal and external trigger inputs to the channel.

The selected trigger affects how the timer operates, using the configuration of TCTRL*n*[TSOT], TCTRL*n*[TSOI], and TCTRL*n*[TROT] (see Table 1075).

Table 1075. Fields that control timer operations

If	=	Then
Timer stop on interrupt (TCTRL*n*[TSOI])	1	The counter stops after MSR[TIF*n*] assertion. To reload and decrement, it requires: • A trigger (if TCTRL*n*[TSOT] = 1). • A T_EN rising edge (if TCTRL*n*[TSOT] = 0).
	0	The counter does not stop after timeout.
Timer reload on trigger (TCTRL*n*[TROT])	1	The counter is loaded after each trigger.
	0	The counter is loaded after every T_EN rising edge or timeout rising edge (timeout is not used in Capture modes).
Timer start on trigger (TCTRL*n*[TSOT])	1	The counter starts decrementing after a trigger. Subsequent triggers are ignored until the counter times out.
	0	The counter decrements immediately after the next clock edge. When the channel is chained or is in Capture mode, TCTRL*n*[TSOT] has no effect.

In different timer modes, the programmable fields listed in Table 1076 affect the timer operation differently.

Table 1076. Timer modes and programmable fields

Mode (TCTRL*n*[MODE])	Fields affecting timer operations
32-bit periodic counter	TCTRL*n*[TSOT], TCTRL*n*[TSOI], and TCTRL*n*[TROT] affect the timer operation as described in Table 1075.
Dual 16-bit periodic counter	
32-bit trigger accumulator	• Only TCTRL*n*[TSOI] controls the timer function. • TCTRL*n*[TROT] and TCTRL*n*[TSOT] have no effect on timer operations.
32-bit input trigger capture	• Only TCTRL*n*[TSOI] and TCTRL*n*[TROT] control the timer function. • TCTRL*n*[TSOT] has no effect on timer operations.

71.3.7 Channel chaining

You can chain individual timer channels together to achieve a larger value of timeout. Chaining enables these channels to work in a "nested loop" manner, thereby leading to an effective timeout value of $TVAL_{CHn} \times (TVAL_{CHn-1} + 1)$.

To chain the channels together, write 1 to TCTRL*n*[CHAIN] for the corresponding channel. When a channel is chained, that channel's timer decrements after the previous channel's timeout pulse, regardless of the timer mode that TCTRL*n*[MODE] defines.

TCTRL*n*[TSOT] does not have any effect if you chain the channel timer (channel *n*) to the previous channel's timer (channel *n* - 1).

71.3.8 Detailed timing

The following table represents various timing diagrams. The diagrams are not "cycle-accurate," which means, they may not show some of the cycles, but they do show the timer channel behavior across several clock cycles.

Table 1077. Timing diagrams

Mode (TCTRL*n*[MODE]) setting		Timing diagram	TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	TCTRL*n*[CHAIN]
32-bit periodic counter (Compare mode)	00	Case 1: TCTRL*n*[MODE] = 0 • For a use case requiring repeated interrupts with reload • Trigger outputs have equal periods	0	0	0	0
		Case 2: TCTRL*n*[MODE] = 0 • Useful for One-Shot Trigger mode • Trigger starts again after TCTRL*n*[T_EN] becomes 1	0	0	1	0
		Case 3: TCTRL*n*[MODE] = 0 • For a use case requiring repeated interrupts with reload • Trigger outputs have unequal periods	0	1	0	0
		Case 4: TCTRL*n*[MODE] = 0 • For a one-shot timer with reload before timeout of Timer mode • Timer starts again after you write 1 to TCTRL*n*[T_EN]	0	1	1	0
		Case 5: TCTRL*n*[MODE] = 0 • Useful for generating periodic interrupts after a predefined event (input trigger) • Output triggers have equal periods	1	0	0	0
		Case 6: TCTRL*n*[MODE] = 0 • Triggers One-Shot Timer mode • Output trigger period depends on the input trigger	1	0	1	0
		Case 7: TCTRL*n*[MODE] = 0 • Repeated interrupts with Reload Timer mode • Outputs triggers have unequal periods	1	1	0	0
		Case 8: TCTRL*n*[MODE] = 0 • Case shown for a nonperiodic input trigger (might not be a use case)	1	1	1	0

Table continues on the next page...

Table 1077. Timing diagrams (continued)

Mode (TCTRL*n*[MODE]) setting		Timing diagram	TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	TCTRL*n*[CHAIN]
		• If input trigger is periodic and greater than timer timeout, it is the same as TCTRL*n*[TROT] = 0 • If input trigger is periodic and less than timer timeout, the timer never times out and always reloads on the input trigger (not a valid use case)				
16-bit dual periodic counter (Compare mode)	01	Case 1: TCTRL*n*[MODE] = 1 • The effect of TCTRL*n*[TSOT], TCTRL*n*[TROT], and TCTRL*n*[TSOI] is the same as that of TCTRL*n*[MODE] = 0 (32-bit Counter Compare mode) • Both halves of the counter are affected in the same way	0	0	0	0
32-bit trigger accumulator mode	10	Case 1: TCTRL*n*[MODE] = 10 • Useful for a continuous pulse counting mode • Trigger and timeout generated after programmed number of pulses are accumulated	X	X	0	0
		Case 2: TCTRL*n*[MODE] = 10 • Useful for One-Shot Pulse Counting mode • Trigger and timeout generated after programmed number of pulses are accumulated	X	X	1	0
32-bit trigger capture mode	11	Case 1: TCTRL*n*[MODE] = 11 • Useful for determining the duration between pulses • Proper clock selection can ensure that the timer does not rollover more than once between two pulses	X	0	0	0
		Case 2: TCTRL*n*[MODE] = 11 • Useful for determining the duration between pulses • Selecting a fast timer clock provides accurate measurements but it can also cause timer rollover between pulses	X	1	0	0

Table continues on the next page...

		Case 3: TCTRL*n*[MODE] = 11 • One-Shot Timer Count mode • You can enable it again by writing 1 to TCTRL*n*[T_EN]	X	0	1	0
Timer chaining: effects on timing operations	XX	Timer chaining	X	X	X	1

71.3.8.1 Case 1: TCTRL*n*[MODE] = 0

The following figure represents case 1 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

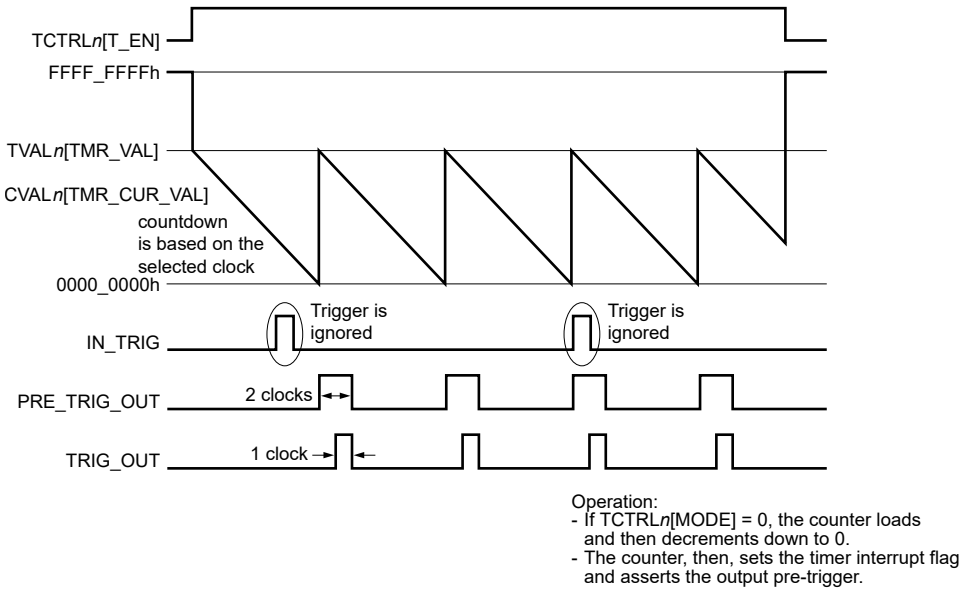

Figure 557. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0

71.3.8.2 Case 2: TCTRL*n*[MODE] = 0

The following figure represents case 2 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

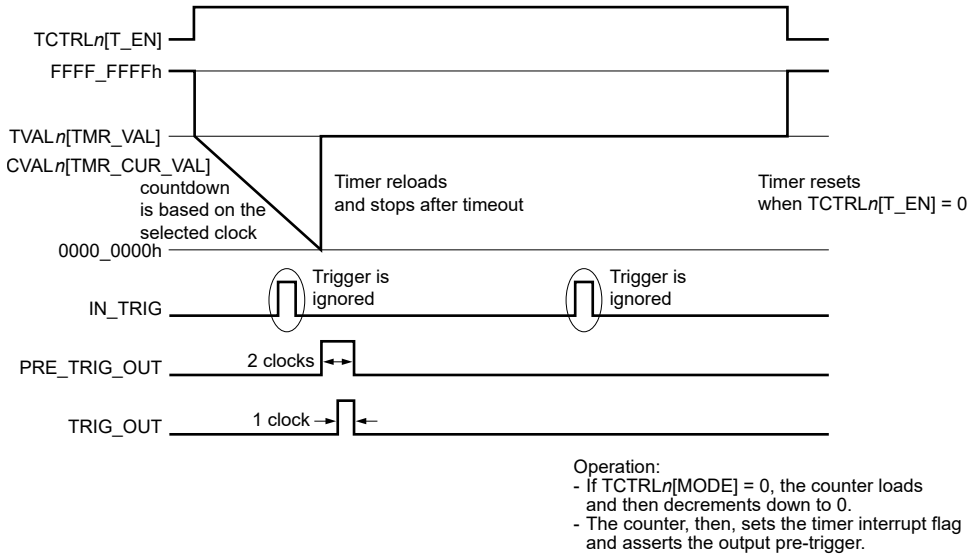

Figure 558. Case 2: TSOT = 0, TROT = 0, TSOI = 1, CHAIN = 0

71.3.8.3 Case 3: TCTRL*n*[MODE] = 0

The following figure represents case 3 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

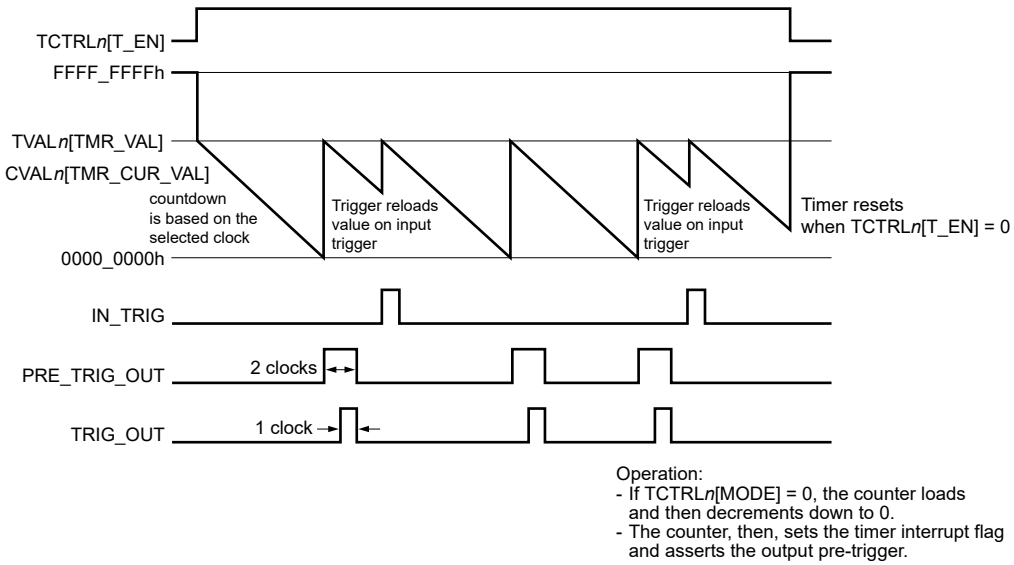

Figure 559. Case 3: TSOT = 0, TROT = 1, TSOI = 0, CHAIN = 0

71.3.8.4 Case 4: TCTRL*n*[MODE] = 0

The following figure represents case 4 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

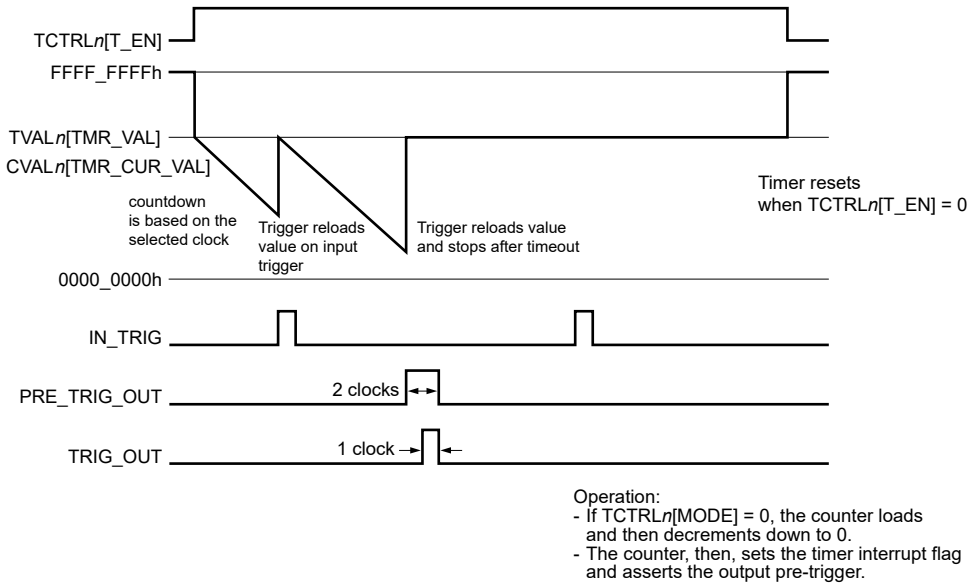

Figure 560. Case 4: TSOT = 0, TROT = 1, TSOI = 1, CHAIN = 0

71.3.8.5 Case 5: TCTRL*n*[MODE] = 0

The following figure represents case 5 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 1
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

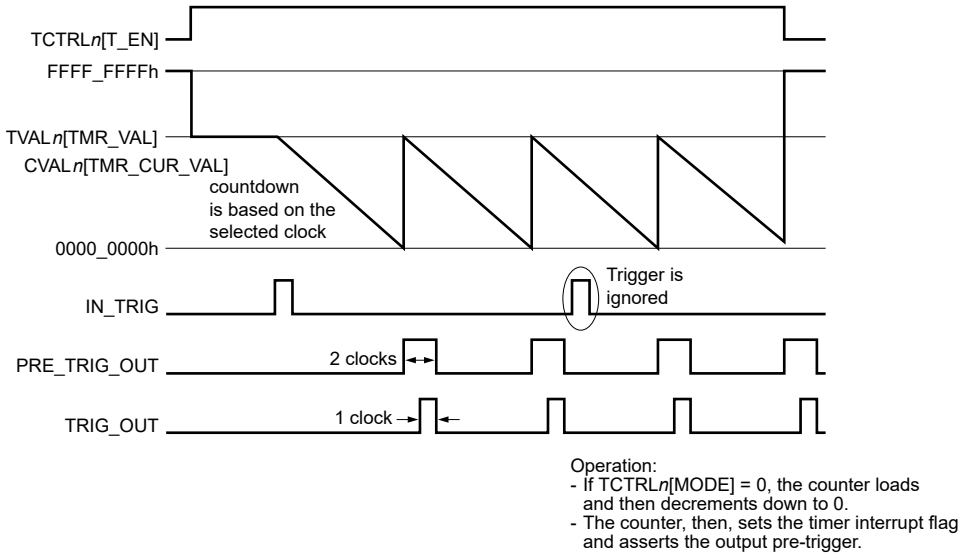

Figure 561. Case 5: TSOT = 1, TROT = 0, TSOI = 0, CHAIN = 0

71.3.8.6 Case 6: TCTRL*n*[MODE] = 0

The following figure represents case 6 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 1
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

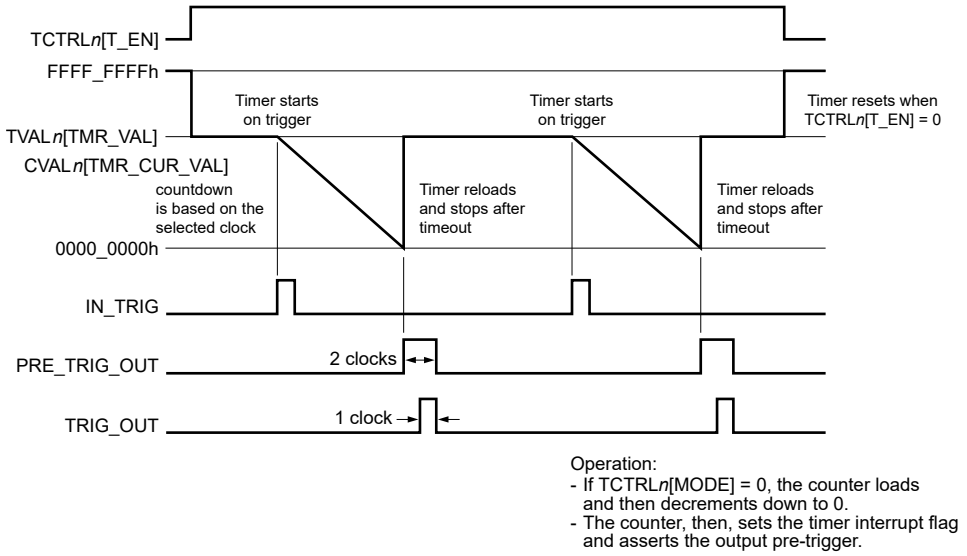

Figure 562. Case 6: TSOT = 1, TROT = 0, TSOI = 1, CHAIN = 0

71.3.8.7 Case 7: TCTRL*n*[MODE] = 0

The following figure represents case 7 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 1
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

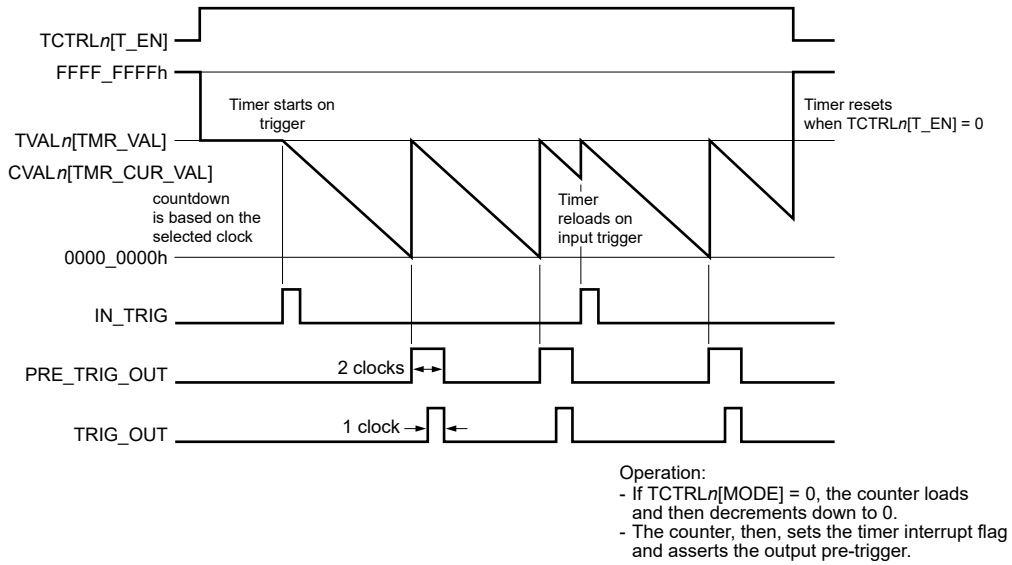

Figure 563. Case 7: TSOT = 1, TROT = 1, TSOI = 0, CHAIN = 0

71.3.8.8 Case 8: TCTRL*n*[MODE] = 0

The following figure represents case 8 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter).

LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 1
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

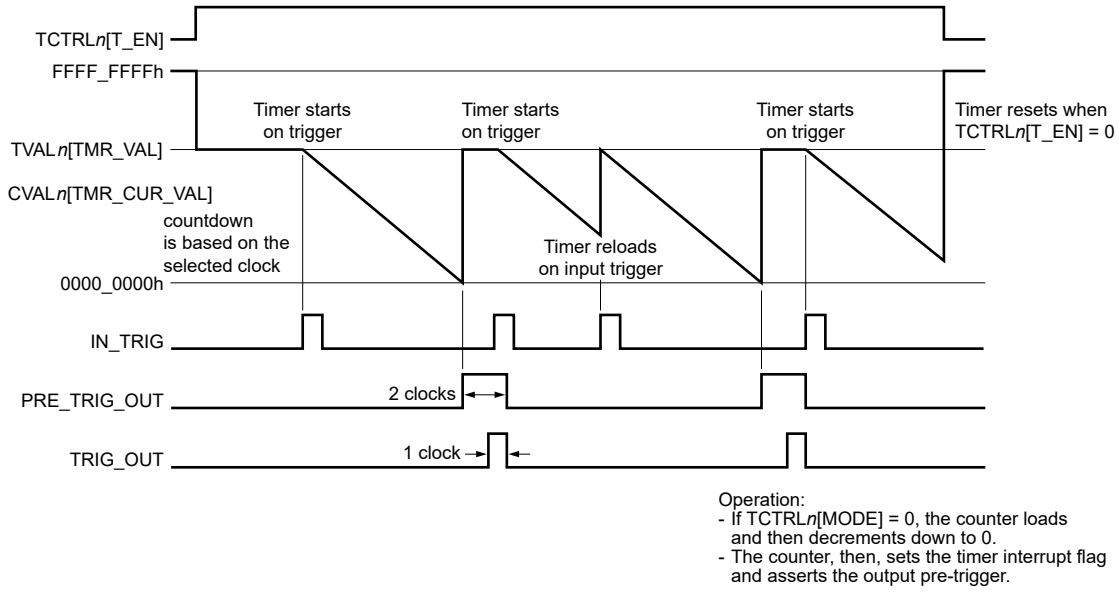

Figure 564. Case 8: TSOT = 1, TROT = 1, TSOI = 1, CHAIN = 0

71.3.8.9 Case 1: TCTRL*n*[MODE] = 1

The following figure represents case 1 in which TCTRL*n*[MODE] = 1 (16-bit dual periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

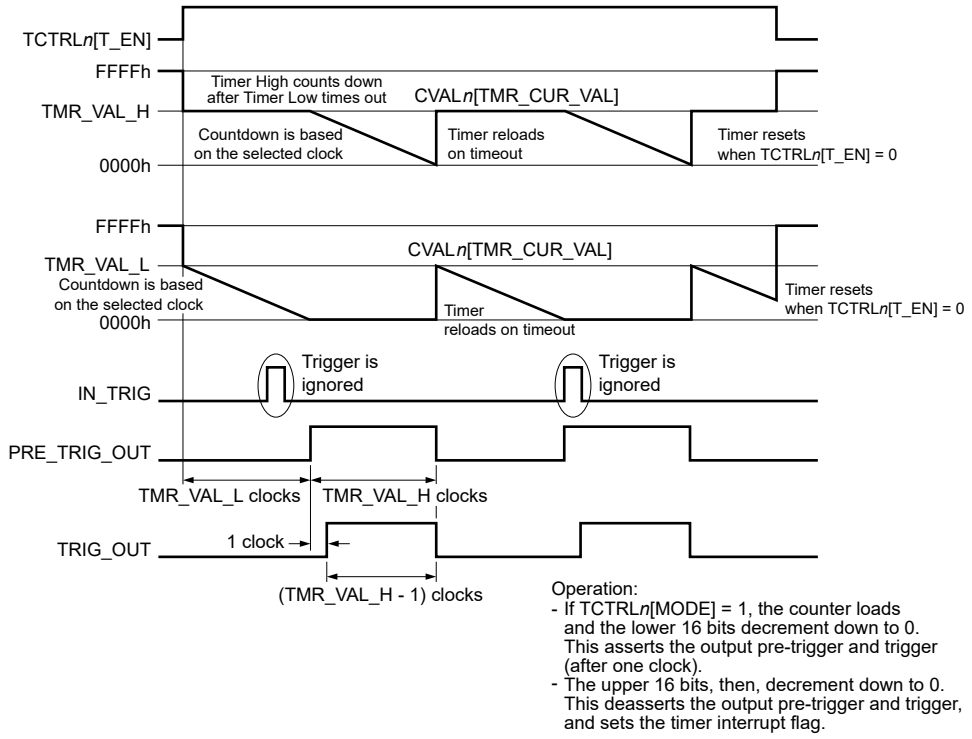

Figure 565. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0

If TCTRL*n*[MODE] = 1:

- The effect of timing control fields is similar to the effect of timer control fields when TCTRL*n*[MODE] = 0. See the individual timing diagrams for cases with TCTRL*n*[MODE] = 0 for more information.
- The timer interrupt (timeout) asserts when {TMR_H,TMR_L} = 0000_0000h.

See the following table for the behavior of timer control fields when TCTRL*n*[MODE] = 1.

Table 1078. Timer control fields when TCTRL*n*[MODE] = 1

TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	Function	Effect on timer
0	0	0	• For repeated interrupts with reload • Trigger outputs have equal periods	Similar to Case 1: TCTRL*n*[MODE] = 1.
0	0	1	One-shot mode	• Similar to Case 2: TCTRL*n*[MODE] = 0. • Both timers stop after first count down and then time out. • Timers do not count again until TCTRL*n*[T_EN] becomes 1.
0	1	0	• For repeated interrupts with reload • Trigger outputs have unequal periods	• Similar to Case 3: TCTRL*n*[MODE] = 0 . • Both timers reload the value of TVAL*n*[TMR_VAL] after the trigger rising edge.

Table continues on the next page...

Table 1078. Timer control fields when TCTRL*n*[MODE] = 1 (continued)

TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	Function	Effect on timer
				• Output triggers clear after reload, if asserted.
0	1	1	Reloadable one-shot mode	• Similar to Case 4: TCTRL*n*[MODE] = 0. • If a trigger occurs before timeout, then both timers reload and count down (as shown); the timers stop after timeout. • A trigger assertion after timeout reloads the value of TVAL*n*[TMR_VAL] into the timers. • The timers do not count again until TCTRL*n*[T_EN] becomes 1 again.
1	0	0	• For generating periodic interrupts after a predefined event (input trigger) • Output triggers have equal periods	• Similar to Case 5: TCTRL*n*[MODE] = 0. • After TCTRL*n*[T_EN] rises, the timers do not start until after the first trigger's rising edge. • Subsequent triggers have no effect.
1	0	1	• Triggered one-shot timer mode • Output trigger period depends on the input trigger	• Similar to Case 6: TCTRL*n*[MODE] = 0. • After TCTRL*n*[T_EN] becomes 1, the timers do not start until after the first trigger's rising edge. • The timer stops counting after a timeout assertion. • The timer does not start counting again until a new trigger's rising edge is detected.
1	1	0	• For repeated interrupts with reload timer mode • Output triggers have unequal periods	• Similar to Case 7: TCTRL*n*[MODE] = 0. • After TCTRL*n*[T_EN] becomes 1, the timers do not start until the first trigger's rising edge. • Subsequent triggers cause the timer to reload the value of TVAL*n*[TMR_VAL] into both counters. • The output triggers clear after a reload, if asserted.
1	1	1	• For a nonperiodic input trigger • If input trigger is periodic and greater than timer timeout, then it is the	• Similar to Case 8: TCTRL*n*[MODE] = 0. • After TCTRL*n*[T_EN] becomes 1, the timers do not start until the first trigger's rising edge.

Table continues on the next page...

Table 1078. Timer control fields when TCTRL*n*[MODE] = 1 (continued)

TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	Function	Effect on timer
			same as TCTRL*n*[TROT] = 0 (which is triggered one-shot timer mode; output trigger period depends on the input trigger)	• The timers stop counting after a timeout assertion. • A trigger's rising edge causes the timers to reload and then count down.

71.3.8.10 Case 1: TCTRL*n*[MODE] = 10

The following figure represents case 1 in which TCTRL*n*[MODE] = 10. LPIT works in 32-bit trigger accumulator mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = X
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

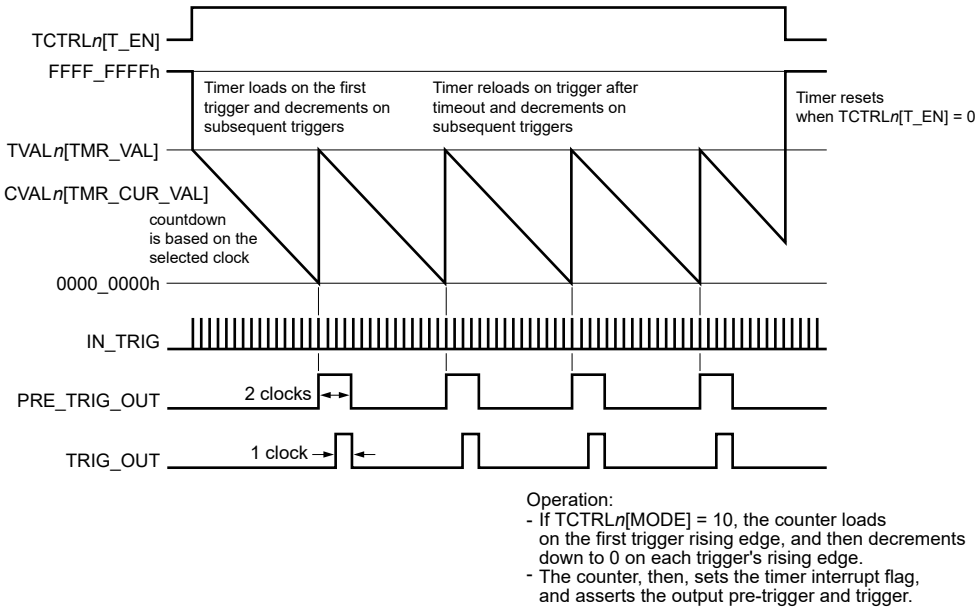

Figure 566. Case 1: TSOT = X, TROT = X, TSOI = 0, CHAIN = 0

71.3.8.11 Case 2: TCTRL*n*[MODE] = 10

The following figure represents case 2 in which TCTRL*n*[MODE] = 10. LPIT works in 32-bit trigger accumulator mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = X
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

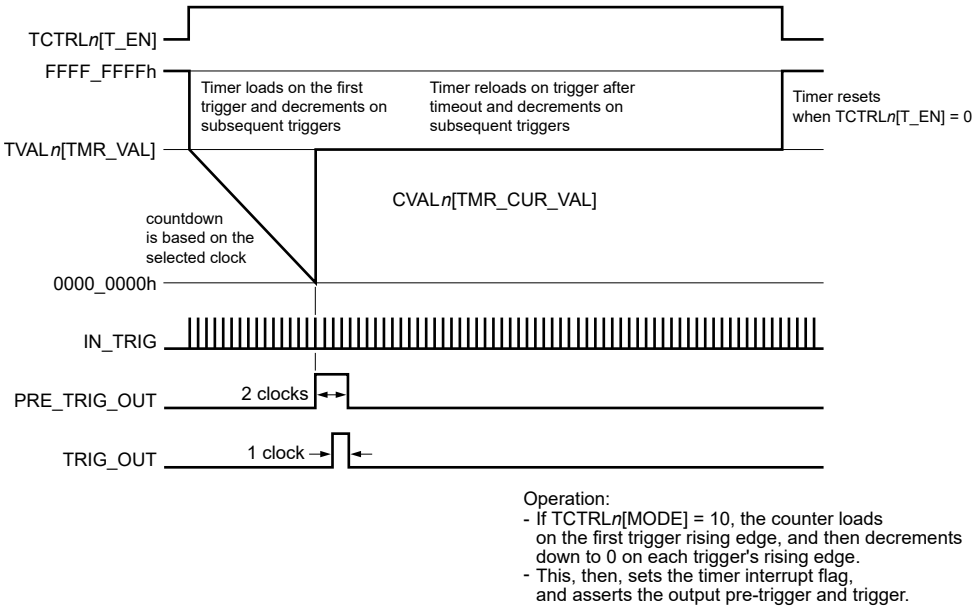

Figure 567. Case 2: TSOT = X, TROT = X, TSOI = 1, CHAIN = 0

71.3.8.12 Case 1: TCTRL*n*[MODE] = 11

The following figure represents case 1 in which TCTRL*n*[MODE] = 11. LPIT works in 32-bit trigger capture mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

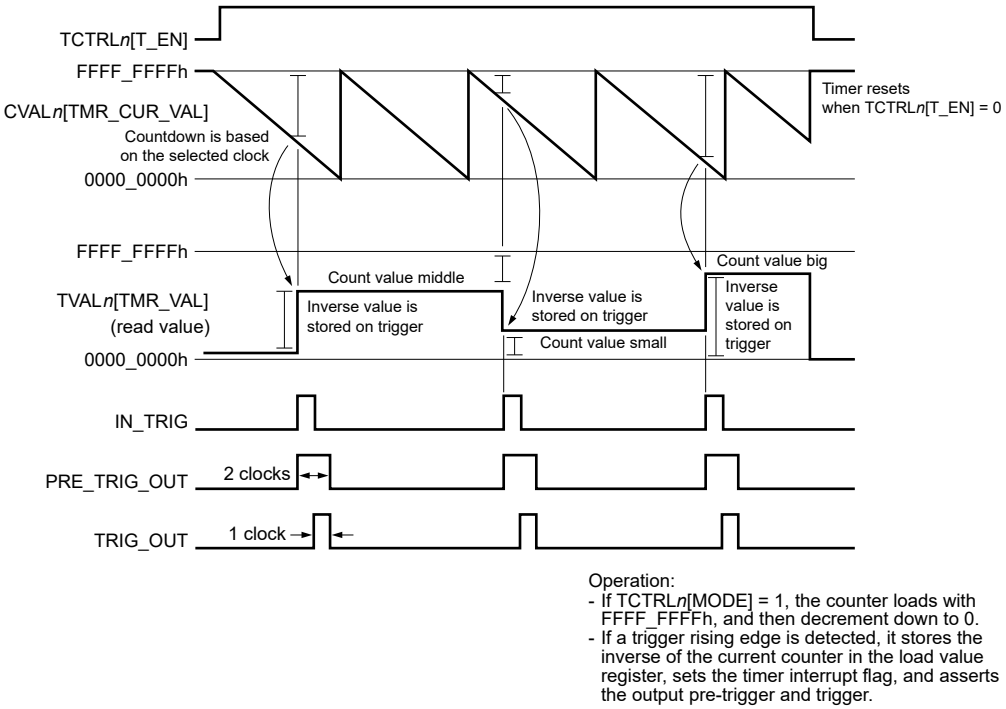

Figure 568. Case 1: TSOT = X, TROT = 0, TSOI = 0, CHAIN = 0

71.3.8.13 Case 2: TCTRL*n*[MODE] = 11

The following figure represents case 2 in which TCTRL*n*[MODE] = 11. LPIT works in 32-bit trigger capture mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

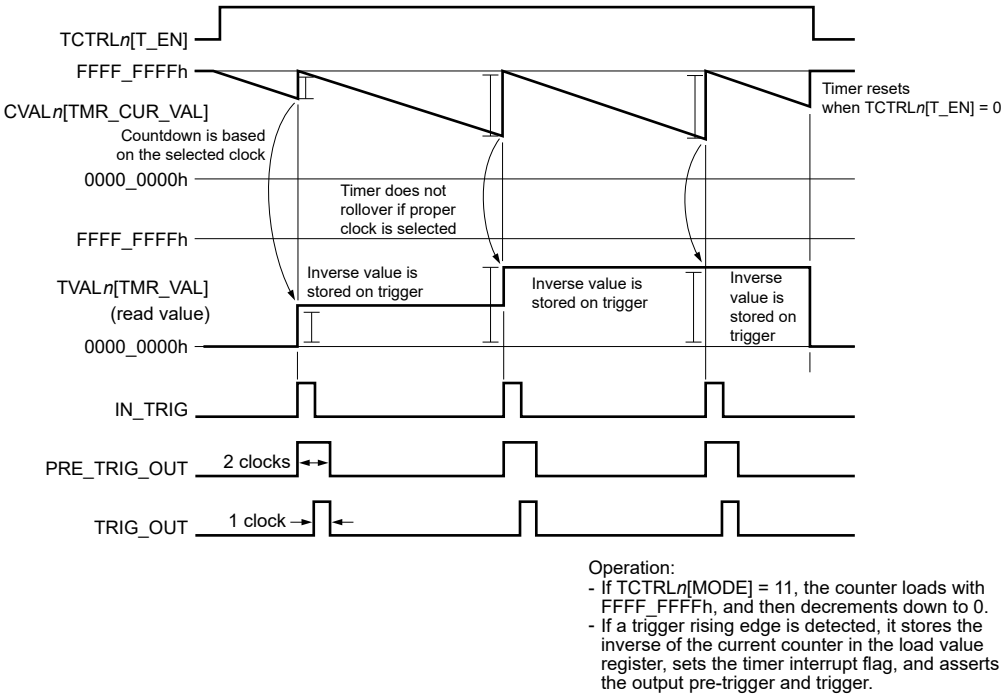

Figure 569. Case 2: TSOT = X, TROT = 1, TSOI = 0, CHAIN = 0

71.3.8.14 Case 3: TCTRL*n*[MODE] = 11

The following figure represents case 3 in which TCTRL*n*[MODE] = 11. LPIT works in 32-bit trigger capture mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

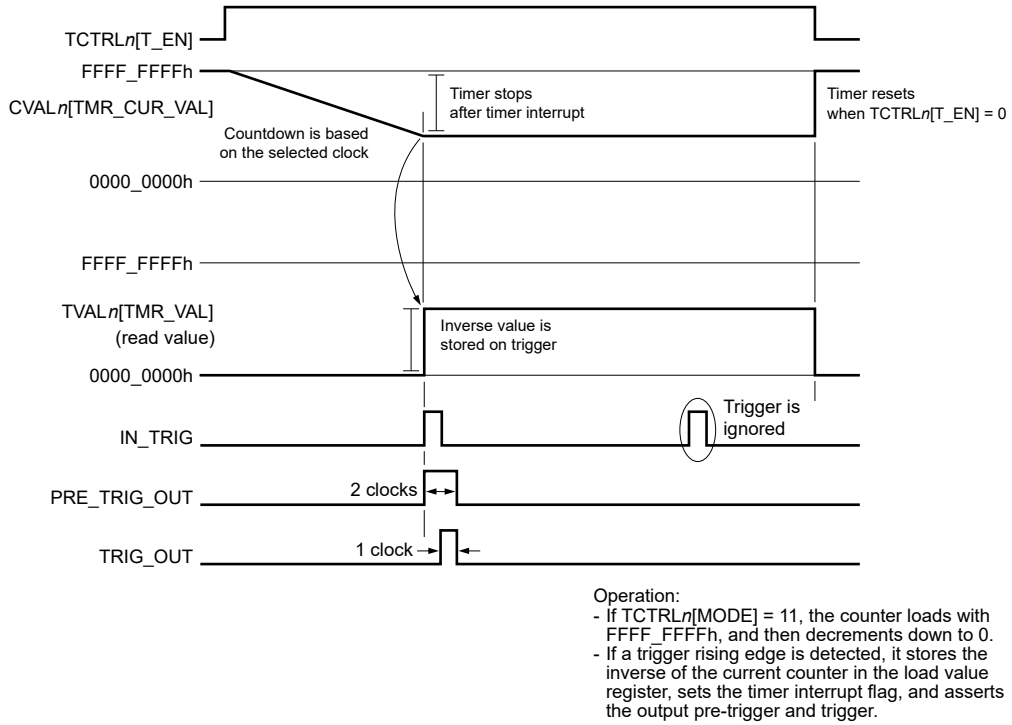

Figure 570. Case 3: TSOT = X, TROT = 0, TSOI = 1, CHAIN = 0

71.3.8.15 Case 4: TCTRL*n*[MODE] = 11

Case 4, in which TCTRL*n*[MODE] = 11, is the same as case 3, except that the timer reloads to FFFF_FFFFh and then stops. The timer does not start until TCTRL*n*[T_EN] becomes 1 again. In this case, LPIT works in 32-bit trigger capture mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

71.3.9 Timer chaining

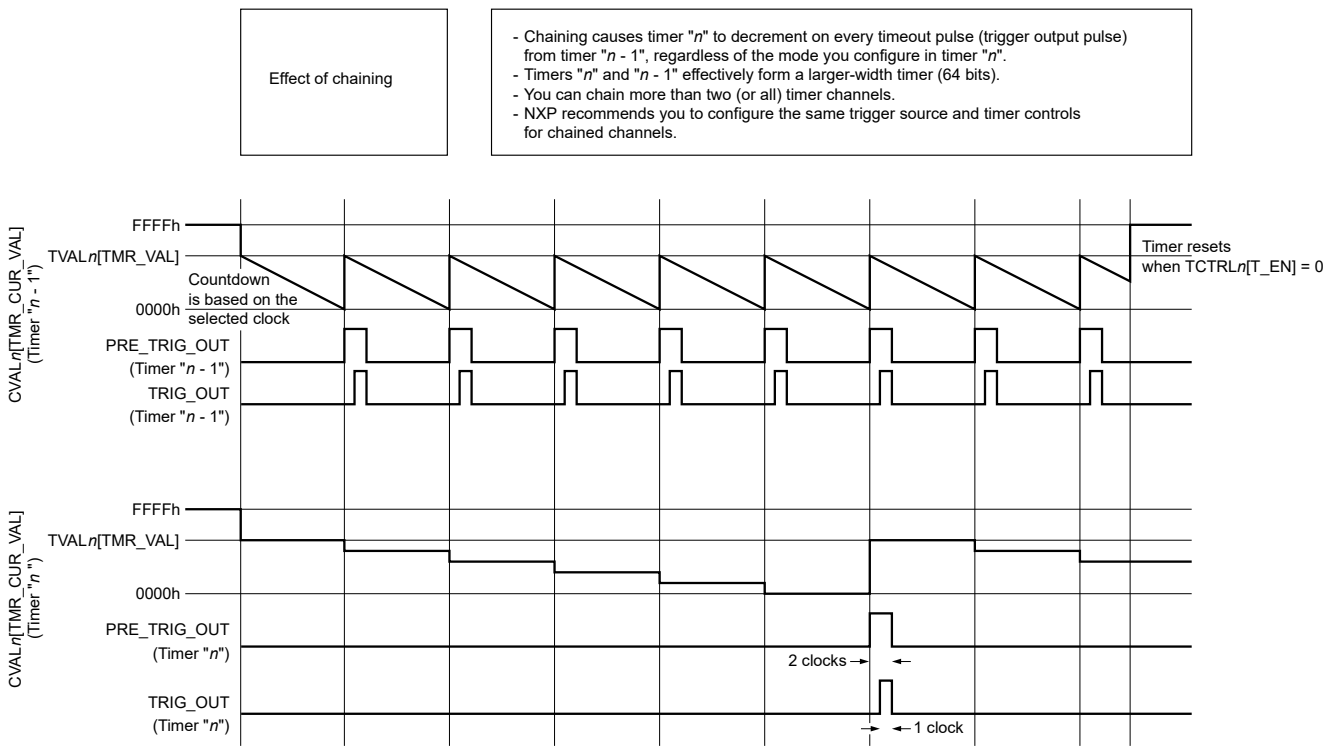

Figure 571. Chaining effects

71.4 Initialization

Table 1079. Initializing LPIT

Step	Action	How or why to perform the step
1	Enable the peripheral clock	By writing 1 to MCR[M_CEN]. **NOTE** • Accessing certain registers (Module Status (MSR), Set Timer Enable (SETTEN), Clear Timer Enable (CLRTEN), Timer Value (TVAL0 - TVAL3), Current Timer Value (CVAL0 - CVAL3), and Timer Control (TCTRL0 - TCTRL3)) while MCR[M_CEN] = 0 leads to the assertion of a transfer error for that bus access. However, writing to CVAL*n* and reserved registers generates a transfer error. • There might be additional clock gating fields in the chip that gate the peripheral clock to this module. When enabling the clock to this module, you must configure those additional clock gating fields (in addition to configuring MCR[M_CEN]).
2	Wait for four peripheral clock cycles	To allow time for clock synchronization and reset deassertion.

Table continues on the next page...

Table 1079. Initializing LPIT (continued)

Step	Action	How or why to perform the step
3	Configure timer control fields	For each timer channel that is to be enabled: • Timer mode of operation fields, TCTRL*n*[MODE] • Trigger source selection fields, TCTRL*n*[TRG_SEL] and TCTRL*n*[TRG_SRC] • Trigger control fields, TCTRL*n*[TROT], TCTRL*n*[TSOT], and TCTRL*n*[TSOI] **NOTE** You must not update timer control fields when the timer is disabled. You can disable a timer by using any one of the following methods: • Write 1 to the specific timer's CLRTEN[CLR_T_EN_*n*] field. • Write 0 to TCTRL*n*[T_EN] for that channel.
4	Configure the channels that are to be chained	By writing 1 to TCTRL*n*[CHAIN] in the corresponding channel's Timer Control (TCTRL0 - TCTRL3).
5	Set the timer timeout value	By programming an appropriate value in TVAL*n*[TMR_VAL] for the channels that you configure in Compare mode.
6	Configure MIER[TIE*n*]	For those channels that are required to generate interrupts after timer timeouts.
7	Configure the low-power modes of the module	By writing 1 to MCR[DBG_EN] and MCR[DOZE_EN]. This is common to all timer channels.
8	Enable the channel timers	By writing 1 to the corresponding TCTRL*n*[T_EN].

NOTE

When you enable a timer channel in Compare mode, the first decrement takes an additional one or two clock cycles because of synchronization logic. This results in the first compare (and therefore interrupt and hardware trigger) occurring slightly later. A faster counter clock minimizes this impact.

Additionally,

- For channels that you configure in Capture mode, you can read the timer value from Timer Value (TVAL0 - TVAL3) when a channel timeout occurs.
- At any time, you can read the current value of the timer for any channel by reading the corresponding channel's Current Timer Value (CVAL0 - CVAL3). Ensure that MCR[M_CEN] = 1 when doing so.
- MSR[TIF*n*] are asserted after timer timeout. To clear these timer interrupt flags, write 1 to them.

71.5 Memory map and registers

71.5.1 LPIT register descriptions

The LPIT memory map comprises 32-bit aligned registers, which you can access via 8-bit, 16-bit, or 32-bit accesses. Read and write accesses to reserved locations generate a transfer error, and the read bus shows all 0s.

NOTE

- The memory map and complete module are in big-endian (BE) format.
- LPIT does not check whether programmed values in these registers are correct—you must write the correct values.

71.5.1.1 LPIT memory map

LPIT1 base address: 442F_0000h

71.5.1.2 Version ID (VERID)

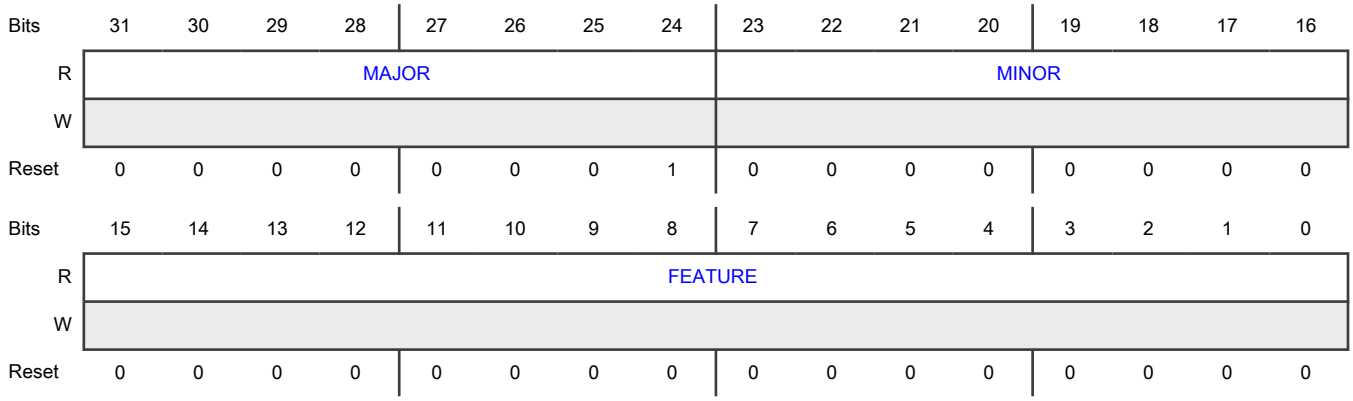
Offset

Register	Offset
VERID	0h

Function

Contains design version specification numbers.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number for the module design specification.
23-16 MINOR	Minor Version Number Indicates the minor version number for the module design specification.
15-0 FEATURE	Feature Number Indicates the feature set number.

71.5.1.3 Parameter (PARAM)

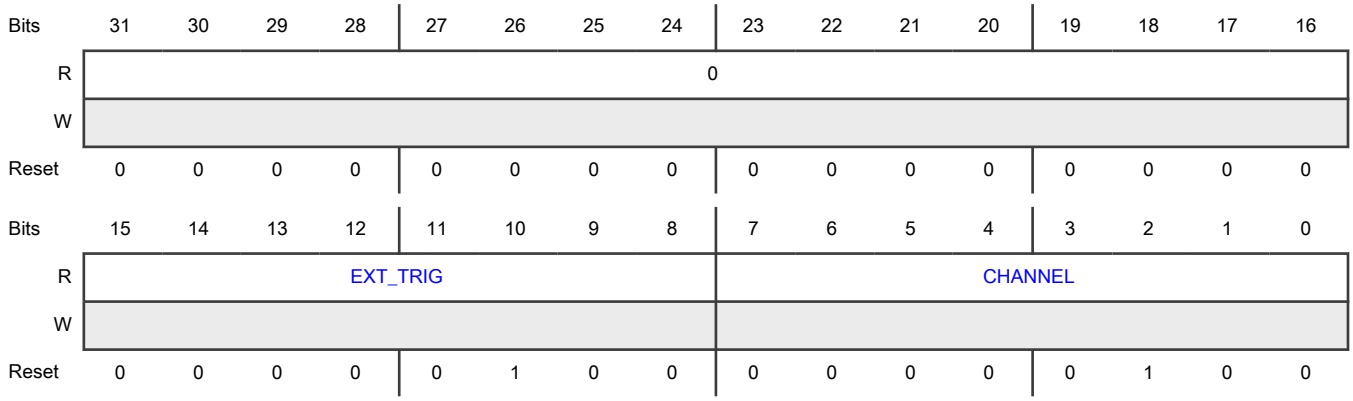
Offset

Register	Offset
PARAM	4h

Function

Provides parameter settings that are used when incorporating this module into the chip.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 EXT_TRIG	Number of External Trigger Inputs Specifies the number of external triggers implemented in this chip.
7-0 CHANNEL	Number of Timer Channels Specifies the number of timer channels implemented in this chip.

71.5.1.4 Module Control (MCR)

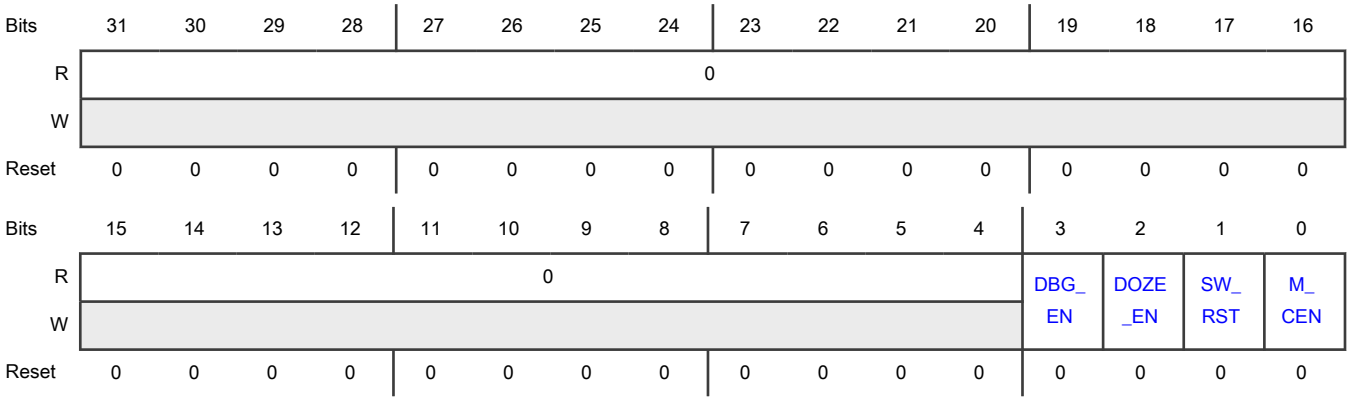
Offset

Register	Offset
MCR	8h

Function

Contains software reset, clock enable, and mode enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 DBG_EN	Debug Mode Enable Stops the timer channels when the chip enters Debug mode. 0b - Stops timer channels 1b - Allows timer channels to continue running
2 DOZE_EN	DOZE Mode Enable Stops the timer channels when the chip enters Doze mode. 0b - Stops timer channels 1b - Allows timer channels to continue running
1 SW_RST	Software Reset Resets all timer channels and registers, except Module Status (MSR). This field remains 1 until software clears it. Before clearing this field, software must wait for four peripheral clocks (for clock synchronization and reset propagation). 0b - Does not reset 1b - Resets
0 M_CEN	Module Clock Enable Enables the peripheral clock to LPIT module timers. This field must become 1 when accessing the following registers: • Module Status (MSR) • Set Timer Enable (SETTEN) • Clear Timer Enable (CLRTEN)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Timer Value (TVAL0 - TVAL3) • Current Timer Value (CVAL0 - CVAL3) • Timer Control (TCTRL0 - TCTRL3) The following considerations apply when using this field: • You must enable both the bus and peripheral clocks to allow clock synchronization and update of the aforementioned registers. Accessing these registers when MCR[M_CEN] = 0 asserts a transfer error for that bus cycle. • Writing to Current Timer Value (CVAL0 - CVAL3) and reserved registers always generates a transfer error. **NOTE** There may be additional clock gating fields available in this chip that gate the peripheral clock to LPIT. You must configure those additional clock gating fields appropriately to enable the peripheral clock to LPIT. 0b - Disable 1b - Enable

71.5.1.5 Module Status (MSR)

Offset

Register	Offset
MSR	Ch

Function

Contains channel timer interrupt flags.

NOTE

Unless the peripheral clock to the timers is enabled (MCR[M_CEN] = 1), reading or writing to this register generates a transfer error.

71.5.1.7 Set Timer Enable (SETTEN)

Offset

Register	Offset
SETTEN	14h

Function

Allows the simultaneous enabling of timer channels.

You can enable timer channels by using either of the following ways:

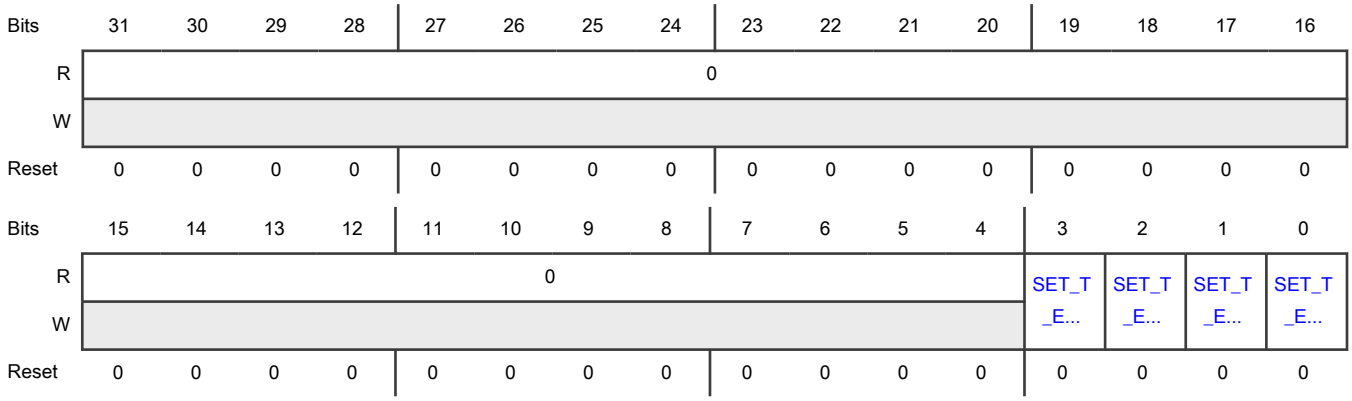
- Writing 1 to TCTRL*n*[T_EN] in the respective TCTRL*n* register.
- Writing 1 to the corresponding SETTEN[SET_T_EN_*n*] field.

To disable timer channels simultaneously, use Clear Timer Enable (CLRTEN). Writing 0 to the fields of this register has no effect.

NOTE

Unless the peripheral clock to the timers is enabled (MCR[M_CEN] = 1), reading or writing to this register generates a transfer error.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 SET_T_EN_3	Set Timer 3 Enable Works with TCTRL3[T_EN] and enables timer channel 3. Writing 0 to this field does not disable the counter; rather it has no effect. This field becomes 0 if any of the following conditions is true: • TCTRL3[T_EN] = 0 • You write 1 to CLRTEN[CLR_T_EN_3] 0b - No effect 1b - Enables timer channel 3
2 SET_T_EN_2	Set Timer 2 Enable Works with TCTRL2[T_EN] and enables timer channel 2. Writing 0 to this field does not disable the counter; rather it has no effect. 71.5.1.11 Timer Control (TCTRL0 - TCTRL3)

Offset

Register	Offset
TCTRL0	28h
TCTRL1	38h
TCTRL2	48h
TCTRL3	58h

Function

Contains control fields for each timer channel:

- TRG_SEL for trigger selection
- TRG_SRC for trigger source selection
- TROT for timer reload
- TSOI for timer stoppage
- TSOT for timer decrementing
- MODE for timer operation mode selection
- CHAIN for channel chaining

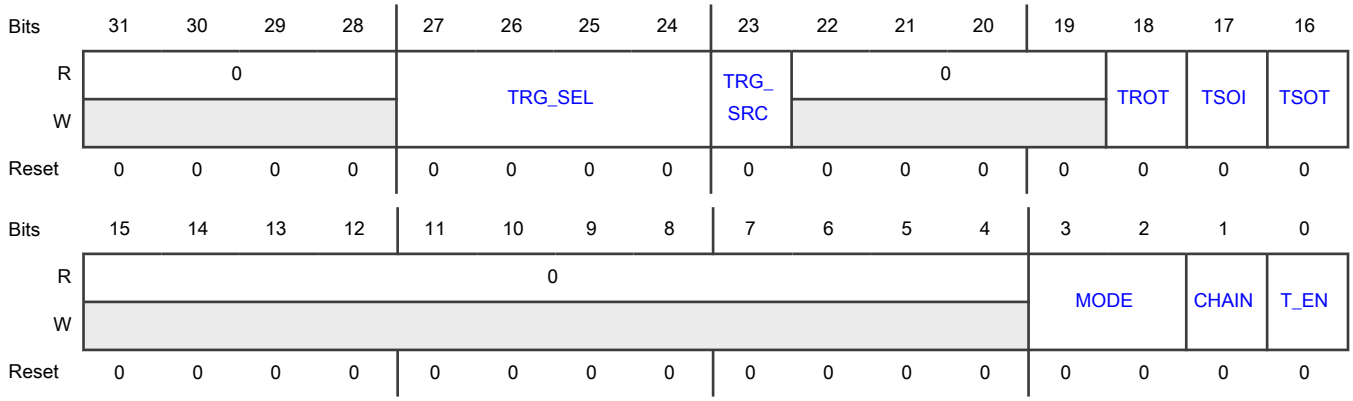
You must update timer controls when the timer is disabled, and use either of the following ways to disable a timer:

- By writing 1 to the specific timer's CLRTEN[CLR_T_EN_*n*] field.
- By writing 0 to T_EN for that channel.

NOTE

Unless the peripheral clock to the timers is enabled (MCR[M_CEN] = 1), reading or writing to this register generates a transfer error.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 TRG_SEL	Trigger Select Selects the trigger to use for starting and/or reloading the LPIT timer. This field selects one trigger from the set of internal or external triggers that TRG_SRC provides. TRG_SRC helps you make a choice between internal and external trigger signals for each channel. **NOTE** You must change the value of this field when the LPIT timer channel is disabled. 0000b-0011b - Timer channel 0–3 trigger source 0100b-1111b - Reserved
23 TRG_SRC	Trigger Source Selects whether to use internal or external trigger sources. You can select the trigger to be used by using this field or the TRG_SEL field. If a channel does not have an associated external trigger, write 1 to TRG_SRC. See LPIT chip-specific information for the available external trigger options. 0b - External 1b - Internal
22-19 —	Reserved
18 TROT	Timer Reload on Trigger Specifies whether the timer reloads after the selected trigger. If this field = 1, the LPIT timer reloads when a rising edge is detected on the selected trigger input. The trigger input is ignored if LPIT is disabled during Debug mode (MCR[DBG_EN] = 0) or Doze mode (MCR[DOZE_EN] = 0). 0b - Does not reload 1b - Reloads
17 TSOI	Timer Stop on Interrupt Controls whether the channel timer stops after being timed out. If this field = 0, the channel timer does not stop after timeout. If this field = 1, the channel timer stops after a timeout and then restarts based on the configuration of TSOT. If TSOT = 0, the channel timer restarts after a rising edge on T_EN is detected, which means that the timer channel is disabled and then enabled. If TSOT = 1, the channel timer restarts after a rising edge on the selected trigger is detected. 0b - Does not stop 1b - Stops

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 TSOT	Timer Start on Trigger Controls when the timer starts decrementing. If this field = 0, the timer starts decrementing immediately based on the restart condition (controlled by TSOI). If this field = 1, the timer starts decrementing when a rising edge on a selected trigger is detected. 0b - Immediately 1b - When a rising edge is detected
15-4 —	Reserved
3-2 MODE	Timer Operation Mode Configures the channel timer's mode of operation. This field controls how the timer decrements. 00b - 32-bit periodic counter 01b - Dual 16-bit periodic counter 10b - 32-bit trigger accumulator 11b - 32-bit trigger input capture
1 CHAIN	Chain Channel Specifies whether channel chaining is enabled. If channel chaining is enabled, the timer channel decrements after the previous channel's timeout (when timer channel N-1 trigger asserts). Timer channel 0 cannot be chained. If channel chaining is disabled, the channel timer runs independently. 0b - Disabled 1b - Enabled
0 T_EN	Timer Enable Enables the timer channel. 0b - Disable 1b - Enable

72.2 Overview

Each TMR contains four identical counter/timer groups. Each 16-bit counter/timer group contains a prescaler, a counter, a load register, a hold register, a capture register, two compare registers, two status and control registers, and one control register. All of the registers except the prescaler are read/writable.

NOTE

This document uses the terms "Timer" and "Counter" interchangeably because the counter/timers may perform either or both tasks.

The load register provides the initialization value to the counter when the counter's terminal value has been reached.

The hold register captures the counter's value when other counters are being read. This feature supports the reading of cascaded counters.

The capture register enables an external signal to take a "snap shot" of the counter's current value.

The COMP1 and COMP2 registers provide the values to which the counter is compared. If a match occurs, the OFLAG (TMR Output signal) can be set, cleared, or toggled. At match time, an interrupt is generated if enabled, and the new compare value is loaded into the COMP1 or COMP2 registers from CMPLD1 and CMPLD2 if enabled.

The prescaler provides different time bases useful for clocking the counter/timer.

The counter provides the ability to count internal or external events.

Within a TMR (set of four timer/counters), the four inputs are shared by the four counters, but the four outputs are dedicated to each counter.

72.2.1 Block diagram

Each of the timer/counter groups within TMR are shown in this figure.

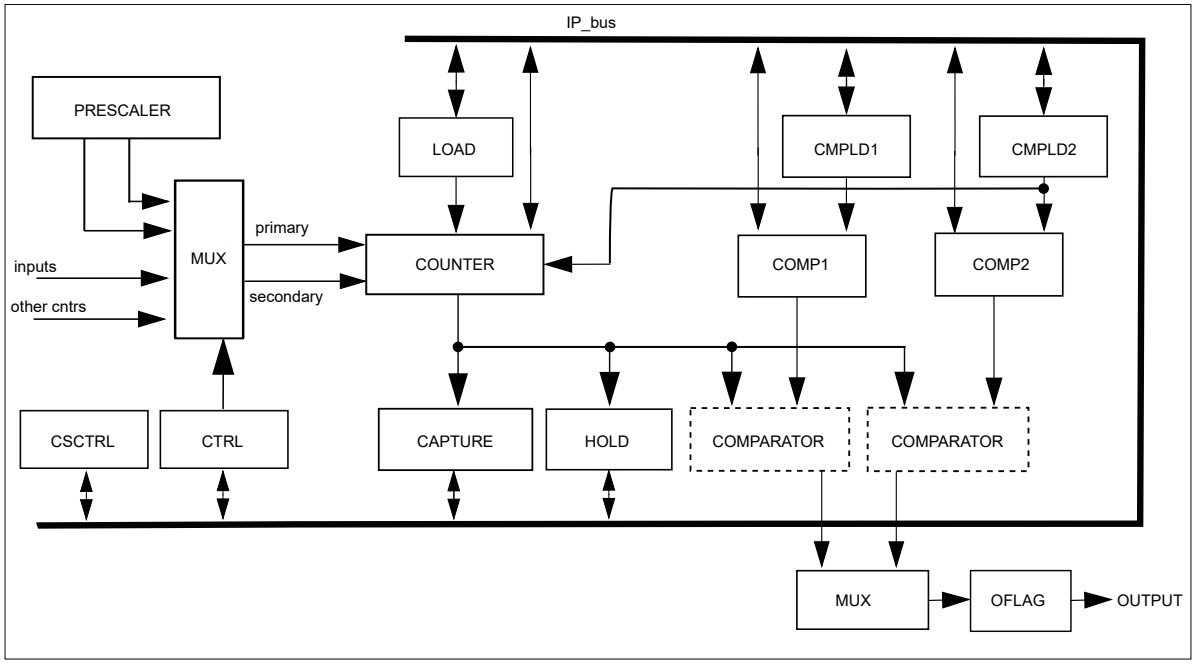

Figure 572. Quad timer block diagram

72.2.2 Features

TMR design includes these features:

- Four 16-bit counters/timers
- Count up/down
- Counters are cascadable
- Programmable count modulo
- Max count rate equals IP Bus Clock 2 for external clocks
- Max count rate equals IP Bus Clock for internal clocks
- Count once or repeatedly
- Counters are preloadable
- Compare registers are preloadable (available with compare load feature)
- Counters can share available input pins
- Separate prescaler for each counter
- Each counter has capture and compare capability
- Programmable operation during debug mode
- Inputs may act as fault inputs
- Programmable input filter
- Counting start can be synchronized across counters

72.3 Functional description

72.3.1 General

The counter/timer has two basic modes of operation: it can count internal or external events, or it can count an internal clock source while an external input signal is asserted, thus timing the width of the external input signal.

- The counter can count the rising, falling, or both edges of the selected input pin.
- The counter can decode and count quadrature encoded input signals.
- The counter can count up and down using dual inputs in a "count with direction" format.
- The counter's terminal count value (modulo) is programmable.
  - The value that is loaded into the counter after reaching its terminal count is programmable.
- The counter can count repeatedly, or it can stop after completing one count cycle.
- The counter can be programmed to count to a programmed value and then immediately reinitialize, or it can count through the compare value until the count "rolls over" to zero.

The external inputs to each counter/timer are shareable among each of the four counter/timers within the module. The external inputs can be used as:

- Count commands
- Timer commands
- They can trigger the current counter value to be "captured"
- They can be used to generate interrupt requests

The polarity of the external inputs are selectable.

The primary output of each timer/counter is the output signal OFLAG. The OFLAG output signal can be:

- Set, cleared, or toggled when the counter reaches the programmed value.
- The OFLAG output signal may be output to an external pin instead of having that pin serve as a timer input.
- The OFLAG output signal enables each counter to generate square waves, PWM, or pulse stream outputs.
- The polarity of the OFLAG output signal is selectable.

Any counter/timer can be assigned as a master. A master's compare signal can be broadcast to the other counter/timers within the module. The other counters can be configured to reinitialize their counters and/or force their OFLAG output signals to predetermined values when a master's counter/timer compare event occurs.

72.3.2 Usage of compare registers

The dual compare registers (COMP1 and COMP2) provide a bidirectional modulo count capability. The COMP1 register is used when the counter is *counting up*, and the COMP2 register is used when the counter is *counting down*. Alternating compare mode is the only exception.

The COMP1 register should be set to the desired maximum count value or FFFFh to indicate the maximum unsigned value prior to roll-over, and the COMP2 register should be set to the minimum count value or 0000h to indicate the minimum unsigned value prior to roll-under.

If CTRL[OUTMODE] is set to 100, the OFLAG will toggle while using alternating compare registers. In this variable frequency PWM mode, the COMP2 value defines the desired pulse width of the on time, and the COMP1 register defines the off time.

Use caution when changing COMP1 and COMP2 while the counter is active. If the counter has already passed the new value, it will count to FFFFh or 0000h, roll over, then begin counting toward the new value. The check is: Count=CMPx, *not* Count > COMP1 or Count < COMP2.

The use of the CMPLD1 and CMPLD2 registers to compare values will help to minimize this problem.

72.3.3 Usage of compare load registers

The CMPLD1, CMPLD2, and CSCTRL registers offer a high degree of flexibility for loading compare registers with user-defined values on different compare events. To ensure correct functionality while using these registers we strongly suggest using the following method described in this section.

The purpose of the compare load feature is to allow quicker updating of the compare registers. In the past, a compare register could be updated using interrupts. However, because of the latency between an interrupt event occurring and the service of that interrupt, there was the possibility that the counter may have already counted past the new compare value by the time the compare register was updated by the interrupt service routine. The counter would then continue counting until it rolled over and reached the new compare value.

To address this, the compare registers are now updated in hardware in the same way the counter register is re-initialized to the value stored in the load register. The compare load feature allows the user to calculate new compare values and store them in to the comparator load registers. When a compare event occurs, the new compare values in the comparator load registers are written to the compare registers eliminating the use of software to do this.

The compare load feature is intended to be used in variable frequency PWM mode. The COMP1 register determines the pulse width for the logic low part of OFLAG and COMP2 determines the pulse width for the logic high part of OFLAG. The period of the waveform is determined by the COMP1 and COMP2 values and the frequency of the primary clock source. See the following figure.

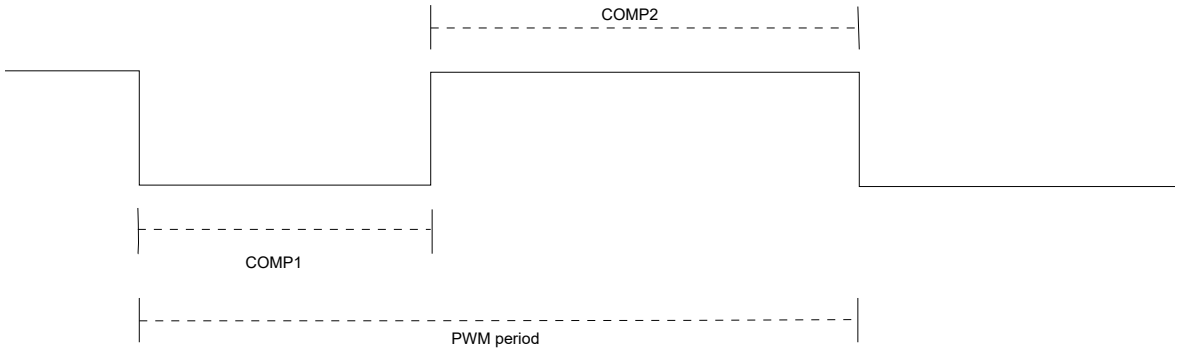

Figure 573. Variable PWM waveform

Should we desire to update the duty cycle or period of the above waveform, we would need to update the COMP1 and COMP2 values using the compare load feature.

72.3.4 Usage of the capture register

The capture register stores a copy of the counter's value when an input edge (positive, negative, or both) is detected. After a capture event occurs, no further updating of the capture register will occur until the SCTRL[IEF] (input edge flag) is cleared by writing a zero to the SCTRL[IEF].

72.3.5 Modes of operation

TMR design operates only in one mode of operation: Functional mode. See Functional mode for the various counting modes in Functional mode.

72.3.5.1 Functional mode

The selected external count signals are sampled at the TMR's base clock rate and then run through a transition detector. The maximum count rate is one-half of the TMR's base clock rate. Internal clock sources can be used to clock the counters at the TMR's base clock rate.

If a counter is programmed to count to a specific value and then stop, the CTRL[CM] field is cleared when the count terminates.

72.3.5.1.1 Stop mode

If CTRL[CM] is set to '000', the counter is inert. No counting will occur. Stop mode will also disable the interrupts caused by input transitions on a selected input pin.

72.3.5.1.2 Count mode

If CTRL[CM] is set to '001', the counter will count the rising edges of the selected clock source. This mode is useful for generating periodic interrupts for timing purposes, or counting external events such as "widgets" on a conveyor belt passing a sensor. If the selected input is inverted by setting SCTRL[IPS] (input polarity select), then the negative edge of the selected external input signal is counted.

Count pulses from external source

```
//    This example uses TMR1 to count pulse (actually counts rising edges of
the pulse)
//      from an external source (QT3).
//
void Pulse_Init(void)
{

  /* TMR1_CTRL: CM=0,PCS=3,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x0600);           /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x00);
  setReg(TMR1_CNTR,0x00);             /* Reset counter register */
  setReg(TMR1_LOAD,0x00);             /* Reset load register */
  setRegBitGroup(TMR1_CTRL,CM,0x01);  /* Run counter */
}
```

Generate periodic interrupt by counting internal clocks

```
//   This example generates an interrupt every 100ms,
//     assuming the chip is operating at 60 MHz.
//
// It does this by using the IP_bus_clk divided by 128 as the counter clock
source.
// The counter then counts to 46874 where it matches the COMP1 value.
// At that time an interrupt is generated, the counter is reloaded and
// the next COMP1 value is loaded from CMPLD1.
//
void TimerInt_Init(void)
{
  /* TMR0_CTRL: CM=0,PCS=0,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR0_CTRL,0x20);             /* Stop all functions of the timer */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR0_SCTRL,0x00);
  setReg(TMR0_LOAD,0x00);            /* Reset load register */
  setReg(TMR0_COMP1,46874);          /* Set up compare 1 register */
  setReg(TMR0_CMPLD1,46874);         /* Also set the compare preload register */
  /* TMR0_CSCTRL:
DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,TCF2EN=0,TCF1EN=1,
                   TCF2=0,TCF1=0,CL2=0,CL1=1 */
  setReg(TMR0_CSCTRL,0x41);          /* Enable compare 1 interrupt and */
                                      /*   compare 1 preload */
  setRegBitGroup(TMR0_CTRL,PCS,0xF); /* Primary Count Source to IP_bus_clk /
128 */
  setReg(TMR0_CNTR,0x00);            /* Reset counter register */
  setRegBitGroup(TMR0_CTRL,CM,0x01); /* Run counter */
}
```

72.3.5.1.3 Edge-Count mode

If CTRL[CM] is set to '010', the counter will count both edges of the selected external clock source. This mode is useful for counting the changes in the external environment, such as a simple encoder wheel.

Count both edges of external source signal

```
//  This example uses TMR1 to count pulse (actually counts both edges of the
pulse)
//    from an external source (QT3).
//
void Pulse_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=3,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x0600);           /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x00);
  setReg(TMR1_CNTR,0x00);             /* Reset counter register */
  setReg(TMR1_LOAD,0x00);             /* Reset load register */
  setRegBitGroup(TMR1_CTRL,CM,0x02);  /* Run counter */
}
```

72.3.5.1.4 Gated-Count mode

If CTRL[CM] is set to '011', the counter will count while the selected secondary input signal is high. This mode is used to time the duration of external events. If the selected input is inverted by setting SCTRL[IPS] (input polarity select), then the counter will count while the selected secondary input is low.

Capture duration of external pulse

```
//   This example uses TMR1 to determine the duration of an external pulse.
//
//   The IP_bus clock is used as the primary counter. If the duration of the
//     external pulse is longer than 0.001 seconds one of the other IP_bus clock
//     dividers can be used. If the pulse duration is longer than 0.128 seconds
//     an external clock source will have to be used as the primary clock
source.
//
void Pulse1_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=8,SCS=1,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x1080);            /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x00);
  setReg(TMR1_CNTR,0x00);             /* Reset counter register */
  setReg(TMR1_LOAD,0x00);             /* Reset load register */
  setRegBitGroup(TMR1_CTRL,CM,0x03);  /* Run counter */
}
```

72.3.5.1.5 Quadrature-Count mode

If CTRL[CM] is set to '100', the counter will decode the primary and secondary external inputs as quadrature encoded signals. Quadrature signals are usually generated by rotary or linear sensors used to monitor movement of motor shafts or mechanical equipment. The quadrature signals are square waves that are 90 degrees out of phase. The decoding of quadrature signal provides both count and direction information.

This figure shows a timing diagram illustrating the basic operation of a quadrature incremental position encoder.

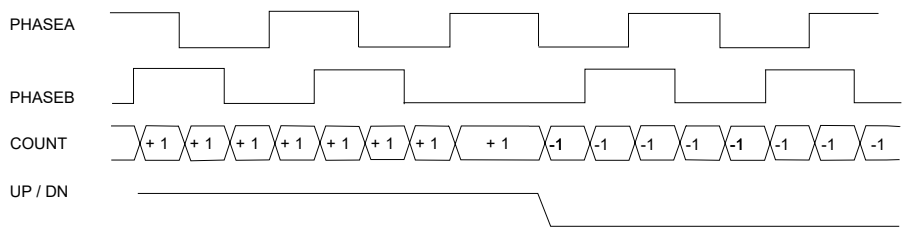

Figure 574. Quadrature incremental position encoder

Quadrature-Count mode example

```
//  This example uses TMR0 for counting states of a quadrature position encoder.
//
//  Timer input 0 is used as the primary count source (PHASEA).
//  Timer input 1 is used as the secondary count source (PHASEB).
//
void Pulse_Init(void)
{
  /* TMR0_CTRL: CM=0,PCS=0,SCS=1,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMRC0_CTRL,0x80);              /* Set up mode */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=1 */
  setReg(TMR0_SCTRL,0x00);
  setReg(TMR0_CNTR,0x00);             /* Reset counter register */
  setReg(TMR0_LOAD,0x00);             /* Reset load register */
  setReg(TMR0_COMP1,0xFFFF);           /* Set up compare 1 register */
  setReg(TMR0_COMP2,0x00);             /* Set up compare 2 register */
  /* TMR0_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR0_CSCTRL,0x00);
  setRegBitGroup(TMR0_CTRL,CM,0x04);  /* Run counter */
}
```

72.3.5.1.6 Quadrature-Count mode with index input

As an extension to the quadrature count mode discussed in the previous paragraph, some rotary shafts have a HOME or INDEX indicator. This would be a third input to the timer that is used to reset the timer's counter.

In this example, channel 0 is used to decode the quadrature inputs, but it doesn't actually count. Because its upper and lower limits are both set to 0, its output is cascaded count up and count down signals each time the quadrature inputs indicate a change in count. Channel 1 works in cascaded count mode receiving its counting instructions from channel 0. When an input capture event occurs, channel 1 is programmed to reset its counter value. The channel 1 counter contains the position value for the shaft.

Quadrature-Count mode with index input example

```
//  This example uses TMR0and TMR1 for counting states of a quadrature position
encoder.
//
// Timer input 0 is used as the primary count source (PHASEA).
// Timer input 1 is used as the secondary count source (PHASEB).
// Timer input 2 is used as the index input source (INDEX).
//
void Pulse_Init(void)
{
  /* TMR0_CTRL: CM=0,PCS=0,SCS=1,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR0_CTRL,0xA0);              /* Set up mode */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR0_SCTRL,0x00);
  setReg(TMR0_CNTR,0x00);             /* Reset counter register */
```

```
  setReg(TMR0_LOAD,0x00);            /* Reset load register */
  setReg(TMR0_COMP1,0x00);          /* Set up compare 1 register */
  setReg(TMR0_COMP2,0x00);           /* Set up compare 2 register */
  /* TMR0_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR0_CSCTRL,0x00);
/* TMR1_CTRL: CM=7,PCS=100,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0xE900);           /* Set up capture edge */
/* TMR1_SCTRL: Capture_Mode=10 */
  setReg(TMR1_SCTRL,0x0080);
/* TMR1_CSCTRL: ROC=1 */
  setReg(TMR1_CSCTRL,0x0800);          /* Set up reload on capture */
setRegBitGroup(TMR0_CTRL,CM,0x04);  /* Run counter */
}
```

72.3.5.1.7 Signed-Count mode

If CTRL[CM] is set to '101', the counter counts the primary clock source while the selected secondary source provides the selected count direction (up/down). If the value of the selected secondary source equals to that of the CTRL[DIR] bit, the count direction is up. Otherwise the count direction is down.

Signed-Count mode example

```
//  This example uses TMR0 for signed mode counting.
//
//  Timer input 2 is used as the primary count source.
//  Timer input 1 is used to determine the count direction.
//
void Pulse_Init(void)
{
  /* TMR0_CTRL: CM=0,PCS=2,SCS=1,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR0_CTRL,0x0480);             /* Set up mode */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR0_SCTRL,0x1000);
  setReg(TMR0_CNTR,0x00);             /* Reset counter register */
  setReg(TMR0_LOAD,0x00);             /* Reset load register */
  setRegBitGroup(TMR0_CTRL,CM,0x05);  /* Run counter */
}
```

72.3.5.1.8 Triggered-Count mode 1

If CSCTRL[TCI] is clear and CTRL[CM] is set to '110', the counter will begin counting the primary clock source after a positive transition (negative edge if SCTRL[IPS]=1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. If a second input transition occurs before a terminal count is reached, counting will stop and SCTRL[TCF] (timer compare flag) will be set. Subsequent secondary input transitions will continue to restart and stop the counting until a compare event occurs.

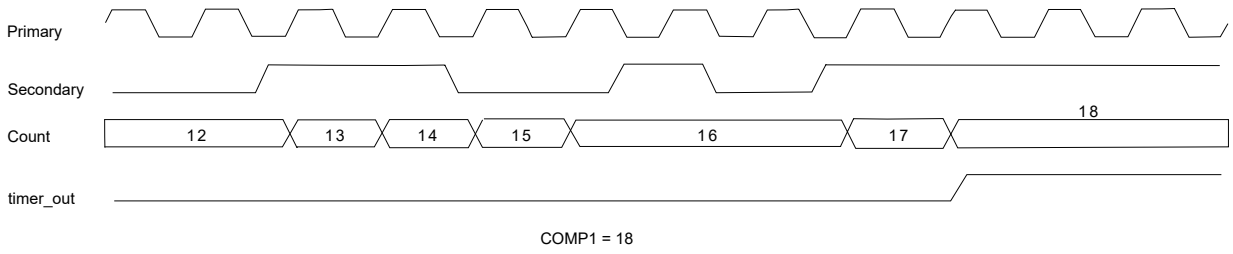

Figure 575. Triggered-Count mode 1 (CTRL[LENGTH]=0)

Triggered-Count mode 1 example

```
//   This example uses TMR1 for triggered mode counting.
//
//   Timer input 3 is used as the primary count source.
//   Timer input 2 is used for the trigger input.
//
void Pulse_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=3,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x0700);            /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x1000);
  setReg(TMR1_CNTR,0x00);              /* Reset counter register */
  setReg(TMR1_LOAD,0x00);              /* Reset load register */
  setReg(TMR1_COMP1,0x0012);            /* Set up compare 1 register */
  /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR1_CSCTRL,0x00);
  setRegBitGroup(TMR1_CTRL,CM,0x06);    /* Run counter */
}
```

72.3.5.1.9 Triggered-Count mode 2

If CSCTRL[TCI] is set and CTRL[CM] is set to '110', the counter will begin counting the primary clock source after a positive transition (negative edge if SCTRL[IPS]=1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. If a second input transition occurs before a terminal count was reached, the counter will reload and continue counting. When CSCTRL[TCI] is set, the OFLAG output mode, CTRL[OUTMODE], should probably be set to '101' (cleared on init, set on compare) to ensure the output will be in a known state after the second input transition and subsequent reload takes place.

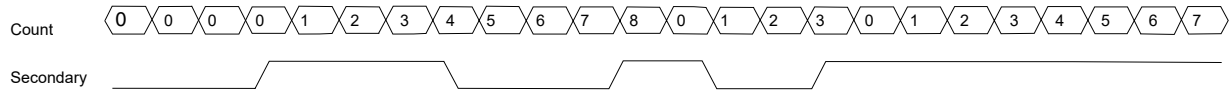

Figure 576. Triggered-Count mode 2 (CTRL[LENGTH]=0)

Triggered-Count mode 2 example

```
//   This example uses TMR1 for triggered mode counting.
//
//   Timer input 3 is used as the primary count source.
//   Timer input 2 is used for the trigger input.
//
void Pulse_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=3,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR1_CTRL,0x0700);            /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x1000);

  setReg(TMR1_CNTR,0x00);              /* Reset counter register */
  setReg(TMR1_LOAD,0x00);              /* Reset load register */
  setReg(TMR1_COMP1,0x0012);            /* Set up compare 1 register */
  /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=1,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR1_CSCTRL,0x400);
```

```
  setRegBitGroup(TMR1_CTRL,CM,0x06); /* Run counter */
}
```

72.3.5.1.10 One-Shot mode

If CTRL[CM] is set to '110', and the counter is set to reinitialize at a compare event (CTRL[LENGTH]=1),and CTRL[OUTMODE] is set to '101' (cleared on init, set on compare), the counter works in a one-shot mode. An external event causes the counter to count, and when the terminal count is reached, the output is asserted. This delayed output can be used to provide timing delays.

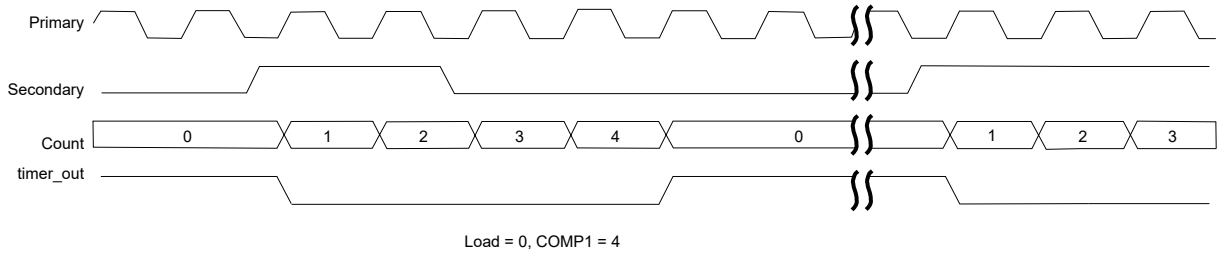

Figure 577. One-Shot mode (CTRL[LENGTH]=1)

One-Shot mode example

```
//  This example uses TMR1 for one-shot mode counting.
//
//  Timer input 3 is used as the primary count source.
//  Timer input 2 is used for the trigger input.
//
void Pulse_Init(void)
{
  /* TMR1_CTRL: CM=0,PCS=3,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=5 */
  setReg(TMR1_CTRL,0x0725);           /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR1_SCTRL,0x1000);
  setReg(TMR1_CNTR,0x00);             /* Reset counter register */
  setReg(TMR1_LOAD,0x00);             /* Reset load register */
  setReg(TMR1_COMP1,0x0004);           /* Set up compare 1 register */
  /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR1_CSCTRL,0x00);
  setRegBitGroup(TMR1_CTRL,CM,0x06);  /* Run counter */
}
```

72.3.5.1.11 Cascade-Count mode

If CTRL[CM] is set to '111', the counter's input is connected to the output of another selected counter. The counter will count up and down as compare events occur in the selected source counter. This cascade or daisy-chained mode enables multiple counters to be cascaded to yield longer counter lengths. When operating in cascade mode, a special high-speed signal path is used between modules rather than the OFLAG output signal. If the selected source counter is counting up and it experiences a compare event, the counter will be incremented. If the selected source counter is counting down and it experiences a compare event, the counter will be decremented.

Up to four counters may be cascaded to create a 64-bit wide synchronous counter. Check the data sheet to see if there are any frequency limits for cascaded counting mode.

Whenever any counter is read within a counter module, all of the counters' values within the module are captured in their respective hold registers. This action supports the reading of a cascaded counter chain. First read any counter of a cascaded counter chain, then read the hold registers of the other counters in the chain. The cascaded counter mode is synchronous.

NOTE

It is possible to connect counters together by using the other (non-cascade) counter modes and selecting the outputs of other counters as a clock source. In this case, the counters are operating in a ripple mode, where higher order counters will transition a clock later than a purely synchronous design.

Generate periodic interrupt cascading two counters

```
// This example generates an interrupt every 30 seconds,
//    assuming the chip is operating at 60 MHz.
//
// To do this, counter 2 is used to count 60,000 IP_bus clocks, which means it
//    will compare and reload every 0.001 seconds.
// Counter 3 is cascaded and used to count the 0.001 second ticks and
//    generate the desired interrupt interval.
//
void TimerInt_Init(void)
{
  // Set counter 2 to count IP_bus clocks
  /* TMR2_CTRL: CM=0,PCS=8,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR2_CTRL,0x1020);           /* Stop all functions of the timer */
  // Set counter 3 as cascaded and to count counter 2 outputs
  /* TMR3_CTRL: CM=7,PCS=6,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
  setReg(TMR3_CTRL,0xEC20);            /* Set up cascade counter mode */
  /* TMR3_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR3_SCTRL,0x00);
  /* TMR2_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
  setReg(TMR2_SCTRL,0x00);
  setReg(TMR3_CNTR,0x00);             /* Reset counter register */
  setReg(TMR2_CNTR,0x00);
  setReg(TMR3_LOAD,0x00);             /* Reset load register */
  setReg(TMR2_LOAD,0x00);
  setReg(TMR3_COMP1, 30000-1);        /* milliseconds in 30 seconds */
  setReg(TMR3_CMPLD1,30000-1);
  setReg(TMR2_COMP1, 60000-1);        /* Set to cycle every milisecond */
  setReg(TMR2_CMPLD1,60000-1);
  /* TMR3_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=1,TCF2=0,TCF1=0,CL2=0,CL1=1 */
  setReg(TMR3_CSCTRL,0x41);           /* Enable compare 1 interrupt and */
                                      /* compare 1 preload              */
  /* TMR2_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                  TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=1 */
  setReg(TMR2_CSCTRL,0x01);           /* Enable Compare 1 preload */
  setRegBitGroup(TMR2_CTRL,CM,0x01);  /* Run counter */
}
```

72.3.5.1.12 Pulse-Output mode

If CTRL[CM]=001, and CTRL[OUTMODE] is set to 111' (gated clock output), and CTRL[ONCE] is set, then the counter will output a pulse stream of pulses that has the same frequency of the selected clock source, and the number of output pulses is equal to the compare value minus the init value. This mode is useful for driving step motor systems.

NOTE

This does not work if CTRL[PCS] is set to 1000 (IP_bus/1).

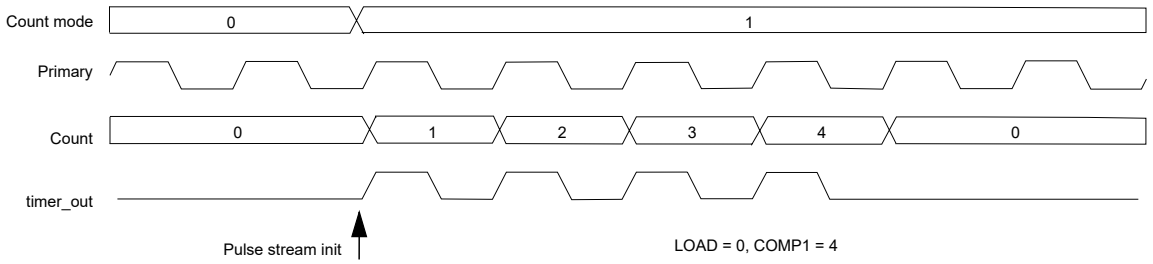

Figure 578. Pulse-Output mode

Pulse outputs using two counters

```
// This example generates six 10ms pulses, from QT1 output.
// Assuming the chip is operating at 60 MHz.
//
// To do this, timer 3 is used to generate a clock with a period of 10ms.
//
// Timer 1 is used to gate these clocks and count the number of pulses that have
//  been generated.
//
void PulseStream_Init(void)
{
// Select IP_bus_clk/16 as the clock source for Timer 3
  /* TMR3_CTRL: CM=0,PCS=0x0C,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=3 */
   setReg(TMR3_CTRL,0x1823);             /* Set up mode */
  /* TMR3_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
   setReg(TMR3_SCTRL,0x00);
   setReg(TMR3_LOAD,0x00);              /* Reset load register */
   setReg(TMR3_COMP1,37500-1);          /* (16 * 37500 ) / 60e6 = 0.01 sec */
 /* TMR3_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                   TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR3_CSCTRL,0x00);             /* Set up comparator control register */

// Timer 3 output is the clock source for this timer.
  /* TMR1_CTRL: CM=0,PCS=7,SCS=0,ONCE=1,LENGTH=1,DIR=0,COINIT=0,OUTMODE=7 */
  setReg(TMR1_CTRL,0x0E67);             /* Set up mode */
  /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=1 */
   setReg(TMR1_SCTRL,0x01);
   setReg(TMR1_CNTR,0x00);              /* Reset counter register */
   setReg(TMR1_LOAD,0x00);              /* Reset load register */
   setReg(TMR1_COMP1,0x04);             /* Set up compare 1 register */

// set to interrupt after the last pulse
  /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
                   TCF2EN=0,TCF1EN=1,TCF2=0,TCF1=0,CL2=0,CL1=0 */
  setReg(TMR1_CSCTRL,0x40);             /* Set up comparator control register */
// Finally, start the counters running
  setReg(TMR3_CNTR,0);                  /* Reset counter */
  setRegBitGroup(TMR3_CTRL,CM,0x01);    /* Run source clock counter */
  setRegBitGroup(TMR1_CTRL,CM,0x01);    /* Run counter */
}
```

72.3.5.1.13 Fixed-Frequency PWM mode

If CTRL[CM]=001, count through roll-over (CTRL[LENGTH]=0), continuous count (CTRL[ONCE]=0) and CTRL[OUTMODE] is '110' (set on compare, cleared on counter roll-over), then the counter output yields a pulse-width modulated (PWM) signal with a frequency equal to the count clock frequency divided by 65,536 and a pulse-width duty cycle equal to the compare value divided by 65,536. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters.

Fixed-Frequency PWM mode example

```
// This example uses TMR0 for Fixed-Frequency PWM mode timing.
//
// The timer will count IP_bus clocks continuously until it rolls over.
// This results in a PWM period of 65536 / 60e6 = 1092.267 usec
//
// Initially, an output pulse width of 25 usec is generated ( 1500 / 60e6 )
//   giving a PWM ratio of 1500 / 65536 = 2.289%
// This pulse width can be changed by changing the COMP1 register value (using
CMPLD1).
//
void PWM1_Init(void)
{
  setReg(TMR0_CNTR,0);           /* Reset counter */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=1,OPS=0,OEN=1 */
  setReg(TMR0_SCTRL,0x05);       /* Enable output */
  setReg(TMR0_COMP1,1500-1);     /* Store initial value to the duty-compare
register */
  /* TMR0_CTRL: CM=1,PCS=8,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=6 */
  setReg(TMR0_CTRL,0x3006);      /* Run counter */
}
```

72.3.5.1.14 Variable-Frequency PWM mode

If CTRL[CM]=001, count until compare (CTRL[LENGTH]=1), continuous count (CTRL[ONCE] = 0) and CTRL[OUTMODE] is '100' (toggle OFLAG and alternate compare registers), then the counter output yields a pulse-width modulated (PWM) signal whose frequency and pulse width is determined by the values programmed into the COMP1 and COMP2 registers, and the input clock frequency. This method of PWM generation has the advantage of allowing almost any desired PWM frequency and/or constant on or off periods. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters. The CMPLD1 and CMPLD2 registers are especially useful for this mode, as they allow the programmer time to calculate values for the next PWM cycle while the PWM current cycle is underway.

To set up the TMR to run in variable frequency PWM mode with compare preload please use the following setup for the specific counter you would like to use. When performing the setup, update the TMR_CTRL register last because the counter will start counting if the count mode is changed to any value other than 000 (assuming the primary count source is already active).

Timer Control Register (CTRL)

- CM=001 (count rising edges of primary source)
- PCS=1000 (IP bus clock for best granularity for waveform timing)
- SCS=Any (ignored in this mode)
- ONCE=0 (want to count repeatedly)
- LENGTH=1 (want to count until compare value is reached and re-initialize counter register)
- DIR=Any (user's choice. The compare register values must be chosen carefully to account for things like roll-under, etc.)
- COINIT=0 (user can set this if they need this function)
- OUTMODE=100 (toggle OFLAG output using alternating compare registers)

Timer Status and Control Register (SCTRL)

- OEN = 1 (output enable to allow OFLAG output to be put on an external pin. Set this bit as needed.)
- OPS = Any (user's choice)
- Make sure the rest of the bits are cleared for this register. We will enable interrupts in the comparator status and control register instead of in this register.

Comparator Status and Control Register (CSCTRL)

- TCF2EN=1 (allow interrupt to be issued when CSCTRL[TCF2] is set)
- TCF1EN=0 (do not allow interrupt to be issued when CSCTRL[TCF1] is set)
- TCF1=0 (clear timer compare 1 interrupt source flag. This is set when counter register equals compare register 1 value and OFLAG is low)
- TCF2=0 (clear timer compare 2 interrupt source flag. This is set when counter register equals compare register 2 value and OFLAG is high)
- CL1=10 (load compare register when CSCTRL[TCF2] is asserted)
- CL2=01 (load compare register when CSCTRL[TCF1] is asserted)

Interrupt Service Routines

To service the CSCTRL[TCF2] interrupts generated by the timer, the interrupt controller must be configured to enable the interrupts for the particular timer being used. Additionally the user will need to write an interrupt service routine to do at a minimum the following:

- Clear CSCTRL[TCF2] and CSCTRL[TCF1] flags.
- Calculate and write new values for both CMPLD1 and CMPLD2.

Timing

This figure contains the timing for using the compare preload feature. The compare preload cycle begins with a compare event on COMP2 causing CSCTRL[TCF2] to be asserted. COMP1 is loaded with the value in the CMPLD1 (c3) one IP bus clock later. In addition an interrupt is asserted by the timer and the interrupt service routine is executed during which both comparator load registers are updated with new values (c4 and c5). When CSCTRL[TCF1] is asserted, COMP2 is loaded with the value in CMPLD2 (c4). And on the subsequent CSCTRL[TCF2] event, COMP1 is loaded with the value in CMPLD1 (c5). The cycle starts over again as an interrupt is asserted and the interrupt service routine clears CSCTRL[TCF1] and CSCTRL[TCF2] and calculates new values for CMPLD1 and CMPLD2.

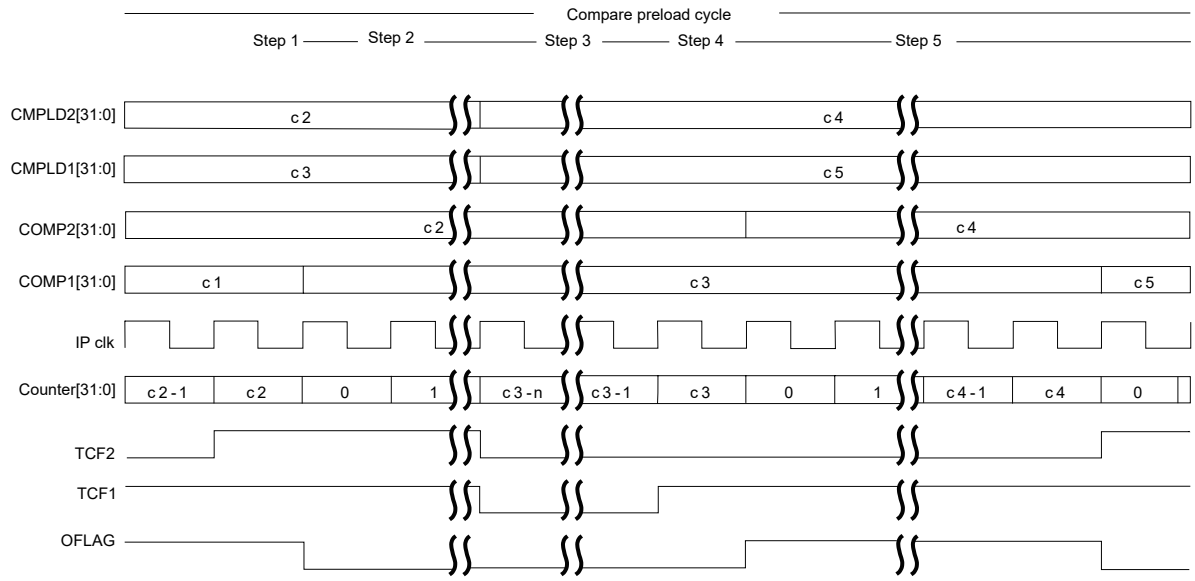

Figure 579. Compare load timing

Variable-Frequency PWM mode

```
// This example starts with an 11 msec with a 31 msec cycle.
// Assuming the chip is operating at 60 MHz, the timer use IP_bus_clk/32 as its
//   clock source.
//
// Initial pulse period: 60e6/32 clocks/sec * 31 ms = 58125 total clocks in
period
// Initial pulse width: 60e6/32 clocks/sec * 11 ms = 20625 clocks in pulse
//
//
// Once the initial values of COMP1/CMPLD1 and COMP2/CMPLD2 are set the pulse
width
//   can be varied by load new values of CMPLD1 and CMPLD2 on each compare
interrupt.
//    (See Usage of compare load registers.)
//
void PPG1_Init(void)
{
  setReg(TMR0_LOAD,0);                 /* Clear load register */
  setReg(TMR0_CNTR,0);                 /* Clear counter */
  /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
                 Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=1,OPS=0,OEN=1 */
  setReg(TMR0_SCTRL,5);                /* Set Status and Control Register */
  // Set compare preload operation and enable an interrupt on compare2 events.
  /* TMR0_CSCTRL: TCF2EN=1,TCF1EN=0,TCF2=0,TCF1=0,CL21=0,CL20=1,CL11=1,CL10=0 */
  setReg(TMR0_CSCTRL,0x86);            /* Set Comparator Status and Control
Register */

  setReg(TMR0_COMP1, 20625-1);         /* Set the pulse width of the off time */
  setReg(TMR0_CMPLD1,20625-1);         /* Set the pulse width of the off time */
  setReg(TMR0_COMP2, 58125-20625-1);   /* Set the pulse width of the on time */
  setReg(TMR0_CMPLD2,58125-20625-1);   /* Set the pulse width of the on time */
  /* TMR0_CTRL: CM=1,PCS=0xD,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=4 */
  setRegBits(TMR0_CTRL,0x3A24);        /* Set variable PWM mode and run counter
*/
}
```

72.3.6 Clocking

72.3.6.1 General

The timer only receives BUS_CLK_ROOT .

72.3.7 Resets

72.3.7.1 General

TMR can be reset by the RST_B signal. This forces all registers to their reset state and clears the OFLAG signal if it is asserted. The counter will be turned off until the settings in the control register are changed.

Table 1081. Reset Summary

Reset	Priority	Source	Characteristics
RST_B	n/a	hardware reset and system software reset	full system reset

72.3.8 Interrupts

72.3.8.1 General

TMR can generate 20 interrupts, Five for each of the four counters/channels.

Table 1082. Interrupt Summary

Core Interrupt	Interrupt	Description
TMR Channel 0	TMR0_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 0
	TMR0_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 0
	TMR0_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 0
	TMR0_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 0
	TMR0_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 0
TMR Channel 1	TMR1_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 1
	TMR1_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 1
	TMR1_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 1
	TMR1_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 1
	TMR1_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 1
TMR Channel 2	TMR2_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 2
	TMR2_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 2

Table continues on the next page...

Table 1082. Interrupt Summary (continued)

Core Interrupt	Interrupt	Description
	TMR2_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 2
	TMR2_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 2
	TMR2_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 2
TMR Channel 3	TMR3_COMP_IRQ_B	Compare Interrupt Request for Timer Channel 3
	TMR3_COMP1_IRQ_B	Compare 1 Interrupt Request for Timer Channel 3
	TMR3_COMP2_IRQ_B	Compare 2 Interrupt Request for Timer Channel 3
	TMR3_OVF_IRQ_B	Overflow Interrupt Request for Timer Channel 3
	TMR3_EDGE_IRQ_B	Input Edge Interrupt Request for Timer Channel 3

72.3.8.2 Description of Interrupt Operation

72.3.8.2.1 Timer Compare Interrupts

These interrupts are generated when a successful compare occurs between a counter and it's compare registers while SCTRL[TCFIE] is set. These interrupts are cleared by writing a zero to the appropriate SCTRL[TCF].

When a timer compare interrupt is set in TMR_SCTRL and the Compare Load registers are available, one of the following two interrupts will also be asserted.

72.3.8.2.1.1 Timer Compare 1 Interrupts (Available with Compare Load Feature)

These interrupts are generated when a successful compare occurs between a counter and its COMP1 register while CSCTRL[TCF1EN] is set. These interrupts are cleared by writing a zero to the appropriate CSCTRL[TCF1].

72.3.8.2.1.2 Timer Compare 2 Interrupts (Available with Compare Load Feature)

These interrupts are generated when a successful compare occurs between a counter and its COMP2 register while CSCTRL[TCF2EN] is set. These interrupts are cleared by writing a zero to the appropriate CSCTRL[TCF2].

72.3.8.2.2 Timer Overflow Interrupts

These interrupts are generated when a counter rolls over its maximum value while SCTRL[TOFIE] is set. These interrupts are cleared by writing zero to the appropriate SCTRL[TOF].

72.3.8.2.3 Timer Input Edge Interrupts

These interrupts are generated by a transition of the input signal (either positive or negative depending on IPS setting) while SCTRL[IEFIE] is set. These interrupts are cleared by writing a zero to the appropriate SCTRL[IEF].

72.3.9 DMA

TMR can generate twelve DMA requests: three for each of the four counters/channels. Refer to the following table.

Table 1083. DMA Summary

DMA Request	DMA Enable	Description
Channels 0-3	DMA[IEFDE]	CAPT contains a value
	DMA[CMPLD1DE]	CMPLD1 needs an update
	DMA[CMPLD2DE]	CMPLD2 needs an update

72.4 External signals

Table 1084. TMR external signals description

Signal	Description	I/O
tmr0_output	Channel 0 output data	O
tmr1_output	Channel 1 output data	
tmr2_output	Channel 2 output data	
tmr3_output	Channel 3 output data	
tmr0_output_en_b	Channel 0 output data enable	O
tmr1_output_en_b	Channel 1 output data enable	
tmr2_output_en_b	Channel 2 output data enable	
tmr3_output_en_b	Channel 3 output data enable	
tmr0_input	Channel 0 input data[1]	I
tmr1_input	Channel 1 input data[1]	
tmr2_input	Channel 2 input data[1]	
tmr3_input	Channel 3 input data[1]	

1. This input signal may be tied low. See chip-specific chapter for more information.

72.5 Memory map/register definition

72.5.1 TMR register descriptions

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level and the address offset is defined at the module level. Make certain to check which quad timer is available on the chip being used, and which timer channels have external I/O.

72.5.1.1 TMR memory map

TMR1 base address: 4269_0000h

TMR2 base address: 426A_0000h

TMR3 base address: 426B_0000h

TMR4 base address: 426C_0000h

TMR5 base address: 426D_0000h

TMR6 base address: 426E_0000h

TMR7 base address: 426F_0000h

TMR8 base address: 4270_0000h

Fields

Field	Function
15-13 CM	Count Mode Controls the basic counting and behavior of the counter. 000b - No operation 001b - Count rising edges of primary source[1] 010b - Count rising and falling edges of primary source[2] 011b - Count rising edges of primary source while secondary input high active 100b - Quadrature count mode, uses primary and secondary sources 101b - Count rising edges of primary source; secondary source specifies direction[3] 110b - Edge of secondary source triggers primary count until compare 111b - Cascaded counter mode (up/down)[4]
12-9 PCS	Primary Count Source Selects the primary count source. **NOTE** A timer selecting its own output for input is not a legal choice. The result is no counting. 0000b - Counter 0 input pin 0001b - Counter 1 input pin 0010b - Counter 2 input pin 0011b - Counter 3 input pin 0100b - Counter 0 output 0101b - Counter 1 output 0110b - Counter 2 output 0111b - Counter 3 output 1000b - IP bus clock divide by 1 prescaler 1001b - IP bus clock divide by 2 prescaler 1010b - IP bus clock divide by 4 prescaler 1011b - IP bus clock divide by 8 prescaler 1100b - IP bus clock divide by 16 prescaler

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1101b - IP bus clock divide by 32 prescaler 1110b - IP bus clock divide by 64 prescaler 1111b - IP bus clock divide by 128 prescaler
8-7 SCS	Secondary Count Source Identifies the external input pin to be used as a count command or timer command. The selected input can trigger the timer to capture the current value of CNTR . The selected input can also be used to specify the count direction. The selected signal can also be used as a fault input when CSCTRL[FAULT] is set. The polarity of the signal can be inverted by SCTRL[IPS]. 00b - Counter 0 input pin 01b - Counter 1 input pin 10b - Counter 2 input pin 11b - Counter 3 input pin
6 ONCE	Count Once Selects between continuous count mode and one-shot count mode. 0b - Count repeatedly. 1b - Count until compare and then stop. If counting up, a successful compare occurs when the counter reaches a COMP1 value. If counting down, a successful compare occurs when the counter reaches a COMP2 value. When output mode $4 is used, the counter re-initializes after reaching the COMP1 value, continues to count to the COMP2 value, and then stops.
5 LENGTH	Count Length Determines whether the counter: • counts to the compare value and then re-initializes itself to the value specified in the LOAD (or CMPLD2) register, or • continues counting past the compare value to the binary roll over. 0b - Count until roll over at $FFFF and then continue by re-initializing the counter from the LOAD register. 1b - Count until compare, then re-initialize using the LOAD register. If counting up, a successful compare occurs when the counter reaches a COMP1 value. If counting down, a successful compare occurs when the counter reaches a COMP2 value. When output mode $4 is used, alternating values of COMP1 and COMP2 are used to generate successful comparisons. For example, the counter counts until a COMP1 value is reached, re-initializes, counts until COMP2 value is reached, re-initializes, counts until COMP1 value is reached, and so on.
4 DIR	Count Direction Selects between the normal count direction (up) and the reverse direction (down). 0b - Count up. 1b - Count down.

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 COINIT	Co-Channel Initialization Enables another counter/timer within the module to force the re-initialization of this counter/timer when it has an active compare event. 0b - Co-channel counter/timers cannot force a re-initialization of this counter/timer 1b - Co-channel counter/timers may force a re-initialization of this counter/timer
2-0 OUTMODE	Output Mode Determines the mode of operation for the OFLAG output signal. 000b - Asserted while counter is active 001b - Clear OFLAG output on successful compare 010b - Set OFLAG output on successful compare 011b - Toggle OFLAG output on successful compare 100b - Toggle OFLAG output using alternating compare registers 101b - Set on compare, cleared on secondary source input edge 110b - Set on compare, cleared on counter rollover 111b - Enable gated clock output while counter is active

1. Rising edges are counted only when SCTRL[IPS] = 0. Falling edges are counted when SCTRL[IPS] = 1. If the primary count source is IP bus clock divide by 1, only rising edges are counted regardless of the value of SCTRL[IPS].
2. IP bus clock divide by 1 cannot be used as a primary count source in edge count mode.
3. Rising edges are counted only when SCTRL[IPS] = 0. Falling edges are counted when SCTRL[IPS] = 1.
4. The primary count source must be set to one of the counter outputs.

72.5.1.9 Timer Channel Status and Control Register (SCTRL0 - SCTRL3)

Fields

Field	Function
15 TCF	Timer Compare Flag Is set when a successful compare occurs, and is cleared by writing a zero to this bit.
14 TCFIE	Timer Compare Flag Interrupt Enable When set, enables interrupts when TCF is set.
13 TOF	Timer Overflow Flag Is set when the counter rolls over its maximum value $FFFF or $0000 (depending on count direction), and is cleared by writing a zero to this bit.
12 TOFIE	Timer Overflow Flag Interrupt Enable When set, enables interrupts when TOF is set.
11 IEF	Input Edge Flag Is set when CAPTMODE is enabled and a proper input transition occurs (on an input selected as a secondary count source) while the count mode does not equal 000, and is cleared by writing a zero to this bit. This bit can also be cleared automatically by a read of CAPT when DMA[IEFDE] is set. **NOTE** Setting the input polarity select bit (IPS) changes the edge to be detected. Also, the control register's secondary count source determines which external input pin is monitored by the detection circuitry.
10 IEFIE	Input Edge Flag Interrupt Enable When set, enables interrupts when IEF is set. **RESTRICTION** Do not set both this bit and DMA[IEFDE].
9 IPS	Input Polarity Select When set, inverts the input signal polarity.
8 INPUT	External Input Signal Indicates the current state of the external input pin selected via the secondary count source after application of IPS and filtering.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-6 CAPTURE_MODE	Input Capture Mode Specifies the operation of the capture register as well as the operation of the input edge flag. The input source is the secondary count source. 00b - Capture function is disabled 01b - Load capture register on rising edge (when IPS=0) or falling edge (when IPS=1) of input 10b - Load capture register on falling edge (when IPS=0) or rising edge (when IPS=1) of input 11b - Load capture register on both edges of input
5 MSTR	Master Mode When set, enables the compare function's output to be broadcasted to the other counters/timers in the module. This signal then can be used to re-initialize the other counters and/or force their OFLAG signal outputs.
4 EEOF	Enable External OFLAG Force When set, enables the compare from another counter/timer within the same module to force the state of this counter's OFLAG output signal.
3 VAL	Forced OFLAG Value Determines the value of the OFLAG output signal when software triggers a FORCE command.
2 FORCE	Force OFLAG Output Forces the current value of VAL to be written to the OFLAG output. VAL and FORCE can be written simultaneously in a single write operation. Write to FORCE only if the counter is disabled. Setting this bit while the counter is enabled may yield unpredictable results.
1 OPS	Output Polarity Select Determines the polarity of the OFLAG output signal. 0b - True polarity. 1b - Inverted polarity.
0 OEN	Output Enable Determines the direction of the external pin. 0b - The external pin is configured as an input. 1b - The OFLAG output signal is driven on the external pin. Other timer groups using this external pin as their input see the driven value. The polarity of the signal is determined by OPS.

Fields

Field	Function
15-14 DBG_EN	Debug Actions Enable Enables the TMR module to perform certain actions in response to the chip entering debug mode. 00b - Continue with normal operation during debug mode. (default) 01b - Halt TMR counter during debug mode. 10b - Force TMR output to logic 0 (prior to consideration of SCTRL[OPS]). 11b - Both halt counter and force output to 0 during debug mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 FAULT	Fault Enable The selected secondary input acts as a fault signal so that the timer OFLAG is cleared when the secondary input is set. When the secondary input is used in this mode, there is no resynchronization of the input so that there is a combinational path to clear the OFLAG. Fault inputs less than two clock periods wide will not be latched. Latched faults will be cleared the next time that the counter logic sets the OFLAG. This bit specifies whether to enable or disable the fault function. 0b - Disables 1b - Enables
12 ALT_LOAD	Alternative Load Enable Allows for an alternative method for loading the counter during modulo counting. Normally, the counter can be loaded only with the value from the LOAD register. When this bit is set, the counter is loaded from the LOAD register when counting up and a match with COMP1 occurs, or the counter is loaded from the CMPLD2 register when counting down and a match with COMP2 occurs. 0b - Counter can be re-initialized only with the LOAD register. 1b - Counter can be re-initialized with the LOAD or CMPLD2 registers depending on count direction.
11 ROC	Reload on Capture Specifies whether to enable or disable the capture function to cause the counter to be reloaded from the LOAD register. 0b - Disables 1b - Enables
10 TCI	Triggered Count Initialization Control During triggered count mode (CTRL[CM] = 110), enables the counter to be re-initialized when a second trigger occurs while the counter is still counting. Normally, the second trigger causes the counting to stop/pause until a third trigger occurs. With this bit set, a second trigger event causes the counter to re-initialize and continue counting. 0b - Stop the counter upon receiving a second trigger event while still counting from the first trigger event. 1b - Reload the counter upon receiving a second trigger event while still counting from the first trigger event.
9 UP	Counting Direction Indicator Indicates the direction of the last count during quadrature count mode (CTRL[CM] = 100). CTRL[DIR] reverses the sense of this bit. 0b - The last count was in the DOWN direction. 1b - The last count was in the UP direction.
8	RESERVED

7 TCF2EN	Timer Compare 2 Interrupt Enable When set, enables an interrupt if TCF2 is set.
6 TCF1EN	Timer Compare 1 Interrupt Enable When set, enables an interrupt if TCF1 is set.
5 TCF2	Timer Compare 2 Interrupt Flag When set, indicates a successful comparison of the timer and the COMP2 register has occurred. This bit is sticky, and remains set until explicitly cleared by writing a zero to it.
4 TCF1	Timer Compare 1 Interrupt Flag When set, indicates a successful comparison of the timer and the COMP1 register has occurred. This bit is sticky, and remains set until explicitly cleared by writing a zero to it.
3-2 CL2	Compare Load Control 2 Controls when COMP2 is preloaded with the value from CMPLD2. 00b - Never preload 01b - Load upon successful compare with the value in COMP1 10b - Load upon successful compare with the value in COMP2 11b - Reserved
1-0 CL1	Compare Load Control 1 Controls when COMP1 is preloaded with the value from CMPLD1. 00b - Never preload 01b - Load upon successful compare with the value in COMP1 10b - Load upon successful compare with the value in COMP2 11b - Reserved

72.5.1.13 Timer Channel Input Filter Register (FILT0 - FILT3)

Offset

Register	Offset
FILT0	16h
FILT1	36h
FILT2	56h
FILT3	76h

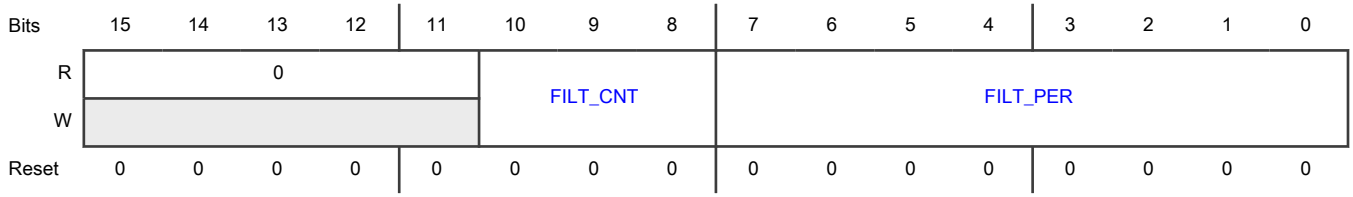
Function

The FILT register programs the values for the filtering of the corresponding input without regard for the fact that any timer channel can use the input as a count source.

Input filter considerations:

- Set the FILT_PER value such that the sampling period is larger than the period of the expected noise. In this way, a noise spike will corrupt only one sample. Choose the FILT_CNT value to reduce the probability that noisy samples cause an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of (FILT_CNT + 3).
- The values of FILT_PER and FILT_CNT must also be balanced against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of (((FILT_CNT + 3) x FILT_PER) + 2) IP bus clock periods.

Diagram



Fields

Field	Function
15-11 —	RESERVED
10-8 FILT_CNT	Input Filter Sample Count Indicates the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0x0 indicates 3 samples. A value of 0x7 indicates 10 samples. The value of FILT_CNT affects the input latency.
7-0 FILT_PER	Input Filter Sample Period Indicates the sampling period (in IP bus clock cycles) of the TMR input signals. Each input is sampled multiple times at the rate specified by this field. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency. When changing values for FILT_PER from one non-zero value to another non-zero value, write a value of zero first to clear the filter.

72.5.1.14 Timer Channel DMA Enable Register (DMA0 - DMA3)

73.2 Overview

eQDC does the following:

- Interfaces to position or speed sensors that are used in industrial motor control applications.
- Decodes shaft position, revolution count, and speed.

eQDC receives the following 8 input signals from position or speed sensors:

- PHASEA
- PHASEB
- INDEX/PRESET
- TRIGGER
- HOME/ENABLE
- ICAP[3:1]

eQDC outputs the following 11 signals for system use:

- POS_MATCH[3:0]
- COMP_FLG[3:0]
- DIR
- CNT_DN

- CNT_UP

NOTE

For eQDC, "asserted" indicates an output of 1 and "de-asserted" indicates an output of 0.

73.2.1 Block diagram

This is the block diagram of eQDC.

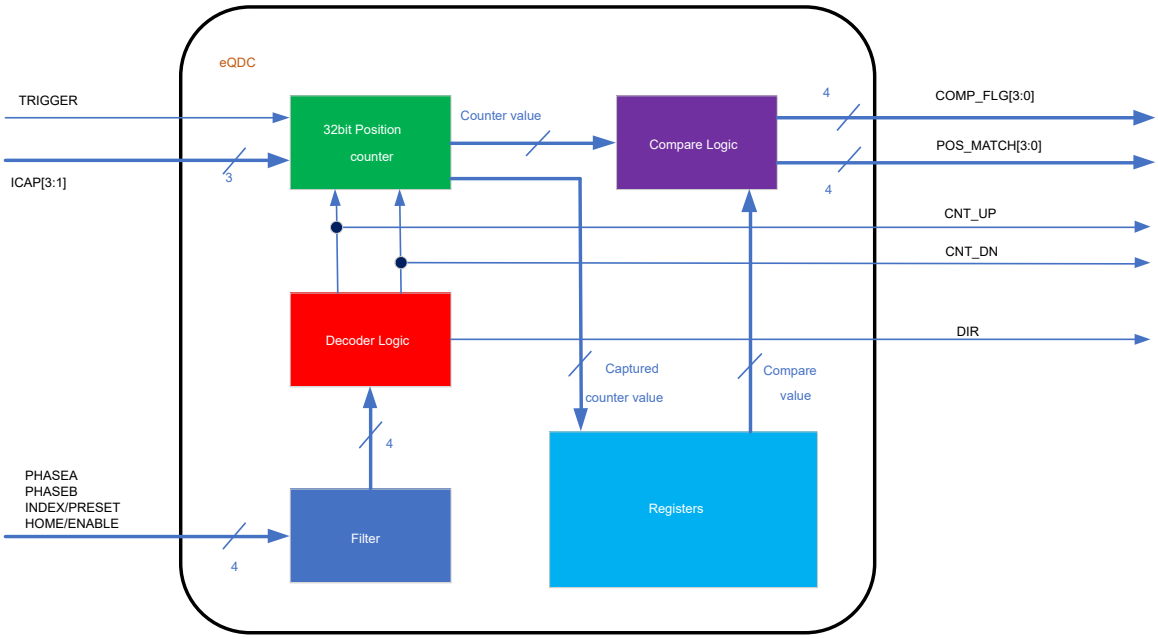

Figure 580. Block diagram

73.2.2 Features

- Logic to decode quadrature signals
- Configurable digital filters for inputs (these filters can be bypassed)
- 32-bit position counter capable of modulo counting
- Position counter that can be initialized by software or external events
- 16-bit position difference register
- Compare function that can indicate when shaft has reached a defined position
- A watchdog timer that can detect a non-rotating shaft condition
- Preloadable 16-bit revolution counter
- Maximum count frequency equals the peripheral clock rate
- Configurable interrupt when both PHASEA and PHASEB inputs change in the same cycle

73.3 Functional description

The following timing diagram shows the basic operation of an incremental position quadrature decoder.

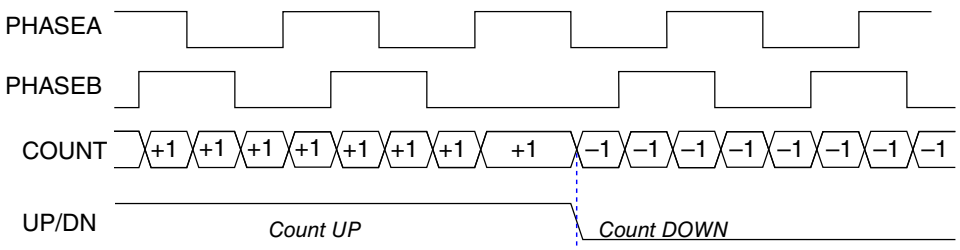

Figure 581. Quadrature decoder signals

73.3.1 Positive versus negative direction

A typical quadrature encoder has 3 outputs: PHASEA signal, PHASEB signal, INDEX pulse (not shown).

- If PHASEA leads PHASEB, then motion is in the positive direction.
- If PHASEA trails PHASEB, then motion is in the negative direction.

Transitions on these phases can be integrated to yield position or differentiated to yield velocity. The quadrature decoder is designed to perform these functions in hardware.

73.3.2 Speed measurement

For applicationswith a fast-moving shaft encoder, the speed can be measured using either of the following methods:

- calculating the change in the position counter per unit time
- reading the position difference counter register

For applications with low motor speeds and low-line count quadrature encoders, the timer module enables high-resolution speed measurement by calculating the time intervals between quadrature phases.

- The timer module uses a 16-bit free running counter operated from a prescaled version of the peripheral clock.
- The prescaler FILT[PRSC] divides the peripheral clock by values ranging from 1 to 32768. A 100 MHz peripheral clock frequency would yield a resolution of from 10 ns to 327.68 µs and a maximum count period of from 0.65535 ms to 21474.5 ms. For example, with a 1000-tooth decoder, speeds could be calculated down to 0.0007 rpm using a prescaler.

73.3.3 Glitch filter

Because the quadrature decoder logic must sense signal transitions, the signal inputs are first run through a glitch filter. This glitch filter has a digital delay line, which samples multiple time points on the signal and verifies a stable new signal state before outputting this new signal state to the internal quadrature decoder logic. To adapt to a variety of signal bandwidths, the sample rate of this delay line is programmable.

73.3.4 Edge detect state machine

TheEdge detect state machine looks for changes in the 4 possible states of the filtered PHASEA and PHASEB input signals. Direction of motion is calculated using these changes. Direction of motion is formatted as Count_Up and Count_Down signals. These signals are routed into up to 3 up/down counters:

- Position counter
- Revolution counter
- Position difference counter

73.3.5 Counter registers, and hold registers and how to initilize

When any of the counter registers is read, the contents of this counter register is written to the corresponding hold register. Taking a snapshot of the counters' values allows a consistent view of a system's position and the speed to be attained. If CTRL2[PMEN] is set, the position difference hold register is only updated when the position difference counter register is read. To capture a time stamp of when these registers are read, use the POS_MATCH output with a timer channel.

73.3.5.1 Position counter (POS)

POS counts up (upper position counter, UPOS) or down (lower position counter, LPOS) on every count pulse generated by the position difference of PHASEA and PHASEB input signals. POS acts as an integration_info, whose count value is proportional to position. De-assertion of ENABLE pin stops the operation of POS. POS is initialized to a pre-determined value (if CTRL[REV]=0,POS is initialized to the initialization register; if CTRL[REV]=1, POS is initialized to the modulus register) if any of the following conditions is met:

- If CTRL2[INITPOS] is set, a positive edge of TRIGGER input occurs.
- A write to CTRL[SWIP]
- If CTRL2[OPMODE] is cleared and CTRL[XIP] is set to 1, INDEX signal transition occurs.
- IfCTRL2[OPMODE] is cleared and CTRL[HIP] is set to 1, HOME signal transition occurs.
- If CTRL2[OPMODE] is set, a positiveedge of PRESET signal occurs.
- Position counter roll-over and roll-under

The INDEX and HOME signals can be programmed to interrupt the processor. When UPOS or LPOS is read, a snapshot of each of the following counter registers is placed into the corresponding hold register:

- position counter register
- If CTRL2[PMEN] is cleared, position difference counter register
- revolution counter register

73.3.5.2 Position counter hold (POSH)

POSH stores a copy of POS when POS is read.

When POS is initialized by any event, the contents of POS are also copied into POSH. Meanwhile, count direction flag IOMR[DIR] is copied into count direction flag hold IOMR[DIRH]. When CTRL2[UPDHLD] is set to1, the rising edge of TRIGGER input takes a snapshot of POS and stores it in UPOSH or LPOS.

Beside taking snapshot of POS counter by positive transient of TRIGGER input, 3 more signals are added to take snapshot of POS counter:

- Positive transition of ICAP[3] input can take snapshot of POS counter into UPOSH3/LPOS3
- Positive transition of ICAP[2] input can take snapshot of POS counter into UPOSH2/LPOS2
- Positive transition of ICAP[1] input can take snapshot of POS counter into UPOSH1/LPOS1

Note: This is used for an error checking mechanism to check of the position counter accumulated the correct number of counts between the same event. As example, the 1024-line incremental encoder must count 4096 counts when moving in the same direction between the index.

73.3.5.3 Position difference counter (POSD)

POSD contains the position difference value occurring between each read of the position register. The position register counts up or down on every count pulse. The position difference counter acts as a differentiator, whose count value is proportional to the change in position since the last time the position counter was read.

POSD is cleared when any of the following conditions is met:

- If CTRL2[PMEN] is cleared, when POS, POSD, or REV register is read, POSD is cleared and its contents are copied into POSDH.
- If CTRL2[PMEN] is cleared, positive edge of TRIGGER input occurs when CTRL2[UPDPOS] is set
- If CTRL2[PMEN] is set, when POSD is read.
- If CTRL2[PMEN] is set, positive edge of TRIGGER input occurs when CTRL2[UPDHLD] is set.

73.3.5.4 Position difference counter hold (POSDH)

POSDH takes and stores a snapshot of POSD. The snapshot is taken when any of the following conditions is met:

- If CTRL2[PMEN] is cleared, when POS, POSD, or REV register is read.
- When POSD is read (no matter CTRL2[PMEN] is clear or set).
- If CTRL2[UPDHLD] is set, a positive edge of the TRIGGER input occurs (no matter CTRL2[PMEN] is cleared or set).

73.3.5.5 Revolution counter (REV)

REV counts or integrates revolutions by counting index pulses. The direction of the count is determined by PHASEA and PHASEB input signals. A different count direction on the rising and falling edges of the index pulse indicates that eQDC changed direction on the index pulse. If CTRL2[OPMODE] is set, de-assertion of ENABLE input signal stops the operation of REV and PRESET signal transition initializes revolution counter to zero.

73.3.5.6 Revolution counter hold (REVH)

REVH takes a snapshot of REV when either of the following conditions is met:

- When POS, POSD, or REV register is read.
- If CTRL2[UPDHLD] is set, when a positive edge of the TRIGGER input signal occurs.

73.3.5.7 Watchdog timer (WDG)

WDG ensures that the algorithm is indicating motion in the shaft; 2 successive counts indicate proper operation and resets the timer. If CTRL2[OPMODE] is set, PRESET signal transition initializes WDG r to zero, and de-assertion of ENABLE input stops the operation of the WDG.

- The timeout value is programmable.
- When a timeout occurs, an interrupt to the processor can be generated.

73.3.5.8 Last edge time counter (LASTEDGE)

LASTEDGE contains the time since the last edge on PHASEA or PHASEB. The last edge time counter counts up on every prescaled clock pulse.

When POSD is read, contents in LASTEDGE are copied into LASTEDGEH.

73.3.5.9 Position difference period counter (POSDPER)

POSDPER contains the accumulated time from the last time the position difference counter was read. It counts up on every prescaled clock pulse and is loaded from the last edge time counter when POSD is read.

73.3.6 Double-set registers loading operation

The following registers are double-set (namely outer or inner-set), which enables them to be re-configured when eQDC is operating:

- Compare registers (UCOMP0/LCOMP0,UCOMP1/LCOMP1,UCOMP2/LCOMP2,UCOMP3/LCOMP3)

- Initial registers (UINIT/LINIT)
- Modulus registers (UMOD/LMOD)

After a value is written to one of these registers, the value is "buffered" into outer-set registers temporarily. Values will be loaded into inner-set registers and take effect using the following two methods:

- If CTRL2[LDMODE] is set to 1, "buffered" values are loaded into inner-set and take effect at the next roll-over or roll-under if CTRL[LDOK] is set.
- If CTRL2[LDMODE] is set to 0, "buffered" values are loaded into inner-set and take effect immediately when CTRL[LDOK] is set.

The double-set registers can be configured manually or automatically.

To configure the double-set registers manually:

1. Initialize the double-set registers:
    a. Set CTRL2[LDMODE] to 0.
    b. Clear CTRL[LDOK] if it is not 0.
    c. Write values into double-set registers, so the values are "buffered" into outer-set registers.
    d. Set CTRL[LDOK] to 1.
    e. Wait for CTRL[LDOK] to become 0, which means the values have been loaded into inner-set registers.
    f. Change CTRL2[LDMODE] value as desired.
2. Update the double-set registers:
    a. Clear CTRL[LDOK] if it is not 0.
    b. Write values into double-set registers, so the values are "buffered" into outer-set registers.
    c. Set CTRL[LDOK] to 1. When the values are loaded into inner-set registers, CTRL[LDOK] is cleared automatically.
    d. Go back to step a for iteration.

To configure the double-set registers automatically:

1. Initialize the double-setregisters:
    a. Set CTRL2[LDMODE] to 0.
    b. Clear CTRL[LDOK] if it is not 0.
    c. Write values into double-set registers, so the values are "buffered" into outer-set registers.
    d. Set CTRL[LDOK] to 1.
    e. Wait for CTRL[LDOK] to become 0, which means the values have been loaded into inner-set registers.
    f. Set CTRL2[LDMODE] to 1.
    g. Set CTRL[DMAEN] to 1 to enable DMA function.
    h. Set CTRL[LDOK] to 1. This step is to ensure the DMA automatic operation occurs properly. DMA is triggered by loading values from outer-set to inner-set.
2. After initialization, the DMA is triggered in the following manner:
    a. Values are loaded into inner-set registers when the counter rolls over or rolls under, then CTRL[LDOK] is cleared automatically and a DMA request is sent out for next outer-set registers value update.
    b. After DMA updates the outer-set registers, CTRL[LDOK] is set to 1 automatically. It then goes back to step 1 for iteration.

73.3.7 Modes of operation

eQDC operates in the following modes:

- Quadrature Decode Operation mode (CTRL[PH1] = 0,CTRL2[OPMODE] = 0)
- Quadrature Count Operation mode (CTRL[PH1] = 0,CTRL2[OPMODE] = 1)
- Single Phase Decode Operation mode (CTRL[PH1] = 1,CTRL2[OPMODE] = 0)
- Single Phase Count Operation mode (CTRL[PH1] = 1,CTRL2[OPMODE] = 1)

These operation modes support the following applications:

- Pulse accumulator
- Frequency Meter
- Period Meter
- PulseTrain Output with optional Quadrature and Direction

73.3.7.1 Quadrature decode (QDC) operation mode (CTRL[PH1] = 0, CTRL2[OPMODE] = 0)

In this mode, PHASEA and PHASEB input signals from speed or position sensors are decoded by the following signals in eQDC:

1. PHASEA/PHASEB: Two 90 degree out of phase pulse trains.
2. INDEX: Can be configured to cause a change of state on REV, initialize POS, and reset POSD.
3. HOME: Can be configured to initialize POS.
4. TRIGGER: Can be configured to take a snapshot of POS, POSD, and REV and to reinitialize POS.
5. ICAP[3:1]: Takes a snapshot of POS.

eQDC outputs the following signals for system use:

- POS_MATCH[3:0]: Position match:

  Records the time at which the position of the shaft matches a user-defined value of the compare regsietr or the time at which the position information is read:

  — If CTRL2[OUTCTL] is cleared, POS_MATCH[x](x range is 0-3) is asserted when the value of POS equals the value of the corresponding compare regsiter (UCOMPx/LCOMPx), and de-asserted when the value of POS does not equal the value of the corresponding compare register (UCOMPx/LCOMPx).

  — If CTRL2[OUTCTL] is set, POS_MATCH[x](x range is 0-3) is asserted a pulse with 1 peripheral clock cycle width when UPOS or LPOS, REV, or POSD is read.

- COMP_FLG[3:0]: Position Counter Compare Output:

  — COMP_FLG[x](x range is 0-3) is asserted when the value of Position Counter is equal to or greater than the value of the corresponding compare register (UCOMPx/LCOMPx).

  — COMP_FLG[x](x range is 0-3) is de-asserted when the value of Position Counter is smaller than the value of the corresponding compare register (UCOMPx/LCOMPx).

- DIR: Direction of position counting:

  — Direction is up when DIR is asserted

  — Direction is down when DIR is de-asserted.

- CNT_UP: Position counter count up: when eQDC decodes a count-up event, CNT_UP outputs a pulse which width is 1 peripheral clock cycle.
- CNT_DN: Position counter count down: when eQDC decodes a count-down event, CNT_DN outputs a pulse which width is 1 peripheral clock cycle.

There are three count modes(if CTRL[REV]=0,it is normal operation; if CTRL[REV]=1,it is reverse operation):

- Mode 0[CM0](CTRL2[CMODE]=00): Normal Quadrature X4 / Reverse Quadrature X4
- Mode 1[CM1](CTRL2[CMODE]=01): Normal Quadrature X2 / Reverse Quadrature X2
- Mode 2[CM2](CTRL2[CMODE]=10): Normal Quadrature X1 / Reverse Quadrature X1

73.3.7.2 Quadrature count (QCT) operation mode (CTRL[PH1] = 0, CTRL2[OPMODE] = 1)

In this mode, PHASEA and PHASEB input signals from speed or position sensors are counted by the following signals in eQDC:

- PHASEA/PHASEB: Two 90 degree out of phase pulse trains.
- PRESET: Initializes POSand resets POSD:
  - If CTRL[REV]=0, a positive edge of PRESET initializes POS to INIT value (UNIT/LINIT).
  - If CTRL[REV]=1, a positive edge of PRESET initializes POS to modulus value (UMOD/LMOD).
- ENABLE: All counters start counting when ENABLE is asserted; all counters stop counting when ENABLE is de-asserted.
- TRIGGER: Can be configured totake a snapshot of POS, POSD, and REV and to reinitialize POS.
- ICAP[3:1]: Takes a snapshot of POS.

eQDC outputs the following signals for system use:

- POS_MATCH[3:0]: position match:

  Records the time at which the position of the shaft matches a user-defined value of the compare regsietr or the time at which the position information is read:
  - If CTRL2[OUTCTL] is cleared, POS_MATCH[x](x range is 0-3) is asserted when the value of POS equals the value of the corresponding compare regsiter (UCOMPx/LCOMPx), and de-asserted when the value of POS does not equal the value of the corresponding compare register (UCOMPx/LCOMPx).
  - If CTRL2[OUTCTL] is set, POS_MATCH[x](x range is 0-3) is asserted a pulse with 1 peripheral clock cycle width when UPOS or LPOS, REV, or POSD is read.
- COMP_FLG[3:0]: Position Counter Compare Output:
  - COMP_FLG[x](x range is 0-3) is asserted when the value of POS is equal to or greater than the value of the corresponding compare register (UCOMPx/LCOMPx).
  - COMP_FLG[x](x range is 0-3) is de-asserted when the value of POS is smaller than the value of the corresponding compare register (UCOMPx/LCOMPx).
- DIR: Direction of position counting:
  - Direction is up when DIR is asserted
  - Direction is down when DIR is de-asserted.
- CNT_UP: Position counter count up: when eQDC decodes a count-up event, CNT_UP outputs a pulse which width is 1 peripheral clock cycle.
- CNT_DN: Position counter count down: when eQDC decodes a count-down event, CNT_DN outputs a pulse which width is 1 peripheral clock cycle.

There are three count modes(if CTRL[REV]=0,it is normal operation; if CTRL[REV]=1,it is reverse operation):

- Mode 0[CM0](CTRL2[CMODE]=00): Normal Quadrature X4 / Reverse Quadrature X4
- Mode 1[CM1](CTRL2[CMODE]=01): Normal Quadrature X2 / Reverse Quadrature X2
- Mode 2[CM2](CTRL2[CMODE]=10): Normal Quadrature X1 / Reverse Quadrature X1

73.3.7.3 Single phase decode (PH1DC) operation mode (CTRL[PH1] = 1, CTRL2[OPMODE] = 0)

In this mode, PHASEA and PAHSEB input signals from speed or position sensors are decoded by the following signals in eQDC:

- PHASEA: Pulse trains.
- PHASEB: Pulse trains or direction.
- INDEX: Can be configured to cause a change of state on REV and to initialize POS.
- HOME: Can be configured to initialize POS.
- TRIGGER: Can be configured to take a snapshot of POS, POSD, and REV and to reinitialize POS.
- ICAP[3:1]: Takes a snapshot of POS.

eQDC outputs the following signals for system use:

- POS_MATCH[3:0]: position match:

  Records the time at which the position of the shaft matches a user-defined value of the compare regsietr or the time at which the position information is read:

  — If CTRL2[OUTCTL] is cleared, POS_MATCH[x](x range is 0-3) is asserted when the value of POS equals the value of the corresponding compare regsiter (UCOMPx/LCOMPx), and de-asserted when the value of POS does not equal the value of the corresponding compare register (UCOMPx/LCOMPx).

  — If CTRL2[OUTCTL] is set, POS_MATCH[x](x range is 0-3) is asserted a pulse with 1 peripheral clock cycle width when UPOS or LPOS, REV, or POSD is read.

- COMP_FLG[3:0]: Position Counter Compare Output:

  — COMP_FLG[x](x range is 0-3) is asserted when the value of POS is equal to or greater than the value of the corresponding compare register (UCOMPx/LCOMPx).

  — COMP_FLG[x](x range is 0-3) is de-asserted when the value of POS is smaller than the value of the corresponding compare register (UCOMPx/LCOMPx).

- DIR: Direction of position counting:

  — Direction is up when DIR is asserted

  — Direction is down when DIR is de-asserted.

- CNT_UP: Position counter count up: when eQDC decodes a count-up event, CNT_UP outputs a pulse which width is 1 peripheral clock cycle.
- CNT_DN: Position counter count down: when eQDC decodes a count-down event, CNT_DN outputs a pulse which width is 1 peripheral clock cycle.

There are three count modes:

- Mode 0[CM0](CTRL2[CMODE]=00): UP/DOWN Pulse Count mode. Both position counter (POS) and position difference counter (POSD) count in the up direction when input PHASEA rising edge occurs. Both counters count in the down direction when input PHASEB rising edge occurs. If CTRL[REV] is 1, then the position counter will count in the opposite direction.
- Mode 1[CM1](CTRL2[CMODE]=01): Signed Count mode (Double Edge). Both position counter (POS) and position difference counter (POSD) count the input PHASEA on both rising edge and falling edge while the input PHASEB provides the selected position counter direction (up/down). If CTRL[REV] is 1, then the position counter will count in the opposite direction.
- Mode 2[CM2](CTRL2[CMODE]=10): Signed Count mode (Single Edge). Both position counter (POS) and position difference counter (POSD) count on the input PHASEA rising edge while the input PHASEB provides the selected position counter direction (up/down). If CTRL[REV] is 1, then the position counter will count in the opposite direction.

NOTE

If the positive edge of both PHASEA and PHASEB occurs simultaneously, an error interrupt is generated CTRL2[SABIRQ] and counter is unchanged.

73.3.7.4 Single phase count (PH1CT) operation mode (CTRL[PH1] =1, CTRL2[OPMODE] = 1)

In this mode, PHASEA and PHASEB input signals from speed or position sensors are counted by the following signals in eQDC:

- PHASEA: Pulse trains.
- PHASEB: Pulse trains or direction.
- PRESET: InitializesPOS and resets POSD:
  - IfCTRL[REV]=0, a positive edge of PRESET initializes POS to initial value (UNIT/LINIT).
  - IfCTRL[REV]=1, a positive edge of PRESET initializes POS to modulus value (UMOD/LMOD).
- ENABLE: All counters start counting when ENABLE is asserted; all counters stop counting when ENABLE is de-asserted.
- TRIGGER: Can be configured to takea snapshot of POS, POSD, and REV, and to reinitialize POS.
- ICAP[3:1]: Takes a snapshot of POS.

eQDC outputs the following signals for system use:

- POS_MATCH[3:0]: position match:

  Records the time at which the position of the shaft matches a user-defined value of the compare regsietr or the time at which the position information is read:

  - If CTRL2[OUTCTL] is cleared, POS_MATCH[x](x range is 0-3) is asserted when the value of POS equals the value of the corresponding compare regsiter (UCOMPx/LCOMPx), and de-asserted when the value of POS does not equal the value of the corresponding compare register (UCOMPx/LCOMPx).
  - If CTRL2[OUTCTL] is set, POS_MATCH[x](x range is 0-3) is asserted a pulse with 1 peripheral clock cycle width when UPOS or LPOS, REV, or POSD is read.
- COMP_FLG[3:0]: Position Counter Compare Output:
  - COMP_FLG[x](x range is 0-3) is asserted when the value of POS is equal to or greater than the value of the corresponding compare register (UCOMPx/LCOMPx).
  - COMP_FLG[x](x range is 0-3) is de-asserted when the value of POS is smaller than the value of the corresponding compare register (UCOMPx/LCOMPx).
- DIR: Direction of position counting:
  - Direction is up when DIR is asserted
  - Direction is down when DIR is de-asserted.
- CNT_UP: Position counter count up: when eQDC decodes a count-up event, CNT_UP outputs a pulse which width is 1 peripheral clock cycle.
- CNT_DN: Position counter count down: when eQDC decodes a count-down event, CNT_DN outputs a pulse which width is 1 peripheral clock cycle.

There are three count modes:

- Mode 0[CM0](CTRL2[CMODE]=00): UP/DOWN Pulse Count mode. Both position counter (POS) and position difference counter (POSD) count in the up direction when input PHASEA rising edge occurs, both counters count in the down direction when input PHASEB rising edge occurs.
- Mode 1[CM1](CTRL2[CMODE]=01): Signed Count mode (Double Edge). Both position counter (POS) and position difference counter (POSD) count the input PHASEA on both rising edge and falling edge while the input PHASEB provides the selected position counter direction (up/down) .
- Mode 2[CM2](CTRL2[CMODE]=10): Signed Count mode (Single Edge). Both position counter (POS) and position difference counter (POSD) count on the input PHASEA rising edge while the input PHASEB provides the selected position counter direction (up/down) .

NOTE

If the positive edge of both PHASEA and PHASEB occurs simultaneously, an error interrupt is generated CTRL2[SABIRQ] and counter is unchanged.

73.3.8 Speed measurement method

This section explains the speed measurement method, including the speed measurement algorithm.

The following figure shows the module working mechanism.

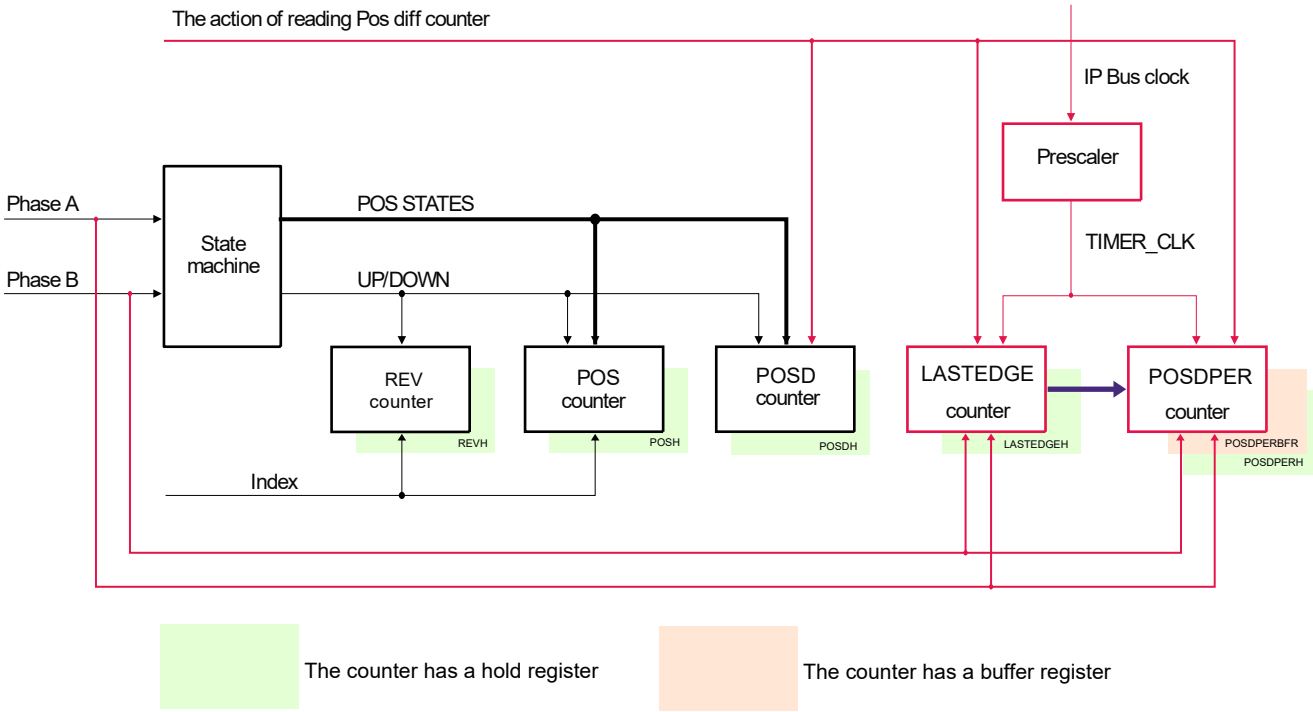

Figure 591. Quadrature decoder working mechanism

The following figure shows counters behavior and updating mechanism in the speed measurement method.

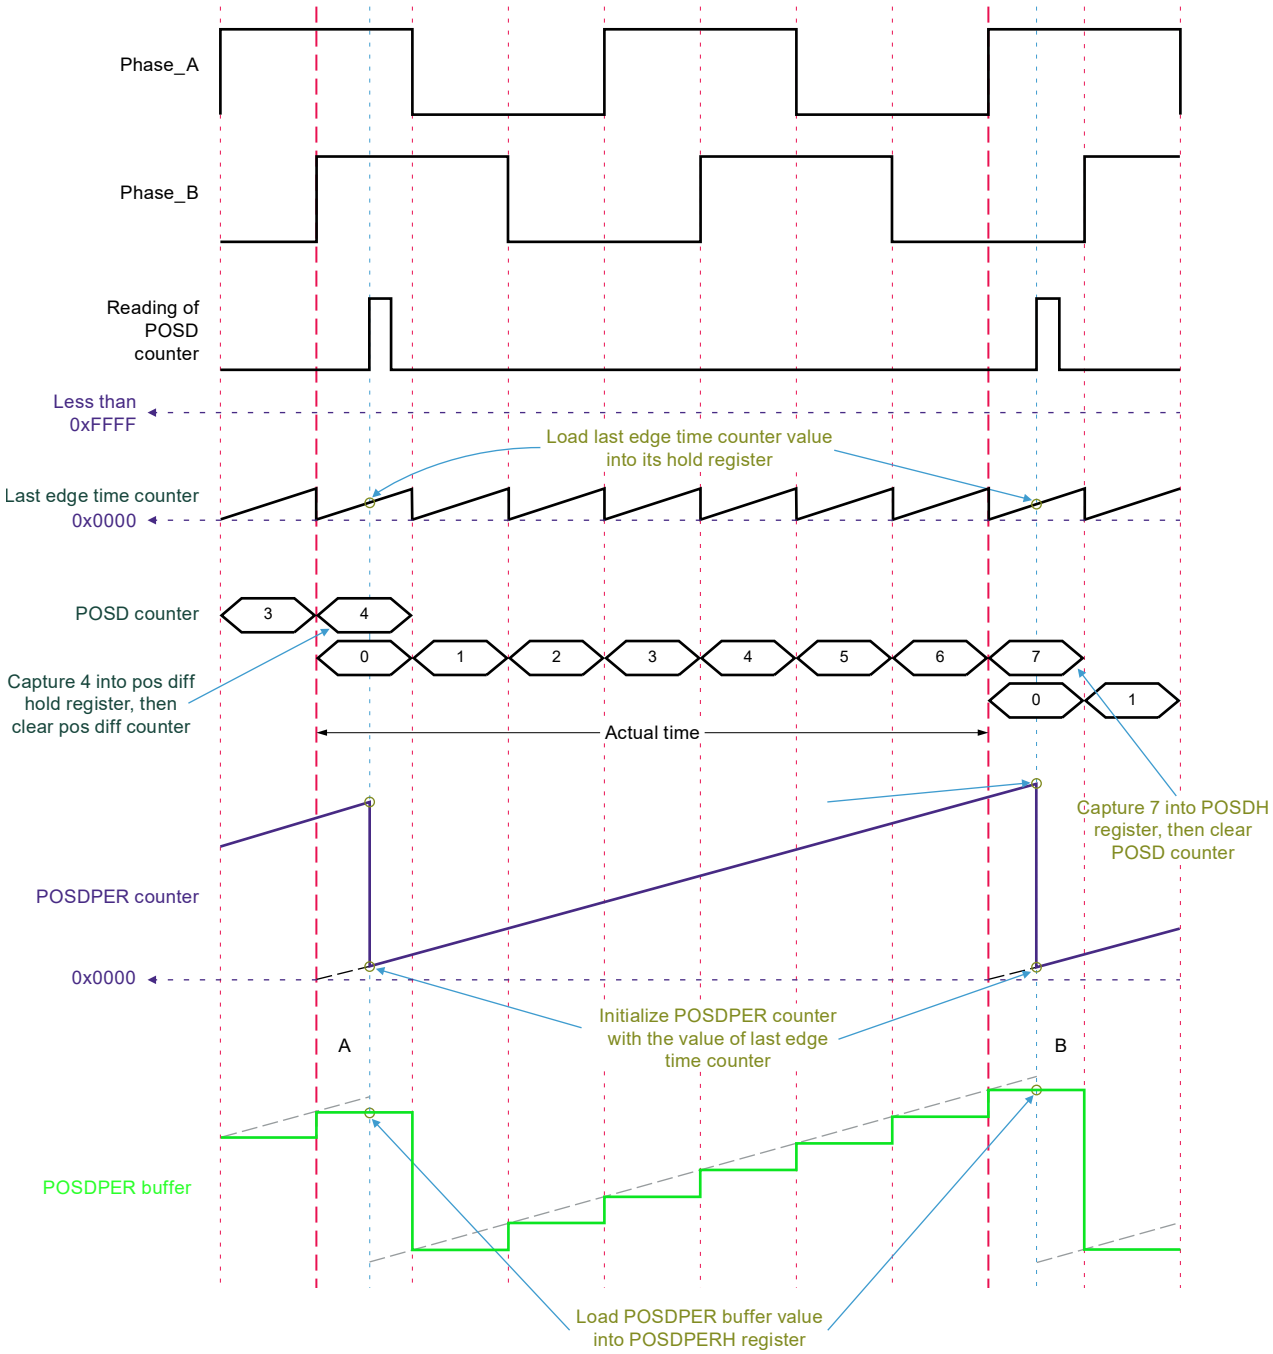

Figure 592. Counters behavior and updating mechanism

A reading of POSD occurs at time point A and it also occurs at time point B. “Actual time” represents the time duration between the first phase_a/b edges right before time points A and B. At time point B, after reading POSD, POSDPERH contains the time length of “Actual time” and POSDH contains the value of phase_a/b pulses within that “Actual time”. Speed can be calculated based on POSDPERH and POSDH. A visualized explanation of speed measurement with this method is shown in the figure below.

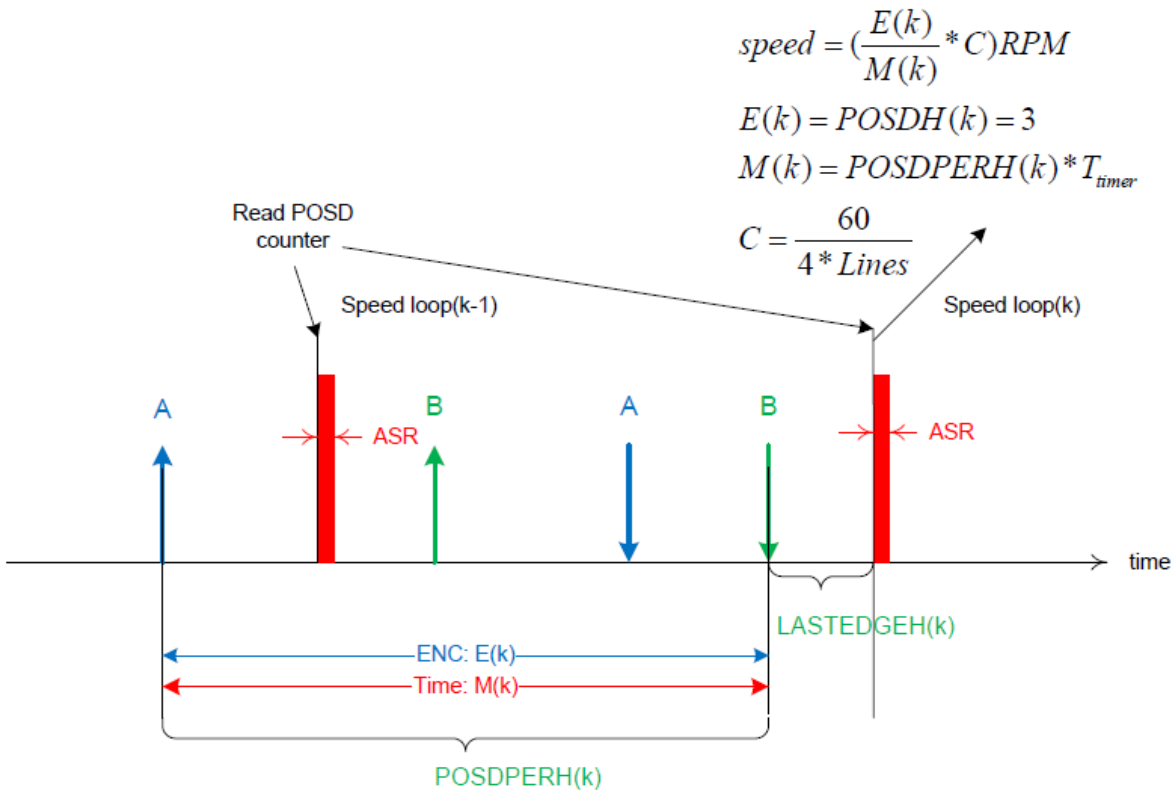

Figure 593. High speed measurement with method

Speed calculation algorithm

In order to cover all the cases in real applications, a simple speed measurement algorithm is necessary. See the algorithm shown below.

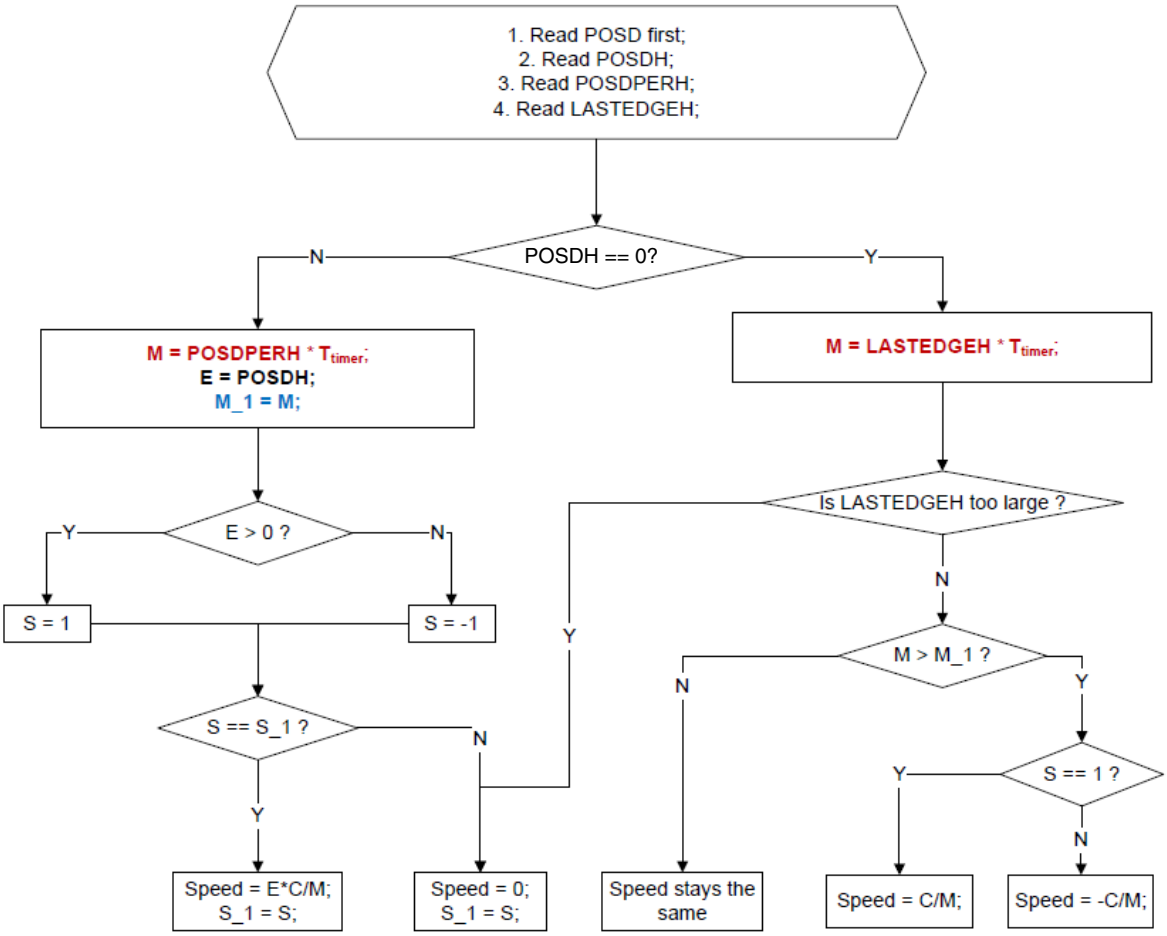

Figure 594. Flowchart of speed calculation with method

73.3.9 Reset

eQDC is reset by any system reset. Make sure you clear all inputs (of PhaseA, PhaseB, and etc.) before resetting eQDC.

73.3.10 Clocking

The peripheral clock is the only clock required when eQDC operates.

73.3.11 Interrupts

The following table lists the module interrupts.

Table 1086. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Description
ipi_int_home	CTRL[HIRQ]	CTRL[HIE]	HOME/ENABLE signal transition interrupt
ipi_int_index	CTRL[XIRQ]	CTRL[XIE]	INDEX/PRESET signal transition interrupt
ipi_int_ro	INTCTRL[ROIRQ]	INTCTRL[ROIE]	roll-over interrupt
ipi_int_ru	INTCTRL[RUIRQ]	INTCTRL[RUIE]	roll-under interrupt

Table continues on the next page...

Table 1086. Interrupt Summary (continued)

Core Interrupt	Interrupt Flag	Interrupt Enable	Description
ipi_int_wdog	CTRL[WDIRQ]	CTRL[WDIE]	Watchdog timeout interrupt
ipi_int_dir	INTCTRL[DIRIRQ]	INTCTRL[DIRIE]	Count direction change interrupt
ipi_int_sab	INTCTRL[SABIRQ]	INTCTRL[SABIE]	Simultaneous PHASEA and PHASEB change interrupt

73.4 External signals

eQDC receives the following 8 input signals from position or speed sensors:

- PHASEA
- PHASEB
- INDEX/PRESET
- TRIGGER
- HOME/ENABLE
- ICAP[3:1]

eQDC outputs the following 11 signals for system use:

- POS_MATCH[3:0]
- COMP_FLG[3:0]
- DIR
- CNT_DN
- CNT_UP

Table 1087. Signals

Signal			Description
PHASEA	Phase A	Input	The PHASEA input can be connected to one of the phases from a two-phase shaft quadrature encoder output. PHASEA and PHASEB are used by eQDC to indicate a decoder increment has passed, and to calculate its direction. • When eQDC is used as a single phase decode/count, PHASEA can also be used as the single input. Direction for two-phase shaft quadrature encoder output when CTRL[REV] = 0: • PHASEA is the leading phase for a shaft rotating in the positive direction. • PHASEA is the trailing phase for a shaft rotating in the negative direction.
PHASEB	Phase B	Input	The PHASEB input can be connected to the other phase from a two-phase shaft quadrature encoder output.

Table continues on the next page...

Table 1087. Signals (continued)

Signal			Description
			• When eQDC is used as a single phase decode/count mode, PHASEB and CTRL[REV] control counter direction. Direction for two-phase shaft quadrature encoder output when CTRL[REV] = 0: • PHASEB is the trailing phase for a shaft rotating in the positive direction. • PHASEB is the leading phase for a shaft rotating in the negative direction.
INDEX/ PRESET	INDEX/ PRESET	Input	• This input can work as INDEX or PRESET, selection bit is CTRL2[OPMODE] • Normally connected to the index pulse output of a quadrature encoder, the INDEX pulse can optionally reset the position counter of eQDC. The INDEX pulse also causes a change of state on the revolution counter. The direction of this state change (increment or decrement) is calculated from the PHASEA and PHASEB inputs. In Quadrature Count mode or Single Phase Count mode, this signal can present the counter PRESET function. • The positive edge of PRESET input can initialize position/revolution/ watchdog counters.
HOME/ENABLE	HOME/ENABLE	Input	The HOME input can be used by eQDC and the timer module. • This input can work as HOME or ENABLE, selection bit is CTRL2[OPMODE] • The HOME input can be used to trigger the initialization of the position counter (UPOS/LPOS). Often the HOME signal is connected to a sensor on the motor or machine, sending notification that it has reached a defined home position. In Quadrature Count mode or Single Phase Count mode, this signal can present the counter ENABLE function. • All counters start counting when ENABLE is asserted,all counters stop counting when ENABLE is de-asserted.
TRIGGER	TRIGGER	Input	• Initializes UPOS or LPOS. • Takes a snapshot of POS, REV, and POSD.
ICAP[3:1]	Input capture	Input	Takes snapshots of POS and stores them into the corresponding UPOSH/LPOSH: • Positive edge of ICAP[3] input takes snapshots of POS and stores it into UPOSH3/LPOSH3. • Positive edge of ICAP[2] input takes snapshots of POS and stores it into UPOSH2/LPOSH2.

Table continues on the next page...

Table 1087. Signals (continued)

Signal			Description
			• Positive edge of ICAP[1] input takes snapshots of POS and stores it into UPOSH1/LPOSH1.
POS_MATCH[3:0]	Position Match	Output	• Records the time at which the position of the shaft matches a user-defined compare value (UCOMPx/LCOMPx), the POS_MATCH[x](x range is 0-3) output can be used to trigger a timer channel. • Alternatively, records the time at which the position information was read, (when the position counters (UPOS and LPOS), revolution counter (REV), or position difference counter (POSD) registers are read) the POS_MATCH[x](x range is 0-3) output can be used to trigger a timer channel. Note: • If CTRL2[OUTCTL] is cleared, POS_MATCH[x](x range is 0-3) is asserted when the value of POS equals the value of the corresponding compare register (UCOMPx/LCOMPx), and de-asserted when the value of POS does not equal the value of the corresponding compare register (UCOMPx/LCOMPx). • If CTRL2[OUTCTL] is set, POS_MATCH[x](x range is 0-3) is asserted a pulse with 1 peripheral clock cycle width when UPOS or LPOS, REV, or POSD is read.
COMP_FLG[3:0]	Position Counter Compare Output	Output	• COMP_FLG[x](x range is 0-3) is asserted when the value of POS is equal to or greater than the value of the corresponding compare register (UCOMPx/LCOMPx). • COMP_FLG[x](x range is 0-3) is de-asserted when the value of POS is smaller than the value of the corresponding compare register (UCOMPx/LCOMPx).
DIR	Direction of position counting	Output	Indicates the direction of position counting: • 1 indicates up. • 0 indicates down.
CNT_UP	Position counter count up	Output	WheneQDC decodes a count-up event, CNT_UP outputs a pulse with a width of 1 peripheral clock cycle.
CNT_DN	position counter count down	Output	When eQDC decodesa count-down event, CNT_DN outputs a pulse with a width of 1 peripheral clock cycle.

73.5 Initialization

This module does not require initialization.

73.6 Register descriptions

This section describes the memory map and registers of eQDC.

73.6.1 Quadrature_Decoder register descriptions

The address of a register is the sum of a base address and an address offset.

73.6.1.1 Quadrature_Decoder memory map

eQDC1 base address: 4271_0000h

eQDC2 base address: 4272_0000h

eQDC3 base address: 4273_0000h

eQDC4 base address: 4274_0000h

Offset	Register	Width (In bits)	Access	Reset value

Fields

Field	Function
15 HIRQ	HOME/ENABLE Signal Transition Interrupt Request HOME/ENABLE Signal Transition Interrupt Request is set when a positive or negative transition on the HOME/ENABLE signal occurs, according to the Use Negative Edge of HOME/ENABLE Input bit (CTRL[HNE]). If HOME/ENABLE Signal Transition Interrupt Request bit is set and HOME/ENABLE Interrupt Enable bit (CTRL[HIE]) is set, then a HOME/ENABLE interrupt occurs. • HOME/ENABLE Signal Transition Interrupt Request bit remains set until it is cleared by software • Write a one to this bit (HIRQ) to clear it 0b - No transition on the HOME/ENABLE signal has occurred 1b - A transition on the HOME/ENABLE signal has occurred
14 HIE	HOME/ENABLE Interrupt Enable Enables/disables HOME/ENABLE signal interrupts. 0b - Disabled 1b - Enabled
13 HIP	Enable HOME to Initialize Position Counter UPOS/LPOS Enables the position counter to be initialized by the HOME signal. 0b - No action 1b - HOME signal initializes the position counter
12 HNE	Use Negative Edge of HOME/ENABLE Input Selects using the positive/negative edge of the HOME/ENABLE input. 0b - When CTRL[OPMODE] = 0,use HOME positive edge to trigger initialization of position counters. When CTRL[OPMODE] = 1,use ENABLE high level to enable POS/POSD/WDG/REV counters 1b - When CTRL[OPMODE] = 0,use HOME negative edge to trigger initialization of position counters. When CTRL[OPMODE] = 1,use ENABLE low level to enable POS/POSD/WDG/REV counters
11 SWIP	Software-Triggered Initialization of Position Counters UPOS and LPOS Writing 1 to Software-Triggered Initialization of Position Counters bit initializes the position counter. • Software-Triggered Initialization of Position Counters bit is always read as 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No action 1b - Initialize position counter
10 REV	Enable Reverse Direction Counting Selects the direction of the count and position counter initial value. 0b - Count normally and the position counter initialization uses upper/lower initialization register UINIT/LINIT 1b - Count in the reverse direction and the position counter initialization uses upper/lower modulus register UMOD/LMOD
9 PH1	Enable Single Phase Mode Bypass/use the quadrature decoder logic. 0b - Standard quadrature decoder, where PHASEA and PHASEB represent a two-phase quadrature signal. 1b - Single phase mode, bypass the quadrature decoder, refer to CTRL2[CMODE] description
8 XIRQ	INDEX/PRESET Pulse Interrupt Request INDEX/PRESET Pulse Interrupt Request is set when a transition on the INDEX/PRESET signal occurs, according to the Use Negative Edge of INDEX/PRESET Pulse bit (CTRL[XNE]). If INDEX/PRESET Pulse Interrupt Request bit is set and INDEX/PRESET Pulse Interrupt Enable bit (CTRL[XIE]) is set, then an INDEX/PRESET interrupt occurs. • INDEX/PRESET Pulse Interrupt Request remains set until cleared by software • Write a one to this bit (XIRQ) to clear it 0b - INDEX/PRESET pulse has not occurred 1b - INDEX/PRESET pulse has occurred
7 XIE	INDEX/PRESET Pulse Interrupt Enable Enables/disables INDEX/PRESET pulse interrupts. 0b - Disabled 1b - Enabled
6 XIP	INDEX Triggered Initialization of Position Counters UPOS and LPOS Enables/disables the position counter to be initialized by the INDEX pulse. 0b - INDEX pulse does not initialize the position counter 1b - INDEX pulse initializes the position counter
5 XNE	Select Positive/Negative Edge of INDEX/PRESET Pulse Selects the positive/negative edge of the INDEX/PRESET pulse. 0b - Use positive edge of INDEX/PRESET pulse

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Use negative edge of INDEX/PRESET pulse
4 WDIRQ	Watchdog Timeout Interrupt Request Watchdog Timeout Interrupt Request is set when a watchdog timeout interrupt occurs. • Watchdog Timeout Interrupt Request remains set until cleared by software • Write a one to this bit (WDIRQ) to clear it • Watchdog Timeout Interrupt Request bit is also cleared when Watchdog Enable (CTRL[WDE]) is disabled (=0) 0b - No Watchdog timeout interrupt has occurred 1b - Watchdog timeout interrupt has occurred
3 WDIE	Watchdog Timeout Interrupt Enable Enables/disables watchdog timeout interrupts. 0b - Disabled 1b - Enabled
2 WDE	Watchdog Enable Enables/disables the watchdog timer that is monitoring the PHASEA and PHASEB inputs for motor movement. 0b - Disabled 1b - Enabled
1 DMAEN	DMA Enable This bit enables DMA for new written buffer values of COMPx/INIT/MOD(x range is 0-3) Please note: When set to 1, this bit can't be cleared by writing 0 to it. 0b - DMA is disabled 1b - DMA is enabled. DMA request asserts automatically when the values in the outer-set of buffered compare registers (UCOMP0/LCOMP0;UCOMP1/LCOMP1;UCOMP2/LCOMP2;UCOMP3/LCOMP3), initial registers(UINIT/LINIT) and modulus registers (UMOD/LMOD) are loaded into the inner-set of buffer and then LDOK is cleared automatically. After the completion of this DMA transfer, LDOK is set automatically, it ensures outer-set values can be loaded into inner-set which in turn triggers DMA again.
0 LDOK	Load Okay This bit enables that the outer-set values of buffered compare registers (UCOMPx/LCOMPx, x=0~3), initial register(UINIT/LINIT) and modulus register(UMOD/LMOD) can be loaded into their inner-sets and take effect. When LDOK is set, this loading action occurs at the next position counter roll-over or roll-under if CTRL2[LDMOD] is set, or it occurs immediately if CTRL2[LDMOD] is cleared. LDOK is automatically cleared after the values in outer-set is loaded into the inner-set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Set LDOK bit by reading it, then write a logic 1 to it. LDOK can be manually cleared before a loading action occurs by writing a logic 0 to it. The outer-set of the registers cannot be written while LDOK is 1. 0b - No loading action taken. Users can write new values to buffered registers (writing into outer-set of these buffered registers) 1b - Outer-set values are ready to be loaded into inner-set and take effect. The loading time point depends on CTRL2[LDMOD].

73.6.1.3 Control 2 Register (CTRL2)

Offset

Register	Offset
CTRL2	2h

Function

Controls various features of eQDC.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-14 CMODE	Counting Mode These bits control the basic counting and behavior of Position Counter and Position Difference Counter. Setting CTRL[REV] to 1 can reverse the counting direction. In quadrature Mode (CTRL[PH1] = 0): 00b - CM0: Normal/Reverse Quadrature X4 01b - CM1: Normal/Reverse Quadrature X2 10b - CM2: Normal/Reverse Quadrature X1 11b - CM3: Reserved In Single Phase Mode (CTRL[PH1] = 1): 00b - CM0: UP/DOWN Pulse Count Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - CM1: Signed Mode, count PHASEA rising/falling edge, position counter counts up when PHASEB is low and counts down when PHASEB is high 10b - CM2: Signed Count Mode,count PHASEA rising edge only, position counter counts up when PHASEB is low and counts down when PHASEB is high 11b - CM3: Reserved
13 ONCE	Count Once This bit selects modulo loop or one shot counting mode. **NOTE** Any of the following event initializes and restarts the position counter: • Write to CTRL[SWIP]. • INDEX signal transition if CTRL2[OPMODE] bit is clear and CTRL[XIP] is set. • HOME signal transition if CTRL2[OPMODE] bit is clear and CTRL[HIP] is set. • PRESET signal transition if CTRL2[OPMODE] bit is set and ENABLE signal is 1. • Positive edge transition of TRIGGER input if CTRL2[INITPOS] is set. 0b - Position counter counts repeatedly 1b - Position counter counts until roll-over or roll-under, then stop.
12 INITPOS	Initial Position Register • When Initial Position Register is set (=1), it allows the rising edge of TRIGGER input to initialize the position counter (UPOS and LPOS registers) to UINIT/LINIT values (if CTRL[REV]=0) or UMOD/LMOD values (if CTRL[REV]=1). • When Initial Position Register is clear (=0), the position counter (UPOS/LPOS) is not initialized on rising edge of TRIGGER input 0b - Don't initialize position counter on rising edge of TRIGGER 1b - Initialize position counter on rising edge of TRIGGER
11 —	Reserved
10 PMEN	Period measurement function enable This bit is used to indicate the period measurement functions of LASTEDGE, LASTEDGEH, POSDPER, POSDPERBFR, and POSDPERH are being used. 0b - Period measurement functions are not used. POSD is loaded to POSDH and then cleared whenever POSD, UPOS, LPOS or REV is read. 1b - Period measurement functions are used. POSD is loaded into POSDH and then cleared only when POSD is read.
9	Output Control

Table continues on the next page...

Table continued from the previous page...

Field	Function
OUTCTL	Output Control controls the pulsing of the POS_MATCH output signal. 0b - POS_MATCH[x](x range is 0-3) is asserted when the Position Counter is equal to according compare value (UCOMPx/LCOMPx)(x range is 0-3), and de-asserted when the Position Counter not equal to the compare value (UCOMPx/LCOMPx)(x range is 0-3) 1b - All POS_MATCH[x](x range is 0-3) are asserted a pulse, when the UPOS, LPOS, REV, or POSD registers are read
8 REVMOD	Revolution Counter Modulus Enable Revolution Counter Modulus Enable selects how the revolution counter (REV) is incremented/ decremented. By default, the revolution counter is controlled based on the count direction and the INDEX pulse. As an option, the revolution counter can be controlled using the roll-over/under detection during modulo counting. 0b - Use INDEX pulse to increment/decrement revolution counter (REV) 1b - Use modulus counting roll-over/under to increment/decrement revolution counter (REV)
7-4 —	Reserved
3 LDMOD	Buffered Register Load (Update) Mode Select This bit selects the loading time point of the buffered compare registers UCOMPx/LCOMPx, x=0~3, initial register (UINIT/LINIT), and modulus register (UMOD/LMOD) 0b - Buffered registers are loaded and take effect immediately upon CTRL[LDOK] is set. 1b - Buffered registers are loaded and take effect at the next roll-over or roll-under if CTRL[LDOK] is set.
2 OPMODE	Operation Mode Select 0b - Decode Mode: Input nodes INDEX/PRESET and HOME/ENABLE are assigned to function of INDEX and HOME. 1b - Count Mode: Input nodes INDEX/PRESET and HOME/ENABLE are assigned to functions of PRESET and ENABLE. In this mode: (1)only when ENABLE=1, all counters (position/ position difference/revolution/watchdog) can run, when ENABLE=0, all counters (position/position difference/revolution/watchdog) can't run. (2) the rising edge of PRESET input can initialize position/revolution/watchdog counters (position counter initialization also need referring to bit CTRL[REV]).
1 UPDPOS	Update Position Registers • When UPDPOS bit is set (=1), it allows the rising edge of TRIGGER input to clear the POSD, REV, UPOS and LPOS registers to zero. • When UPDPOS bit is clear (=0), the rising edge of TRIGGER input does not clear POSD, REV, UPOS and LPOS registers to zero. • If both UPDPOS bit and INITPOS bit are set, then when rising edge of TRIGGER input occurs, the UPOS/LPOS registers are not cleared to zero, but be initialized to value of UINIT/LINIT registers(if CTRL[REV]=0) or value of UMOD/LMOD registers(if CTRL[REV]=1).

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>• Do not set this bit when using the LASTEDGE and POSDPER registers to measure speed.</td></tr>
<tr><td>0
UPDHLD</td><td>Update Hold Registers
• When UPDHLD bit is set (=1), it allows the rising edge of TRIGGER input to cause an update of the POSDH, REVH, UPOSH, and LPOSH registers
• When UPDHLD bit is clear (=0), the hold registers (POSDH, REVH) are not updated by the rising edge of TRIGGER input, and hold registers UPOSH/LPOSH are not updated by the rising edge of TRIGGER input if INITPOS bit is also clear.
• Do not set this bit when using the LASTEDGE and POSDPER registers to measure speed.
UPOSH/LPOSH has little difference with POSDH and REVH on UPDHLD bit, both UPDHLD bit and INITPOS bit allow the rising edge of TRIGGER input to take effect on UPOSH/LPOSH, so make a list here:
<table>
<tr><th>INITPOS</th><th>UPDHLD</th><th>State of UPOSH/LPOSH</th></tr>
<tr><td>0</td><td>0</td><td>Rising edge of TRIGGER input does not take effect on UPOSH/LPOSH</td></tr>
<tr><td>0</td><td>1</td><td>Rising edge of TRIGGER input updates UPOSH/LPOSH with the value of POS counter</td></tr>
<tr><td>1</td><td>0</td><td>Rising edge of TRIGGER input updates UPOSH/LPOSH with the value of POS counter, and then POS counter is initialized</td></tr>
<tr><td>1</td><td>1</td><td>Rising edge of TRIGGER input updates UPOSH/LPOSH with the value of POS counter, and then POS counter is initialized</td></tr>
</table>
Note:Updating the Position Difference Hold Register (POSDH) also causes the Position Difference Counter Register (POSD) to be cleared.</td></tr>
</table>

73.6.1.4 Input Filter Register (FILT)

Offset

Register	Offset
FILT	4h

Function

The Input Filter Register sets the values of the input filter sample period (FILT_PER) and the input filter sample count (FILT_CNT).

- The Input Filter Sample Period (FILT_PER) should be set so that the sampling period is larger than the period of the expected noise. Doing this means that a noise spike only corrupts one sample.
- The Input Filter Sample Count (FILT_CNT) should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of FILT_CNT+3.

The values of the Input Filter Sample Period (FILT_PER) and the Input Filter Sample Count (FILT_CNT) must also be traded off against the desire for minimal latency in recognizing valid input transitions. Turning on the input filter (setting the Input Filter Sample Period (FILT_PER) to a non-zero value) introduces a latency of ((FILT_CNT+3)*FILT_PER+2) IPBus clock periods.

The filter latency can be measured:

- Drive the quadrature decoder inputs (PHASEA, PHASEB, INDEX, HOME)
- Monitor the filtered output in the Input Monitor Register (IMR)
- Determine how many IPBus clock cycles that it takes before the output shows up, by using the following equations, where f is FILT_PER and s is FILT_CNT.
  - DELAY (IPBus clock cycles) = f * (s+3) +1 (to read the filtered output)
  - DELAY (IPBus clock cycles) = f * (s+3) +2 (to monitor the output in the IMR)

One more additional IPBus clock cycle is needed to read the filtered output, and 2 more IPBus clock cycles are needed to monitor the filtered output in the IMR. The sample rate is set when it reaches the number f. The following examples use the preceding equations:

- Example: when f = 0, the filter is bypassed: DELAY = 1 or 2 clock cycles.
- Example: when f = 5 and s = 2: DELAY = 5 * (2+3) + (1 or 2) = 26 or 27 clock cycles.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PRSC				FILT_CS	FILT_CNT			FILT_PER							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 PRSC	Prescaler The Prescaler field is used to prescale the peripheral clock that is used by the LASTEDGE and POSDPER counters as well as watchdog timer and Input Filter. The clock is prescaled by a value of 2^PRSC which means that the prescaler logic can divide the clock by a minimum of 1 and a maximum of 32,768.
11 FILT_CS	Filter Clock Source selection 0b - Peripheral Clock 1b - Prescaled peripheral clock by PRSC
10-8 FILT_CNT	Input Filter Sample Count The Input Filter Sample Count represents the number of consecutive samples that must agree, before the input filter accepts an input transition.

Table continues on the next page...

Table continued from the previous page...

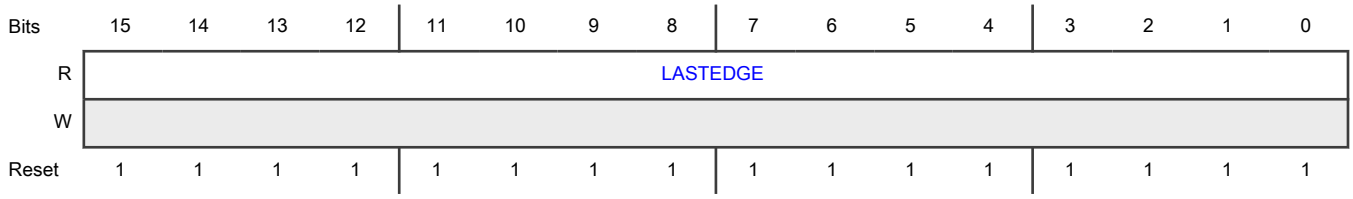
Field	Function
	• A value of 0x0 represents 3 samples • A value of 0x7 represents 10 samples The value of the Input Filter Sample Count (FILT_CNT) affects the input latency.
7-0 FILT_PER	Input Filter Sample Period The Input Filter Sample Period represents the sampling period (in IPBus clock cycles) of the decoder input signals. Each input is sampled multiple times at the rate specified by the Input Filter Sample Period. • If FILT_PER is 0x00 (default), then the input filter is bypassed. Bypassing the digital filter enables the position/position difference counters to operate with count rates up to the IPBus frequency. • The value of the Input Filter Sample Period (FILT_PER) affects the input latency. • When changing the Input Filter Sample Period (FILT_PER) from a non-zero value to another non-zero value, write a value of 0 first, to clear the filter.

73.6.1.5 Last Edge Time Register (LASTEDGE)

Offset

Register	Offset
LASTEDGE	6h

Diagram



Fields

Field	Function
15-0 LASTEDGE	Last Edge Time Counter The Last Edge Time counter represents the time since the last edge occurred on PHASEA or PHASEB. LASTEDGE counts up using the peripheral clock that is prescaled by FILT[PRSC]. Any edge on PHASEA or PHASEB resets this register to 0 and starts counting. If the LASTEDGE count reaches 0xffff, the counting stops in order to prevent an overflow. Counting continues when an edge occurs on PHASEA or PHASEB.

73.6.1.6 Position Difference Period Counter Register (POSDPER)

Offset

Register	Offset
POSDPER	8h

Diagram

Function
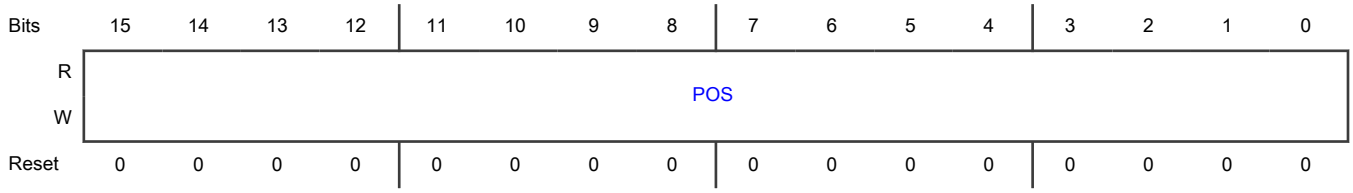
Contains the lower (least significant) half of the Position Counter. This is the binary count from the Position Counter.

Diagram



Fields

Field	Function
15-0 POS	POS The lower (least significant) half of the Position Counter

73.6.1.10 Position Difference Counter Register (POSD)

Offset

Register	Offset
POSD	10h

Function

The Position Difference Counter Register contains the position change in value occurring between each read of the Position Register. The value of the Position Difference Counter Register can be used to calculate velocity.

- The 16-bit Position Difference Counter computes up or down on every count pulse.
- This Position Difference Counter acts as a differentiator, whose count value is proportional to the change in position since the last time that the Position Counter was read.
- When the Position Difference Counter (POSD) is read, its contents are copied into the Position Difference Hold Register (POSDH) and the Position Difference Counter is cleared.

Diagram

73.6.1.20 Upper Modulus Register (UMOD)

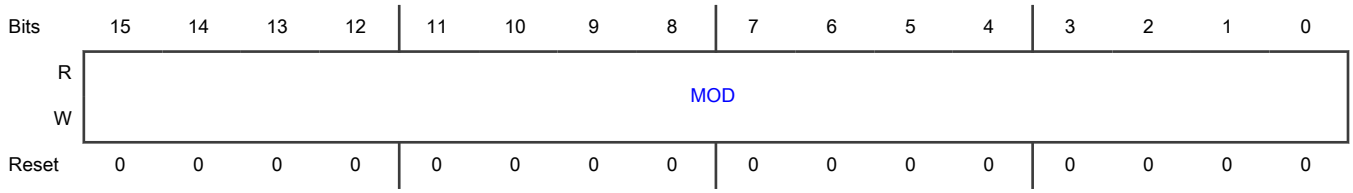
Offset

Register	Offset
UMOD	24h

Function

The Upper Modulus Register contains the upper (most significant) half of the Modulus register. MOD acts as the upper bound during modulo counting, and as the upper reload value when rolling over from the lower bound. It is a double-set register (please refer to chapter "Double-set Registers Loading Operation"). Writing this register actually writes to the out-set, and reading this register returns inner-set value which is the value that is taking effect.

Diagram



Fields

Field	Function
15-0 MOD	MOD Upper (most significant) half of the Modulus register

73.6.1.21 Lower Modulus Register (LMOD)

Offset

Register	Offset
LMOD	26h

Function

The Lower Modulus Register contains the lower (least significant) half of the Modulus register. MOD acts as the upper bound during modulo counting, and as the upper reload value when rolling over from the lower bound. It is a double-set register (please refer to chapter "Double-set Registers Loading Operation"). Writing this register actually writes to the out-set, and reading this register returns inner-set value which is the value that is taking effect.

Field	Function
15-0 MOD	MOD Lower (least significant) half of the Modulus register

73.6.1.22 Upper Position Compare Register 0 (UCOMP0)

Offset

Register	Offset
UCOMP0	28h

Function

The Upper Position Compare Register contains the upper (most significant) half of the Position Compare register 0. When the value of the Position counter (POS) matches the value of the Position Compare register 0(COMP0), the Compare Interrupt Request flag (INTCTRL[CMP0IRQ]) is set and the POS_MATCH[0] output is asserted. COMP_FLG[0] is asserted when the Position Counter is equal or greater than COMP0. COMP_FLG[0] is de-asserted when the Position Counter is less than COMP0. Note: If COMP0 value equals initial value (INIT) or modulus value (MOD), COMP_FLG[0] does not take effect. It is a double-set register (please refer to chapter "Double-set Registers Loading Operation"). Writing this register actually writes to the out-set, and reading this register returns inner-set value which is the value that is taking effect.

Diagram

73.6.1.26 Lower Position Compare 1 (LCOMP1)

Offset

Register	Offset
LCOMP1	2Eh

Function

The Lower Position Compare Register contains the upper (most significant) half of the Position Compare register 1. When the value of the Position counter (POS) matches the value of the Position Compare register 1 (COMP1), the Compare Interrupt Request flag (INTCTRL[CMP1IRQ]) is set and the POS_MATCH[1] output is asserted. COMP_FLG[1] is asserted when the Position Counter is equal or greater than COMP1. COMP_FLG[1] is de-asserted when the Position Counter is less than COMP1. Note: If COMP1 value equals initial value (INIT) or modulus value (MOD), COMP_FLG[1] does not take effect. It is a double-set register (please refer to chapter "Double-set Registers Loading Operation"). Writing this register actually writes to the out-set.

This event typically indicates an error condition, because quadrature coding requires only one of these inputs to change at a time. • Simultaneous PHASEA and PHASEB Change Interrupt Request bit remains set until it is cleared by software or a reset • Write 1 to this bit (SABIRQ) to clear it 0b - No simultaneous change of PHASEA and PHASEB has occurred 1b - A simultaneous change of PHASEA and PHASEB has occurred
0 SABIE	Simultaneous PHASEA and PHASEB Change Interrupt Enable Simultaneous PHASEA and PHASEB Change Interrupt Enable bit enables simultaneous PHASEA and PHASEB change interrupts, based on the Simultaneous PHASEA and PHASEB Change Interrupt Request (SABIRQ) bit being set. 0b - Disabled 1b - Enabled

73.6.1.37 Watchdog Timeout Register (WTR)

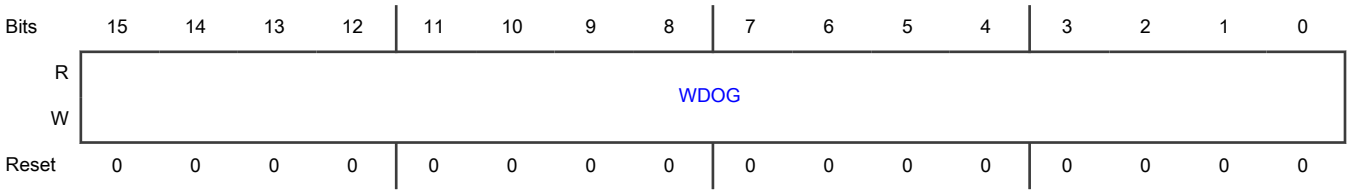
Offset

Register	Offset
WTR	3Ah

Function

The Watchdog Timeout Register stores the timeout count for the quadrature decoder module watchdog timer. This quadrature decoder module watchdog timer is separate from any other watchdog timer(s) that may also be in the device.

Diagram



Fields

Field	Function
15-0 WDOG	WDOG WDOG[15:0] is a binary representation of the number of clock cycles, using the peripheral clock prescaled by FILT[PRSC], 0xFFFF plus one count in this register determines the timing out period.

73.6.1.38 Input Monitor Register (IMR)

Offset

Register	Offset
IMR	3Ch

Function

The Input Monitor Register contains the values of the raw and filtered PHASEA, PHASEB, INDEX/PRESET and HOME/ENABLE input signals. The reset value depends on the values of the raw and filtered values of PHASEA, PHASEB, INDEX/PRESET and HOME/ENABLE input signals:

- The Input Monitor Register [3:0] contains the values of the raw value of PHASEA, PHASEB, INDEX/PRESET and HOME/ENABLE input signals.
- The Input Monitor Register [7:4] contains the values of the filtered value of PHASEA, PHASEB, INDEX/PRESET and HOME/ENABLE input signals.
- The Input Monitor Register [7:4] supply filter bypass function for PHASEA, PHASEB, INDEX/PRESET and HOME/ENABLE input signals.
- The Input Monitor Register [11:8] contains the values of the 4 POS counter CMPs flag.
- The Input Monitor Register [15:14] contains the values of the count direction flag and count direction flag hold.
- If no pull-up or pull-down is connected to PHASEA, PHASEB, INDEX/PRESET and HOME/ENABLE input signals, then the reset value of the 4 lower bits of the Input Monitor Register (IMR) are all unknown.

73.6.1.39 Test Register (TST)

Offset

Register	Offset
TST	3Eh

Function

The Test Register controls and sets the frequency of a quadrature signal generator; it provides a quadrature test signal to the inputs of the quadrature decoder module.

- The TEST_COUNT value is counted down to zero when the test module is enabled (TEN = 1) and the counter is enabled (TCE = 1).

- Each count value of one represents a single quadrature cycle interpreted as a count of one by the position counter (UPOS and LPOS) if it is enabled (TEN = 1, TCE = 1).
- Repeated writing of new values to TEST_COUNT can cause an extra phase transition and therefore an extra count by the Position Counter.
- The period field determines the length (in IPBus clock cycles) of each quadrature cycle phase.

The Test Register is a factory test feature; however, it can also be useful in customer software development and testing.

When RTWDOG interrupt is enabled by setting INT bit of CS register, RTWDOG backup reset could happen to trigger the system reset which means the counter value (CNT) could be twice of Timeout Value (TOVAL). However, it still requires SW refreshing before TOVAL value.

The following options are available for the CS[CLK] field:

Table 1089. CS[CLK] Options

CLK value	Description
00	Don't use/Reserved
01	32KHz clock
10	Don't use/Reserved
11	24MHz RC Oscillator

74.2 Overview

WDOG is an independent timer that is available for system use. It provides a safety feature to ensure that the software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If WDOG is not serviced (refreshed) within a certain period, it resets the MCU.

74.2.1 Block diagram

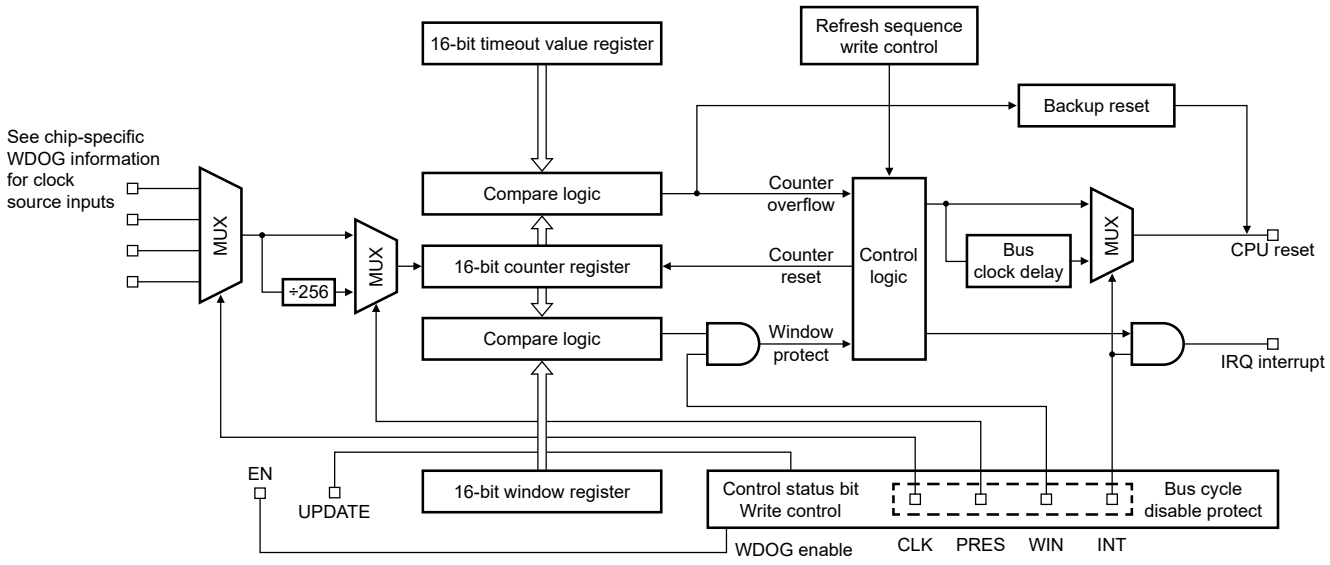

Figure 604. Block diagram

74.2.2 Features

- Configurable clock source inputs independent of the bus clock
- Programmable timeout period
  - Programmable 16-bit timeout value
  - Optional, fixed 256 clock prescaler when longer timeout periods are needed
- Robust write sequences for counter refresh: provision to refresh the sequence of writing to WDOG Counter (CNT)
- Window mode option for the refresh mechanism
  - Programmable 16-bit window value
  - Robust check to ensure that program flow is faster than expected
  - Early refresh attempts that trigger a reset
- Optional timeout interrupt to allow post-processing diagnostics
  - Interrupt request to CPU with an interrupt vector for an interrupt service routine (ISR)
  - Forced reset that occurs 128 bus clocks after the interrupt vector fetch
- Write-once-after-reset configuration fields to ensure that WDOG configuration is not altered mistakenly
- Robust write sequence for unlocking write-once configuration fields
  - Unlock sequence of writing to WDOG Counter (CNT), for allowing updates to write-once configuration fields
  - You must make updates within 1024 bus clocks after unlocking and before WDOG closing unlock window

74.3 Functional description

WDOG provides a fail-safe mechanism to ensure that you can reset the system to a known state of operation in case of system failure, such as the CPU clock stopping or there being a runaway condition in the software code. The WDOG counter runs continuously off a selectable clock source and expects to be serviced (refreshed) periodically. If it is not refreshed, it generates a reset triggering event.

74.3.1 Refresh mechanism

WDOG resets the MCU if the WDOG counter is not refreshed. A robust refresh mechanism makes it very unlikely for a runaway code to refresh WDOG.

To refresh the WDOG counter, you must execute a refresh write sequence before the timeout period expires. In addition, in case of Window mode, you must not start the refresh sequence until you set the time value in Watchdog Window (WIN). See the following figure for more.

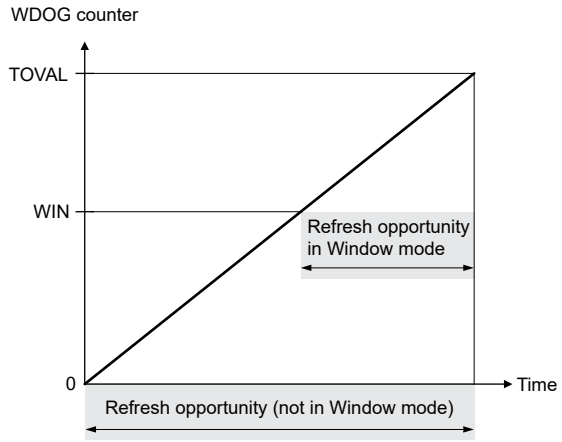

Figure 605. Refresh opportunity for the WDOG counter

74.3.1.1 Using Window mode

Software finishing its main control loop faster than expected could be an indication of a problem. Depending on the requirements of the application, you can program WDOG to force a reset when refresh attempts are early.

When Window mode is enabled, you must refresh WDOG after the counter has reached a minimum expected time value; otherwise, WDOG resets the MCU. The minimum expected time value is specified in Watchdog Window (WIN). Writing 1 to WIN enables Window mode.

74.3.1.2 Refreshing WDOG

The refresh write sequence is based on the following methods:

- Either two 16-bit writes (A602h, B480h) or four 8-bit writes (A6h, 02h, B4h, 80h) to WDOG Counter (CNT) if CMD32EN = 0
- One 32-bit write (B480_A602h) to WDOG Counter (CNT) if CMD32EN = 1

You must apply these methods before WDOG times out; otherwise, it resets the MCU.

Before starting the refresh sequence, disable the global interrupts. Otherwise, an interrupt could effectively invalidate the refresh sequence, if the interrupt occurs before the refresh writes finish. After the sequence finishes, restore the global interrupt control state.

See Application information for example code.

74.3.2 Configuring WDOG

74.3.2.1 Configuring WDOG once

All WDOG control fields, timeout value, and window value are write-once after reset. This means that after a write has occurred, they cannot be changed unless a reset occurs. You can ensure this by configuring the window and timeout values first, followed by the other control fields, when UPDATE = 0.

This provides a robust mechanism to configure WDOG and ensure that a runaway condition cannot mistakenly disable or modify the WDOG configuration, after the module is configured.

The new configuration takes effect only after you write to all registers except WDOG Counter (CNT) after reset. Otherwise, WDOG uses the reset values by default. If you do not use Window mode (WIN), you do not need to write to Watchdog Window (WIN) to bring the new configuration into effect.

74.3.2.2 Reconfiguring WDOG

In some cases (for example, when supporting a bootloader function), you may want to reconfigure or disable WDOG, without forcing a reset first:

- By writing 1 to UPDATE on the initial configuration of WDOG after a reset, you can reconfigure WDOG at any time by executing an unlock sequence.
- Conversely, if UPDATE remains 0, the only way to reconfigure WDOG is by initiating a reset.

The unlock sequence is similar to the refresh sequence but uses different values.

74.3.2.3 Unlocking WDOG

The unlock sequence is based on the following two methods:

- Either two 16-bit writes (C520h, D928h) or four 8-bit writes (C5h, 20h, D9h, 28h) to WDOG Counter (CNT), after WDOG is configured, if CMD32EN = 0
- One 32-bit write (D928_C520h) to WDOG Counter (CNT), after WDOG is configured, if CMD32EN = 1

An improper unlock sequence causes WDOG to reset. On completing the unlock sequence, you must reconfigure WDOG within 1024 bus clocks; otherwise, WDOG closes the unlock window.

NOTE

Because it requires 1024 bus clocks to reconfigure WDOG, you must insert some delays before executing stop or wait instructions after reconfiguring WDOG. This ensures that WDOG's new configuration takes effect before the MCU enters Low-Power mode. Otherwise, the MCU may not wake up from Low-Power mode.

74.3.3 Functionality in Debug and Low-Power modes

By default, WDOG is not functional in Debug, Wait, or Stop modes. However, it can remain functional in these modes as follows:

- For Debug mode, write 1 to DBG (this way WDOG is functional in Debug mode even when Debug mode holds the CPU).
- For Wait mode, write 1 to WAIT.
- For Stop mode, write 1 to STOP and WAIT, and ensure that the clock source is active in Stop mode.

NOTE

WDOG can generate an interrupt in Stop mode.

For Debug and Stop modes, in addition to the aforementioned configuration, you must use a clock source other than the bus clock as the reference clock for the counter; otherwise, WDOG cannot function.

74.3.4 Fast testing of WDOG

Before executing the application code in safety-critical applications, you must test that WDOG works as expected and resets the MCU. Testing every bit of a 16-bit counter by letting it run to the overflow value takes a relatively long time (64 k clocks).

To help minimize the startup delay for application code after reset, WDOG implements a feature that tests its functioning more quickly by splitting the counter into its constituent byte-wide stages. The low and high bytes are run independently and tested for a timeout against the corresponding byte of WDOG Timeout Value (TOVAL). For a complete coverage when testing the high byte of the counter, the test feature feeds the input clock via the 8th bit of the low byte, thus ensuring that the overflow connection from the low byte to the high byte is tested.

Using this test feature reduces the test time to 512 clocks (not including overhead, such as, user configuration and reset vector fetches). To further speed testing, use a faster clock (such as the bus clock) for the counter reference.

On a POR, the POR field in the system reset register becomes 1, indicating that you must perform the WDOG fast test.

74.3.4.1 Testing each byte of the counter

Perform this procedure to test each byte of the counter:

1. Program the preferred WDOG timeout value in WDOG Timeout Value (TOVAL) during the WDOG configuration period.
2. Select a byte of the counter to test by using the configuration TST = 10b for the low byte, and TST = 11b for the high byte.
3. Wait for WDOG to timeout. Optionally, in the idle loop, increment RAM locations as a parallel software counter for later comparison. Because RAM is not affected by a WDOG reset, the timeout period of the WDOG counter can be compared with the software counter to verify whether the timeout period occurred as expected.

   The WDOG counter times out and forces a reset.
4. Confirm that the WDOG flag in the system reset register is set, indicating that WDOG caused the reset (the POR flag remains clear).
5. Confirm that TST showing a test (10b or 11b) was performed.

If confirmed, the count and compare functions work for the selected byte. Repeat the procedure, selecting the next byte in step 2.

NOTE

Only a POR writes 0 to TST, which is not affected by other resets.

74.3.4.2 Entering User mode

After successfully testing the low and high bytes of the WDOG counter, you can configure TST to 01b to indicate that WDOG is ready for use in application User mode. Therefore, if a reset occurs again, you can recognize the reset trigger as a real WDOG reset caused by runaway or faulty application code.

As an ongoing test when using the default clock source, you can periodically read WDOG Counter (CNT) to ensure that the counter is being incremented.

74.3.5 Clocking

You can program CLK to select clock source options in the WDOG counter. See the chip-specific WDOG information for available clock inputs and the default option for this chip.

The option allows you to select a clock source that is independent of the bus clock for applications that need to meet more robust safety requirements. Using a clock source other than the bus clock ensures that the WDOG counter continues to run if the bus clock is somehow halted (see Backup reset).

For WDOG to function properly, you must enable the default WDOG clock source after its functional reset is deasserted.

An optional fixed prescaler for all clock sources allows longer timeout periods. When PRES = 1, the clock source is prescaled by 256 before clocking the WDOG counter.

The following table summarizes examples of the different available WDOG timeout periods. In the table, RCP means "reference clock period".

Table 1090. WDOG timeout availability

Reference clock	Prescaler	WDOG timeout availability
REF_CLK	Pass through	1 × RCP to 65535 × RCP
	Enable	256 × RCP to 16776960 × RCP

NOTE

When you switch clock sources during reconfiguration, WDOG holds the counter at zero for 2.5 periods of the previous clock source and 2.5 periods of the new clock source after the configuration period (1024 bus clocks) ends. This delay ensures a smooth transition before restarting the counter with the new configuration.

74.3.6 Backup reset

The backup reset function is a safeguard feature that independently generates a reset in case the main WDOG logic loses its clock (the bus clock) and can no longer monitor the counter. If the WDOG counter overflows twice in succession (without an intervening reset), the backup reset function takes effect and generates a reset.

The backup reset becomes valid when an interrupt is enabled and the WDOG clock is not from a bus clock. If an interrupt is enabled after the bus clock is cut off before exiting an interrupt routine, the normal WDOG reset is blocked. In this case, the second overflow causes a backup reset directly.

NOTE

You must use a clock source other than the bus clock as a reference clock for the counter; otherwise, the backup reset function becomes unavailable.

74.3.7 Interrupts

WDOG can generate an interrupt request to delay resets.

When interrupts are enabled (INT = 1), and after a reset-triggering event (such as a counter timeout or invalid refresh attempt), WDOG:

1. Generates an interrupt request.
2. Waits 128 bus clocks (from the interrupt vector fetch, not the reset-triggering event).
3. Forces a reset.

This process allows the ISR to perform tasks such as analyzing the stack to debug code.

When interrupts are disabled (INT = 0), WDOG does not wait before forcing a reset.

74.4 External signals

This module has no external signals.

74.5 Initialization

See Configuring WDOG once.

74.6 Application information

You must disable WDOG to reconfigure it before the first WDOG timeout. Disabling or reconfiguring WDOG must occur at the very beginning of the software code, for example, at the beginning of the startup or main function.

NOTE

- After you configure WDOG, it needs at least 2.5 periods of WDOG clock to take effect. This means you must have a gap of at least 2.5 clocks between two configurations.
- When the chip starts from boot ROM and then jumps to flash memory, you must disable WDOG at the beginning of the bootloader and enable it after the bootloader exits. To reconfigure WDOG using the flash memory program, it also needs the interval of at least 2.5 WDOG clocks after the bootloader exits.

To disable or reconfigure WDOG without forcing a reset, you must write 1 to UPDATE during the initial WDOG configuration. You can use the unlock sequence at any time, within the timeout limit, to reconfigure WDOG.

74.6.1 Disabling WDOG

To disable WDOG, you must first perform the unlock sequence. Then, write 0 to EN. The following code snippet shows an example of a 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
WDOG_CS &= ~WDOG_CS_EN_MASK; //disable watchdog
EnableInterrupts; //enable global interrupt
```

74.6.2 Disabling WDOG after reset

All WDOG registers are unlocked by reset. Therefore, an unlock sequence is unnecessary but it needs to be written to all WDOG registers to make the new configuration take effect. The following code snippet shows an example of disabling WDOG after reset.

```
DisableInterrupts; // disable global interrupt
WDOG_CS &= ~WDOG_CS_EN_MASK; // disable watchdog
WDOG_TOVAL= 0xFFFF;
while(WDOG_CS[ULK]);  // waiting for lock
while(~WDOG_CS[RCS]); // waiting for new configuration to take effect
EnableInterrupts; // enable global interrupt
```

74.6.3 Configuring WDOG

You can write 0 to UPDATE to configure WDOG. After that, you cannot reconfigure WDOG until a reset. To reconfigure without forcing a reset, write 1 to UPDATE when configuring WDOG. The following example code shows how to configure WDOG without Window mode, clock source as LPO, interrupt enabled, and timeout value to 256 clocks. The following code snippet shows an example of a 32-bit write.

74.6.3.1 Configuring once

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(0);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

74.6.3.2 Configuring for Reconfigurable mode

```
DisableInterrupts; //disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(1);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

74.6.4 Refreshing WDOG

To refresh WDOG and reset the WDOG counter to zero, you require a refresh sequence. The following code snippet shows an example of a 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xB480A602; // refresh watchdog
EnableInterrupts; // enable global interrupt
```

74.7 Memory map and register definition

74.7.1 WDOG register descriptions

Fields

Field	Function
31-16 —	Reserved
15 WIN	WDOG Window Enables Window mode. See Using Window mode for more information. You can write to this field only once. 0b - Disable 1b - Enable
14 FLG	WDOG Interrupt Flag Acts as an interrupt indicator when INT = 1. 0b - No interrupt occurred 1b - An interrupt occurred
13 CMD32EN	Command 32 Enable Enables or disables WDOG support for 32-bit (otherwise 16-bit or 8-bit) refresh or unlock command write words. If this field = 0, it disables support for 32-bit refresh or unlock command write words. Only a 16-bit or 8-bit write is supported. If this field = 1, it enables support for 32-bit refresh or unlock command write words. A 16-bit or 8-bit write is not supported. This is a write-once field, and you must unlock WDOG after writing to this field for reconfiguration. 0b - Disable 1b - Enable
12 PRES	WDOG Prescaler Enables a fixed 256 prescaling of the WDOG counter reference clock. See Block diagram that shows the clock divider option.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This is a write-once field. 0b - Disable 1b - Enable
11 ULK	Unlock Status Indicates whether WDOG is unlocked. 0b - Locked 1b - Unlocked
10 RCS	Reconfiguration Success Indicates whether the reconfiguration is successful. This field becomes 1 when new configuration takes effect, and becomes 0 with a successful unlock command. 0b - Unsuccessful 1b - Successful
9-8 CLK	WDOG Clock Indicates the clock source that feeds the WDOG counter. You can write to this field only once.
7 EN	WDOG Enable Enables the WDOG counter to start counting. You can write to this field only once. 0b - Disable 1b - Enable
6 INT	WDOG Interrupt Configures WDOG to immediately generate an interrupt request upon a reset-triggering event (timeout or illegal write to WDOG), before forcing a reset. After the interrupt vector fetch (that takes place after the reset-triggering event), the reset occurs after a delay of 128 bus clocks. If this field = 0, it disables WDOG interrupts (WDOG resets are not delayed). If this field = 1, it enables WDOG interrupts (WDOG interrupts are delayed by 128 bus clocks from the interrupt vector fetch). You can write to this field only once. 0b - Disable 1b - Enable
5 UPDATE	Updates Allowed Allows you to reconfigure WDOG without a reset. If this field = 0, you cannot update WDOG after the initial configuration, without forcing a reset. If this field = 1, you can modify the WDOG configuration registers within 1024 bus clocks after performing the unlock write sequence.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You can write to this field only once. 0b - Updates not allowed 1b - Updates allowed
4-3 TST	WDOG Test Enables Fast Test mode, which allows you to exercise all bits of the counter to demonstrate that WDOG is functioning properly. See Fast testing of WDOG for more information. If this field = 0, it disables WDOG Test mode. If this field = 1, it enables WDOG User mode and disables WDOG Test mode. After testing WDOG, you must use this setting to indicate that WDOG is functioning normally in User mode. If this field = 10, it enables WDOG Test mode; only the low byte is used. CNTLOW is compared with TOVALLOW. If this field = 11, it enables WDOG Test mode; only the high byte is used. CNTHIGH is compared with TOVALHIGH. This write-once field is cleared (0:0) on POR only. Any other reset does not affect the value of this field. 00b - Disable WDOG Test mode 01b - Enable WDOG User mode 10b-11b - Enable WDOG Test mode
2 DBG	Debug Enable Enables WDOG to operate when the chip is in Debug mode. You can write to this field only once. 0b - Disable 1b - Enable
1 WAIT	Wait Enable Enables WDOG to operate when the chip is in Wait mode. You can write to this field only once. 0b - Disable 1b - Enable
0 STOP	Stop Enable Enables WDOG to operate when the chip is in Stop mode. You can write to this field only once. 0b - Disable 1b - Enable

74.7.1.3 WDOG Counter (CNT)

Offset

Register	Offset
CNT	4h

Function

Provides access to the value of the free-running WDOG counter. You can read the counter register at any time but cannot write directly to it. However, the following write sequences to this register have special functions:

1. The refresh sequence resets WDOG counter to 0000h. See Refreshing WDOG for more information.
2. The unlock sequence allows WDOG to be reconfigured without forcing a reset (when UPDATE = 1). See Configuring for Reconfigurable mode for more information.

NOTE

All other writes to this register are illegal and force a reset.

7-0 CNTLOW	Counter High Byte Contains the WDOG high byte.

74.7.1.4 WDOG Timeout Value (TOVAL)

Offset

Register	Offset
TOVAL	8h

Function

Contains the 16-bit value used to set the timeout period of WDOG.

The WDOG counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, WDOG forces a reset triggering event.

NOTE

Do not write 0 to this register (if TST = 11b, then TOVALHIGH cannot be written as 0; if TST = 10b, then TOVALLOW cannot be 0); otherwise, WDOG always generates a reset.

75.2 Overview

For safety purposes, a redundant watchdog system, EWM, is designed to monitor external circuits and the MCU software flow. This provides a backup mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The internal watchdog is used to monitor the flow and execution of the embedded software within the MCU. It consists of a counter that, if allowed to overflow, forces an internal, asynchronous reset to all on-chip peripherals. The counter also optionally asserts the RESET_B pin to reset external devices and circuits. The watchdog counter must not overflow if the software code works well and services the watchdog to restart the actual counter.

The EWM does not reset the MCU's CPU and peripherals, making it different from internal watchdog. The EWM module provides an independent ewm_out_b signal that, when asserted, resets or places an external circuit into a safe mode. The ewm_out_b

signal asserts upon EWM counter timeout. An optional external input, ewm_in, allows additional control when asserting the ewm_out_b signal.

75.2.1 Block diagram

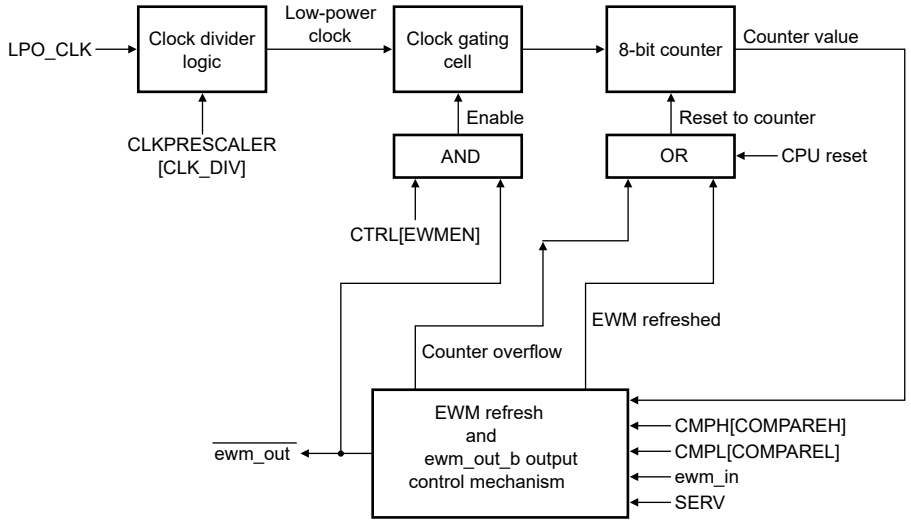

Figure 606. Block diagram

75.2.2 Features

- Independent LPO_CLK source
- Programmable timeout period, specified in terms of the number of EWM LPO_CLK cycles
- Windowed refresh option that provides:
  - A robust check to confirm that the program flow is faster than expected.
  - A programmable window.
  - Refresh outside the window, leading to assertion of the ewm_out_b signal.
- Robust refresh mechanism:
  - Write values of B4h and 2Ch to Service (SERV) within 15 peripheral bus clock cycles.
- One output port, ewm_out_b, which when asserted is used to reset or place the external circuit into Safe mode
- One input port, ewm_in, which allows an external circuit to control the assertion of the ewm_out_b signal

75.3 Functional description

The following sections discuss these aspects of EWM:

- Functional details
- Operating modes

NOTE

If the BUS_CLK is lost, EWM does not generate the ewm_out_b signal and no refresh operation is possible.

75.3.1 Modes of operation

75.3.1.1 Stop mode

When EWM is in Stop mode, the CPU cannot refresh EWM. After entering Stop mode, the EWM counter freezes.

Following are the possible ways to exit Stop mode:

- Through a reset: EWM remains disabled in this case.
- Through an interrupt: EWM is re-enabled and the counter continues to be clocked from the same value as prior to Stop mode entry.

NOTE

Consider the following if EWM enters Stop mode during the CPU refresh mechanism:

- While exiting Stop mode through an interrupt, the refresh mechanism starts from the previous state. That is, if you write the refresh command correctly and EWM enters Stop mode immediately, you must write the next command in *15* peripheral bus clocks after exiting Stop mode.
- You must mask all interrupts before executing the EWM refresh instructions.

75.3.1.2 Wait mode

The EWM module treats the Stop and Wait modes as the same. EWM functionality remains the same in both modes.

75.3.1.3 Debug mode

EWM remains unimpacted when entering Debug mode:

- If EWM is enabled before entering Debug mode, it remains enabled.
- If EWM is disabled before entering Debug mode, it remains disabled.

75.3.2 Using the EWM counter

EWM uses an 8-bit ripple counter that is fed by a clock source independent of the peripheral bus clock source. As the preferred timeout is between 1 ms and 100 ms, the actual clock source must be in the kHz range.

The counter is reset to 0 in these conditions:

- After CPU reset
- After the EWM refresh action completes
- At counter overflow

The CPU cannot access the counter value.

75.3.3 Using compare registers

You can write to Compare Low (CMPL) and Compare High (CMPH) only once after a CPU reset and you cannot modify them until another CPU reset occurs. These registers are used to create a refresh window for the EWM module.

You cannot program Compare Low (CMPL) and Compare High (CMPH) with the same value. In case of any attempt, the ewm_out_b signal asserts as soon as the counter reaches the value of Compare Low (CMPL) + 1.

NOTE

- You must update Compare Low (CMPL) and Compare High (CMPH) before enabling EWM. Therefore, you must provide a reasonable time after POR for the external monitoring circuit to stabilize. You must also ensure that the ewm_in pin is deasserted.
- Service should be requested after 1 clock period of slowest clock frequency while updating Compare Low (CMPL) register.

75.3.4 Using the refresh mechanism

Other than the initial configuration of EWM, the CPU can access EWM only through Service (SERV). The CPU must access this register by correctly writing unique data within the windowed time frame, as determined by Compare Low (CMPL) and Compare High (CMPH) for the correct EWM refresh operation. The following table describes conditions that exist and the refresh mechanisms that apply to those conditions.

Table 1093. Refresh mechanisms

Condition	Mechanism
The EWM refresh action completes when the value of Compare Low (CMPL) ≤ the counter value ≤ the value of Compare High (CMPH).	The software behaves as expected and the EWM counter resets to 0. The ewm_out_b output signal remains in Deasserted state if, during the EWM refresh action, the ewm_in input is in Deasserted state.
The EWM refresh action completes when the counter value < the value of Compare Low (CMPL).	The software refreshes EWM before the windowed time frame, the counter resets to 0, and the ewm_out_b output signal asserts no matter what the value of the ewm_in input signal is.
The counter value becomes greater than the value of Compare High (CMPH) prior to completion of the EWM refresh action.	The software does not refresh EWM. The EWM counter resets to 0 and the ewm_out_b output signal asserts no matter what the value of the ewm_in input signal is.

See Service (SERV) for more on the refresh mechanism.

75.3.5 Interrupt

When the ewm_out_b signal asserts, an interrupt request can be generated to indicate the assertion of the EWM reset out signal. The interrupt is enabled when CTRL[INTEN] = 1. Writing 0 to this field clears the interrupt request but does not affect the ewm_out_b signal, which can be deasserted only by forcing a system reset.

75.3.6 Clocking

The following table shows EWM clocks.

Table 1094. EWM Clocks

Clock	Description
IPG_CLK	This is the system clock and should be turned on for EWM to be able to work properly. During low power modes in which the core is powered down, this clock is disabled,
IPG_CLK_S	This is the IPS clock and is synchronous with IPG_CLK. It is disabled except during IPS write accesses. it is enabled with EWM's IPS_MODULE_EN
LPO_CLOCK[3:0]	EWM can have 4 different clock sources for running its EWM counter and one of them can be selected by EWM_CLKCTRL [CLK_SEL]. This clock is gated when EWM is disabled or when EWM_out is asserted.

75.3.7 Selecting the EWM counter clock

You can program CLKCTRL[CLKSEL] to select from the available low-power clock sources for the EWM counter.

75.3.8 Using the counter clock prescaler

You can program CLKPRESCALER[CLK_DIV] to divide the EWM counter clock source. This divided clock is used to run the EWM counter.

NOTE

The divided clock used to run the EWM counter must not exceed half the frequency of the bus clock.

75.4 External signals

EWM includes external signals and internal options for the counter clock sources, as shown in the following table.

NOTE

All active-low signals are represented with the suffix "_b" throughout the chapter.

Table 1095. Signal descriptions

Signal	Description	I/O
ewm_in	EWM's input for the safety status of external safety circuits. You can program the polarity of ewm_in by using CTRL[ASSIN]. The default polarity is active-low.	I
ewm_out_b	EWM's reset out signal	O
lpo_clk[3:0]	Low-power clock sources for the running counter	I

75.4.1 Using the ewm_out_b signal

The ewm_out_b signal is a digital output signal used to gate an external circuit (application-specific) that controls critical safety functions. For example, EWM_out must be connected to the high-voltage transistor circuits that control an AC motor in a large appliance.

The ewm_out_b signal remains deasserted when the CPU regularly refreshes EWM within the programmable refresh window, indicating that the application code is executing as expected.

The ewm_out_b signal asserts in any of the following conditions:

- An EWM refresh action occurs when the counter value is less than the value of Compare Low (CMPL).
- The EWM counter value becomes greater than the value of Compare High (CMPH) and no EWM refresh occurs.
- The functionality of the ewm_in pin is enabled and the ewm_in pin asserts when refreshing EWM.
- After any reset.

The ewm_out_b signal asserts after any reset by the virtue of the external pulldown mechanism on the ewm_out_b pin. To deassert the ewm_out_b signal, write 1 to CTRL[EWMEN] to enable EWM.

If the ewm_out_b signal shares its pad with a digital I/O pin, this actual pad defers to being an input signal on reset. The ewm_out_b signal controls the pad state only after CTRL[EWMEN] enables EWM.

NOTE

The ewm_out_b pad must be in Pulldown state when the EWM functionality is being used and EWM is under reset.

75.4.2 Using the ewm_out_b pin state in low-power modes

During Wait, Stop, and Power-Down modes, the ewm_out_b pin enters a high-impedance state. You have the option to control the logic state of the pin by using an external pull device or by configuring the internal pull device. When the CPU enters Run mode

from Wait or Stop mode recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode after exiting Power-Down mode, the pin returns to its reset state.

75.4.3 Using the ewm_in signal

The ewm_in signal is a digital input signal for the safety status of external safety circuits. This signal allows an external circuit to control the assertion of the ewm_out_b signal. For example, in the application, an external circuit monitors a critical safety function, and if there is a fault with the safety function, the external circuit can actively initiate the ewm_out_b signal, which controls the gating circuit.

The ewm_in signal is ignored if EWM is disabled, or if CTRL[INEN] = 0 after any reset.

After you enable EWM (by writing 1 to CTRL[EWMEN]) and the ewm_in functionality (by writing 1 to CTRL[INEN]), the ewm_in signal must be in Deasserted state before the CPU starts refreshing EWM. This ensures that the ewm_out_b signal stays in Deasserted state; otherwise, the ewm_out_b output signal asserts.

75.5 Memory map and register definitions

This section contains the module memory map and registers.

NOTE

EWM supports only 8-bit register accesses; 16-bit and 32-bit accesses are not supported.

75.5.1 EWM register descriptions

75.5.1.1 EWM memory map

EWM base address: 427B_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (CTRL)	8	RW	00h
1h	Service (SERV)	8	W	00h
2h	Compare Low (CMPL)	8	RW	00h
3h	Compare High (CMPH)	8	RW	FFh
4h	Clock Control (CLKCTRL)	8	RW	00h
5h	Clock Prescaler (CLKPRESCALER)	8	RW	00h

75.5.1.2 Control (CTRL)

Offset

Register	Offset
CTRL	0h

Function

Controls the functionality of EWM.

NOTE

You can write to CTRL[INEN], CTRL[ASSIN], and CTRL[EWMEN] only once after a CPU reset. Modifying these fields more than once generates a bus transfer error.

Diagram

Bits	7	6	5	4	3	2	1	0

Fields

Field	Function
7-4 —	Reserved
3 INTEN	Interrupt Enable Enables interrupt request generation. If this field = 1 and the ewm_out_b signal is asserted, an interrupt request is generated. To deassert interrupt requests, write 0 to this field. 0b - Deasserts interrupt requests 1b - Generates interrupt requests
2 INEN	Input Enable Enables the ewm_in port. When this field = 1, it enables the ewm_in port. 0b - Disables 1b - Enables
1 ASSIN	Assertion State Select Specifies the asserted state of the ewm_in signal. By default, the asserted state of the ewm_in signal is logic 0 (active-low), which is when this field = 0. When this field = 1, the ewm_in asserted state is logic 1 (active-high). You can use this field to change the expected polarity of the ewm_in signal. 0b - Logic 0 1b - Logic 1
0 EWMEN	EWM Enable Enables the EWM module. If this field = 1, it enables the EWM module, and if the field = 0, it disables the EWM module. You cannot re-enable this field until the next reset because of its write-once nature.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disables 1b - Enables

75.5.1.3 Service (SERV)

Offset

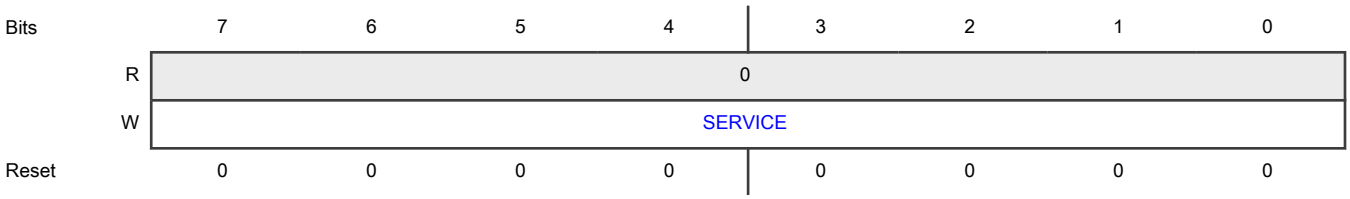
Register	Offset
SERV	1h

Function

Provides an interface from the CPU to the EWM module.

Attempted reads of this register return 0.

Diagram



Fields

Field	Function
7-0 SERVICE	Service Provides an interface from the CPU to the EWM module. The EWM refresh mechanism requires the CPU to write these values to this field: a first data byte of B4h, followed by a second data byte of 2Ch. The EWM refresh action is invalid if either of the following conditions is true: • The first or second data byte is not written correctly. • The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte, known as EWM_refresh_time. The number of peripheral bus clock cycles required for EWM_refresh_time is 15.

75.5.1.4 Compare Low (CMPL)

Offset

Register	Offset
CMPL	2h

Function

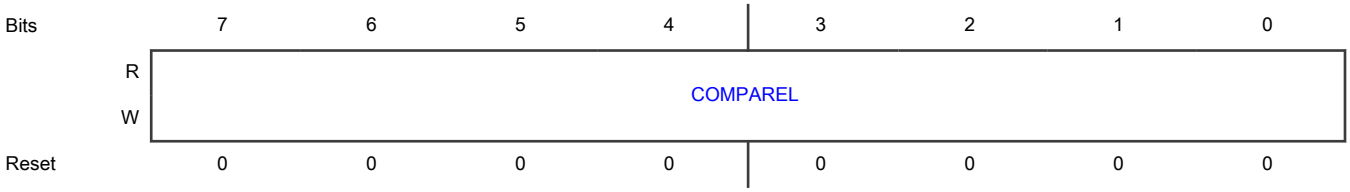
Determines the lower value of the windowed time frame for the correct EWM refresh operation.

This register is reset to 0 after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error.

Diagram



Fields

Field	Function
7-0 COMPAREL	Compare Low Configures the minimum counter value when refreshes are allowed. If a refresh is attempted while the counter value is lower than COMPAREL, then the ewm_out_b signal is asserted. To prevent runaway code from changing the value of this field, you must write to this field after a CPU reset even if the (default) minimum refresh time is required.

75.5.1.5 Compare High (CMPH)

Offset

Register	Offset
CMPH	3h

Function

Determines the higher value of the windowed time frame for the correct EWM refresh operation.

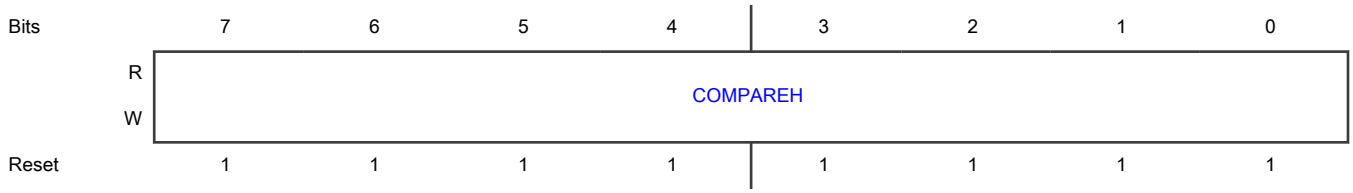
This register is reset to FFh after a CPU reset. This provides a maximum time of up to 256 clocks for the CPU to refresh the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error.

The valid values for this register are up to FEh because the EWM counter never expires when the value of COMPAREH = FFh. The expiration happens only if the EWM counter is greater than the value of COMPAREH.

Diagram



Fields

Field	Function
7-0 COMPAREH	Compare High Configures the maximum counter value till when refreshes are allowed. If a refresh is not attempted while the counter value is greater than COMPAREH, then the ewm_out_b signal is asserted. To prevent runaway code from changing the value of this field, you must write to this field after a CPU reset.

75.5.1.6 Clock Control (CLKCTRL)

Offset

Register	Offset
CLKCTRL	4h

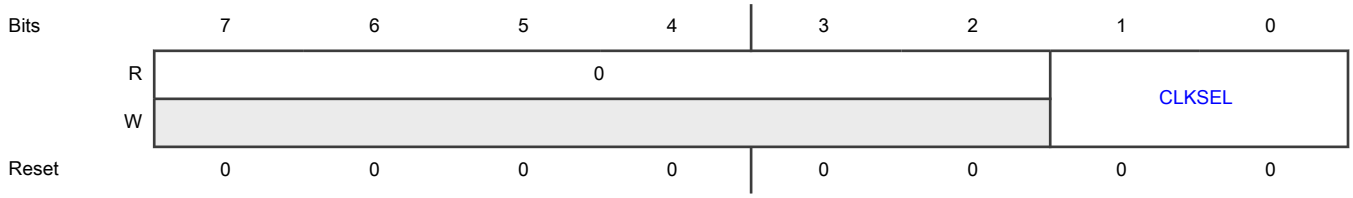
Function

Provides a selection mechanism for low-power clock sources to run the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error. You must select the required low-power clock before enabling EWM.

Diagram



Fields

Field	Function
7-2 —	Reserved
1-0 CLKSEL	Clock Select Provides a selection mechanism for low-power clock sources to run the EWM counter. EWM has the following available low-power clock sources for running the EWM counter. Write an appropriate value to this field to select one of the clock sources. • 00 - lpo_clk[0] • 01 - lpo_clk[1] • 10 - lpo_clk[2] • 11 - lpo_clk[3] See the chip-specific information for low power clock sources used in your device.

75.5.1.7 Clock Prescaler (CLKPRESCALER)

Offset

Register	Offset
CLKPRESCALER	5h

Function

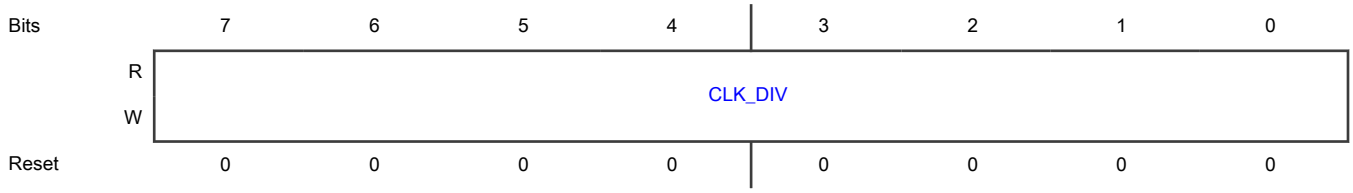
Prescales the EWM counter clock source by a clock divider.

This register is reset to 00h after a CPU reset.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error. You must write the required prescaler value before enabling EWM.

Diagram



Fields

Field	Function
7-0 CLK_DIV	Clock Divider Prescales the selected low-power clock source for running the EWM counter: Prescaled clock frequency = low-power clock source frequency ÷ (1 + the value of CLK_DIV) See chip-specific information for low-power clock source frequency used in your device.

Chapter 76
On Chip Cross-Triggers Overview

76.1 Overview

This chip integrates an on-chip cross trigger network.

See XBAR Resource Assignments for diagram of the cross trigger network of this device.

76.1.1 Cross BAR (XBAR)

Each crossbar switch is an array of MUXes with shared inputs. Each mux output provides one output of the crossbar. The number of inputs and the number of MUXes/outputs is user configurable and registers are provided to select which of the shared inputs is routed to each output. The crossbar switches are used to reconfigure data paths between peripherals (peripheral output to peripheral input) as well as between peripherals and GPIO.

76.1.2 And-Or-Inverter (AOI)

The AOI module provides an universal Boolean function generator using a four-term sum of products expression, with each product term containing true or complement values of the four selected inputs (A, B, C, D).

Chapter 77
And-Or-Inverter (AOI)

77.1 Chip-specific AOI Information

Table 1096. Reference links to related information

Topic	Related module	Reference
System memory map	-	System memory map
Clocking	CCM ANADIG - XTALOSC, PLL	Clock Generation Overview Clock Control Module (CCM) ANADIG - Crystal Oscillator (XTALOSC) ANADIG - Phase Locked Loop (PLL)

Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

A typical application of the AOI module is to be integrated with one or more inter-peripheral crossbar switch modules as illustrated in the following figure. The 20 external inputs are shared by two crossbar switch modules. The crossbar switch on the top is used to select the inputs to four 4-input AOI functions in the AOI module. The outputs of these four AOI functions are output from the AOI module and are added to the original 20 external inputs to provide a total of 24 inputs to the bottom crossbar switch. As a result, the bottom crossbar can not only direct any of the original 20 external inputs to any of its outputs, it can also now direct any one of four 4-input AOI functions of those external inputs to any of its outputs.

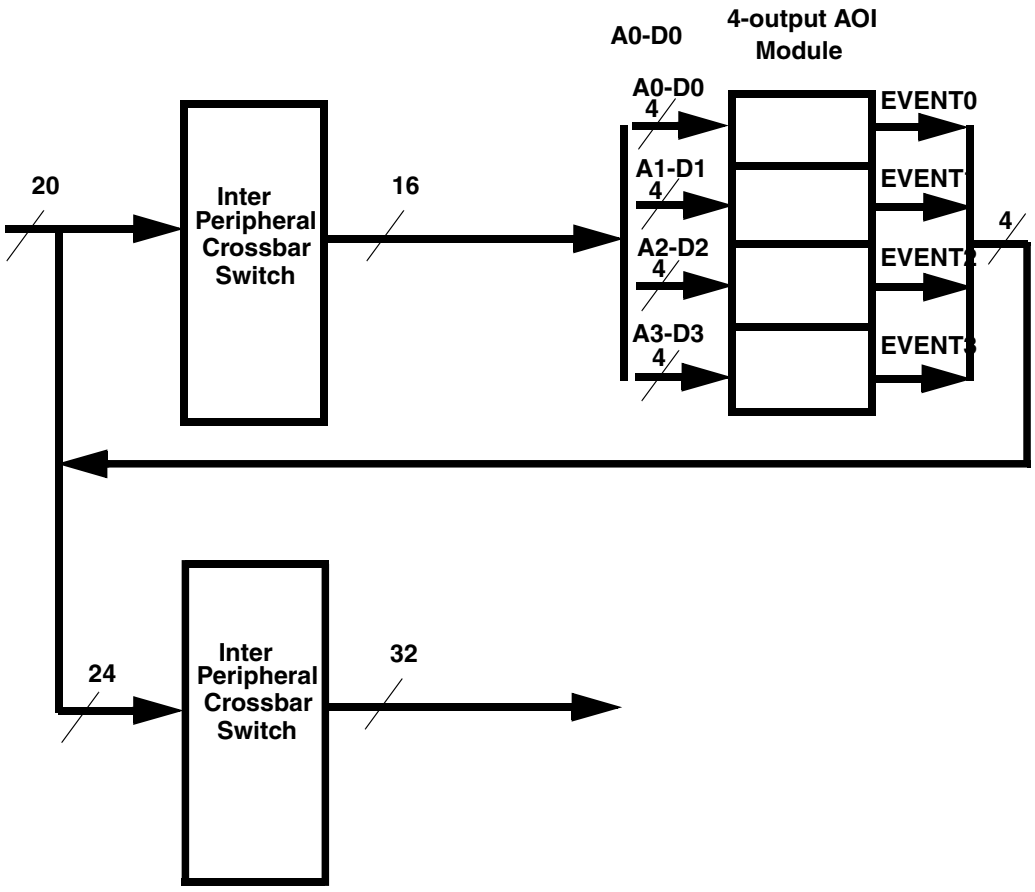

Figure 607. Integration Example of AOI with two Inter-Peripheral Crossbar Switches

77.2 Overview

AOI supports the generation of a configurable number of EVENT signals. Each output EVENT*n* is a configurable AOI function of four associated AOI inputs: A*n*, B*n*, C*n*, and D*n*, where *n* represents the number of channels.

The AOI controller is a target peripheral module that connects event input indicators from a variety of modules and generates event output signals routed to other peripherals. You can access its programming model through the standard IPS target interface.

You can configure AOI to implement different Boolean functions.

77.2.1 Block diagram

AOI supports 4 event outputs, each representing a programmable, combinational Boolean function.

NOTE

The connections from AOI outputs to other functions are chip-specific.

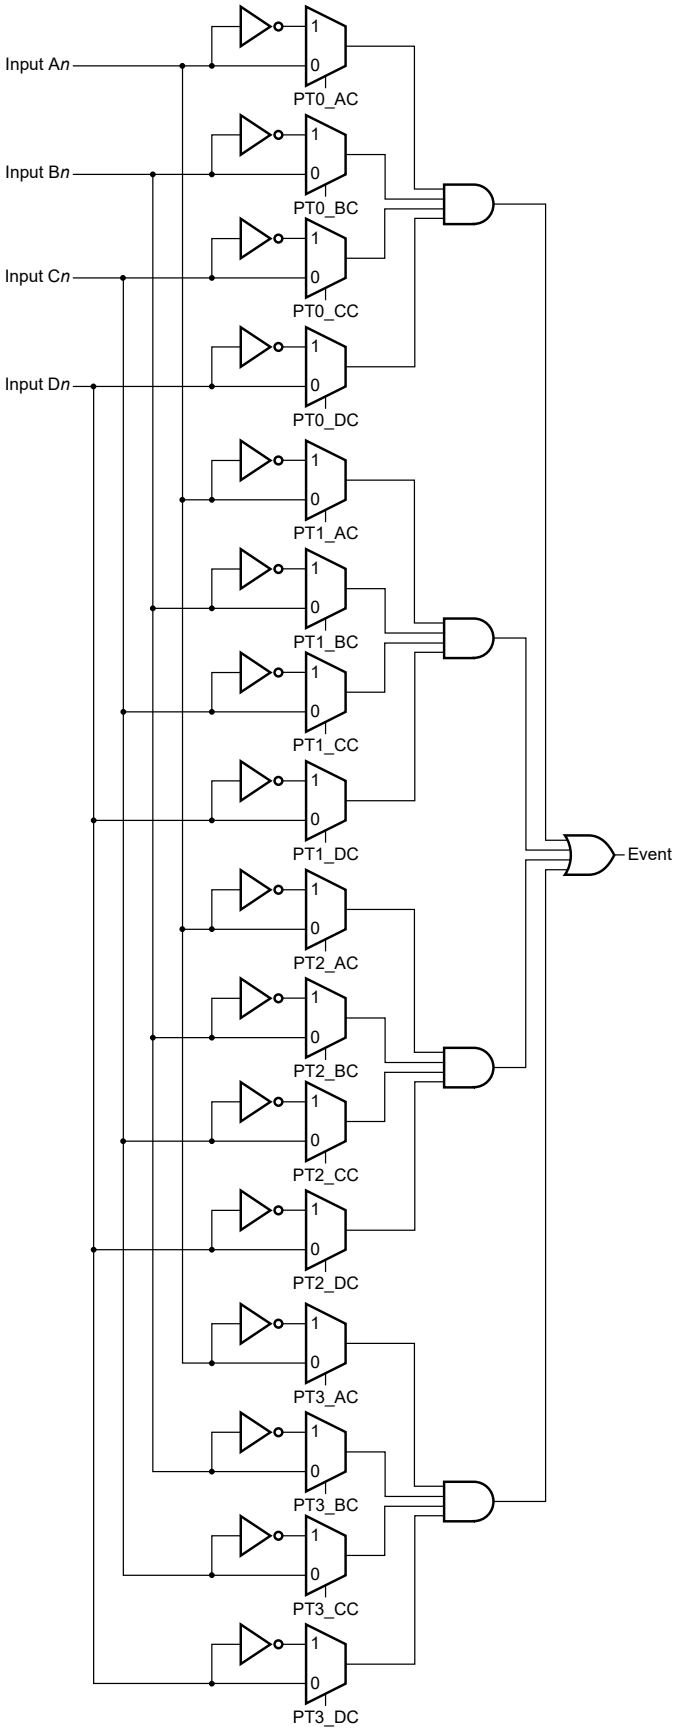

Figure 608. Block diagram

77.2.2 Features

- Enables you to create combinational Boolean events for use as hardware triggers:
  - Each channel includes four event inputs and one output
  - Evaluation of a combinational Boolean expression as the sum of four products, where each product term includes all four selected input sources available as true or complement values
  - Event output is formed as purely combinational logic and operates as a hardware trigger
- Includes a memory-mapped chip connected to the target peripheral (IPS) bus (programming model organized per channel for simplified software)

77.3 Functional description

AOI is highly programmable–you can use it for creating combinational Boolean outputs for use as hardware triggers. Each AOI output channel, as shown in Figure 608, has one logic function: Evaluation of combinational Boolean expression as a sum of four products, where each product term includes all four selected input sources available as true or complement values.

77.3.1 Modes of operation

AOI does not support any special modes of operation.

77.3.2 Clocks

The system uses the bus clock for register accesses, but AOI functions are asynchronous and do not use a clock.

77.3.3 Interrupts

This module has no interrupts.

77.4 External signals

This module has no external signals.

77.5 Initialization

This module does not require initialization.

77.6 Application information

The following sections describe configuration examples and Boolean expressions that you could use when programming AOI for your use.

77.6.1 Configuration examples for Boolean function evaluation

This section presents examples of the programming model configuration for simple Boolean expressions.

AOI provides a universal Boolean function generator using a four-term sum of product expression. Each product term contains true or complement values of the four selected event inputs (A*n*, B*n*, C*n*, and D*n*). See Code Listing 1 that presents a 4×4 Boolean expression defining the event output:

```
EVENTn
      = (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 0
      | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 1
```

```
      | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 2
      | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 3
```

Code Listing 1. Boolean expression defining event inputs (A*n*, B*n*, C*n*, and D*n*)

You can configure each selected input term in each product term to produce a logical 0 or 1, or pass the true or complement value of the selected event input. Each product term uses 8 bits of configuration information, 2 bits for each of the four selected event inputs. See Code Listing 2 that presents the actual Boolean expression implemented in each channel:

```
EVENTn
      = (PT0_AC[0] & An |  PT0_AC[1] & ~An)// product term 0
      & (PT0_BC[0] &  Bn | PTO_BC[1] & ~Bn)
      & (PT0_CC[0] &  Cn | PTO_CC[1] & ~Cn)
      & (PT0_DC[0] &  Dn | PTO_DC[1] & ~Dn)

| (PT1_AC[0] & An |  PT1_AC[1] & ~An)// product term 1
& (PT1_BC[0] &  Bn | PT1_BC[1] & ~Bn)
& (PT1_CC[0] &  Cn | PT1_CC[1] & ~Cn)
& (PT1_DC[0] &  Dn | PT1_DC[1] & ~Dn)

| (PT2_AC[0] & An |  PT2_AC[1] & ~An)// product term 2
& (PT2_BC[0] &  Bn | PT2_BC[1] & ~Bn)
& (PT2_CC[0] &  Cn | PT2_CC[1] & ~Cn)
& (PT2_DC[0] &  Dn | PT2_DC[1] & ~Dn)

| (PT3_AC[0] & An |  PT3_AC[1] & ~An)// product term 3
& (PT3_BC[0] &  Bn | PT3_BC[1] & ~Bn)
& (PT3_CC[0] &  Cn | PT3_CC[1] & ~Cn)
& (PT3_DC[0] &  Dn | PT3_DC[1] & ~Dn)
```

Code Listing 2. Boolean expressions for EVENT*n*

The combined fields of {Boolean Function Term 0 and 1 Configuration for EVENTn (BFCRT010 - BFCRT013), Boolean Function Term 2 and 3 Configuration for EVENTn (BFCRT230 - BFCRT233)} correspond to the `PT{0-3}_{A,B,C,D}C[1:0]` terms in the aforementioned example.

Consider the settings of the combined 32-bit registers {Boolean Function Term 0 and 1 Configuration for EVENTn (BFCRT010 - BFCRT013), Boolean Function Term 2 and 3 Configuration for EVENTn (BFCRT230 - BFCRT233)} for several simple Boolean expressions, as shown in Table 1097.

Table 1097. BFCRT*n* values for simple boolean expressions

Event output expression	PT0	PT1	PT2	PT3	{Boolean Function Term 0 and 1 Configuration for EVENTn (BFCRT010 - BFCRT013), Boolean Function Term 2 and 3 Configuration for EVENTn (BFCRT230 - BFCRT233)}
A & B	A & B	0	0	0	01011111_00000000_00000000_00000000
A & B & C	A & B & C	0	0	0	01010111_00000000_00000000_00000000
(A & B & C) + D	A & B & C	D	0	0	01010111_11111101_00000000_00000000
A + B + C + D	A	B	C	D	01111111_11011111_11110111_11111101
(A & ~B) + (~A & B)	A & ~B	~A & B	0	0	01101111_10011111_00000000_00000000

As explained through the aforementioned examples, the resulting logic provides a simple yet powerful Boolean function evaluation for defining an event output.

77.7 AOI register descriptions

You can access the AOI programming model via a 16-bit peripheral bus connection. AOI is designed to support 16-bit accesses only. Other accesses are undefined.

AOI supports a specific number of event outputs. Each output EVENT*n* outputs a four-term AOI function of four binary inputs: A*n*, B*n*, C*n*, and D*n*. A pair of 16-bit registers configures this four-term AOI function: Boolean Function Term 0 and 1 Configuration for EVENTn (BFCRT010 - BFCRT013) and Boolean Function Term 2 and 3 Configuration for EVENTn (BFCRT230 - BFCRT233) define the configuration for the evaluation of the Boolean function defining EVENT*n*, where *n* is the event output channel number. Boolean Function Term 0 and 1 Configuration for EVENTn (BFCRT010 - BFCRT013) defines the configuration of product terms 0 and 1, and Boolean Function Term 2 and 3 Configuration for EVENTn (BFCRT230 - BFCRT233) defines the configuration of product terms 2 and 3.

AOI provides a universal Boolean function generator using a four-term sum of product expression with each product term containing true or complement values of the four selected event inputs (A*n*, B*n*, C*n*, and D*n*). Specifically, the following "4 x 4" Boolean expression defines the EVENT*n* output:

```
EVENTn
                          = (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product
term 0
                          | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product
term 1
                          | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product
term 2
                          | (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product
term 3
```

Code Listing 3. Boolean expression defining the EVENT*n* output

Using the aforementioned expression, you can configure each selected input in each product term to produce a logical 0 or 1 or pass the true or complement value of the selected event input. Each product term uses 8 bits of configuration information, 2 bits for each of the four selected event inputs. The resulting logic provides a simple yet powerful Boolean function evaluation for defining an event output.

These AOI functions are combinational in nature. You must sample and use them synchronously.

Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

This device has three instances of the XBAR module: XBAR1, XBAR2, and XBAR3.

On this device, the instantation information of XBAR1 and XBAR2/3 is different, as shown in the following table.

Table 1099. XBAR instantiation

Instance	Number of inputs (N)	Number of outputs (M)	Number of outputs with control function (P)	Select registers	Control registers
XBAR1	216	221	4	SEL0-SEL110	CTRL0-CTRL1
XBAR2	178	32	0	SEL0-SEL15	NA
XBAR3	178	32	0	SEL0-SEL15	NA

NOTE

Only XBAR1 has control registers (CTRL*n*), which configure edge detection, interrupt, and DMA features for a subset of the crossbar outputs (XBAR_OUT[0] ~ XBAR_OUT[P-1]). XBAR2 and XBAR3 do not have control registers and corresponding functions.

NOTE

The XBAR_INn and XBAR_OUTn signals (n = 4 to 37) share the same IOs. The user needs to configure the corresponding XBAR_DIR_CTRL1[IOMUXC_XBAR_DIR_SEL_n] and XBAR_DIR_CTRL2[IOMUXC_XBAR_DIR_SEL_n] bit of BLK_CTRL_WAKEUP, to use either XBAR_IN or XBAR_OUT.

78.2 Overview

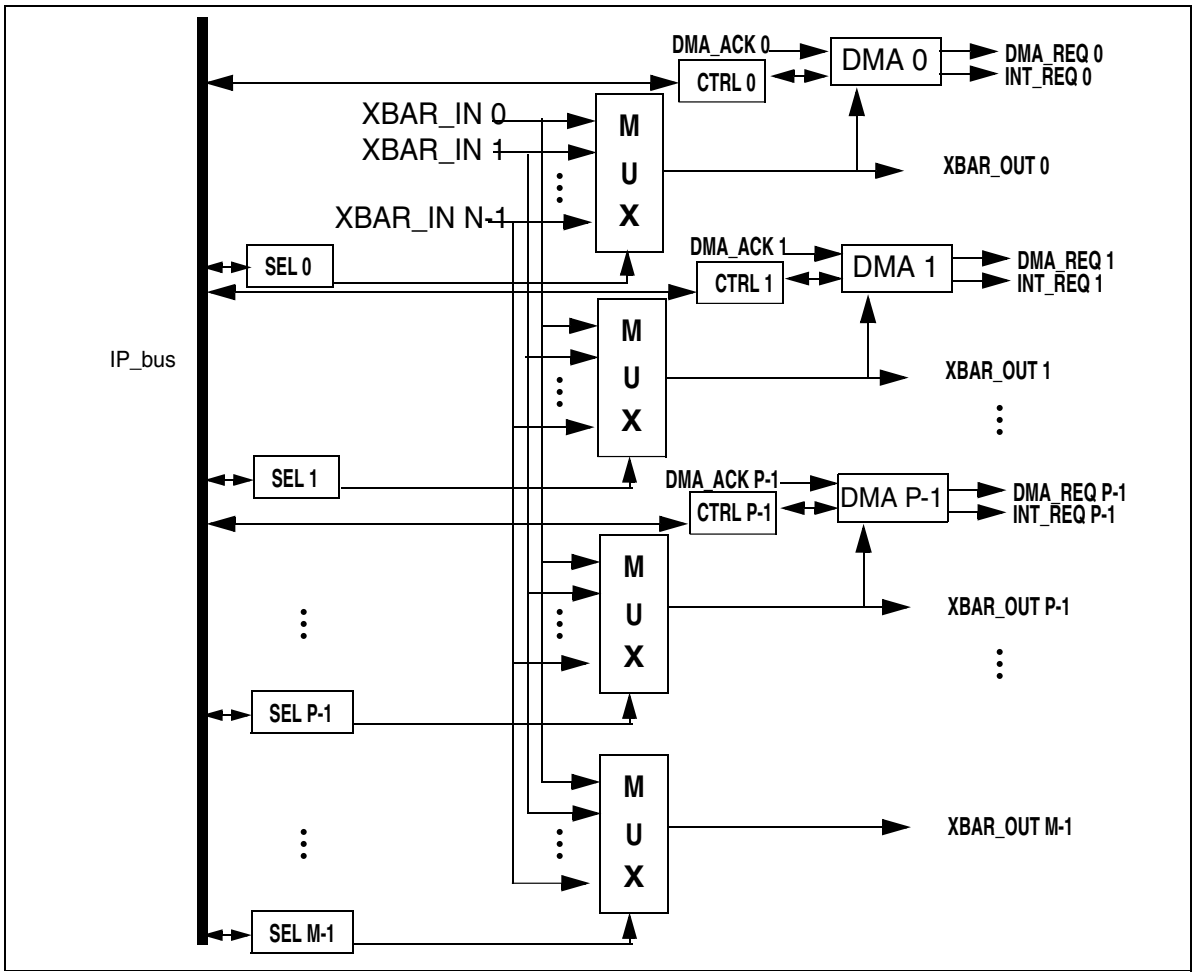
This module implements an array of M N-input combinational muxes. All muxes share the same N inputs in the same order, but each mux has its own independent select field.

The intended application of this module is to provide a flexible crossbar switch function that allows any input (typically from external GPIO or internal module outputs) to be connected to any output (typically to external GPIO or internal module inputs) under user control. This is used to allow user configuration of data paths between internal modules and between internal modules and GPIO.

A subset of the muxes (P in total) can be configured to support edge detection and either interrupt or DMA request generation based on detected signal edges on the mux output. This allows signal transitions on the signals feeding the crossbar to trigger interrupts or initiate data transfers via DMA into or out of other system modules.

78.2.1 Block Diagram

The block diagram for XBAR is shown in Figure 609.



Note: Control field support can be restricted to a subset of outputs. CTRLn represents the memory mapped control fields in the XBAR_CTRL registers for each corresponding XBAR_OUT output. Control fields provide edge status, edge selection, and interrupt/DMA generation controls.

Figure 609. XBAR Block Diagram

78.2.2 Features

The XBAR module design includes these distinctive features:

- M identical N-input muxes with individual select fields.
- Edge detection with associated interrupt or DMA request generation for a subset of mux outputs (XBAR_OUT[0] ~ XBAR_OUT[P-1]).
- Memory mapped registers with IPBus interface for select and control fields.

78.3 Functional Description

78.3.1 Functional Mode

XBAR has only one mode of operation: functional mode.

The value of each mux output is XBAR_OUT[n] = XBAR_IN[SELn]. The SELn select values are configured in the XBAR_SEL registers. All muxes share the same inputs in the same order.

The following is an example to show how to specify the specific input for the specific output:

To connect XBAR_IN03 with XBAR_OUT07, according to the index of XBAR_OUT07, select the SEL07 (same number with the selected XBAR_OUT index) fields in the MSBs of the Select Register 3 (XBAR_SEL3), and assign the index (0x03, Hexadecimal) of the selected XBAR_IN in it.

```
XBAR_SEL3 &= 0x00FF; /* Clear the SEL7 fields */
XBAR_SEL3 |= 0x0300; /* Assign the 0x03 to the SEL7 fields */
```

A subset of crossbar outputs (XBAR_OUT[0] ~ XBAR_OUT[P-1]) has dedicated control fields in a Crossbar Control (XBAR_CTRL) register. Control fields provide the ability to perform edge detection on the corresponding XBAR_OUT output. Edge detection in turn can optionally be used to trigger an interrupt or DMA request. The intention is that, by detecting specified edges on signals propagating through the Crossbar, interrupts or DMA requests can be triggered to perform data transfers to or from other system components.

Control fields include an edge status field (STS), an detected edge type field (EDGE), and interrupt and DMA enable fields (IEN and DEN). STSn is set to 1 when an edge consistent with EDGEn occurs on XBAR_OUT[n]. STSn is cleared by writing 1 to it. Writing 0 has no effect. See Interrupts and DMA Requests for details on the use of STSn for DMA and interrupt request generation.

78.3.2 Clocks

All sequential functionality is controlled by the Bus Clock.

78.3.3 Resets

The XBAR module can be reset by only a hard reset, which forces all registers to their reset state.

78.3.4 Interrupts and DMA Requests

For each XBAR_OUT[n] output with XBAR_CTRL register support, DMA or interrupt functionality can be enabled by setting the corresponding CTRL[DENn] or CTRL[IENn] to 1. DENn and IENn should not be set to 1 at the same time for the same output XBAR_OUT[n].

Setting DENn to 1 enables DMA functionality for XBAR_OUT[n]. When DMA functionality is enabled, the output DMA_REQ[n] reflects the value of STSn. Thus the DMA request asserts when the edge specified by EDGEn is detected on XBAR_OUT[n]. Also, a rising edge on DMA_ACK[n] sets STSn to zero and thus clears the DMA request when the data transfer is completed. When DEN is 0, DMA_REQ[n] is held low and DMA_ACK[n] is ignored.

Setting IENn to 1 enables interrupt functionality for XBAR_OUT[n]. When interrupt functionality is enabled, the output INT_REQ[n] reflects the value of STSn. Thus the interrupt request asserts when the edge specified by EDGEn is detected on XBAR_OUT[n]. The interrupt request is cleared by writing a 1 to STSn. When IENn is 0, INT_REQ[n] is held low.

78.4 External Signals

The following table summarizes the module's external signals.

Table 1100. Control Signal Properties

Name	I/O Type	Function	Reset State	Notes
XBAR_OUT[0:M-1]	O	Mux Outputs	XBAR_IN[0]	
XBAR_IN[0:N-1]	I	Mux Inputs	*	
DMA_REQ[0:P-1]	O	DMA request	0	
INT_REQ[0:P-1]	O	Interrupt request	0	
DMA_ACK[0:P-1]	I	DMA acknowledge	0	

At reset, each output XBAR_OUT[n] contains the reset value of the signal driving XBAR_IN[0].

78.4.1 XBAR_OUT[0:M-1] - MUX Outputs

This is a one-dimensional array of the mux outputs. The value on each output XBAR_OUT[n] is determined by the setting of the corresponding memory mapped register SELn such that XBAR_OUT[n] = XBAR_IN[SELn].

78.4.2 XBAR_IN[0:N-1] - MUX Inputs

This is a one-dimensional array consisting of the inputs shared by each mux. All muxes share the same inputs in the same order.

78.4.3 DMA_REQ[0:P-1] - DMA Request Output(s)

DMA_REQ[n] is a DMA request to the DMA controller.

78.4.4 DMA_ACK[0:P-1] - DMA Acknowledge Input(s)

DMA_ACK[n] is a DMA acknowledge input from the DMA controller.

78.4.5 INT_REQ[0:P-1] - Interrupt Request Output(s)

INT_REQ[n] is an interrupt request output to the interrupt controller.

78.5 Memory Map and Register Descriptions

78.5.1 XBAR register descriptions

The XBAR module has select registers and control registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBAR_IN) is muxed to each mux output (XBAR_OUT). There is one SELn field per mux and therefore one per XBAR_OUT output. Crossbar output XBAR_OUT[n] presents the signal chosen by XBAR_IN[SELn]. In a select register (SELy for example), the lower 8 bits represent the input for XBAR_OUT[2y] and the higher 8 bits represent the input for XBAR_OUT[2y+1].

The actual signals connected to XBAR_IN and XBAR_OUT are application specific and are described in the XBAR Assignments tables.

The XBAR control registers configure edge detection, interrupt, and DMA features for a subset of the XBAR_OUT outputs.

78.5.1.113 Crossbar Control Register (CTRL0)

Offset

Register	Offset
CTRL0	DEh

Function

Use this register to configure edge detection, interrupt, and DMA features for the XBAR_OUT0 and XBAR_OUT1 outputs.

The XBAR_CTRL registers are organized similarly to the XBAR_SEL registers, with control fields for two XBAR_OUT outputs in each register. In control register 0, the LSBs contain the control fields for XBAR_OUT0, and the MSBs contain the control fields for XBAR_OUT1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 STS1	Edge detection status for XBAR_OUT1 This bit reflects the results of edge detection for XBAR_OUT1. This field is set to 1 when an edge consistent with the current setting of EDGE1 is detected on XBAR_OUT1. This field is cleared by writing 1 to it or by a DMA_ACK1 reception when DEN1 is set. Writing 0 to the field has no effect. When interrupt or DMA functionality is enabled for XBAR_OUT1, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared. 0b - Active edge not yet detected on XBAR_OUT1 1b - Active edge detected on XBAR_OUT1
11-10 EDGE1	Active edge for edge detection on XBAR_OUT1 This field selects which edges on XBAR_OUT1 cause STS1 to assert. 00b - STS1 never asserts 01b - STS1 asserts on rising edges of XBAR_OUT1 10b - STS1 asserts on falling edges of XBAR_OUT1 11b - STS1 asserts on rising and falling edges of XBAR_OUT1
9 IEN1	Interrupt Enable for XBAR_OUT1 This bit enables the interrupt function on the corresponding XBAR_OUT1 output. When the interrupt is enabled, the output INT_REQ1 reflects the value STS1. When the interrupt is disabled, INT_REQ1 remains low. The interrupt request is cleared by writing a 1 to STS1. **RESTRICTION** IEN1 and DEN1 should not both be set to 1. 0b - Interrupt disabled 1b - Interrupt enabled
8 DEN1	DMA Enable for XBAR_OUT1 This bit enables the DMA function on the corresponding XBAR_OUT1 output. When enabled, DMA_REQ1 presents the value STS1. When disabled, the DMA_REQ"1" output remains low. **RESTRICTION** IEN1 and DEN1 should not both be set to 1. 0b - DMA disabled 1b - DMA enabled
7-5 —	RESERVED
4	Edge detection status for XBAR_OUT0

Table continues on the next page...

Table continued from the previous page...

Field	Function
STS0	This bit reflects the results of edge detection for XBAR_OUT0. This field is set to 1 when an edge consistent with the current setting of EDGE0 is detected on XBAR_OUT0. This field is cleared by writing 1 to it or by a DMA_ACK0 reception when DEN0 is set. Writing 0 to the field has no effect. When interrupt or DMA functionality is enabled for XBAR_OUT0, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared. 0b - Active edge not yet detected on XBAR_OUT0 1b - Active edge detected on XBAR_OUT0
3-2 EDGE0	Active edge for edge detection on XBAR_OUT0 This field selects which edges on XBAR_OUT0 cause STS0 to assert. 00b - STS0 never asserts 01b - STS0 asserts on rising edges of XBAR_OUT0 10b - STS0 asserts on falling edges of XBAR_OUT0 11b - STS0 asserts on rising and falling edges of XBAR_OUT0
1 IEN0	Interrupt Enable for XBAR_OUT0 This bit enables the interrupt function on the corresponding XBAR_OUT0 output. When the interrupt is enabled, the output INT_REQ0 reflects the value STS0. When the interrupt is disabled, INT_REQ0 remains low. The interrupt request is cleared by writing a 1 to STS0. **RESTRICTION** IEN0 and DEN0 should not both be set to 1. 0b - Interrupt disabled 1b - Interrupt enabled
0 DEN0	DMA Enable for XBAR_OUT0 This bit enables the DMA function on the corresponding XBAR_OUT0 output. When enabled, DMA_REQ0 presents the value STS0. When disabled, the DMA_REQ"0" output remains low. **RESTRICTION** IEN0 and DEN0 should not both be set to 1. 0b - DMA disabled 1b - DMA enabled

78.5.1.114 Crossbar Control Register (CTRL1)

Offset

Register	Offset
CTRL1	E0h

Function

Use this register to configure edge detection, interrupt, and DMA features for the XBAR_OUT2 and XBAR_OUT3 outputs.

The XBAR_CTRL registers are organized similarly to the XBAR_SEL registers, with control fields for two XBAR_OUT outputs in each register. In control register 0, the LSBs contain the control fields for XBAR_OUT2, and the MSBs contain the control fields for XBAR_OUT3.

Diagram

8 DEN3	DMA Enable for XBAR_OUT3 This bit enables the DMA function on the corresponding XBAR_OUT3 output. When enabled, DMA_REQ3 presents the value STS3. When disabled, the DMA_REQ"3" output remains low. **RESTRICTION** IEN3 and DEN3 should not both be set to 1. 0b - DMA disabled 1b - DMA enabled
7-5 —	RESERVED
4 STS2	Edge detection status for XBAR_OUT2 This bit reflects the results of edge detection for XBAR_OUT2. This field is set to 1 when an edge consistent with the current setting of EDGE2 is detected on XBAR_OUT2. This field is cleared by writing 1 to it or by a DMA_ACK2 reception when DEN2 is set. Writing 0 to the field has no effect. When interrupt or DMA functionality is enabled for XBAR_OUT2, this field is 1 when the interrupt or DMA request is asserted and 0 when the interrupt or DMA request has been cleared. 0b - Active edge not yet detected on XBAR_OUT2 1b - Active edge detected on XBAR_OUT2
3-2 EDGE2	Active edge for edge detection on XBAR_OUT2 This field selects which edges on XBAR_OUT2 cause STS2 to assert. 00b - STS2 never asserts 01b - STS2 asserts on rising edges of XBAR_OUT2 10b - STS2 asserts on falling edges of XBAR_OUT2 11b - STS2 asserts on rising and falling edges of XBAR_OUT2
1 IEN2	Interrupt Enable for XBAR_OUT2 This bit enables the interrupt function on the corresponding XBAR_OUT2 output. When the interrupt is enabled, the output INT_REQ2 reflects the value STS2. When the interrupt is disabled, INT_REQ2 remains low. The interrupt request is cleared by writing a 1 to STS2. **RESTRICTION** IEN2 and DEN2 should not both be set to 1. 0b - Interrupt disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Interrupt enabled
0 DEN2	DMA Enable for XBAR_OUT2 This bit enables the DMA function on the corresponding XBAR_OUT2 output. When enabled, DMA_REQ2 presents the value STS2. When disabled, the DMA_REQ"2" output remains low. **RESTRICTION** IEN2 and DEN2 should not both be set to 1. 0b - DMA disabled 1b - DMA enabled

78.5.2 XBAR register descriptions

The XBAR module has select registers and control registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBAR_IN) is muxed to each mux output (XBAR_OUT). There is one SELn field per mux and therefore one per XBAR_OUT output. Crossbar output XBAR_OUT[n] presents the signal chosen by XBAR_IN[SELn]. In a select register (SELy for example), the lower 8 bits represent the input for XBAR_OUT[2y] and the higher 8 bits represent the input for XBAR_OUT[2y+1].

The actual signals connected to XBAR_IN and XBAR_OUT are application specific and are described in the XBAR Assignments tables.

The XBAR control registers configure edge detection, interrupt, and DMA features for a subset of the XBAR_OUT outputs.

Chapter 79
Analog Overview

79.1 Overview

The following analog modules are integrated in this chip:

- Analog-Digital-Converter (ADC) - Supports up to 3.6MS/s sampling rate and up to 30 single-ended external analog inputs
- Comparator (CMP) - Operational over the entire supply range and features a integrated 8-bit DAC and a integrated 6 to 1 channel mux
- Digital-Analog-Converter (DAC) - 12-bit resolution with on-chip programmable reference generator output
- SINC Filter (SINC) - Converts external ADC sigma-delta modulator bit stream to data stream
- Voltage Reference (VREF) - Provides a reference voltage to external devices or used internally in the chip as a reference to analog peripherals

79.2 Analog-to-Digital Converter (ADC)

i.MX RT1180 integrates 2 ADCs.

The main features are:

- Linear successive approximation algorithm with up to 16-bit resolution
- Up to 3.6MS/s sampling rate
- Up to 30 single-ended external analog inputs
- Selectable asynchronous hardware conversion trigger with hardware channel select
- Supports both differential and single-end inputs

79.3 Analog Comparator (CMP)

i.MX RT1180 integrates 4 CMPs.

The analog comparator (CMP) allows for comparing two analog input voltages while the Analog MUX allows for selecting an analog input signal from six channels. The CMP is operational across the full range of the supply voltage. The integrated 8-bit DAC provides a selectable voltage reference for applications where voltage reference is needed.

79.4 Digital-Analog Converter (DAC)

i.MX RT1180 integrates 1 DAC.

The DAC module is 12-bit resolution with on-chip programmable reference generator output. The voltage output range is from 1/4096 Vin to Vin, and the step is 1/4096 Vin, where Vin is the input voltage from ADC_VREFH.

79.5 SINC Filter (SINC)

i.MX RT1180 integrates 3 SINCs.

The SINC Filter is an integrated module to convert external ADC sigma-delta modulator bit stream to data stream. The converters are based on up to 5-order SINC digital decimation filters with selectable oversampling ratio up to 512. Additional filtering can be done in software.

79.6 Reference Voltage (VREF)

The VREF can be used in applications to provide a reference voltage to external devices, or used internally in the device as a reference to analog peripherals (such as the ADC, DAC, or CMP). The Voltage Reference (VREF) can supply an accurate voltage output that can be trimmed in 0.5*(4/3) mV steps. The voltage reference has 3 operating modes that provide different levels of supply rejection and power consumption.

The ADC supports the following voltage reference options CFG[REFSEL]:

- 00 - VREFH - connected as the primary reference option. An external reference voltage can be used. If an external reference voltage is not available, the on chip VREF_OUT can be used instead
- 01/10 - VDDA_ADC_1P8 - connected as the alternative reference option
- 11 - Reserved

NOTE

V_{SSA} and V_{REFL} is tied to common ground V_{SS} in package.

The only hardware triggers for ADC are from XBAR.

In the table above, each of the numeric pairs (for example, A0/B0, A1/B1, and so on) can be converted differentially by setting CMDLn[CTYPE]=10. There are eight differential pairs available on ADC1 and seven differential pairs available on ADC2. It is not recommended to convert differentially on non-designated channels (for example, A0 and B1).

NOTE

Each ADC includes an internal temperature sensor connected as an input channel to the ADC. The ADC channel assignment for temp sensor is channel A26/B26 on this chip. It is recommended to set CMDL[ALTBEN]=0. See Temperature sensor for additional information.

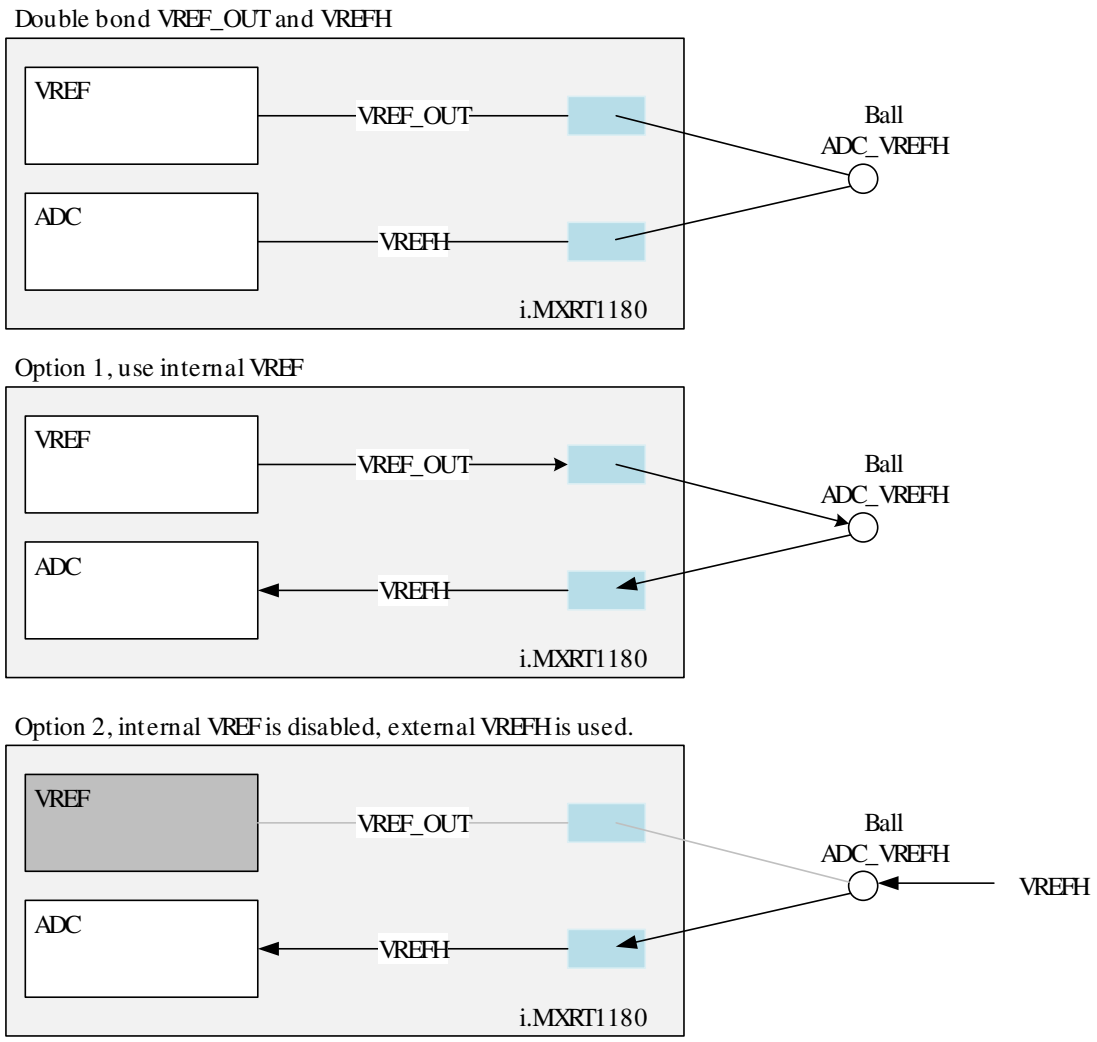

Figure 610. VREF connections and VREF_OUT and ADC_VREFH double bonding

80.2 Overview

The 16-bit analog-to-digital converter (ADC) is a dual successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

NOTE

For the chip specific modes of operation, see the power management information of the device.

80.2.1 Block diagram

The following figure is the ADC module block diagram.

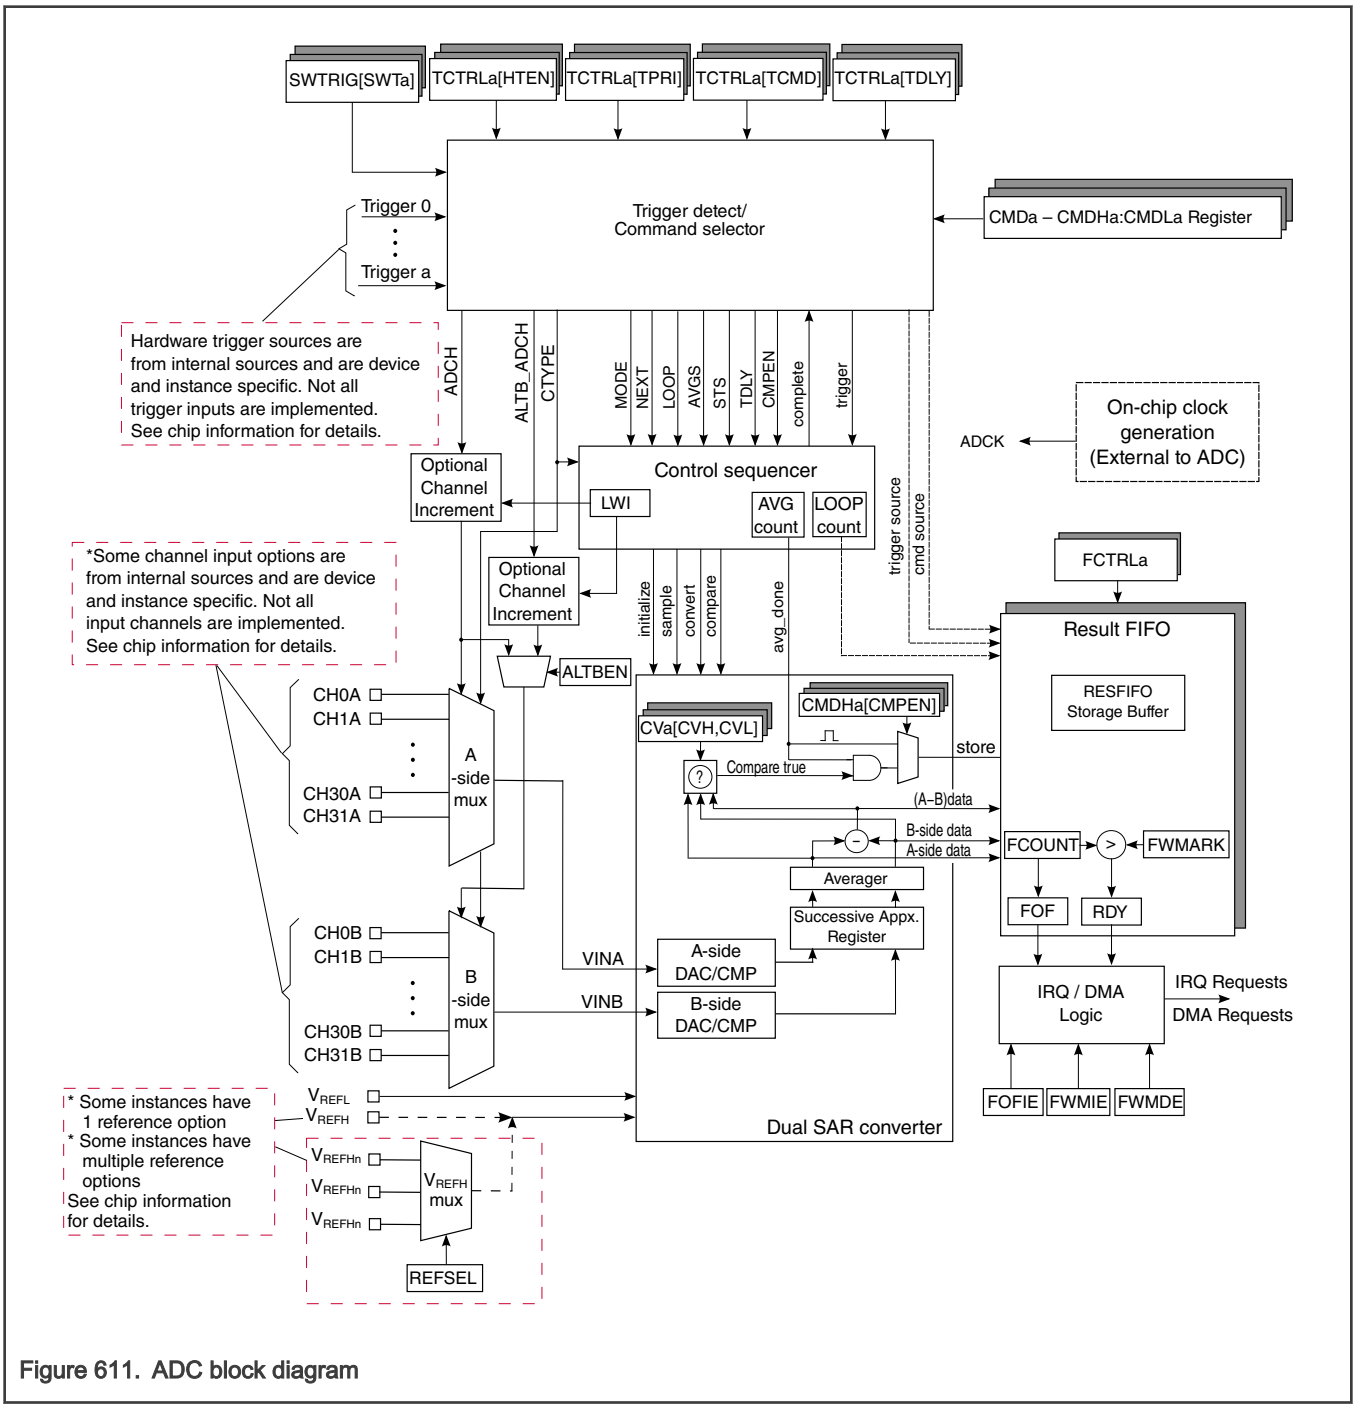

Figure 611. ADC block diagram

80.2.2 Features

Following are the features of the ADC module.

- Linear successive approximation algorithm
  - differential operation with 16-bit or 13-bit resolution
  - single-ended operation with 16-bit or 12-bit resolution
  - One ADC supports for two simultaneous single ended conversions.
- Channel scaling allows input voltage levels higher than the ADC reference voltage
- Configurable analog input sample time
- Configurable speed options to accommodate operation in low power modes of SoC
- Trigger detect with up to 8 trigger sources with priority level configuration. Software or hardware trigger option for each.
- 15 command buffers allow independent options selection and channel sequence scanning.
- Automatic compare for less-than, greater-than, within range, or out-of-range with "store on true" and "repeat until true" options
- 2 independent result FIFOs each contains 16 entries. Each FIFO has configurable watermark and overflow detection
- Interrupt, DMA or polled operation
- Linearity and gain adjustment calibration logic

80.3 Functional description

The ADC module performs analog-to-digital conversions on any of the software selectable analog input channels by a successive approximation algorithm. The module initializes to its lowest power state during reset. The ADC analog circuits can optionally be pre-enabled for faster starts to conversions at the expense of higher idle currents. Conversions are initiated by selectable trigger events from software or hardware sources. The trigger detect logic includes a configurable enable and priority scheme for the available trigger sources. The module includes multiple command buffers that provide configurable flexibility for channel scanning and independent channel selections for different trigger sources. Multiple command buffers also allow variable option selection such as input scaling factor, differential vs. single-ended, sample time and averaging on a per-channel basis.

The ADC module optionally averages the result of multiple conversions on a channel before storing the calculated result. The hardware average function is enabled by setting CMDH*a*[AVGS] bitfield to a non-zero value and operates in any of the conversion modes and configurations.

When the conversion and averaging loops are completed, the resulting data is placed in one of 2 available FIFO data buffers along with other tag information associated with the result. A configurable watermark level supports interrupt or DMA requests when the number of stored datawords exceeds the setting. Interrupts can also be enabled to indicate when FIFO overflow errors occur.

The ADC module optionally compares the result of a conversion with the contents of two value registers for less-than, greater-than, inside-range or outside-range detection. The compare function operates in any of the conversion modes and configurations.

The ADC module includes hardware calibration logic to correct for offset, gain and linearity errors. Calibration steps should be executed after any reset or power up. Each SAR conversion utilizes calibration data calculated during the calibration routine.

The sequencing of a ADC command is summarized in the flow diagram shown below.

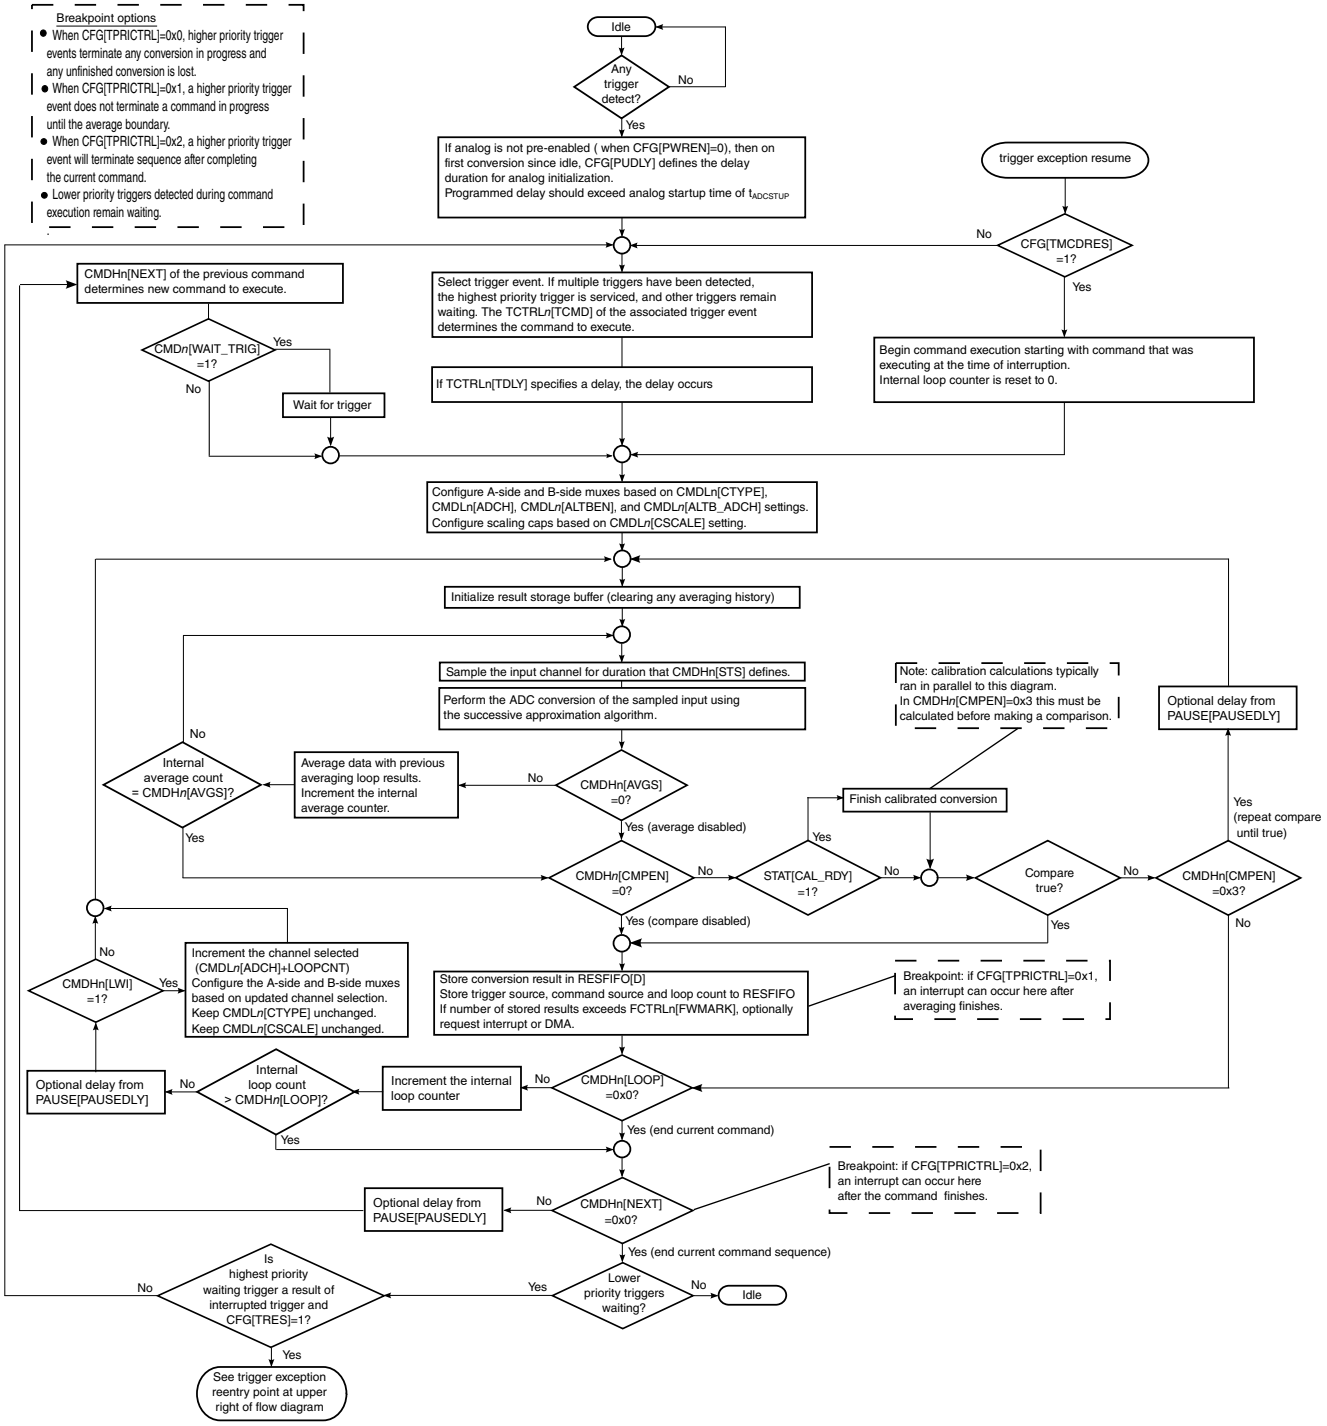

Figure 612. ADC command execution flow diagram

80.3.1 Power control mode

The default setting for the ADC analog circuits is disabled while the ADC is in its Idle state. When a trigger is detected and ADC command processing is initiated, the analog circuits are enabled and require a period of initialization before the first conversion cycle. The CFG[PUDLY] should be programmed such that a delay duration longer than $t_{ADCSTUP}$ is incurred. Accuracy of the initial conversion(s) after activation is degraded if CFG[PUDLY] is set to too small a value.

Faster conversion startup times can be achieved by optionally setting the CFG[PWREN] field to pre-enable the analog circuits of the ADC at the expense of power consumption even while the module is in an idle state. When CFG[PWREN] is set, the Power Enable timer is activated and enforces the minimum startup (controlled by the CFG[PUDLY] register field) before detected triggers are allowed to initiate ADC conversions.

80.3.2 ADC modes of operation

The ADC module supports the chip low power modes described in the following table. See section Clocking for more information.

Table 1103. Chip modes supported by the ADC module

Chip mode	ADC Operation
Run	Normal operation
Deepsleep/Sleep	When the Doze Enable bit (CTRL[DOZEN]) is 0, the ADC can continue to operate and the module is using an external or internal clock source which remains operating during Deepsleep/Sleep modes. ADC is allowed to continue operation while the system is transitioned to the low power state. Any conversion in progress is not disrupted. External hardware trigger detect and active conversions are operational. When the DOZEN bit is 1, the module waits for the current averaging iteration/FIFO storage to complete before acknowledging Deepsleep or Sleep mode entry. There is no associated ack/handshake and the system transitions to low power state without ADC interaction. ADC operation should terminate after completion of any conversion in progress.
Deep Powerdown	The Doze Enable (CTRL[DOZEN]) bit is ignored and the module waits for the current transfer to complete any pending operation before acknowledging Deep Powerdown mode entry.

80.3.3 Voltage reference

The voltage reference high (V_{REFH}) used by the ADC is supplied from either an on-chip voltage reference source or from an off-chip source supplied through external pins. V_{REFL} is always from an external pin and must be at the same voltage potential as V_{SSA}. See the chip configuration information on the voltage reference options specific to this packaged device.

This block supports a programmable selection of the Voltage Reference used for ADC conversions (via the CFG[REFSEL] field). See the chip configuration information on the voltage reference options specific to this packaged device.

80.3.4 Trigger detect and command execution

See Figure 612 for a flow diagram of command execution sequencing.

ADC command execution is initiated from up to 8 trigger sources. Each trigger can be software generated by writing 0b1 to the corresponding SWTRIG[SWT*n*] bitfield. Alternatively, hardware triggers can be generated from asynchronous input sources at the periphery of the module. The number and sources of hardware triggers implemented is device specific. See the chip-specific ADC information for description of available hardware trigger sources for this device.

Each hardware trigger source is enabled by setting the associated enable bit (TCTRLa[HTEN]). Each trigger source is assigned a priority via the associated priority control field (TCTRLa[TPRI]). Each of the trigger sources is associated with a command buffer via the associated command select field (TCTRLa[TCMD]).

When a hardware trigger input is enabled, hardware trigger events are detected on the rising-edge of the associated hardware trigger source.

Each trigger source has an associated priority field TCTRLa[TPRI] which allows for arbitration between trigger sources. Arbitration is in control of two things: selecting which trigger sequence to execute next, and selecting how to handle a trigger exception. Trigger exceptions are defined as allowing a higher priority trigger sequence to interrupt operation of a lower priority sequence. When a trigger exception occurs, programmable arbitration allows the configurable stop and resume points for low priority sequences. The fields affecting arbitration are CFG[HPT_EXDI],CFG[TCMDRES],CFG[TRES], and CFG[TPRICTRL].

1. If CFG[HPT_EXDI] is set to 1b, then trigger exceptions are disabled and any higher priority triggers are left pending until the current sequence completes. Note that new triggers are accepted based on priority.
2. If CFG[HPT_EXDI] is set to 0b (default), then exceptions are enabled and the higher priority sequence begins executing at a user specified breakpoint.

Breakpoint locations are determined by the register CFG[TPRICTRL]. CFG[TPRICTRL] has an affect on latency for accepting a trigger exception.

1. When CFG[TPRICTRL]=0x0, a higher priority trigger causes an immediate command abort and the new command specified by the trigger is immediately started.
2. When CFG[TPRICTRL]=0x1, the current conversion is allowed to complete (including averaging) before the higher priority exception is initiated. In this mode, if the command is running through a series of averages, this series completes. However, there is no requirement to finish the entire command before being interrupted. For example, if the command consists of 4 loop iterations, there is no requirement to complete all 4 iterations before the interrupt occurs.
3. When CFG[TPRICTRL]=0x2, a higher priority trigger begins once the current command is completed. If a command consists of 5 loop iterations each containing 8 averages, then all 5x8 conversions must be completed before accepting the trigger exception.

CFG[TCMDRES] and CFG[TRES] determine what the ADC does after accepting a trigger exception. The module can be programmed to resume commands after returning from a trigger exception.

1. If CFG[TRES] = 0x0 then commands are not automatically resumed after being stopped by an exception. However, an interrupt is set to indicate this case has occurred. The flag TSTAT[TEXC_NUM] can be used to resolve which trigger was stopped by the exception.
2. If CFG[TRES] = 0x1 the ADC automatically resumes commands after they were stopped by an exception.

By utilizing CFG[TRES] in conjunction with CFG[TCMDRES], the module can be programmed to resume commands at one of two possible locations.

1. If CFG[TCMDRES] = 0x0 then the trigger which was stopped by an exception is resumed from the beginning of its associated command sequence. Note, triggers which are waiting to be resumed take the same priority programmed to TCTRLa[TPRI].
2. If CFG[TCMDRES] = 0x1 then the trigger is resumed from the command that it was executing before being interrupted by an exception.

If a lower priority trigger occurs (i.e., a trigger event occurs that is configured for a lower priority than the trigger source associated with the currently executing command), the trigger detect is left pending until completion of the current command sequence. Lower priority trigger events cannot be serviced until a higher priority triggered command (or command sequence) completes.

When a conversion is completed (including hardware averaging when CMDHa[AVGS] is non-zero), the result is placed in a RESFIFO buffer. When an ADC command selects looping (when CMDHa[LOOP] is non-zero) a command stores multiple conversion results to the FIFO during execution of that command.

At the end of command execution, CMDHa[NEXT] selects the next command to be executed. Multiple commands can be executed sequentially by configuration of each commands CMDHa[NEXT] field. Setting the next command to 0x0 causes conversions to terminate at the completion of the current command. Unending circular command execution is allowed by setting the CMDHa[NEXT] field in the last command in a sequence to the first command in the sequence.

By default, command sequences executes automatically in the order that CMDHa[NEXT] fields are programmed. However, by utilizing the CMDHa[WAIT_TRIG], command execution can be stalled and launched based on trigger inputs. For example, if TRIGGER2 is programmed to start the command sequence CMD1, CMD2, CMD3, then receiving TRIGGER 2 one time unconditionally runs this sequence to completion. If CMDH2[WAIT_TRIG] is set to 0x1, however, then the sequence pauses after CMD1 until TRIGGER2 is received again. Therefore, sequences can be stalled until receiving a trigger assertion.

Disabling the ADC by writing 0b0 to the CTRL[ADCEN] bitfield terminates any active ADC command processing. Writing 0b0 to the CTRL[ADCEN] bitfield causes the current command (or command sequence) to terminate, clears any pending triggers and sends the ADC module to an IDLE state.

80.3.5 Pause option

When the maximum conversion rate is not required by an application the effective conversion rate can be reduced by implementing periodic trigger events to initiate ADC conversions or by selecting a reduced frequency clock as the ADACK source. Both of these options are chip specific and are dependent on ADC triggering and clocking options external to the ADC module. The latency associated with ADC analog power up delays results in a limit on the maximum conversion rate when using periodic triggering.

Another means of reducing conversion rates is by inserting a pause of a programmable duration between LOOP iterations, between commands in a sequence, and between conversions when command is executing in the "Compare Until True" configuration. When PAUSE[PAUSEEN] is set, the PAUSE[PAUSEDLY] field controls the duration of pausing during command execution sequencing. The pause delay is a count of (PAUSE[PAUSEDLY]*4) ADCK cycles. Note, the PAUSE register should not be changed while the CTRL[ADCEN] bit is set. Writes to the PAUSE register while CTRL[ADCEN] is set can lead to metastable operation.

See Figure 612 for the places during command execution sequencing where the pause is optionally inserted.

80.3.6 Resync functionality

Any trigger source (SW or HW) can be configured to act as a resync trigger. Trigger based resync functionality is used to interrupt a running trigger (resync target) and clear the FIFO it's writing to. This can either be used to abort a running sequence, or restart a running sequence depending on the configuration of CFG[TRES]. If CFG[TRES] = 0b1 then the target sequence is aborted, the FIFO cleared, and the sequence restarted after the resync occurs. If CFG[TRES] = 0b0 then the target sequence is aborted and the FIFO is cleared after the RESYNC occurs. Note, the FIFO(s) cleared are based on the resync target TCTRLm[FIFO_SEL_A] and TCTRLm[FIFO_SEL_B]. To only clear one FIFO, TCTRLm[FIFO_SEL_A] == TCTRLm[FIFO_SEL_B]. Any results not associated with the resync target are lost if they are stored in either TCTRLm[FIFO_SEL_A] or TCTRLm[FIFO_SEL_B] at the time of the resync.

A resync trigger needs to have a specific target. The resync only occurs if the resync target is running at the time of the trigger. For the following description, let n be the resync trigger number, let m be the resync target number. According to these variables, trigger n should resync trigger m. To enable a trigger source to act as a resync trigger, the following conditions must be satisfied:

1. The resync trigger TCTRLn[RSYNC] must be set to 0b1.
2. The resync trigger must have higher priority than the resync target (TCTRLn[TPRI] must be less than TCTRLm[TPRI]).
3. The resync target is specified using TCTRLn[TCMD]. In this case the resync target, m, must be equal to TCTRLn[TCMD].
4. The resync target, m, must be executing commands when the resync trigger, n, is asserted.
5. Trigger m must have at least one conversion left to begin when trigger n is received.

If a trigger source n has TCTRLn[RSYNC] set to 0b1, but some of the above conditions are not met then the trigger source n is ignored.

The following figure illustrates a resync trigger sequence executing. Note, in this example, trigger source 1 is configured to resync trigger source 0.

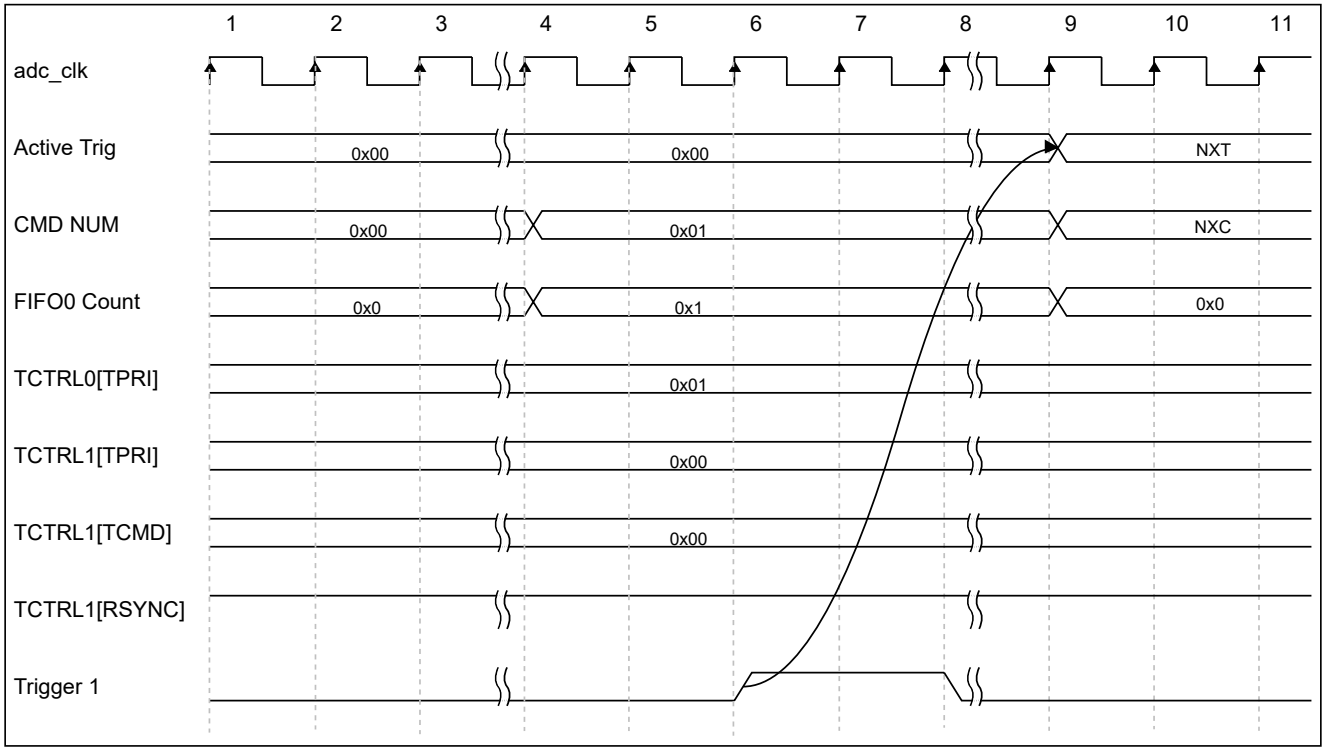

Figure 613. ADC Resync Example

In this figure, trigger source 0 was executing a sequence of commands when trigger source 1 was asserted. Notice that trigger source 0 is stopped when trigger source 1 is asserted (after some synchronization delay). In addition, the FIFO being written to by trigger source 0 is cleared (FIFO0 in this example). After the trigger 0 sequence is stopped, the ADC runs the next trigger pending with the highest priority. This is marked as NXT, for next trigger. If resume functionality is enabled, and trigger source 0 had the highest priority pending, then NXT = 0x00.

80.3.7 Temperature sensor

The ADC module has a dedicated input channel for an on-chip temperature sensor. Refer to the chip specific channel definition to determine which channel is connected to the on-chip temperature sensor.

To calculate the temperature, application software must first execute a conversion of the temperature sensor channel with some configuration requirements. This sequence for converting the temperature sensor channel is outlined below:

1. Refer to chip specific channel definition to determine which channel corresponds to the temperature sensor.
2. Configure a command buffer register to convert the temperature sensor channel. CMDLa[ADCH] = Temperature Sensor Channel.
3. The command buffer must also be programmed with the following parameters:
   - 16 bit mode (CMDLa[MODE] = 0x1)
   - Differential (CMDLa[CTYPE] = 0x2)
   - Max averaging (CMDHa[AVGS] = 0xA)
   - Max sample time (CMDHa[STS] = 0x7)
   - LOOP set to 1 (CMDHa[LOOP] = 0x1)
   - Loop with increment disabled (CMDHa[LWI] = 0x0)
   - Compare function disabled (CMDHa[CMPEN] = 0x0)

4. Configure a trigger control register TCTRLa with the following parameters:
   - TCTRLa[TCMD] = command buffer used in steps 2 and 3.
   - TCTRLa[FIFO_SEL_A] will direct conversion results to FIFO0 or FIFO1
5. Trigger a conversion of the temperature sensor channel. Software triggers the conversion by writing "1" to the associated bit in SWTRIG register (i.e., the trigger configured in step 4).

After completion of the conversion of the temperature sensor channel, two results are stored in the FIFO selected with TCTRLa[FIFO_SEL_A]. Each result corresponds to a component of the overall temperature value. Application software reads these values from the FIFO and uses the equation below to calculate the ambient temperature.

$$Temp = A * [\frac{\alpha * (Vbe8 - Vbe1)}{Vbe8 + (\alpha * (Vbe8 - Vbe1))}] - B$$

Figure 614. Temperature sensor function

Where:

- Vbe1 is the first value stored to the FIFO as a result of the temperature sensor channel conversion
- Vbe8 is the second value stored to the FIFO as a result of the temperature sensor channel conversion
- A is the slope factor
- B is the offset factor
- α is the bandgap coefficient

A, B, and α are specified constant values from the ADC Electrical information in the device datasheet.

80.3.8 Result FIFO operation

The ADC includes 2 16 entry FIFOs in which the result of ADC conversions are stored. In addition, a valid indicator bit, the trigger source, the source command and the loop count are also stored along with the data. FCTRLa[FCOUNT] indicates how many valid datawords are stored in each RESFIFO.

A programmable watermark threshold supports configurable notification of data availability. When FCTRLa[FCOUNT] is greater than FCTRLa[FWMARK], the associated RDY flag is asserted. When IE[FWMIEx] is set, a watermark interrupt request is issued. When DE[FWMDEx] is set, a DMA request is issued. Reading RESFIFO provides the oldest unread dataword entry in the FIFO and decrements FCTRLa[FCOUNT]. When FCTRLa[FCOUNT] falls equal to or below FCTRLa[FWMARK], the RDY flag is cleared.

Each FIFO can be emptied by successive reads of RESFIFOa. When the RESFIFOa[VALID] bit is 1 the associated FIFO entry is valid. Reading RESFIFOa when the FIFO is empty (when RESFIFOa[VALID] is clear and FCTRLa[FCOUNT]=0x0) provides an undefined dataword. All FIFOs are reset by writing 0b1 to the CTRL[RSTFIFOx] bit.

If the ADC attempts to store a dataword to the FIFO when the FIFO is full the FIFO overflow flag (FCTRLa[FOF]) is set. When IE[FOFIEx] is set, a overflow interrupt request is issued. The FOF flag is cleared by writing 1 to STAT[FOFx]. On overflow events no new data is stored and the data associated with the store that triggered the overflow is lost.

Conversion results can be steered to any FIFO in the design. TCTRLa[FIFO_SEL_A] and TCTRLa[FIFO_SEL_B] is utilized to determine which FIFO to write the final result. Therefore, depending on which trigger is executing the results can be steered to different locations. Depending on the type of conversion selected the FIFO destination register fields are interpreted differently. During either differential or single-ended mode (CMDLa[CTYPE] != 0x3) only one result is produced. The destination during these modes is determined from TCTRLa[FIFO_SEL_A]. In dual-single-ended mode, both TCTRLa[FIFO_SEL_A] and TCTRLa[FIFO_SEL_B] are used to determine the Channel A and Channel B destinations respectively.

80.3.9 Sampling modes

The ADC module supports three different sampling modes: differential, single-ended, and dual single-ended. The sampling mode is determined by the currently executing command using the register field CMDLa[CTYPE]. When executing a command in

dual single-ended mode, two independent conversion results are calculated and stored in selectable FIFO destinations. Note, however, that command processing is not individually controlled for each independent channel being sampled. When operating in dual single-ended mode both channels are sampled and processed simultaneously. The selection of Channel B is controlled by the CMDLa[ALTBEN] control bit. When CMDLa[ALTBEN] bit is set, the channel for the B-side is selected independently (via CMDLa[ALTB_ADCH] setting). When CMDLa[ALTBEN] bit is clear, the Channel B selection is controlled by CMDLa[ADCH] and Channel A and Channel B are paired (ex. CH0A/CH0B, CH1A/CH1B, ...). If comparisons are enabled in dual single-ended mode, then only the A-side channels (CH0A, CH1A, CH2A, ...) are used for the comparison. The A-side comparison is used to determine if both the A-side and B-side results are written to the FIFOs:

- If the A-side comparison passes, both the A-side and B-side results are stored.
- If the A-side comparison fails, neither the A-side nor B-side results are written to the FIFOs.

Single-ended mode is configurable to allow either A-side or B-side channels to be sampled. In single-ended mode, the results from each conversion can be written to a selectable FIFO using TCTRLa[FIFO_SEL_A]. In differential mode, the final SAR calculation is equivalent to V(CHA) - V(CHB). If the result is negative, then the value is stored in sign-extended two's complement format. TCTRLa[FIFO_SEL_A] also determines where differential conversion results are stored. In dual single-ended mode, however, two independent results are produced. Individual control is provided by using TCTRLa[FIFO_SEL_A] and TCTRLa[FIFO_SEL_B] to select a FIFO destination for both results during this mode. Note that both single-ended results may be written to the same destination by programming TCTRLa[FIFO_SEL_A] = TCTRLa[FIFO_SEL_B]. In this case, the CH_A result is always stored before the CH_B result.

80.3.10 Compare function

After the input is sampled and converted and any averaging iterations are performed, the CMDH*a*[CMPEN] field guides operation of the automatic compare function to optionally only store when the compare operation is true. There are multiple options on command sequencing related to the compare function as summarized in the table below.

NOTE

Latency is added to the end of a compare until true conversion to resolve the next command or loop in a sequence. This latency is necessary to calibrate the SAR data before resolving the result of a comparison. Delay for this feature is only added when resolving the result of a conversion. This means that intermediate samples during averaging do not include extra latency. Only loop and command boundaries experience this delay. The latency is always less than or equal to 5 ADC clock cycles.

NOTE

Not all Command Buffers have an associated Compare Value register. The compare function is only available on Command Buffers that have a corresponding Compare Value register.

Table 1104. Compare modes

CMDH*a*[CMPEN]	Compare Function	Description
0b00	Compare disabled	Do not perform compare operation. Always store the conversion result to the FIFO.
0b01	Reserved	
0b10	Store on true	Perform compare operation. Store conversion result to FIFO at end of averaging only if compare is true. If compare is false do not store the result to the FIFO. In either the true or false condition, the LOOP setting is considered and increments the LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required.
0b11	Repeat compare until true	Perform compare operation. Store conversion result to FIFO at end of averaging only if compare is true. Once the true condition is found the

Table continues on the next page...

Table 1104. Compare modes (continued)

CMDH*a*[CMPEN]	Compare Function	Description
		LOOP setting is considered and increments the LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required. If the compare is false do not store the result to the FIFO. The conversion is repeated without consideration of LOOP setting and does not increment the LOOP counter.

Depending on CV*a*[CVH] and CV*a*[CVL] values programmed, the compare operation checks whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. The compare values are used as described in the following table.

Table 1105. Compare operations

CV*a*[CVL] vs. CV*a*[CVH]	Operation	Description
set CVa[CVL] < CVa[CVH]	Outside range (General form)	Compare true if the result is less than CVa[CVL] value **OR** greater than CVa[CVH] value.
set CVa[CVH] to max value set CVa[CVL] to compare point	Less than	Compare true if the result is less than CVa[CVL] value.
set CVa[CVL] to min value set CVa[CVH] to compare point	Greater than	Compare true if the result is greater than CVa[CVH] value.
set CVa[CVL] > CVa[CVH]	Inside range	Compare true if the result is less than CVa[CVL] value **AND** greater than CVa[CVH] value.

NOTE

In low power modes where the ADC continues to operate, the compare function can monitor the voltage and only wake the device when the compare condition is met.

80.3.11 Clocking

The ADC operates from the ADCK clock input provided from an on-chip clock select block and is used by the SAR conversion control sequencing logic and the FIFO storage buffer. The ADCK frequency must be within the specified frequency range for ADCK. Refer to the device datasheet for the supported frequency range.

The ADC continues operating in Deepsleep and Sleep modes provided the Doze Enable bit (CTRL[DOZEN]) is clear and the on-chip clock select block continues to supply an ADCK clock source. Note, in Deepsleep mode with CTRL[DOZEN] == 0b0, the bus clock can be shut off, and asynchronous interrupts and DMA requests can be configured. In addition, the ADC continues processing commands and writing data to the internal FIFO. The ADC has four sources for async interrupts during Deepsleep mode: watermark, FIFO overflow, TCOMP, and TEXC. To enable them, properly configure the bits IE[FWMIEx], IE[FOFIEx], IE[TCOMP_IE], and IE[TEXC_IE] before entering Deepsleep mode.

When the CTRL[DOZEN] bit is set in Deepsleep and Sleep modes, the ADC waits for the current averaging iteration/FIFO storage to complete before acknowledging Deepsleep or Sleep mode entry. Any pending triggers are dropped when a Deepsleep/Sleep mode request is made with CTRL[DOZEN] set. The ADC is forced into its lowest power setting after acknowledging the CTRL[DOZEN] Deepsleep/Sleep mode request. The same behavior is observed when entering a Deep Powerdown Mode.

80.3.12 Resets

Table 1106. ADC Resets

Signal	Description
Chip reset	The logic and registers for the ADC are reset to their default state on a chip reset.
Software reset	The ADC implements a software reset bit in its Control Register. The CTRL[RST] bit resets all logic and registers to their default state, except for the CTRL register itself.
FIFO reset	The ADC implements write-only control that reset the FIFO0 (CTRL[RSTFIFO0]) and FIFO1 (CTRL[RSTFIFO1]). After a FIFO is reset, that FIFO is empty.

80.3.13 Interrupts and DMA requests

The ADC includes several sources for interrupts and/or DMA requests. The table below summarizes these sources.

A programmable watermark threshold supports configurable notification of data availability and can generate either an interrupt exception or a DMA request. When FCTRLn[FCOUNT] is greater than FCTRLn[FWMARK], the associated RDYn flag is asserted. Masking for this exception is controlled by the IE[FWMIEn] and DE[FWMDEn] control bits. When RDYn is asserted and mask control bit IE[FWMIEn] is set, a watermark interrupt request is issued. When RDYn is asserted and mask control bit DE[FWMDEn] is set, a DMA request is issued.

The other exception sources can only generate interrupts and do not have a DMA request option. Each of these sources has a mask control bit in the IE register and no corresponding bit in the DE register.

Table 1107. ADC Interrupts and DMA Requests

Status Register (STAT)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
RDYn	Result FIFO n Ready Flag	Conversion result data is written to Result FIFO and has a watermark configurable trigger level to generate an exception request as controlled by FCTRLn[FWMARK].	Y	Y	Y
FOFn	Result FIFO n Overflow Flag	Attempts to store data to the FIFO when the FIFO is full is an error condition.	Y	N	Y
TCOMP_INT	Trigger Completion Flag	A trigger sequence has been completed (all associated commands have been run).	Y	N	Y
TEXC_INT	High Priority Trigger Flag	A high priority trigger exception has occurred.	Y	N	Y

80.4 External signals

The ADC module supports analog channel inputs with differential and single-ended conversion options for all channels. The module also requires supply and ground connections.

Table 1108. ADC signal descriptions

Signal	Description	I/O

Table continues on the next page...

Table 1108. ADC signal descriptions (continued)

Signal	Description	I/O
CHnA–CH0A[1]	A-side Analog Channel Inputs	I
CHnB–CH0B[1]	B-side Analog Channel Inputs	I

1. where n is the maximum channel number supported in the chip. See the chip-specific information to know the number of channels supported on your device.

80.4.1 Analog Channel Inputs (CH*n*A and CH*n*B)

The CMDLa[ADCH] and CMDLa[CTYPE] bitfields control selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each CMDLa[ADCH] channel selection has an associated A side and an associated B side input. Each CMDLa[ADCH] pair can optionally be converted in a differential mode but only limited pairs are intended to be converted as differential channels (i.e., adjacent pins that have been designed with matched impedance). For the pin pairings available for differential conversions for your device, see the Chip Configuration details.

NOTE

Some of the input channels are from on-chip sources such as temperature sensors and reference voltage sources and may only be connected to individual instances of the ADC module. Some of the input channel options in the bitfield-setting descriptions may not be available for your device. Refer to chip-specific information for the channels supported on this device.

80.5 Initialization

80.5.1 Calibration

The ADC module has multiple calibration functions that must be executed as part of ADC setup to achieve the specified accuracy. Calibration must be run after any reset and before a conversion is initiated. Prior to offset calibration or calibration, the user must configure the ADC's clock source and frequency according to the application's clock source availability and needs. The ADC must be enabled (CTRL[ADCEN] = 0x1) before a calibration function will run. If calibration is requested while the ADC is actively converting, that sequence completes before calibration function is initiated.

Improved accuracy can be achieved during the calibration routines by averaging multiple conversions. It is recommended to set CTRL[CAL_AVGS] for minimum of 256 averaging during calibration steps. If the application uses the ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected, or multiple calibrations can be done for the different configurations.

16 bit Offset Calibration function:

The OFSTRIM16 register is used to trim for ADC comparator offset voltage for 16 bit ADC conversions. The ADC supports an offset calibration function in which the OFSTRIM16 register is automatically updated. Below are the steps for executing the function.

1. Configure for the desired averaging via CTRL[CAL_AVGS] bitfield. The minimum recommended setting is for 256 averaging (CTRL[CAL_AVGS] set to 0x8 or greater).
2. Initiate 16 bit Offset Calibration by setting CTRL[CALOFS] with CTRL[CALOFSMODE] set.
3. Poll the STAT[CAL_RDY] flag. When STAT[CAL_RDY] is asserted, the offset calibration function has completed and the OFSTRIM16 register has updated.

12 bit Offset Calibration function:

The OFSTRIM12 register is used to trim for ADC comparator offset voltage for 12 bit ADC conversions. The ADC supports an offset calibration function in which the OFSTRIM12 register is automatically updated. Below are the steps for executing the function.

1. Configure for the desired averaging via CTRL[CAL_AVGS] bitfield. The minimum recommended setting is for 256 averaging (CTRL[CAL_AVGS] set to 0x8 or greater).

2. Initiate 12 bit Offset Calibration by setting CTRL[CALOFS] with CTRL[CALOFSMODE] clear.
3. Poll the STAT[CAL_RDY] flag. When STAT[CAL_RDY] is asserted, the offset calibration function has completed and the OFSTRIM12 register has updated.

Calibration function:

The ADC includes hardware calibration logic in which the A-side and B-side converters are calibrated for gain error and linearity error correction of the raw conversion result. The GCR0[GCALR] and CAL_GAR registers control calibration for the A-side converter. The GCR1[GCALR] and CAL_GBR registers control calibration for the B-side converter. The ADC supports a calibration function in which the CAL_GAR and CAL_GBR registers are automatically updated. The calibration function also updates GCC0[GAIN_CAL] (associated with A-side calibration) and GCC1[GAIN_CAL] (associated with B-side calibration). For A-side calibration, a software calculation is required to derive GCR0[GCALR] from GCC0[GAIN_CAL]. For B-side calibration, a corresponding calculation is needed to derive GCR1[GCALR] from GCC1[GAIN_CAL]. Below are the steps for completing calibration setup.

1. Execute the 16 bit Offset Calibration function described above. The OFSTRIM16 register is used during calibration to trim for comparator offset voltage.
2. Configure for the desired averaging via CTRL[CAL_AVGS] bitfield. The minimum recommended setting is for 256 averaging (CTRL[CAL_AVGS] set to 0x8 or greater).
3. Initiate the calibration routine by setting CTRL[CAL_REQ]. Once set, the CTRL[CAL_REQ] bit remains set until the CAL routine has been accepted by the ADC. After acceptance, CTRL[CAL_REQ] is automatically cleared.
4. The A-side calibration data is updated first. Poll the GCC0[RDY] flag. When it is asserted, the hardware controlled A-side calibration operation is complete and CAL_GAR and GCC0[GAIN_CAL] registers are updated. The updated value in GCC0[GAIN_CAL] is needed for further software processing described in the following steps.
5. Read the GCC0[GAIN_CAL] register and store for use in the gain_adjustment calculation.
6. Calculate the A-side gain_adjustment = (131072)/(131072-GCC0[GAIN_CAL]). GCC0[GAIN_CAL] is 2's complement value. This results in a floating point value between 0 and 2.
7. Convert the floating point value to its integer component (0 or 1) and its fractional component rounded to 16-bits. The integer value is stored to GCR0[GCALR[16]] and the fractional component is stored to GCR0[GCALR[15:0]]. Write this value to the GCR0[GCALR] register.
8. Next, execute the same calculation for the B-side converter. Poll the GCC1[RDY] flag. When it is asserted, the hardware controlled B-side calibration operation is complete and CAL_GBR and GCC1[GAIN_CAL] registers are updated. The updated value in GCC1[GAIN_CAL] is needed for further software processing.
9. Read the GCC1[GAIN_CAL] register and store for use in the gain_adjustment calculation.
10. Calculate the B-side gain_adjustment = (131072)/(131072-GCC1[GAIN_CAL]). Formatting for the value is the same as the A-side.
11. Write this value to the GCR1[GCALR] register.
12. Once GCR0[GCALR] and GCR1[GCALR] contain the results from the gain_adjustment calculations, set the GCR0[RDY] and GCR1[RDY] flags to indicate they are valid. It is acceptable for the GCRa[GCALR] and corresponding GCRa[RDY] bit to be updated on the same write cycle.

After completing the steps above, the calibration sequence is complete and the STAT[CAL_RDY] flag is set. The STAT[CAL_RDY] flag remains set until the user resets the system or requests a new calibration sequence.

When STAT[CAL_RDY] is set, the ADC is configured to run in calibrated mode. Each conversion uses a combination of linearity and gain calibration results to correct SAR data. Calibration conversion latency is required to process each sample. However, due to the pipelined nature of data and control sequences, each conversion can still be initiated without experiencing this calibration delay.

The diagram below shows how calibration data is both calculated and utilized. The left portion of this image represents the calibration sequencing, and the right portion represents how calibration data is used.

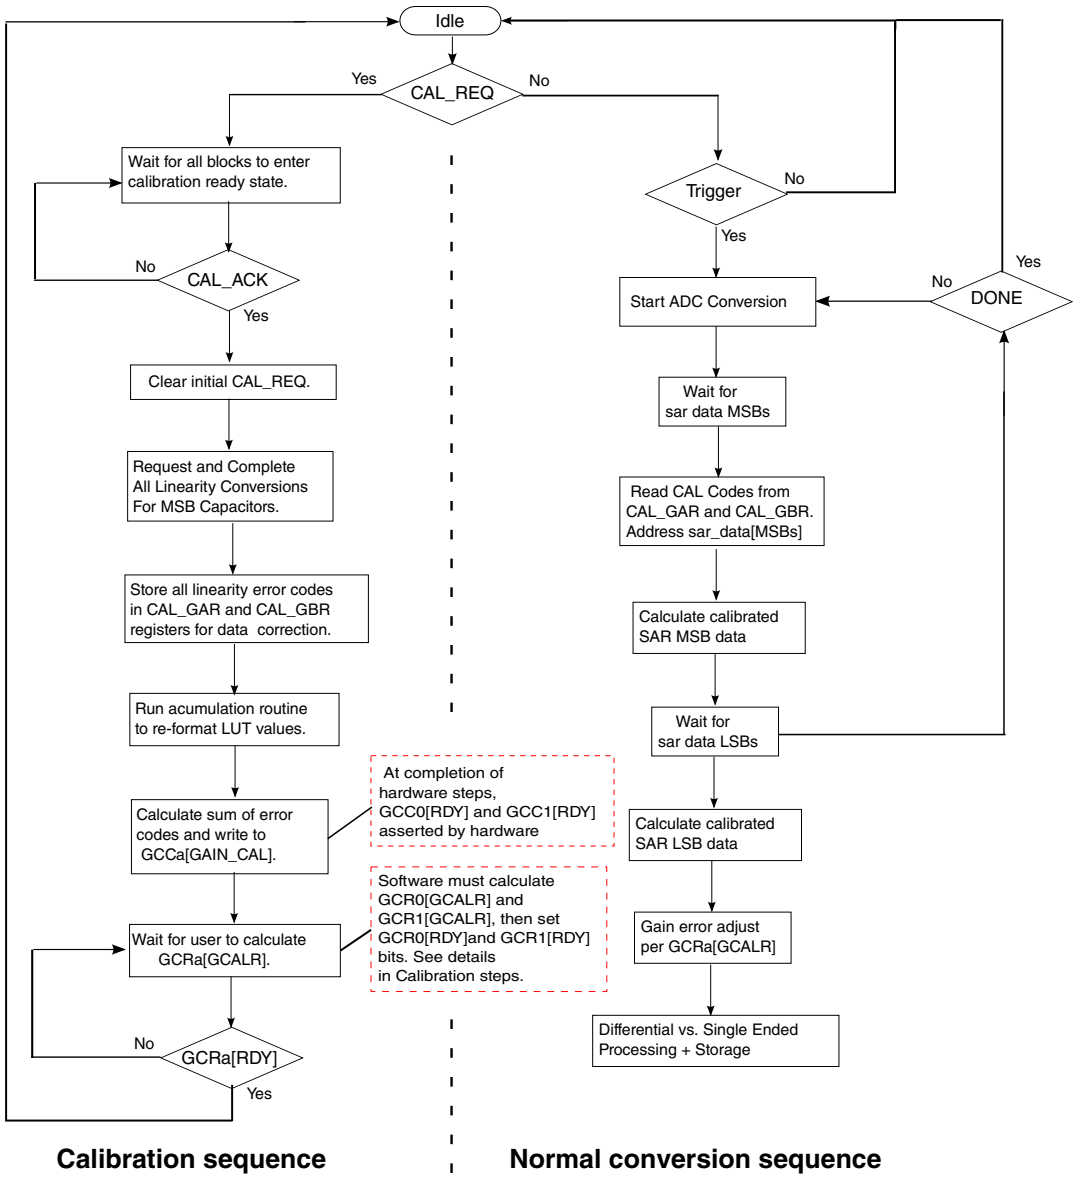

Figure 615. Simplified flow diagram for ADC calibration and conversion

80.5.1.1 Calibration General A-Side and B-Side Register valid ranges

The general calibration value registers CAL_GARa and CAL_GBRa have 33 registers in each array. The data in each register is a signed 16-bit value but has a variable range of possible values. The following table defines the valid range each register supports.

Table 1109. Calibration General Registers Valid Values

Element CAL_GxR[N]	Valid Range
N = 0x00, 0x20	–1024 to +1023
N = 0x01	–2048 to +2047

Table continues on the next page...

Table 1109. Calibration General Registers Valid Values (continued)

Element CAL_GxR[N]	Valid Range
N = 0x02–0x03	–4096 to +4095
N = 0x04–0x07	–8192 to +8191
N = 0x08–0x0F	–16384 to +16383
N = 0x10–0x1F	–32768 to +32767

These registers are typically updated automatically during the self calibration sequence. To reduce the latency associated with ADC setup, the CAL_GxR values from a calibration sequence can be stored in non-volatile memory after an initial calibration and written to the CAL_GxR registers via software prior to the first ADC conversion. If these registers are set to values not generated by the calibration function, the linearity error specifications may not be met. Note, these values can only be written in a single access, byte accesses are not supported.

80.6 ADC register descriptions

This section describes the ADC registers.

80.6.1 ADC memory map

ADC1 base address: 4260_0000h

ADC2 base address: 42E0_0000h

Fields

Field	Function
31-24 MAJOR	Major Version Number This read-only field returns the major version number for the module specification.
23-16 MINOR	Minor Version Number This read-only field returns the minor version number for the module specification.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 —	Reserved This read-only field is reserved and always has the value 0.
14-12 NUM_FIFO	Number of FIFOs This read-only field indicates the number of result FIFOs implemented in the design. 000b - N/A 001b - This design supports one result FIFO. 010b - This design supports two result FIFOs. 011b - This design supports three result FIFOs. 100b - This design supports four result FIFOs.
11 NUM_SEC	Number of Single Ended Outputs Supported This read-only field indicates the number of single ended channels which can be processed simultaneously. 0b - This design supports one single ended conversion at a time. 1b - This design supports two simultaneous single ended conversions.
10 CALOFSI	Calibration Function Implemented This read-only field indicates if the ADC contains hardware calibration functions. When supported, CTRL[CALOFS] and CTRL[CAL_REQ] can be used to request the calibration routines to run. 0b - Calibration Not Implemented. 1b - Calibration Implemented.
9 IADCKI	Internal ADC Clock Implemented This read-only field indicates if this implementation of the ADC block includes an internal clock source. When supported, the CFG[ADCKEN] field is available and documented for enabling the clock source. When available, this clock source is used in clock selection logic external to the module for use within the system. 0b - Internal clock source not implemented. 1b - Internal clock source (and CFG[ADCKEN]) implemented.
8 VR1RNGI	Voltage Reference 1 Range Control Bit Implemented This read-only field indicates if a control bit is implemented for selecting the input voltage range on Voltage Reference Option 1.When range control is required, the CFG[VREF1RNG] field is available and documented for controlling the Voltage Reference Option 1. 0b - Range control not required. CFG[VREF1RNG] is not implemented. 1b - Range control required. CFG[VREF1RNG] is implemented.
7 —	Reserved This read-only field is reserved and always has the value 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6-4 CSW	Channel Scale Width This read-only field indicates if channel scaling is supported by this implementation. When supported, each command buffer has a control field (CMDLa[CSCALE]) for setting input scaling. 000b - Channel scaling not supported. CSCALE control field not implemented. 001b - Channel scaling supported. 1-bit CSCALE control field. 110b - Channel scaling supported. 6-bit CSCALE control field.
3 MVI	Multi Vref Implemented This read-only field indicates if multiple Voltage Reference High inputs are supported by this implementation. When multiple voltage references are supported, the CFG[REFSEL] field is available and documented for selecting the Voltage Reference High options. 0b - Single voltage reference high (VREFH) input supported. 1b - Multiple voltage reference high (VREFH) inputs supported.
2 —	Reserved This read-only field is reserved and always has the value 0.
1 DIFFEN	Differential Supported This read-only field indicates if differential operation is supported by this implementation. When supported, each command buffer has control fields (CMDLa[CTYPE]) for configuring for differential operation and expanding the number of supported channels from 32 to 64. 0b - Differential operation not supported. 1b - Differential operation supported. CMDLa[CTYPE] controls fields implemented.
0 RES	Resolution This read-only field indicates the maximum accuracy supported by this implementation. When RES=1, each command buffer has a control field (CMDLa[MODE]) for selecting resolution of conversions for the associated command. 0b - Up to 13-bit differential/12-bit single ended resolution supported. 1b - Up to 16-bit differential/16-bit single ended resolution supported.

80.6.3 Parameter Register (PARAM)

Offset

Register	Offset
PARAM	4h

Function

The Parameter register indicates the size of several variable integration options for this instance on the device.

23-16 CV_NUM	Compare Value Number Number of compare value registers implemented.
15-8 FIFOSIZE	Result FIFO Depth The maximum number of conversion datawords that can be stored in the result FIFO before an overflow occurs. This field is read-only. 0000_0001b - Result FIFO depth = 2 dataword. 0000_0100b - Result FIFO depth = 4 datawords. 0000_1000b - Result FIFO depth = 8 datawords. 0001_0000b - Result FIFO depth = 16 datawords. 0010_0000b - Result FIFO depth = 32 datawords. 0100_0000b - Result FIFO depth = 64 datawords.
7-0 TRIG_NUM	Trigger Number Number of Triggers implemented.

80.6.4 Control Register (CTRL)

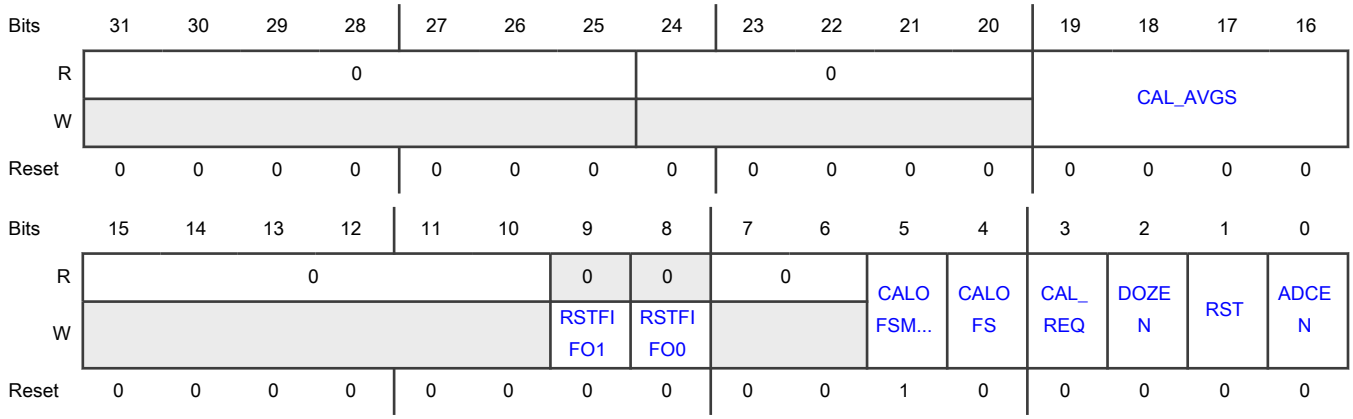
Offset

Register	Offset
CTRL	10h

Function

Control Register includes primary control bits.

Diagram



Fields

Field	Function
31-25 —	Reserved This read-only field is reserved and always has the value 0.
24-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 CAL_AVGS	Auto-Calibration Averages Selects how many ADC conversions are averaged to calculate each calibration value. Selecting a higher number of averages will lead to more accurate conversions after completing calibration. The recommended minimum setting is for 256 averaging (CAL_AVGS set to 0x8 or greater). The CAL_AVGS bit field applies to both CALOFS and CAL_REQ calibration types. This value should be fixed when requesting and running calibration with CTRL[CAL_REQ] or CTRL[CALOFS]. 0000b - Single conversion. 0001b - 2 conversions averaged. 0010b - 4 conversions averaged. 0011b - 8 conversions averaged. 0100b - 16 conversions averaged. 0101b - 32 conversions averaged. 0110b - 64 conversions averaged. 0111b - 128 conversions averaged. 1000b - 256 conversions averaged. 1001b - 512 conversions averaged. 1010b - 1024 conversions averaged.
15-10 —	Reserved This read-only field is reserved and always has the value 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 RSTFIFO1	Reset FIFO 1 0b - No effect. 1b - FIFO 1 is reset.
8 RSTFIFO0	Reset FIFO 0 0b - No effect. 1b - FIFO 0 is reset.
7-6 —	Reserved This read-only field is reserved and always has the value 0.
5 CALOFSMODE	Configure Mode for Offset Calibration Function When CALOFSMODE=1, Executing the offset calibration function configures the analog block for 16-bit mode and results are updated to the OFSTRIM16 register. When CALOFSMODE=0, Executing the offset calibration function configures the analog block for 12-bit mode and results are updated to the OFSTRIM12 register. 0b - Configure offset calibration for 12-bit mode. 1b - Configure offset calibration for 16-bit mode.
4 CALOFS	Offset Calibration Request Setting CALOFS to 1 initiates a hardware offset calibration calculation. The CTRL[CALOFSMODE] setting controls whether a 16 bit Offset Calibration or a 12 bit Offset Calibration is executed. Any conversions in progress are completed before launching the offset calibration function. After being accepted, the ADC calculates the offset value and depending on the CTRL[CALOFSMODE] setting updates either the OFSTRIM16 or the OFSTRIM12 register automatically. The CALOFS bit is cleared by hardware upon completion of the offset calibration calculation. The STAT[CAL_RDY] bit indicates when the offset calibration routine has completed. 0b - Calibration function disabled 1b - Request for offset calibration function
3 CAL_REQ	Auto-Calibration Request Request the hardware calibration routine to run. This bit is automatically cleared when the system accepts the hardware calibration request. Note, the status flag STAT[CAL_RDY] will indicate when this calibration routine has been completed. 0b - No request for hardware calibration has been made. 1b - A request for hardware calibration has been made
2 DOZEN	Doze Enable Controls system transition to Deepsleep/Sleep power modes while ADC is converting. When DOZEN is clear, immediate entries to Deepsleep or Sleep modes are allowed and ADC conversion functions remain enabled. Any conversion in progress is not disrupted. Note that the selected clock source provided from the on-chip clock source must be able to continue operating. When the DOZEN bit is set, If the ADC is actively converting, when the system is entering in low power mode, the ADC waits for

Table continues on the next page...

Table continued from the previous page...

Field	Function
	the current averaging iteration/FIFO storage to complete before acknowledging low power entry request. After system entry to the low power state, the ADC is kept in inactive state until the system exits the low power state. When the system is entering Deep Powerdown mode, the DOZEN bit is ignored and the ADC waits for the current transfer to complete any pending operation. 0b - ADC is enabled in low power mode. 1b - ADC is disabled in low power mode.
1 RST	Software Reset Resets all internal logic and registers, except the Control Register. Remains set until cleared by software. 0b - ADC logic is not reset. 1b - ADC logic is reset.
0 ADCEN	ADC Enable 0b - ADC is disabled. 1b - ADC is enabled.

80.6.5 Status Register (STAT)

Offset

Register	Offset
STAT	14h

Function

The Status Register provides the current status of the ADC module.

Diagram

Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 CMDACT	Command Active CMDACT is a read-only status field indicating the command that is actively being processed. Note, commands are only shown here when they are actively being processed by the SAR routine. Use CMDACT in conjunction with ADC_ACTIVE to determine which conversion is running. 0000b - No command is currently in progress. 0001b - Command 1 currently being executed. 0010b - Command 2 currently being executed. 0011b-1111b - Associated command number is currently being executed.
23-19 —	Reserved This read-only field is reserved and always has the value 0.
18-16 TRGACT	Trigger Active TRGACT is a read-only status field indicating the trigger actively being processed. This can be used to determine which trigger is running through a trigger delay or being converted by the SAR routine. The command associated with TRGACT will be running through a conversion when CMDACT is non-zero. 000b - Command (sequence) associated with Trigger 0 currently being executed. 001b - Command (sequence) associated with Trigger 1 currently being executed. 010b - Command (sequence) associated with Trigger 2 currently being executed. 011b-111b - Command (sequence) from the associated Trigger number is currently being executed.
15-12 —	Reserved This read-only field is reserved and always has the value 0.
11 ADC_ACTIVE	ADC Active This flag shows if the module is currently processing a conversion, or has pending triggers to service. When the ADC is IDLE, this bit is set to 0b0. 0b - The ADC is IDLE. There are no pending triggers to service and no active commands are being processed. 1b - The ADC is processing a conversion, running through the power up delay, or servicing a trigger.
10 CAL_RDY	Calibration Ready This flag shows if the adc CTRL[CAL_REQ] or CTRL[CALOFS] request for calibration has been completed and the results are ready. This flag is automatically cleared when a new hardware calibration or offset calibration request is made.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Calibration is incomplete or hasn't been ran. 1b - The ADC is calibrated.
9 TCOMP_INT	Interrupt Flag For Trigger Completion When a trigger sequence has been completed (all associated commands have been run) the TCOMP_INT flag is asserted. Note that IE[TCOMP_IE] must be set for the specific trigger source to flag an interrupt upon completion. 0b - Either IE[TCOMP_IE] is set to 0, or no trigger sequences have run to completion. 1b - Trigger sequence has been completed and all data is stored in the associated FIFO.
8 TEXC_INT	Interrupt Flag For High Priority Trigger Exception When a high priority trigger exception has occurred and CFG[TRES] = 0, this flag is asserted. This flag only asserts if trigger exception interrupts are enabled (IE[TEXC_IE] = 0x1). This flag can be used in conjunction with TSTAT[TEXC_NUM] to resolve which trigger source was interrupted. 0b - No trigger exceptions have occurred. 1b - A trigger exception has occurred and is pending acknowledgement.
7-4 —	Reserved This read-only field is reserved and always has the value 0.
3 FOF1	Result FIFO1 Overflow Flag Indicates that more data has been written to the Result FIFO1 than it can hold. The newer data is not stored and the FIFO remains holding the original contents. This flag asserts regardless of the value of IE[FOFIE1]. However, an interrupt request is issued only if IE[FOFIE1] is set. This flag is cleared by writing a 1. 0b - No result FIFO1 overflow has occurred since the last time the flag was cleared. 1b - At least one result FIFO1 overflow has occurred since the last time the flag was cleared.
2 RDY1	Result FIFO1 Ready Flag Indicates when the number of valid datawords in the result FIFO1 is greater than the watermark level set in the FCTRL[FWMARK] bitfield. This flag asserts regardless of the value of IE[FWMIE1]. However, an interrupt request or DMA request occurs only when the associated control bit (IE[FWMIE1] and DE[FWMDE1]) is set. This flag is cleared when the FCTRLa[FCOUNT] (which decrements on each read of the RESFIFO register) is less than or equal to the watermark level set in the FCTRL[FWMARK] bitfield. 0b - Result FIFO1 data level not above watermark level. 1b - Result FIFO1 holding data above watermark level.
1 FOF0	Result FIFO 0 Overflow Flag Indicates that more data has been written to the Result FIFO 0 than it can hold. The newer data is not stored and the FIFO remains holding the original contents. This flag asserts regardless of the value of

Table continues on the next page...

Table continued from the previous page...

Field	Function
	IE[FOFIE0]. However, an interrupt request is issued only if IE[FOFIE0] is set. This flag is cleared by writing a 1. 0b - No result FIFO 0 overflow has occurred since the last time the flag was cleared. 1b - At least one result FIFO 0 overflow has occurred since the last time the flag was cleared.
0 RDY0	Result FIFO 0 Ready Flag Indicates when the number of valid datawords in the result FIFO 0 is greater than the watermark level set in the FCTRL[FWMARK] bitfield. This flag asserts regardless of the value of IE[FWMIE0]. However, an interrupt request or DMA request occurs only when the associated control bit (IE[FWMIE0] and DE[FWMDE0]) is set. This flag is cleared when the FCTRLa[FCOUNT] (which decrements on each read of the RESFIFO register) is less than or equal to the watermark level set in the FCTRL[FWMARK] bitfield. 0b - Result FIFO 0 data level not above watermark level. 1b - Result FIFO 0 holding data above watermark level.

80.6.6 Interrupt Enable Register (IE)

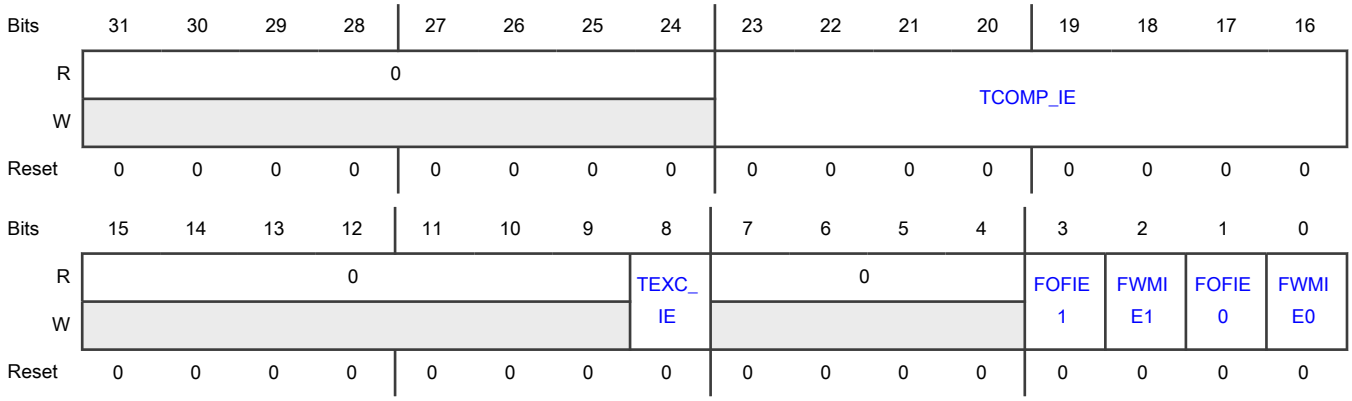
Offset

Register	Offset
IE	18h

Function

Interrupt Enable Register includes system interrupt masking control bits.

Diagram



Fields

Field	Function
31-24 —	Reserved This read-only field is reserved and always has the value 0.
23-16 TCOMP_IE	Trigger Completion Interrupt Enable Each bit in TCOMP_IE corresponds to a trigger source. (TCOMP_IE[0] corresponds to trigger 0, TCOMP_IE[1] corresponds to trigger 1, ...) A trigger completion interrupt is used to indicate when a complete trigger command sequence has been executed. All results will be stored in the FIFO when a sequence is considered complete. 0000_0000b - Trigger completion interrupts are disabled. 0000_0001b - Trigger completion interrupts are enabled for trigger source 0 only. 0000_0010b - Trigger completion interrupts are enabled for trigger source 1 only. 0000_0011b-1111_1110b - Associated trigger completion interrupts are enabled. 1111_1111b - Trigger completion interrupts are enabled for every trigger source.
15-9 —	Reserved This read-only field is reserved and always has the value 0.
8 TEXC_IE	Trigger Exception Interrupt Enable This register field enables the ADC to assert an interrupt request when a high priority trigger exception occurs. TSTAT[TEXC_NUM] will contain the value of the corresponding trigger which was affected by the exception. 0b - Trigger exception interrupts are disabled. 1b - Trigger exception interrupts are enabled.
7-4 —	Reserved This read-only field is reserved and always has the value 0.
3 FOFIE1	Result FIFO1 Overflow Interrupt Enable Configures the module to generate overflow interrupt requests when FOF1 flag is asserted. 0b - No result FIFO1 overflow has occurred since the last time the flag was cleared. 1b - At least one result FIFO1 overflow has occurred since the last time the flag was cleared.
2 FWMIE1	FIFO1 Watermark Interrupt Enable Configures the module to generate watermark interrupt requests when STAT[RDY1] flag is asserted. 0b - FIFO1 watermark interrupts are not enabled. 1b - FIFO1 watermark interrupts are enabled.
1 FOFIE0	Result FIFO 0 Overflow Interrupt Enable Configures the module to generate overflow interrupt requests when FOF flag is asserted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - FIFO 0 overflow interrupts are not enabled. 1b - FIFO 0 overflow interrupts are enabled.
0 FWMIE0	FIFO 0 Watermark Interrupt Enable Configures the module to generate watermark interrupt requests when STAT[RDY0] flag is asserted. 0b - FIFO 0 watermark interrupts are not enabled. 1b - FIFO 0 watermark interrupts are enabled.

80.6.7 DMA Enable Register (DE)

Offset

Register	Offset
DE	1Ch

Function

DMA Enable Register includes DMA request masking control bits.

30	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	This read-only field is reserved and always has the value 0.
29 —	Reserved This read-only field is reserved and always has the value 0.
28 PWREN	ADC Analog Pre-Enable Enables the ADC analog circuits. When setting CFG[PWREN], user code should delay for a period exceeding the analog startup time of $t_{ADCSTUP}$ before enabling the ADC for operation. The module is still operational even when CFG[PWREN] is left clear but command execution start is delayed for a period defined by CFG[PUDLY]. Refer to the device datasheet for ADC idle and ADC active power consumption parameters. 0b - ADC analog circuits are only enabled while conversions are active. Performance is affected due to analog startup delays. 1b - ADC analog circuits are pre-enabled and ready to execute conversions without startup delays (at the cost of higher DC current consumption). Note that a single power up delay (CFG[PUDLY]) is executed immediately once PWREN is set, and any detected trigger does not begin ADC operation until the power up delay time has passed. After this initial delay expires the analog remains pre-enabled and no additional delays are executed.
27-24 —	Reserved This read-only field is reserved and always has the value 0.
23-16 PUDLY	Power Up Delay The PUDLY must be programmed to a non-zero value to enable the ADC. Note, the PUDLY is executed in one of two modes depending on the value configured in PWREN: When CFG[PWREN]=0b0, the ADC analog circuits are only powered on while the module is active. The delay defined by CFG[PUDLY] is executed after an initial trigger transitions the ADC from its Idle state. This delay allows time for the analog circuits to stabilize after being powered on. The startup delay count of (PUDLY*4) ADCK cycles must result in a longer delay than the analog startup time of $t_{ADCSTUP}$. Accuracy of the initial conversion(s) after activation is degraded if CFG[PUDLY] is set to too small a value. At the end of active conversions, if there are no subsequent pending conversions, the ADC analog is automatically reverted back to its low power idle state and the PUDLY runs again after the ADC is awakened with a later trigger. When CFG[PWREN]=0b1 prior to ADC activation, the analog circuits are pre-enabled and the activation delay defined by CFG[PUDLY] is executed immediately. After the delay has been executed, the analog remains enabled regardless of ADC activity. This configuration has the benefit of beginning conversions immediately after trigger event detection at the cost of increased DC power consumption of the analog circuits. Note, the ADC does not begin an initial conversion until the PUDLY has been executed regardless of the PWREN setting.
15 —	Reserved This read-only field is reserved and always has the value 0.
14-11	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	This read-only field is reserved and always has the value 0.
10 HPT_EXDI	High Priority Trigger Exception Disable Controls how higher priority trigger events are handled. See section Trigger detect and command execution for a detailed description on trigger exception handling. 0b - High priority trigger exceptions are enabled. 1b - High priority trigger exceptions are disabled.
9 TCMDRES	Trigger Command Resume Determines where to resume from a high priority trigger exception. CFG[TRES] must be asserted for TCMDRES to be used. If asserted, the interrupted trigger sequence is resumed from the command where it was interrupted. If de-asserted the trigger sequence is restarted from the beginning. **NOTE** The trigger interrupted when TCMDRES = 1b, will be resumed at the command it was interrupted and if in LOOP mode, the CMDHa[LOOP] count will always re-start back at 1st loop count iteration. 0b - Trigger sequences interrupted by a high priority trigger exception is automatically restarted. 1b - Trigger sequences interrupted by a high priority trigger exception is resumed from the command executing before the exception.
8 TRES	Trigger Resume Enable Determines what happens after completing a high priority trigger exception. If CFG[TRES] is asserted, the interrupted trigger sequence is resumed or restarted automatically. The sequence can be resumed along command boundaries or restarted from the beginning of a sequence. This is controlled by CFG[TCMDRES]. If CFG[TRES] is de-asserted an interrupted trigger sequence does not resume automatically. In this case, interrupted triggers can be resumed via software by monitoring STAT[TEXC_INT] bit (or ISR handling for a trigger exception interrupt when IE[TEXC_IE] is set). Software determines which trigger was interrupted by reading TSTAT[TEXC_NUM] and re-starts the trigger with a write of 1 to the corresponding SWTRIG[SWTx] bit. 0b - Trigger sequences interrupted by a high priority trigger exception are not automatically resumed or restarted. 1b - Trigger sequences interrupted by a high priority trigger exception are automatically resumed or restarted.
7-6 REFSEL	Voltage Reference Selection Selects the voltage reference high used for conversions. **NOTE** See the chip-specific ADC information on the voltage reference options specific to this packaged device. 00b - (Default) Option 1 setting.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Option 2 setting. 10b - Option 3 setting. 11b - Reserved
5-2 —	Reserved This read-only field is reserved and always has the value 0.
1-0 TPRICTRL	ADC Trigger Priority Control Controls how higher priority trigger exceptions are handled. See Trigger detect and command execution for a detailed explanation trigger event handling. 00b - If a higher priority trigger is detected during command processing, the current conversion is aborted and the new command specified by the trigger is started. 01b - If a higher priority trigger is received during command processing, the current command is stopped after completing the current conversion. If averaging is enabled, the averaging loop will be completed. However, CMDHa[LOOP] will be ignored and the higher priority trigger will be serviced. 10b - If a higher priority trigger is received during command processing, the current command will be completed (averaging, looping, compare) before servicing the higher priority trigger. 11b - RESERVED

80.6.9 Pause Register (PAUSE)

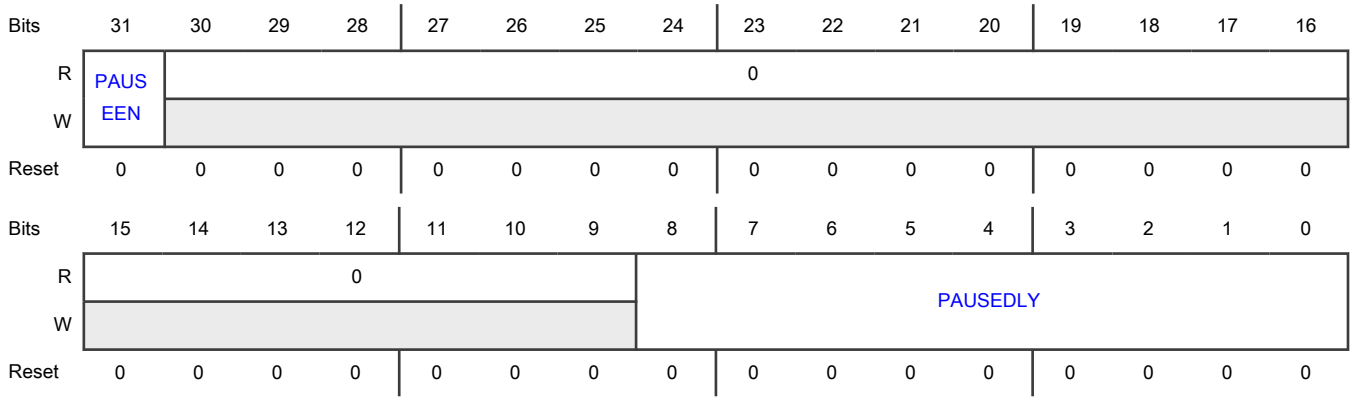
Offset

Register	Offset
PAUSE	24h

Function

The Pause Register controls an optional inserted delay between conversions. Note, the PAUSE register should not be modified while the CTRL[ADCEN] bit is set.

Diagram



Fields

Field	Function
31 PAUSEEN	PAUSE Option Enable Enables the ADC pausing function. When enabled, a programmable delay is inserted during command execution sequencing between LOOP iterations, between commands in a sequence, and between conversions when command is executing in for "Compare Until True" configuration. Note, CMDHa[WAIT_TRIG] and PAUSE are mutually exclusive. CMDHa[WAIT_TRIG] will take priority over PAUSE between commands when both are enabled. 0b - Pause operation disabled 1b - Pause operation enabled
30-9 —	Reserved This read-only field is reserved and always has the value 0.
8-0 PAUSEDLY	Pause Delay When PAUSEEN is set, the PAUSEDLY field controls the duration of pausing during command execution sequencing. The pause delay is a count of (PAUSEDLY*4) ADCK cycles.

80.6.10 Software Trigger Register (SWTRIG)

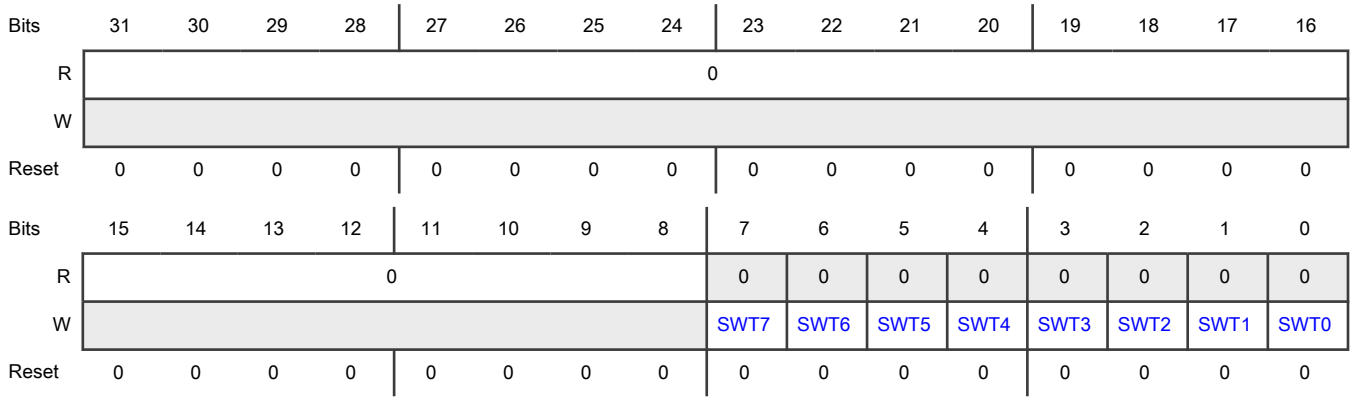
Offset

Register	Offset
SWTRIG	34h

Function

The Software Trigger Register (SWTRIG) is written to initiate software triggered conversions. Writes to SWTRIG register are ignored while CTRL[ADCEN] is clear. Note that there is an approximately 3 ADC Clock cycle synchronization delay between asserting CTRL[ADCEN] until SWTRIG can be accepted.

Diagram



Fields

Field	Function

2 SWT2	Software Trigger 2 Event Write 1 to SWT2 generates a trigger 2 event. Writing 1 to SWT2 is ignored while the trigger 2 event is being serviced or is pending. 0b - No trigger 2 event generated. 1b - Trigger 2 event generated.
1 SWT1	Software Trigger 1 Event Write 1 to SWT1 generates a trigger 1 event. Writing 1 to SWT1 is ignored while the trigger 1 event is being serviced or is pending. 0b - No trigger 1 event generated. 1b - Trigger 1 event generated.
0 SWT0	Software Trigger 0 Event Write 1 to SWT0 generates a trigger 0 event. Writing 1 to SWT0 is ignored while the trigger 0 event is being serviced or is pending. 0b - No trigger 0 event generated. 1b - Trigger 0 event generated.

80.6.11 Trigger Status Register (TSTAT)

Offset

Register	Offset
TSTAT	38h

Function

This register contains status flags to indicate when trigger sequences have been completed or interrupted by a high priority trigger exception. Each bit in this register is set by hardware and cleared by software. To clear a bit in this register, write a 0b1 to the corresponding bit position.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	0000_0010b - Trigger 1 has been interrupted by a high priority exception. 0000_0011b-1111_1110b - Associated trigger sequence has interrupted by a high priority exception. 1111_1111b - Every trigger sequence has been interrupted by a high priority exception.

80.6.12 Offset Trim 16 bit Register (OFSTRIM16)

Offset

Register	Offset
OFSTRIM16	40h

Function

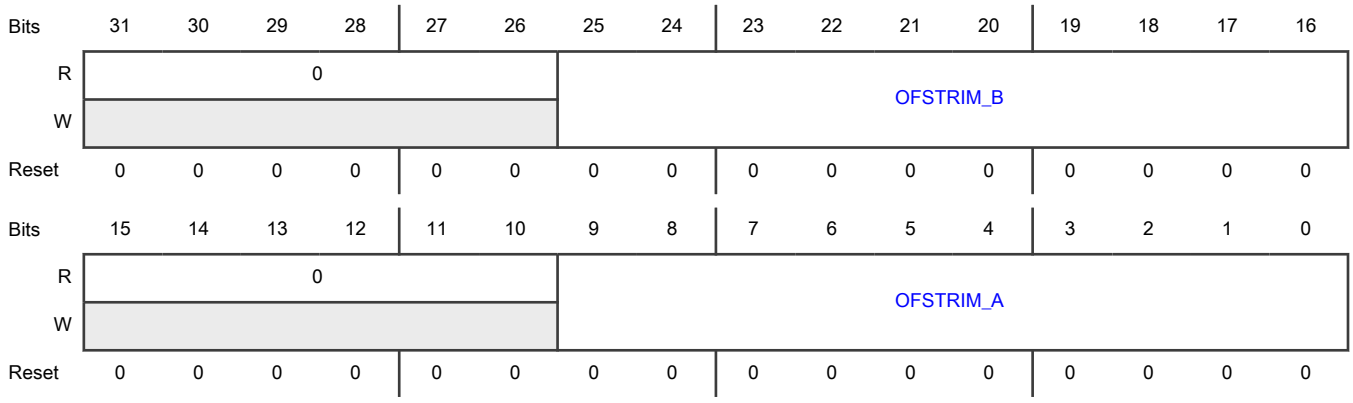
The Offset Trim 16 bit register is used to trim for comparator offset for 16 bit ADC conversions (CMDLa[MODE] == 0b1). The ADC supports an offset calibration function in which the OFSTRIM16 register is automatically updated.

To trigger the automatic update of OFSTRIM16, set the CTRL[CALOFS] bit with CTRL[CALOFSMODE] set to 0b1. Upon completion of the offset calibration sequence, the STAT[CAL_RDY] bit is set to 0b1 and the OFSTRIM16[OFSTRIM_A] and OFSTRIM16[OFSTRIM_B] bitfields are updated with 10-bit signed values.

The OFSTRIM16[OFSTRIM_A] and OFSTRIM16[OFSTRIM_B] values are used to minimize offset for normal 16 bit conversions (when CMDLa[MODE] is set). The OFSTRIM registers support a range of -512 to 511. Each increment is 1/2 LSB resulting in a programmable offset range of -256 to +255.5 LSB for 16-bit conversions.

The OFSTRIM16 trim values are also used in the calibration function.

Diagram



Fields

Field	Function
31-26 —	Reserved This read-only field is reserved and always has the value 0.
25-16 OFSTRIM_B	Trim for Offset in B-side Converter for 16-bit Conversions OFSTRIM_B is a 10-bit signed value between -512 and 511. This value is subtracted from the raw ADC B-side conversion result.
15-10 —	Reserved This read-only field is reserved and always has the value 0.
9-0 OFSTRIM_A	Trim for Offset in A-side Converter for 16-bit Conversions OFSTRIM_A is a 10-bit signed value between -512 and 511. This value is subtracted from the raw ADC A-side conversion result.

80.6.13 Offset Trim 12 bit Register (OFSTRIM12)

Offset

Register	Offset
OFSTRIM12	44h

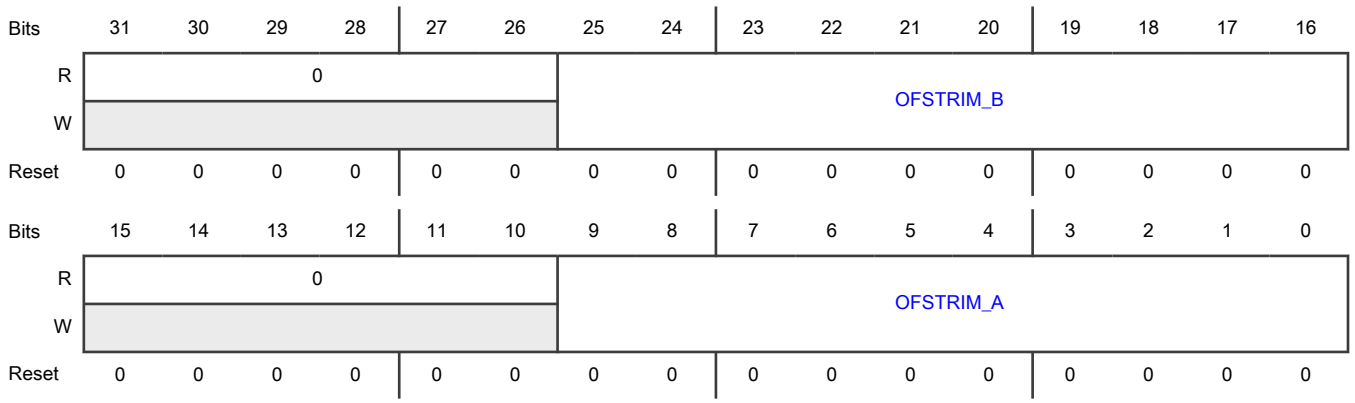
Function

The Offset Trim 12 bit register is used to trim for comparator offset for 12 bit ADC conversions (CMDLa[MODE] == 0b0). The ADC supports an offset calibration function in which the OFSTRIM12 register is automatically updated.

To trigger the automatic update of OFSTRIM12, set the CTRL[CALOFS] bit with CTRL[CALOFSMODE] set to 0b0. Upon completion of the offset calibration sequence, the STAT[CAL_RDY] bit is set to 0b1 and the OFSTRIM12[OFSTRIM_A] and OFSTRIM12[OFSTRIM_B] bitfields are updated with 10-bit signed values.

The OFSTRIM12[OFSTRIM_A] and OFSTRIM12[OFSTRIM_B] values are used to minimize offset for normal 12 bit conversions (when CMDLa[MODE] is clear). The OFSTRIM registers support a range of -512 to 511. Each increment is 1/32 LSB resulting in a programmable offset range of -16 to +15.96875 LSB for 12-bit conversions.

Diagram



Fields

Field	Function
31-26 —	Reserved This read-only field is reserved and always has the value 0.
25-16 OFSTRIM_B	Trim for Offset in B-side Converter for 12-bit Conversions OFSTRIM_B is a 10-bit signed value between -512 and 511. This value is subtracted from the raw ADC B-side conversion result.
15-10 —	Reserved This read-only field is reserved and always has the value 0.
9-0 OFSTRIM_A	Trim for Offset in A-side Converter for 12-bit Conversions OFSTRIM_A is a 10-bit signed value between -512 and 511. This value is subtracted from the raw ADC A-side conversion result.

80.6.14 Trigger Control Register (TCTRL0 - TCTRL7)

Offset

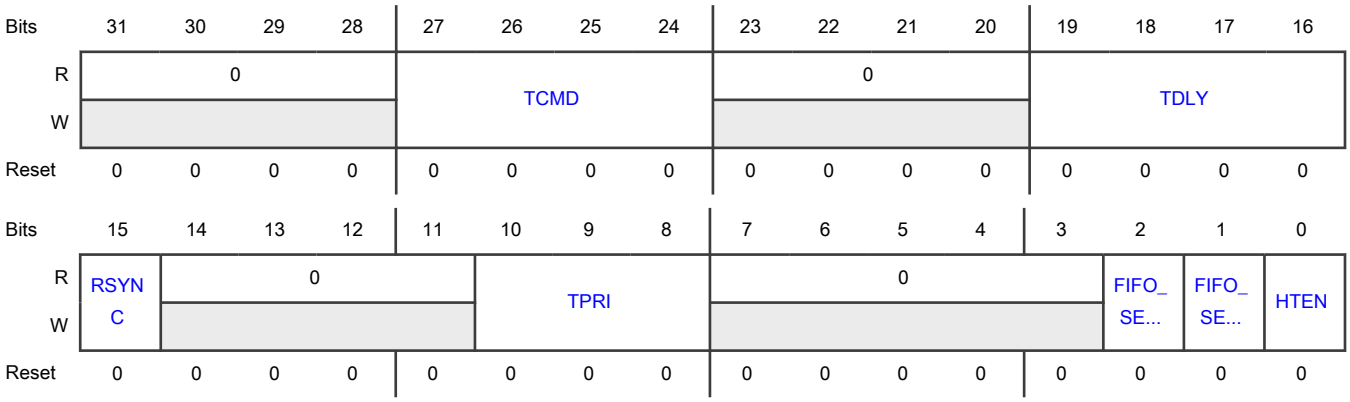
For a = 0 to 7:

Register	Offset
TCTRLa	A0h + (a × 4h)

Function

The Trigger Control (TCTRLa) register implements control fields associated with each implemented trigger source. When the ADC is actively executing commands, only one of the TCTRLa registers is actively controlling ADC conversions. The actively controlling TCTRLa register should not be updated while the ADC is active. A write to a TCTRLa registers while that trigger control register is controlling the ADC operation may cause unpredictable behavior.

Diagram



Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 TCMD	Trigger Command Select Selects the command from command buffer to execute upon detection of the associated trigger event. When a trigger is received while the ADC is busy converting and the new trigger has higher priority than the trigger associated with the current command being executed, the command in this register, associated with the new trigger, is executed under control of CFG[TPRICTRL]. See section Trigger detect and command execution for a more detailed description on the relationship between CFG[TPRICTRL] and TCMD. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - CMD1 is executed 0010b-1110b - Corresponding CMD is executed 1111b - CMD15 is executed
23-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 TDLY	Trigger Delay Select Selects the trigger delay duration to wait at the start of servicing a trigger event. Each trigger source has an associated programmable delay prior to beginning an initial conversion. When TDLY field is clear, then no delay is incurred. When TDLY is set to a non-zero value, the duration for the delay is 2^{TDLY} ADCK cycles.
15 RSYNC	Trigger Resync If RSYNC is set to 1, this trigger source will be used as a resync trigger. A resync trigger can be configured to restart or abort a running trigger sequence (the target). Each resync trigger is configured to have a resync target. When a resync trigger is asserted, the target sequence will be aborted, the target FIFO destination(s) will be cleared, and the target sequence can optionally be restarted depending on CFG[TRES]. Multiple conditions must be met for a resync trigger to execute properly. 1. The resync trigger must have higher priority than the resync target. 2. The resync trigger TCTRLa[RSYNC] must be set to 0b1. 3. The resync target, specified by TCTRLa[TCMD], must be executing when the resync trigger is asserted. Please see Resync functionality for more information.
14-11 —	Reserved This read-only field is reserved and always has the value 0.
10-8 TPRI	Trigger Priority Setting This bitfield sets the priority of the associated trigger source. If two or more triggers have the same priority level setting, the lower order trigger event has the higher priority (e. g., if Trigger 0 and Trigger

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1 are both pending triggers and TCTRL0[TPRI] is configured the same as TCTRL1[TPRI], then the command associated with Trigger 0 is serviced first). 000b - Set to highest priority, Level 1 001b-110b - Set to corresponding priority level 111b - Set to lowest priority, Level 8
7-3 —	Reserved This read-only field is reserved and always has the value 0.
2 FIFO_SEL_B	SAR Result Destination for Channel B This register field is only used during dual single-ended mode CMDLa[CTYPE]=0b11. In this mode, the SAR result from Channel B will be written to the FIFO number specified by TCTRLa[FIFO_SEL_B]. See Sampling modes for more information. 0b - Result written to FIFO 0 1b - Result written to FIFO 1
1 FIFO_SEL_A	SAR Result Destination for Channel A Conversion results will be stored in the FIFO number specified by TCTRLa[FIFO_SEL_A] under the following conditions: Single ended mode: CMDLa[CTYPE]=0b01 or CMDLa[CTYPE]=0b00. Differential mode: CMDLa[CTYPE]=0b10. Dual single ended mode: CMDLa[CTYPE]=0b11. TCTRLa[FIFO_SEL_A] will provide the destination for all single ended conversions, differential conversions, and A side conversions in dual single-ended mode. 0b - Result written to FIFO 0 1b - Result written to FIFO 1
0 HTEN	Trigger Enable Enables hardware trigger source to initiate conversion on the rising-edge of the input trigger source. **NOTE** Enabling hardware trigger will not disable software triggers. 0b - Hardware trigger source disabled 1b - Hardware trigger source enabled

80.6.15 FIFO Control Register (FCTRL0 - FCTRL1)

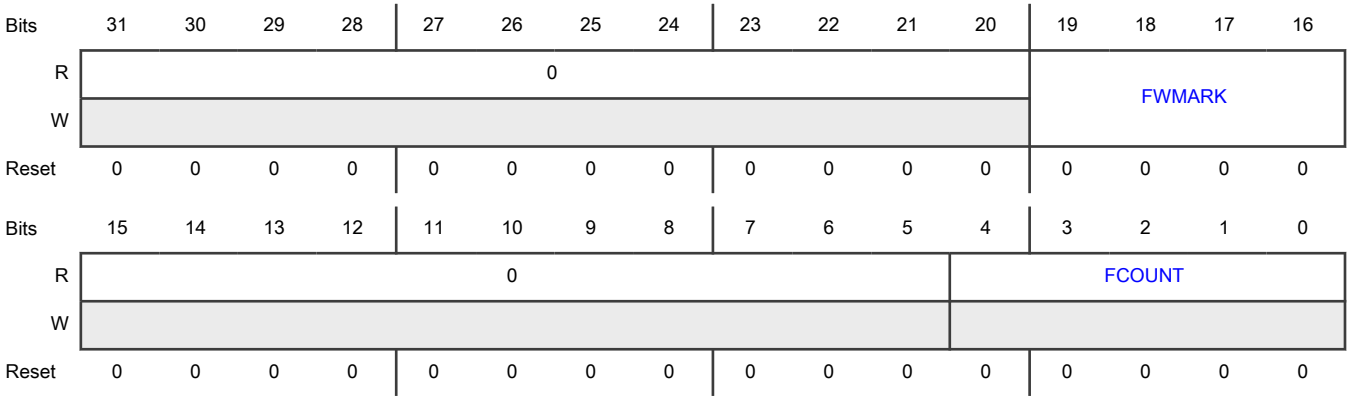
Offset

Register	Offset
FCTRL0	E0h
FCTRL1	E4h

Function

The FIFO Control (FCTRL*a*) registers contain control and status fields for each FIFO in the design. A programmable watermark can be set for each FIFO which can be used to trigger an interrupt. In addition, the number of entries stored in each FIFO can be monitored by reading FCTRLa[FCOUNT].

Diagram



Fields

Field	Function
31-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 FWMARK	Watermark Level Selection FWMARK is a programmable threshold setting. When the number of datawords stored in the ADC Result FIFO is greater than the value in FWMARK, the STAT[RDY] flag is asserted to indicate stored data has reached the programmable threshold. When IE[FWMIEx] is set, an interrupt request is generated. When DE[FWMDEx] is set, a DMA request is generated.
15-5 —	Reserved This read-only field is reserved and always has the value 0.
4-0 FCOUNT	Result FIFO Counter This read-only field indicates the number of datawords that are stored in the result FIFO. This value may be used in conjunction with PARAM[FIFOSIZE] to calculate how much room is left in the result FIFO. FCOUNT is incremented with each store of new data to the result FIFO and decrements with

Table continues on the next page...

Table continued from the previous page...

Field	Function
	each read of the result FIFO. The FIFO is reset by writing to the CTRL[RSTFIFOx] bit, resulting in FCTRLa[FCOUNT] initialized to 0x0.

80.6.16 Gain Calibration Control (GCC0 - GCC1)

Offset

Register	Offset
GCC0	F0h
GCC1	F4h

Function

The Gain Calibration Control register (GCC0 and GCC1) hold intermediate values that are utilized as part of the calibration steps. GCC0 is associated with the A-side converter and GCC1 is associated with the B-side converter. The GCCa[GAIN_CAL] field is calculated with hardware and auto updated during the calibration steps. Once the hardware calibration sequence has updated GCCa[GAIN_CAL] the GCCa[RDY] status flag is asserted automatically. Note that requesting a calibration routine automatically clears the GCCa[RDY] bit until the new GCCa[GAIN_CAL] value is calculated. For the calibration steps to be completed, further software processing is needed where the GCCa[GAIN_CAL] value is used to calculate the gain adjustment and the result is stored to GCRa[GCALR]. For more information see Calibration in the functional description.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	GAIN_CAL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-25 —	Reserved This read-only field is reserved and always has the value 0.
24	Hardware Calculated GAIN_CAL Value Ready This status flag indicates when the data stored in GCCa[GAIN_CAL] is valid.

Table continues on the next page...

Table continued from the previous page...

Field	Function
RDY	0b - The GAIN_CAL value is invalid. Run the hardware calibration routine for this value to be set. 1b - The GAIN_CAL value is valid. GAIN_CAL should be used by software to derive GCRa[GCALR].
23-16 —	Reserved This read-only field is reserved and always has the value 0.
15-0 GAIN_CAL	Gain Calibration Value GAIN_CAL is read-only. As part of the hardware calibration steps, GAIN_CAL is automatically updated with a 16-bit signed number and is used in the gain adjustment calculations to derive the value written to the GCRa[GCALR] register. For more information see Calibration in the functional description.

80.6.17 Gain Calculation Result (GCR0 - GCR1)

Offset

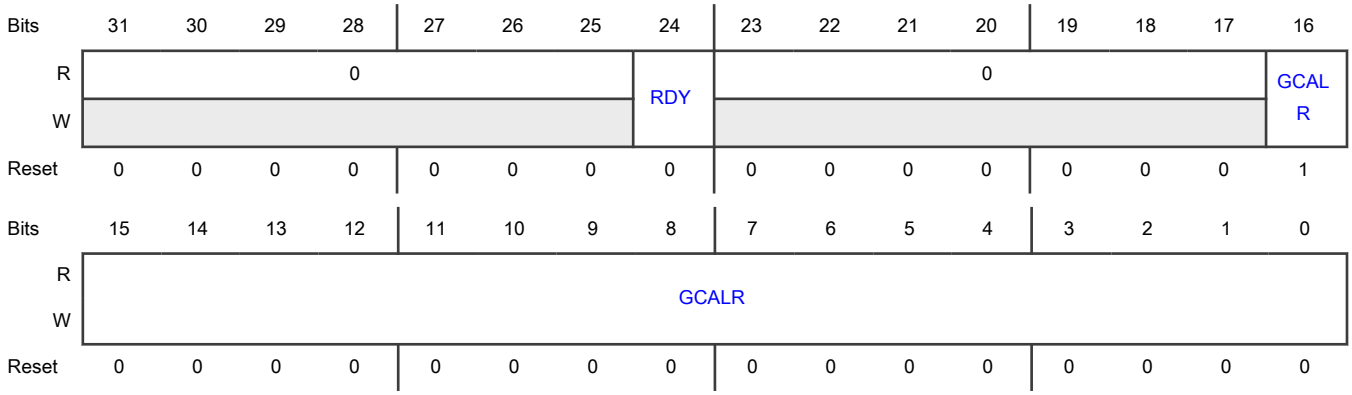
Register	Offset
GCR0	F8h
GCR1	FCh

Function

The Gain Calculation Result register (GCR0 and GCR1) is used during ADC conversions for automated gain error adjustment. GCR0 is associated with the A-side converter and GCR1 is associated with the B-side converter. Determining the values to store to GCC0[GCALR] and GCC1[GCALR] is the result of software calculations described in setup steps in Calibration. There is a RDY status flag in the GCR register which indicates whether the value GCRa[GCALR] is valid. Upon writing the GCRa[GCALR] value, the user should also assert GCRa[RDY] to indicate that the gain adjustment result is valid.

After beginning a calibration sequence by asserting CTRL[CAL_REQ], the calibration sequence is not complete until GCRa[GCALR] is calculated and GCRa[RDY] is asserted. The gain adjustment calculation results in a floating point value between 0 and 2. GCRa[GCALR][16] holds the integer value (0 or 1) and GCRa[GCALR][15:0] holds the 16-bit fractional component of the gain adjustment calculation. To convert the GCRa[GCALR] value back into the gain adjustment value in decimal format, this would be calculated as: 1*GCRa[16]+0.5*GCRa[15]+0.25*GCRa[14]+0.125*GCRa[13]+...

Diagram



Fields

Field	Function
31-25 —	Reserved This read-only field is reserved and always has the value 0.
24 RDY	Gain Calculation Ready The RDY flag indicates to the ADC when the data stored in GCRa[GCALR] is valid and is used for gain adjustment. The GCRa[GCALR] must be written from memory or calculated each time the calibration routine is run. The RDY flag must be asserted by the user after writing valid data into the GCALR field. The RDY flag is cleared automatically when requesting a new calibration sequence. 0b - The GCALR value is invalid. 1b - The GCALR value is valid.
23-17 —	Reserved This read-only field is reserved and always has the value 0.
16-0 GCALR	Gain Calculation Result This value holds the 17-bit value generated from the gain adjustment calculation during the calibration steps.

80.6.18 Command Low Buffer Register (CMDL1 - CMDL15)

Offset

For a = 1 to 15:

Register	Offset
CMDLa	F8h + (a × 8h)

Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDH*a*:CMDL*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling

command by association to a trigger event via configuration of the TCTRLa[TCMD] bitfield. When the ADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer should not be updated while the ADC is active. A write to a CMD buffer while that CMD buffer is controlling the ADC operation may cause unpredictable behavior.

NOTE

The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these are likely to be defined as two 15-element arrays that are indexed from 0. I.e., the type declaration would be:

```
unsigned int CMDH[15];

unsigned int CMDL[15];
```

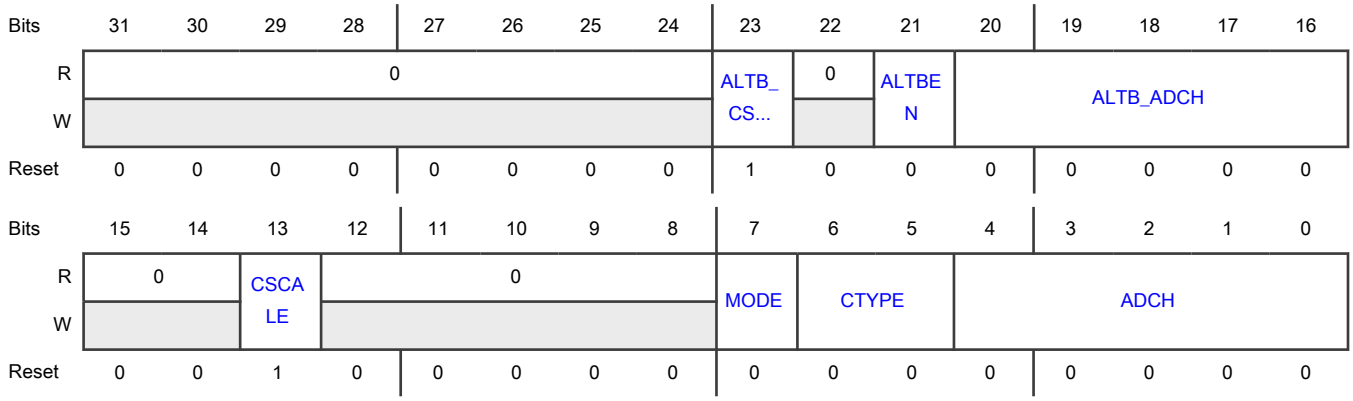
and software would access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

The CMDLa[ADCH] and CMDLa[CTYPE] bitfields control selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each ADCH channel selection has an associated A side and an associated B side input. Each ADCH pair can optionally be converted in a differential mode but only limited pairs are intended to be converted as differential channels (i.e., adjacent pins that have been designed with matched impedance). For the pin pairings available for differential conversions for your device, see the Chip Configuration details.

NOTE

Some of the input channels are from on-chip sources such as temperature sensors and reference voltage sources and may only be connected to individual instances of the ADC module. Some of the input channel options in the bitfield-setting descriptions may not be available for your device. Refer to chip-specific information for the channels supported on this device.

Diagram



Fields

Field	Function
31-24 —	Reserved This read-only field is reserved and always has the value 0.
23 ALTB_CSCALE	Alt Channel B Scale When ALTBEN is set, reduces the selected ADC analog channel B input voltage level by a factor. The maximum possible voltage on the ADC channel input should be considered when selecting a CSCALE value to ensure that the reducing factor always results voltage level at or below the selected voltage

Table continues on the next page...

Table continued from the previous page...

Field	Function
	reference. This reducing capability allows conversion of analog inputs higher than selected voltage reference. When ALTBEN is disabled, B-side channel inputs are both scaled using the CSCALE field. 0b - Scale selected analog channel (Factor of 1/2) 1b - (Default) Full scale (Factor of 1)
22 —	Reserved This read-only field is reserved and always has the value 0.
21 ALTBEN	Alternate Channel B Select Enable Enables the ALTB_ADCH to select the input for Channel B independent of ADCH register settings when CTYPE is configured to 0b01 or 0b11. **NOTE** Setting CTYPE to differential (0b10) will still work but not recommended 0b - ALTBEN_ADCH disabled. Channel A and Channel B inputs are selected based on ADCH settings. 1b - ALTBEN_ADCH enabled. Channel A inputs selected by ADCH setting and Channel B inputs selected by ALTB_ADCH setting.
20-16 ALTB_ADCH	Alternate Channel B Input Channel Select When ALTBEN is set, ALTB_ADCH selects the Channel B input when CTYPE is configured to 0b01 or 0b11. **NOTE** Some of the input channels are from internal resources such as temperature sensors and bandgap voltage sources and may only be connected to individual instances of the ADC module. Some of the input channel options in the bitfield-setting descriptions might not be available for your device. For the ADC channel assignments for your device, see the chip-specific information. 0_0000b - Select CH0B 0_0001b - Select CH1B 0_0010b - Select CH2B 0_0011b - Select CH3B 0_0100b-1_1101b - Select corresponding channel CHnB 1_1110b - Select CH30B 1_1111b - Select CH31B
15-14 —	Reserved This read-only field is reserved and always has the value 0.
13 CSCALE	Channel Scale Reduces the selected ADC analog channel input voltage level by a factor. The maximum possible voltage on the ADC channel input should be considered when selecting a CSCALE value to ensure that

Table continues on the next page...

Table continued from the previous page...

Field	Function
	the reducing factor always results voltage level at or below the selected voltage reference. This reducing capability allows conversion of analog inputs higher than selected voltage reference. A-side and B-side channel inputs are both scaled using the CSCALE field. 0b - Scale selected analog channel (Factor of 1/2) 1b - (Default) Full scale (Factor of 1)
12-8 —	Reserved This read-only field is reserved and always has the value 0.
7 MODE	Select Resolution of Conversions The MODE field, selects the ADC resolution. 0b - Standard resolution. Single-ended 12-bit conversion; Differential 13-bit conversion with 2's complement output. 1b - High resolution. Single-ended 16-bit conversion; Differential 16-bit conversion with 2's complement output.
6-5 CTYPE	Conversion Type Chooses how a pair of A and B channels are converted. 00b - Single-Ended Mode. Only A side channel is converted. 01b - Single-Ended Mode. Only B side channel is converted. 10b - Differential Mode. A-B. 11b - Dual-Single-Ended Mode. Both A side and B side channels are converted independently.
4-0 ADCH	Input Channel Select Each ADCH channel selection has an associated A side and an associated B side input. The ADCH setting in conjunction with the CTYPE bitfield settings selects the input from one of the channel inputs or one of the input pairs. See the CTYPE bitfield descriptions. **NOTE** Not all pairs are intended to be converted as differential channels. For the pin pairings available for differential conversions for your device, see the chip-specific information. **NOTE** Some of the input channels are from internal resources such as temperature sensors and bandgap voltage sources and may only be connected to individual instances of the ADC module. Some of the input channel options in the bitfield-setting descriptions might not be available for your device. For the ADC channel assignments for your device, see the chip-specific information. 0_0000b - Select CH0A or CH0B or CH0A/CH0B pair. 0_0001b - Select CH1A or CH1B or CH1A/CH1B pair. 0_0010b - Select CH2A or CH2B or CH2A/CH2B pair.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0_0011b - Select CH3A or CH3B or CH3A/CH3B pair. 0_0100b-1_1101b - Select corresponding channel CHnA or CHnB or CHnA/CHnB pair. 1_1110b - Select CH30A or CH30B or CH30A/CH30B pair. 1_1111b - Select CH31A or CH31B or CH31A/CH31B pair.

80.6.19 Command High Buffer Register (CMDH1 - CMDH4)

Offset

Register	Offset
CMDH1	104h
CMDH2	10Ch
CMDH3	114h
CMDH4	11Ch

Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDH*a*:CMDL*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of the TCTRLa[TCMD] bitfield. When the ADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer should not be updated while the ADC is active. A write to a CMD buffer while that CMD buffer that is controlling ADC operation may result in unpredictable behavior.

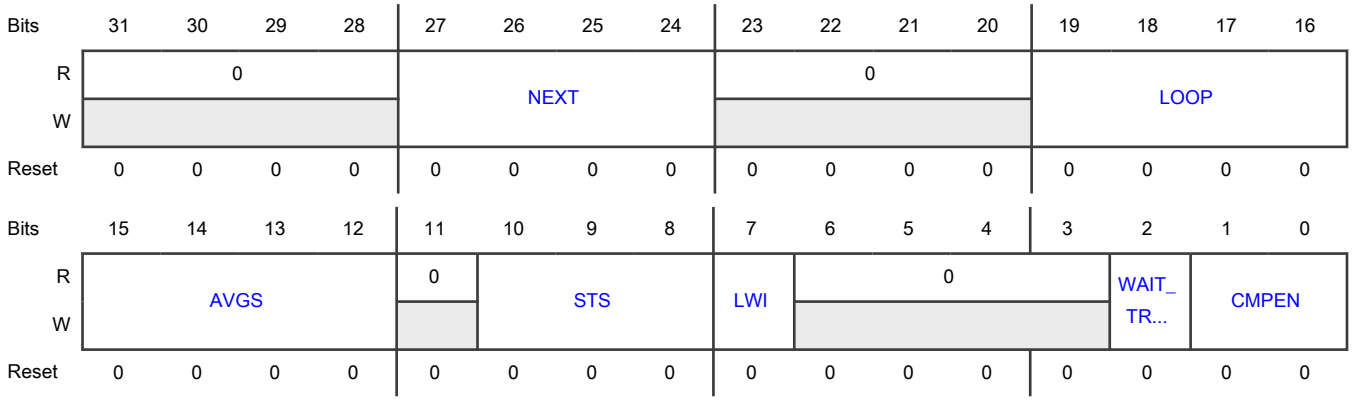
NOTE

The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these are likely to be defined as two 15-element arrays that are indexed from 0. I.e., the type declaration would be:

```
unsigned int CMDH[15];
unsigned int CMDL[15];
```

and software would access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

Diagram



Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 NEXT	Next Command Select Selects the next command to be executed after this command completes. Multiple commands can be configured in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order and the order of execution is strictly controlled by the NEXT field (for example, a sequence of commands could be CMD2 to CMD1 to CMD3). Unending circular command execution is allowed by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0x0 causes conversions to terminate at the completion of the command. Lower priority trigger events cannot be serviced until a higher priority triggered command (or sequence of commands) completes. 0000b - No next command defined. Terminate conversions at completion of current command. If lower priority trigger pending, begin command associated with lower priority trigger. 0001b - Select CMD1 command buffer register as next command. 0010b-1110b - Select corresponding CMD command buffer register as next command 1111b - Select CMD15 command buffer register as next command.
23-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 LOOP	Loop Count Select Selects how many times this command executes (and stores conversion result to RESFIFO) before finish and transition to the next command or Idle state. LWI field controls whether a single channel is converted on each iteration or auto channel increment results in channel scanning functionality. 0000b - Looping not enabled. Command executes 1 time. 0001b - Loop 1 time. Command executes 2 times.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0010b - Loop 2 times. Command executes 3 times. 0011b-1110b - Loop corresponding number of times. Command executes LOOP+1 times. 1111b - Loop 15 times. Command executes 16 times.
15-12 AVGS	Hardware Average Select Selects how many ADC conversions are averaged to create the ADC result (2^{AVGS}). An internal storage buffer is used to capture temporary results while the averaging iterations are executed. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description for more detailed description on usage of AVGS, LOOP, and NEXT bitfields in command execution sequencing. 0000b - Single conversion. 0001b - 2 conversions averaged. 0010b - 4 conversions averaged. 0011b - 8 conversions averaged. 0100b - 16 conversions averaged. 0101b - 32 conversions averaged. 0110b - 64 conversions averaged. 0111b - 128 conversions averaged. 1000b - 256 conversions averaged. 1001b - 512 conversions averaged. 1010b - 1024 conversions averaged.
11 —	Reserved This read-only field is reserved and always has the value 0.
10-8 STS	Sample Time Select When programmed to 0b000 the minimum sample time of 3.5 ADCK cycles is selected. When STS is programmed to a non-zero value the sample time is ($3.5 + 2^{STS}$) ADCK cycles. The shortest sample time maximizes conversion speed for lower impedance inputs. Extending sample time allows higher impedance inputs to be accurately sampled. Longer sample times can also be used to lower overall power consumption when command looping and sequencing is configured and high conversion rates are not required. 000b - Minimum sample time of 3.5 ADCK cycles. 001b - $3.5 + 2^1$ ADCK cycles; 5.5 ADCK cycles total sample time. 010b - $3.5 + 2^2$ ADCK cycles; 7.5 ADCK cycles total sample time. 011b - $3.5 + 2^3$ ADCK cycles; 11.5 ADCK cycles total sample time. 100b - $3.5 + 2^4$ ADCK cycles; 19.5 ADCK cycles total sample time. 101b - $3.5 + 2^5$ ADCK cycles; 35.5 ADCK cycles total sample time.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - 3.5 + 2^6 ADCK cycles; 67.5 ADCK cycles total sample time. 111b - 3.5 + 2^7 ADCK cycles; 131.5 ADCK cycles total sample time.
7 LWI	Loop with Increment When LWI is clear, the LOOP field selects the number of times the selected channel is converted consecutively. When LWI is set, auto channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 0x8, LWI = 0b0, CMDLa[CTYPE] = 0x0, CMDLa[ADCH] = 0xD. Convert on channel 13A 9 times. Example 2: LOOP = 0x8, LWI= 0b1, CMDLa[CTYPE] = 0x0, CMDLa[ADCH] = 0xD. Run channels 13A, 14A, 15A, ... 21A each one time. Maximum channel scanning using a single command buffer then is defined by the maximum value of the LOOP field (16). 0b - Auto channel increment disabled 1b - Auto channel increment enabled
6-3 —	Reserved This read-only field is reserved and always has the value 0.
2 WAIT_TRIG	Wait for Trigger Assertion before Execution. Controls if commands are automatically executed or if a trigger must be received before execution. If WAIT_TRIG is asserted, wait states will be added before the command until the active trigger is asserted again. When WAIT_TRIG is disabled, each command will be automatically executed when called. 0b - This command will be automatically executed. 1b - The active trigger must be asserted again before executing this command.
1-0 CMPEN	Compare Function Enable After an ADC channel input is sampled and converted and any averaging iterations are performed, the CMDH*a*[CMPEN] field guides operation of the automatic compare function to optionally only store when the compare operation is true. When compare is enabled, the conversion result is compared to the compare value registers (CV*a*[CVH] and CV*a*[CVL]). There are multiple options on command sequencing related to the compare function. See Compare function for a detailed explanation of the compare options. **NOTE** Not all Command Buffers have implemented the CMPEN field. The CMPEN field is only available in Command Buffers that have a corresponding Compare Value register. 00b - Compare disabled. 01b - Reserved 10b - Compare enabled. Store on true. 11b - Compare enabled. Repeat channel acquisition (sample/convert/compare) until true.

80.6.20 Command High Buffer Register (CMDH5 - CMDH15)

Offset

For a = 5 to 15:

Register	Offset
CMDHa	FCh + (a × 8h)

Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDH*a*:CMDL*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of the TCTRLa[TCMD] bitfield. When the ADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer should not be updated while the ADC is active. A write to a CMD buffer while that CMD buffer that is controlling ADC operation may result in unpredictable behavior.

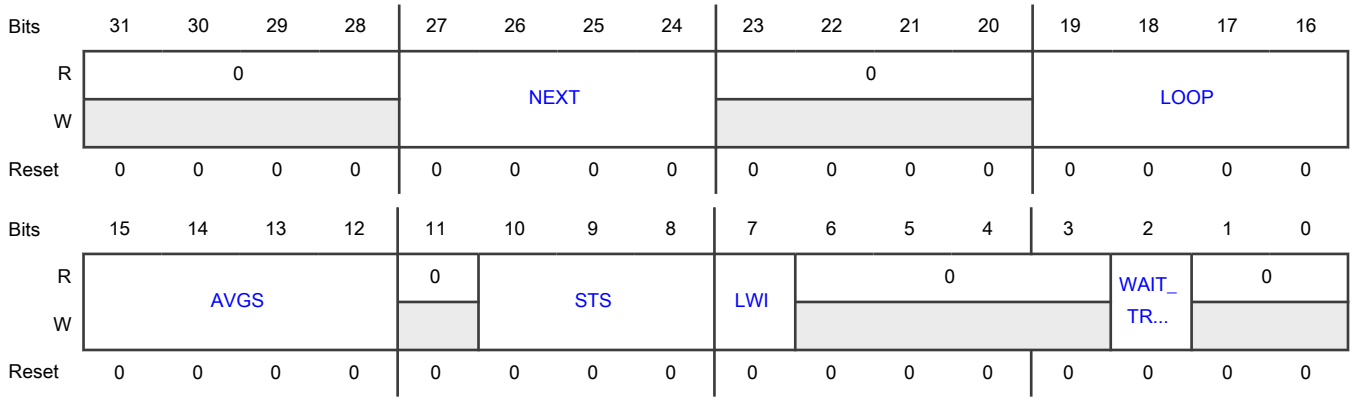
NOTE

The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these are likely to be defined as two 15-element arrays that are indexed from 0. I.e., the type declaration would be:

```
unsigned int CMDH[15];
unsigned int CMDL[15];
```

and software would access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

Diagram



Fields

Field	Function
31-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24	Next Command Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
NEXT	Selects the next command to be executed after this command completes. Multiple commands can be configured in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order and the order of execution is strictly controlled by the NEXT field (for example, a sequence of commands could be CMD2 to CMD1 to CMD3). Unending circular command execution is allowed by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0x0 causes conversions to terminate at the completion of the command. Lower priority trigger events cannot be serviced until a higher priority triggered command (or sequence of commands) completes. 0000b - No next command defined. Terminate conversions at completion of current command. If lower priority trigger pending, begin command associated with lower priority trigger. 0001b - Select CMD1 command buffer register as next command. 0010b-1110b - Select corresponding CMD command buffer register as next command 1111b - Select CMD15 command buffer register as next command.
23-20 —	Reserved This read-only field is reserved and always has the value 0.
19-16 LOOP	Loop Count Select Selects how many times this command executes (and stores conversion result to RESFIFO) before finish and transition to the next command or Idle state. LWI field controls whether a single channel is converted on each iteration or auto channel increment results in channel scanning functionality. 0000b - Looping not enabled. Command executes 1 time. 0001b - Loop 1 time. Command executes 2 times. 0010b - Loop 2 times. Command executes 3 times. 0011b-1110b - Loop corresponding number of times. Command executes LOOP+1 times. 1111b - Loop 15 times. Command executes 16 times.
15-12 AVGS	Hardware Average Select Selects how many ADC conversions are averaged to create the ADC result (2^{AVGS}). An internal storage buffer is used to capture temporary results while the averaging iterations are executed. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description for more detailed description on usage of AVGS, LOOP, and NEXT bitfields in command execution sequencing. 0000b - Single conversion. 0001b - 2 conversions averaged. 0010b - 4 conversions averaged. 0011b - 8 conversions averaged. 0100b - 16 conversions averaged. 0101b - 32 conversions averaged.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0110b - 64 conversions averaged. 0111b - 128 conversions averaged. 1000b - 256 conversions averaged. 1001b - 512 conversions averaged. 1010b - 1024 conversions averaged.
11 —	Reserved This read-only field is reserved and always has the value 0.
10-8 STS	Sample Time Select When programmed to 0b000 the minimum sample time of 3.5 ADCK cycles is selected. When STS is programmed to a non-zero value the sample time is ($3.5 + 2^{STS}$) ADCK cycles. The shortest sample time maximizes conversion speed for lower impedance inputs. Extending sample time allows higher impedance inputs to be accurately sampled. Longer sample times can also be used to lower overall power consumption when command looping and sequencing is configured and high conversion rates are not required. 000b - Minimum sample time of 3.5 ADCK cycles. 001b - $3.5 + 2^1$ ADCK cycles; 5.5 ADCK cycles total sample time. 010b - $3.5 + 2^2$ ADCK cycles; 7.5 ADCK cycles total sample time. 011b - $3.5 + 2^3$ ADCK cycles; 11.5 ADCK cycles total sample time. 100b - $3.5 + 2^4$ ADCK cycles; 19.5 ADCK cycles total sample time. 101b - $3.5 + 2^5$ ADCK cycles; 35.5 ADCK cycles total sample time. 110b - $3.5 + 2^6$ ADCK cycles; 67.5 ADCK cycles total sample time. 111b - $3.5 + 2^7$ ADCK cycles; 131.5 ADCK cycles total sample time.
7 LWI	Loop with Increment When LWI is clear, the LOOP field selects the number of times the selected channel is converted consecutively. When LWI is set, auto channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 0x8, LWI = 0b0, CMDLa[CTYPE] = 0x0, CMDLa[ADCH] = 0xD. Convert on channel 13A 9 times. Example 2: LOOP = 0x8, LWI= 0b1, CMDLa[CTYPE] = 0x0, CMDLa[ADCH] = 0xD. Run channels 13A, 14A, 15A, ... 21A each one time. Maximum channel scanning using a single command buffer then is defined by the maximum value of the LOOP field (16). 0b - Auto channel increment disabled 1b - Auto channel increment enabled
6-3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	This read-only field is reserved and always has the value 0.
2 WAIT_TRIG	Wait for Trigger Assertion before Execution. Controls if commands are automatically executed or if a trigger must be received before execution. If WAIT_TRIG is asserted, wait states will be added before the command until the active trigger is asserted again. When WAIT_TRIG is disabled, each command will be automatically executed when called. 0b - This command will be automatically executed. 1b - The active trigger must be asserted again before executing this command.
1-0 —	Reserved This read-only field is reserved and always has the value 0.

80.6.21 Compare Value Register (CV1 - CV4)

Offset

Register	Offset
CV1	200h
CV2	204h
CV3	208h
CV4	20Ch

Function

The compare value registers (CV*a*) contain values used to compare the conversion result when the compare function is enabled. This register is formatted in the same way as the D field in the RESFIFO registers in different modes of operation for both bit position definition and value format using unsigned or signed 2's complement. There is a direct association of each compare value register to a specific command buffer register (i.e., CV1 is only used during execution of CMD1 command).

NOTE

Not all Command Buffers have an associated Compare Value register. The compare function is only available on Command Buffers that have a corresponding Compare Value register.

When the ADC is actively executing commands, the CV*a* register associated with the active command (CMD*a*) should not be updated. Writes to associated CV*a* register during this time may result in unpredictable behavior.

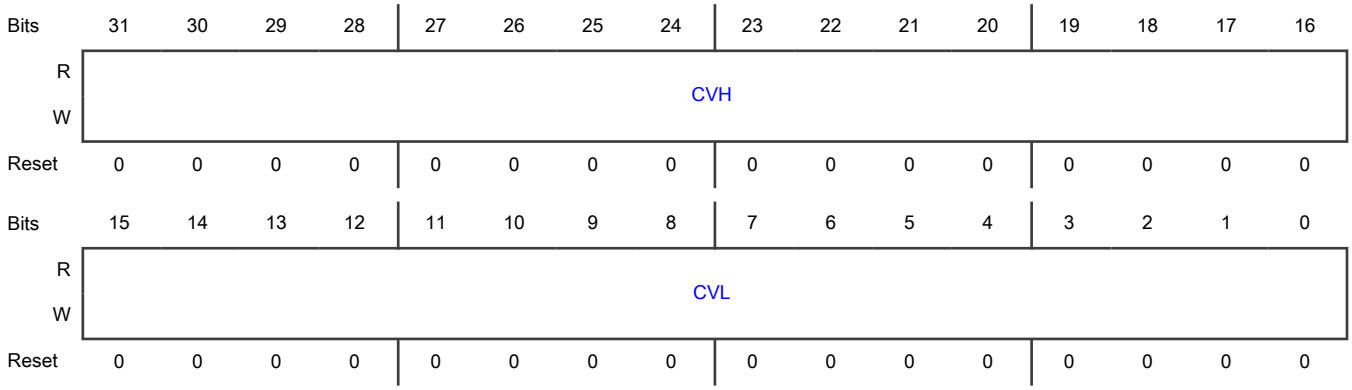
NOTE

The 4 compare value registers are numbered [CV1] through [CV4]. In NXP-supplied header files, this is likely to be defined as a 4-element array that is indexed from 0. I.e., the type declaration would be:

```
unsigned int CV[4];
```

and software would access ADC0 CV1 as `ADC0->CV[0]` and ADC0 CV4 as `ADC0->CV[3]`.

Diagram



Fields

Field	Function
31-16 CVH	Compare Value High The compare function can be configured to check whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. After the input is sampled and converted and any averaging iterations are performed, the compare values in CVL and CVH are optionally used in a compare operation on the result. See Compare function for a description on how CVH is used.
15-0 CVL	Compare Value Low The compare function can be configured to check whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. After the input is sampled and converted and any averaging iterations are performed, the compare values in CVL and CVH are optionally used in a compare operation on the result. See Compare function for a description on how CVL is used.

80.6.22 Data Result FIFO Register (RESFIFO0 - RESFIFO1)

Offset

Register	Offset
RESFIFO0	300h
RESFIFO1	304h

Function

The data result FIFO register (RESFIFO) is a 16 entry FIFO that stores the data result of ADC conversions. In addition, several tag fields of source command and trigger information are stored along with the data. FCTRLa[FCOUNT] indicates how many valid datawords are stored in the RESFIFO. Reading RESFIFO provides the oldest unread dataword entry in the FIFO and decrements FCTRLa[FCOUNT]. The FIFO can be emptied by successive reads of RESFIFO. The FIFO is reset by writing 0b1 to the CTRL[RSTFIFOx] bit.

The following table describes the format of data in the result FIFO in the different modes of operation. The sign bit is the (MSB) in signed 2's complement modes. For example, when configured for 12-bit single-ended mode, D[15] and D[2:0] are cleared. When configured for 13-bit differential mode, D[15] is the sign bit and D[2:0] are cleared.

Table 1110. Data result register format description

Conversion mode	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	Format
16-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Signed 2's complement, JLEFT=X
16-bit single-ended	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Unsigned, 16-bit magnitude, JLEFT=X
13-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Signed 2's complement, left-justified, zero extended, JLEFT=X
12-bit single-ended	0	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Unsigned, JLEFT=0, zero in D[15] and D[2:0]
12-bit single-ended	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	0	Unsigned, JLEFT=1, zero in D[3:0]

NOTE

S: Sign bit;

D: Data, which is 2's complement data if indicated

Diagram

Fields

Field	Function
31 VALID	FIFO Entry is Valid Indicate the FIFO entry is valid. When the FIFO is holding data the VALID bit is set. When the FIFO is empty the VALID bit is clear. 0b - FIFO is empty. Discard any read from RESFIFO. 1b - FIFO record read from RESFIFO is valid.

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-28 —	Reserved This read-only field is reserved and always has the value 0.
27-24 CMDSRC	Command Buffer Source Indicate the command buffer being executed that generated this result. 0000b - Not a valid value CMDSRC value for a dataword in RESFIFO. 0x0 is only found in initial FIFO state prior to an ADC conversion result dataword being stored to a RESFIFO buffer. 0001b - CMD1 buffer used as control settings for this conversion. 0010b-1110b - Corresponding command buffer used as control settings for this conversion. 1111b - CMD15 buffer used as control settings for this conversion.
23-20 LOOPCNT	Loop Count Value Indicate the loop count value during command execution that generated this result. When CMDHa[LOOP] is non-zero, the command execution stores off a result multiple times during command execution (at the loop boundary). 0000b - Result is from initial conversion in command. 0001b - Result is from second conversion in command. 0010b-1110b - Result is from LOOPCNT+1 conversion in command. 1111b - Result is from 16^{th} conversion in command.
19 —	Reserved This read-only field is reserved and always has the value 0.
18-16 TSRC	Trigger Source Indicate the trigger source that initiated a conversion and generated this result. When multiple commands are chained together using the CMDHa[NEXT] field, the TSRC field for all datawords stored to the RESFIFO indicate the trigger source that started the sequence of commands. 000b - Trigger source 0 initiated this conversion. 001b - Trigger source 1 initiated this conversion. 010b-110b - Corresponding trigger source initiated this conversion. 111b - Trigger source 7 initiated this conversion.
15-0 D	Data Result The formatting for the data in D is summarized in Table 1110.

80.6.23 Calibration General A-Side Registers (CAL_GAR0 - CAL_GAR32)

Offset

For a = 0 to 32:

Register	Offset
CAL_GARa	400h + (a × 4h)

Function

The A-side general calibration value registers (CAL_GAR0 - CAL_GAR32) are used to correct for linearity errors of the A-side converter. All 33 CAL_GAR registers contain calibration information that is automatically updated during the self calibration sequence. See Calibration for more information on completing ADC calibration steps.

The calibration values in the CAL_GAR registers affect the end conversion result by conditionally being subtracted from the conversion before the end result is transferred into the FIFOs. Calibration must be run each time the ADC is powered down or a hard reset is issued. To reduce the latency required to run calibration, the CAL_GAR values can be stored in non-volatile memory after an initial calibration and recovered prior to the first ADC conversion. If these registers are set to values not generated by the calibration function, the linearity error specifications may not be met.

The CAL_GAR registers are only read write accessible when the ADC is disabled with CTRL[ADCEN] = 0b0. Note that access time when writing to these registers is larger than 3 ADC clock cycles. Wait states are inserted on the bus to meet synchronization timing to the associated CAL_GAR register.

Note that the values in each register is a 16-bit signed value but has non-uniform supported range of values. The valid range of each register is summarized in Calibration General A-Side and B-Side Register valid ranges.

15-0 CAL_GAR_VAL	Calibration General A Side Register Element The CAL_GAR_VAL is a 16-bit signed value. The valid range for each register in this array is non-uniform and summarized in Calibration General A-Side and B-Side Register valid ranges.

80.6.24 Calibration General B-Side Registers (CAL_GBR0 - CAL_GBR32)

Offset

For a = 0 to 32:

Register	Offset
CAL_GBRa	500h + (a × 4h)

Function

The B-side general calibration value registers (CAL_GBR0 - CAL_GBR32) are used to correct for linearity errors of the B-side converter. All 33 CAL_GBR registers contain calibration information that is automatically updated during the self calibration sequence. See Calibration for more information on completing ADC calibration steps.

The calibration values in the CAL_GBR registers affect the end conversion result by conditionally being subtracted from the conversion before the end result is transferred into the FIFOs. Calibration must be run each time the ADC is powered down or a hard reset is issued. To reduce the latency required to run calibration, the CAL_GBR values can be stored in non-volatile memory after an initial calibration and recovered prior to the first ADC conversion. If these registers are set to values not generated by the calibration function, the linearity error specifications may not be met.

The CAL_GBR registers are only read write accessible when the ADC is disabled with CTRL[ADCEN] = 0b0. Note that access time when writing to these registers is larger than 3 ADC clock cycles. Wait states are inserted on the bus to meet synchronization timing to the associated CAL_GBR register.

Note that the values in each register is a 16-bit signed value but has non-uniform supported range of values. The valid range of each register is summarized in Calibration General A-Side and B-Side Register valid ranges.

81.2 Overview

ACMP includes the following submodules:

- High-speed comparator (CMP) (see ACMP block diagram)
- Digital-to-analog converter (DAC) (see CMP block diagram)
- Analog mux (ANMUX) (see ANMUX key features)

CMP provides a circuit to compare two analog input voltages. The comparator circuit operates across the full range of the supply voltage, known as rail-to-rail operation.

ANMUX provides a circuit to select an analog input signal from eight channels. DAC provides one signal. The mux circuit operates across the full range of the supply voltage.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. It divides the supply reference, V_{in}, into 256 voltage levels. An 8-bit digital register input selects the output voltage level, which varies from V_{in} to $V_{in}/256$. You can select V_{in} from two voltage sources—V_{in1} or V_{in2}.

81.2.1 ACMP block diagram

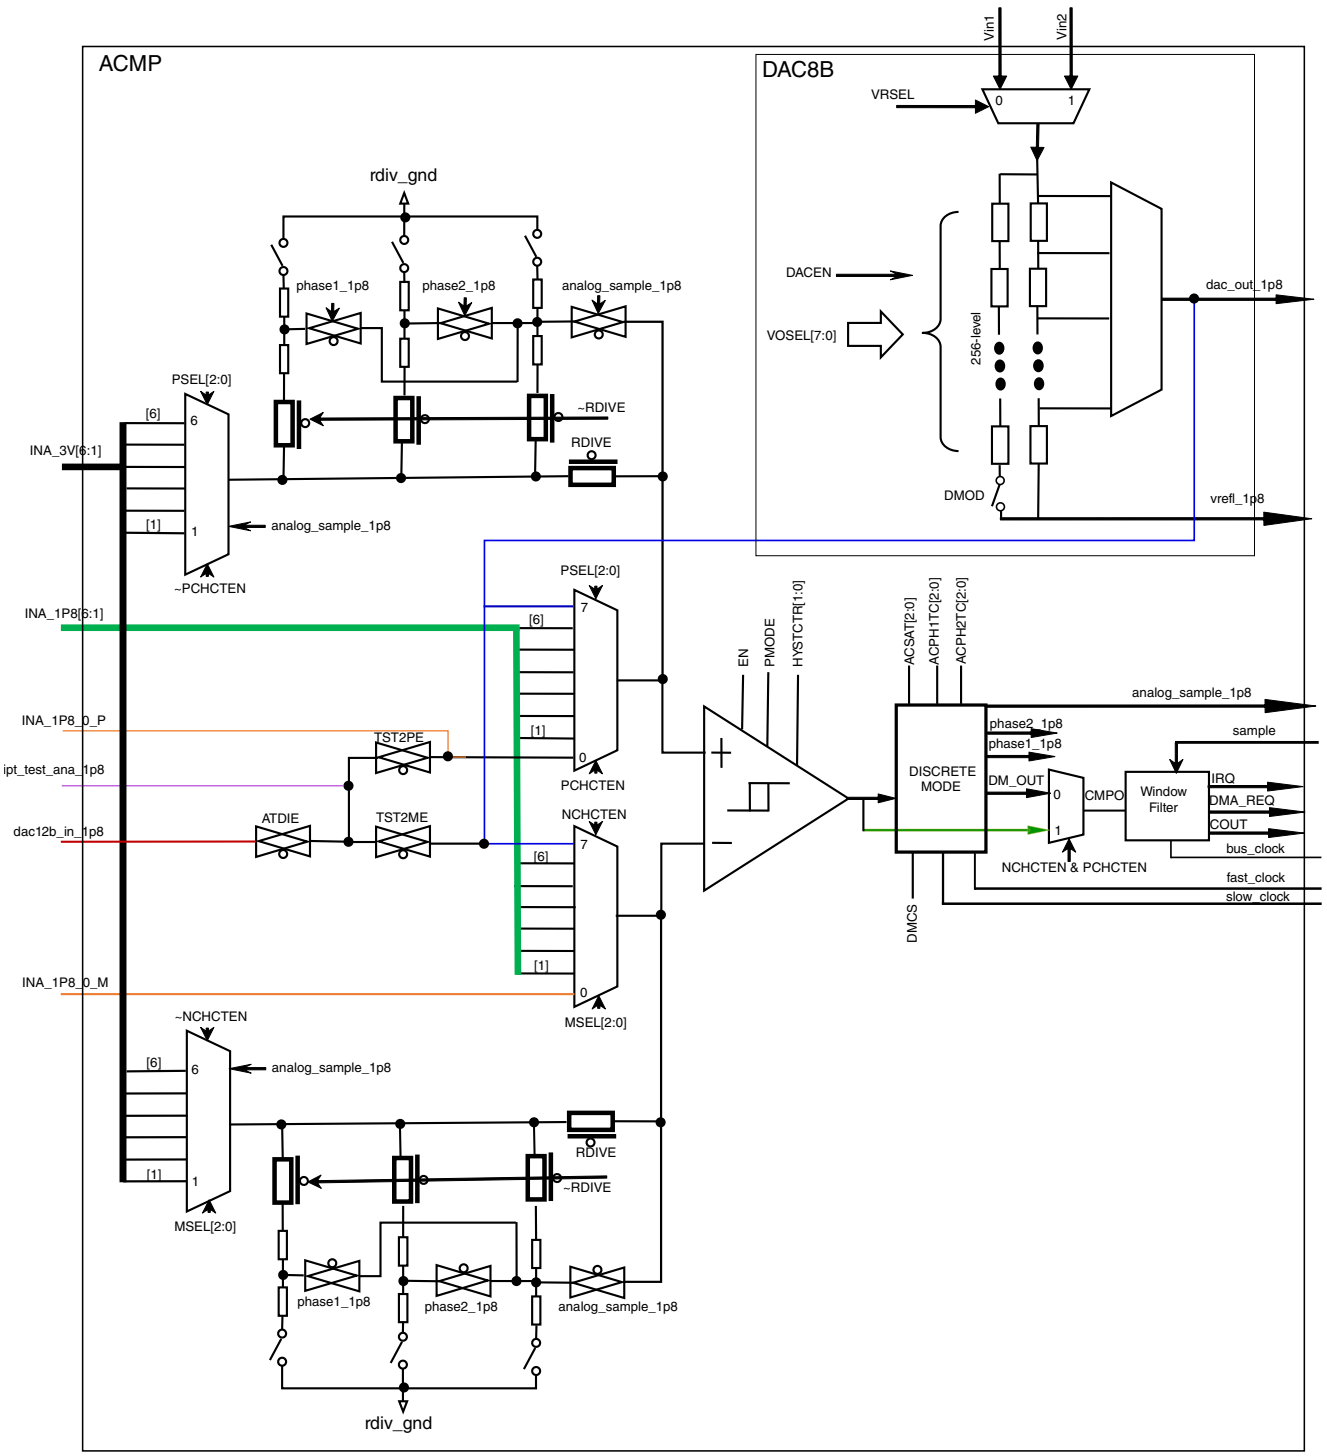

Figure 616. ACMP block diagram

81.2.2 CMP block diagram

In Figure 617 CMP:

- Bypasses the window control block when C0[WE] = 0.

- Samples the comparator output on every bus clock when the Window signal is 1 to generate COUTA, if C0[WE] = 1. Sampling does not occur when the Window signal is 0.
- Bypasses the filter block when it is not in use.

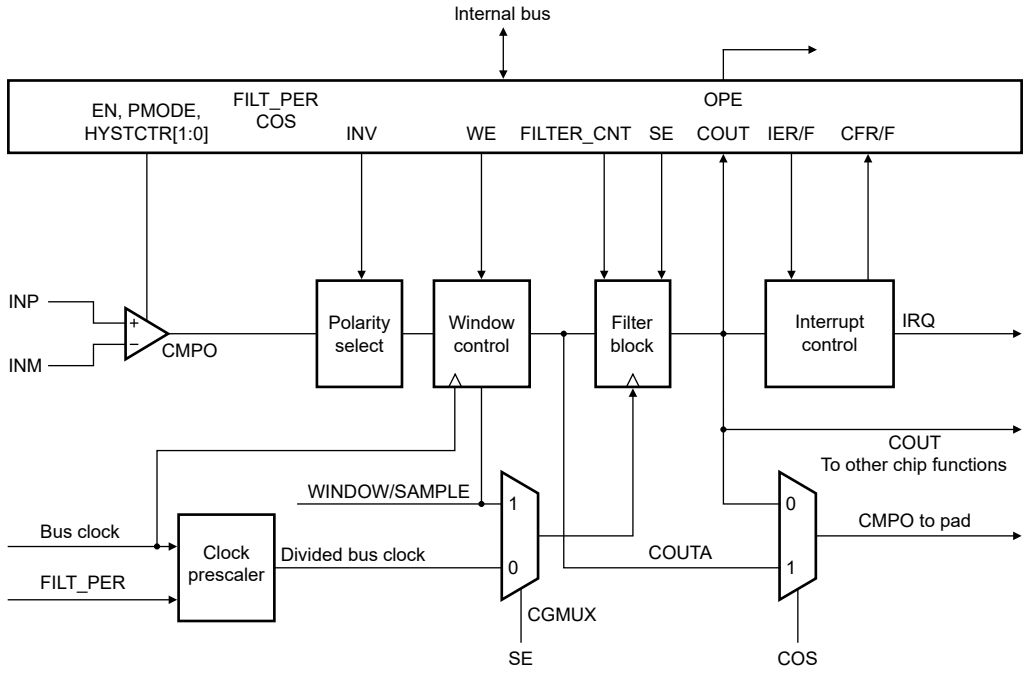

Figure 617. CMP block diagram

The filter block bypass operates as follows:

- The filter block acts as a simple sampler if you bypass the filter and C0[FILTER_CNT] becomes 01h.
- The filter block filters based on multiple samples when you bypass the filter and C0[FILTER_CNT] becomes greater than 01h.
  - If C0[SE] = 1, use the external Sample input as the sampling clock.
  - If C0[SE] = 0, use the divided bus clock as the sampling clock.
- If enabled, the filter block incurs an additional latency penalty of up to one bus clock on COUT. This is because COUT, which crosses clock domain boundaries, must resynchronize with the bus clock.
- C0[WE] and C0[SE] are mutually exclusive.
- If enabled, the filter clock and sample period must be at least four times slower than the system clock to the comparator.
- If C0[SE] = 0, ACMP bypasses the filter block when you write 00h to C0[FILTER_CNT] or when you write 00h to C0[FPR].

81.2.3 Features

The following subsections list the features of high-speed CMP, 8-bit DAC, and ANMUX.

81.2.3.1 CMP features

- Operates over the entire supply range
- Supports rail-to-rail inputs
- Supports programmable hysteresis control
- Provides a selectable interrupt on rising-edge, falling-edge, or both comparator outputs

- Provides a selectable inversion on comparator output
- Includes the capability to produce a wide range of outputs, such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered:
    - Bypass filter
    - Clocks via an external Sample signal or a scaled bus clock
- Uses external hysteresis at the same time that the output filter is used for internal functions
- Supports two software selectable performance levels:
  - Shorter propagation delay at the expense of higher power
  - Low power, with a longer propagation delay
- Supports DMA transfer (CMP can select a comparison event to trigger a DMA transfer)
- Functional in all MCU power modes

CMP's window and filter functions are unavailable in Stop modes.

Other peripherals trigger the comparator.

81.2.3.2 8-bit DAC key features

- 8-bit resolution
- Selectable supply reference source
- Low-Power mode or High-Speed mode that you can configure
- Power-Down mode to conserve power when not in use
- Routing of the output of the 8-bit DAC to the internal comparator input, where you can select it as one of the CMP inputs as a reference for comparison

81.2.3.3 ANMUX key features

- Two 8-to-1 channel MUXes that can be selected as the source for comparator input
- Operation over the entire supply range

81.3 CMP functional description

CMP can compare two analog input voltages applied to INP and INM. CMPO is high when the non inverting input is greater than the inverting input, and it is low when the non inverting input is less than the inverting input. Write 1 to C0[INVT] to selectively invert this signal.

C0[IER] and C0[IEF] select the condition that causes CMP to assert an interrupt to the processor. C0[CFF] sets on a falling edge, and C0[CFR] sets on a rising edge of the comparator output. You can read the optionally filtered CMPO directly through C0[COUT].

81.3.1 CMP functional modes

CMP includes the following main sub-blocks:

- Comparator
- Window function
- Filter function

You can clock C0[FILTER_CNT] from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

Enable the external sample input using C0[SE]. When C0[SE] is 1, sample the output of the comparator only on the rising edges of the sample input.

Write 1 to C0[WE] to enable the window function. When C0[WE] is 1, sample the comparator output only when the Window signal is 1. You can use this feature to ignore the comparator output during time periods in which the input voltages are not valid. This is useful when you implement zero-crossing detection for certain PWM applications.

Combine the comparator filter and sampling features as shown in the following table. Individual modes are also discussed.

Table 1113. Comparator sample or filter controls

Mode		C0[EN]	C0[WE]	C0[SE]	C0[FILTER_CNT]	C0[FPR]	Operation
Name	#						
Disabled	1	0	X	X	X	X	See Disabled mode.
Continuous	2A	1	0	0	00h	X	See Continuous mode.

Name	#						
							which resamples and filters to generate COUT. See Windowed/Filtered mode.
Trigger	8	1	1	1	X	X	In Run mode, comparator is configured to the modes same with Windowed mode, Windowed/Resampled mode, and Windowed/Filtered mode as described in the aforementioned rows, depending on the settings of C0[FILTER_CNT] and C0[FPR]. In Stop mode, trigger the comparator, and possibly the 8-bit DAC works periodically. The active channels follow the round-robin cycling scheme. See Trigger mode.
All other combinations of C0[EN], C0[WE], C0[SE], C0[FILTER_CNT], and C0[FPR] are illegal.							

For cases where a comparator drives a fault input, for example, for a motor-control module such as FTM or FlexPWM, it must configure to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

NOTE

Filtering and sampling settings must change only after writing 0 to C0[SE] and C0[FPR], and 00h to C0[FILTER_CNT]. This resets the filter to a known state.

81.3.1.1 Disabled mode

In this mode:

- The analog comparator is nonfunctional and consumes no power.
- CMPO is 0.

81.3.1.2 Continuous mode

In this mode, the analog comparator block is powered and active. CMPO may be optionally inverted but is not subject to external sampling or filtering. CMP completely bypasses both window control and filter blocks and update C0[COUT] continuously. The path from comparator input pins to output pins operates in a combinational unclocked mode. COUT and COUTA are identical.

See CMP block diagram section for control configurations that result in disabling the filter block.

NOTE

See the chip-specific ACMP information for the source of sample or window input.

Figure 618 describes the comparator operation in Continuous mode.

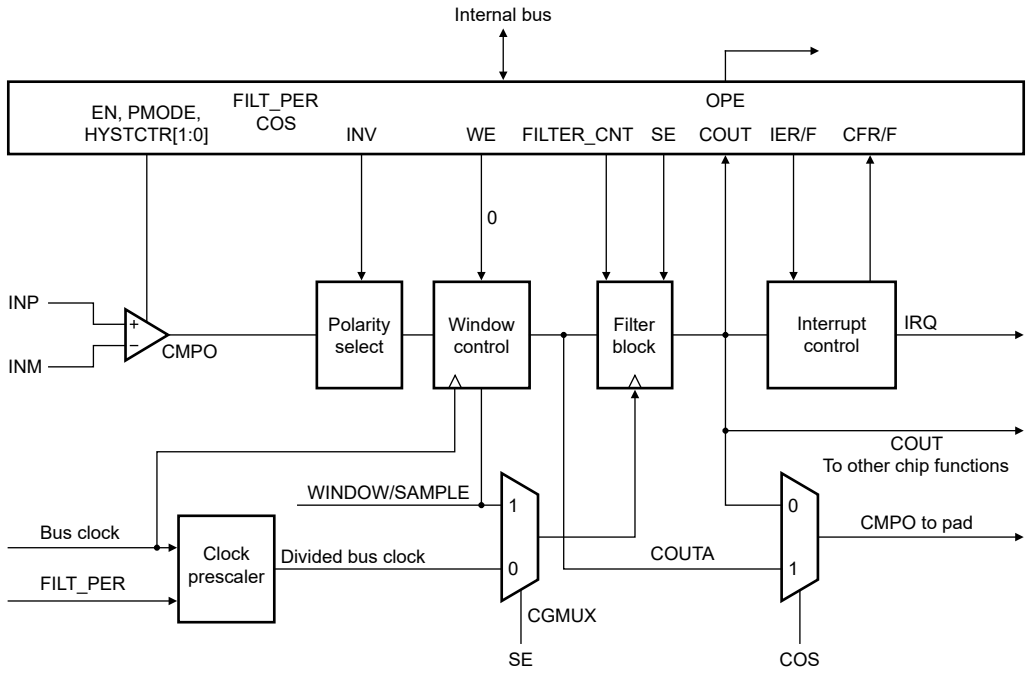

Figure 618. Comparator operation in Continuous mode

81.3.1.3 Sampled, Nonfiltered mode

In this mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. CMP completely bypasses the windowing control. Sample COUTA whenever you detect a rising edge on the filter block clock input.

The only operational difference between Sampled, Nonfiltered and Sampled, Nonfiltered modes (3A and 3B in Table 1113) is how the clock to the filter block is derived. In Sampled, Nonfiltered mode (3A in Table 1113) , the clock-to-filter block is externally derived (see Figure 619) and in Sampled, Nonfiltered mode (3B in Table 1113), the clock-to-filter block is internally derived (see Figure 620).

The comparator filter has no other function than sampling or holding the comparator output in this mode (3B in Table 1113).

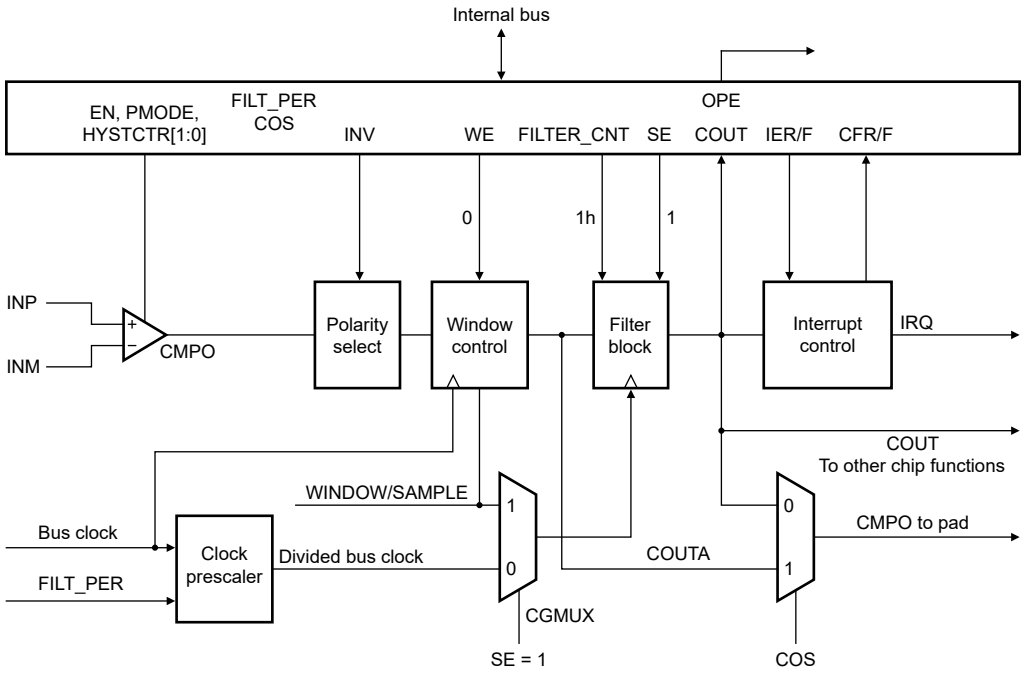

Figure 619. Sampled, Nonfiltered (# 3A): sampling point externally driven

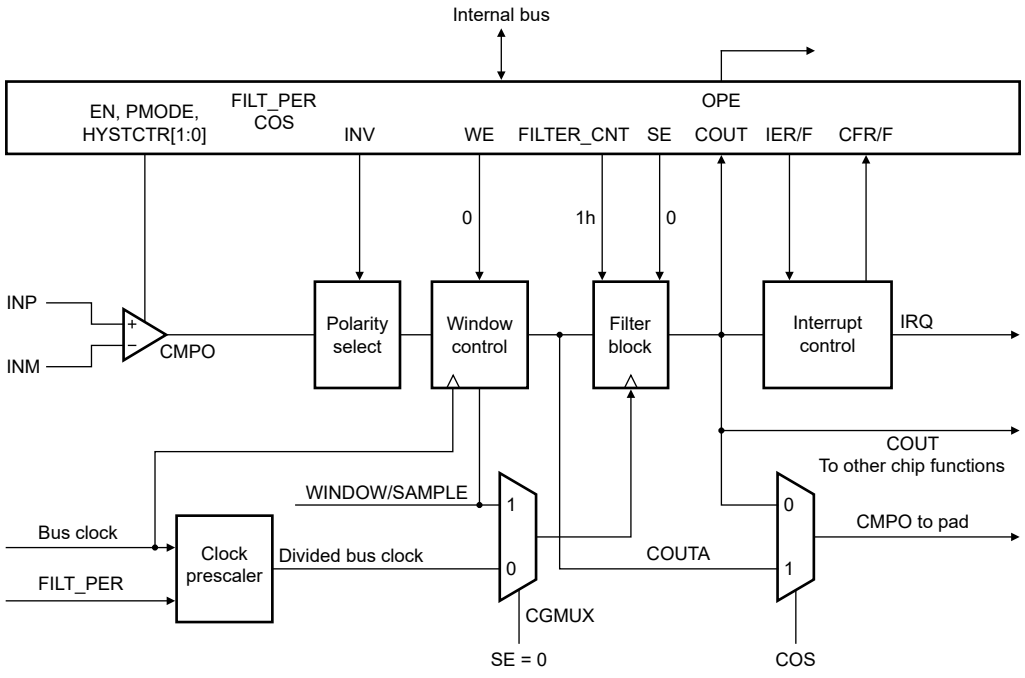

Figure 620. Sampled, Nonfiltered (# 3B): sampling interval internally derived

81.3.1.4 Sampled, Filtered mode

In this mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Completely bypass the windowing control and sample COUTA whenever you detect a rising edge on the filter block clock input.

The only operational difference between Sampled, Nonfiltered and Sampled, Filtered modes (3A and 4A in Table 1113) is C0[FILTER_CNT] > 1, which activates the filter operation (see Figure 621).

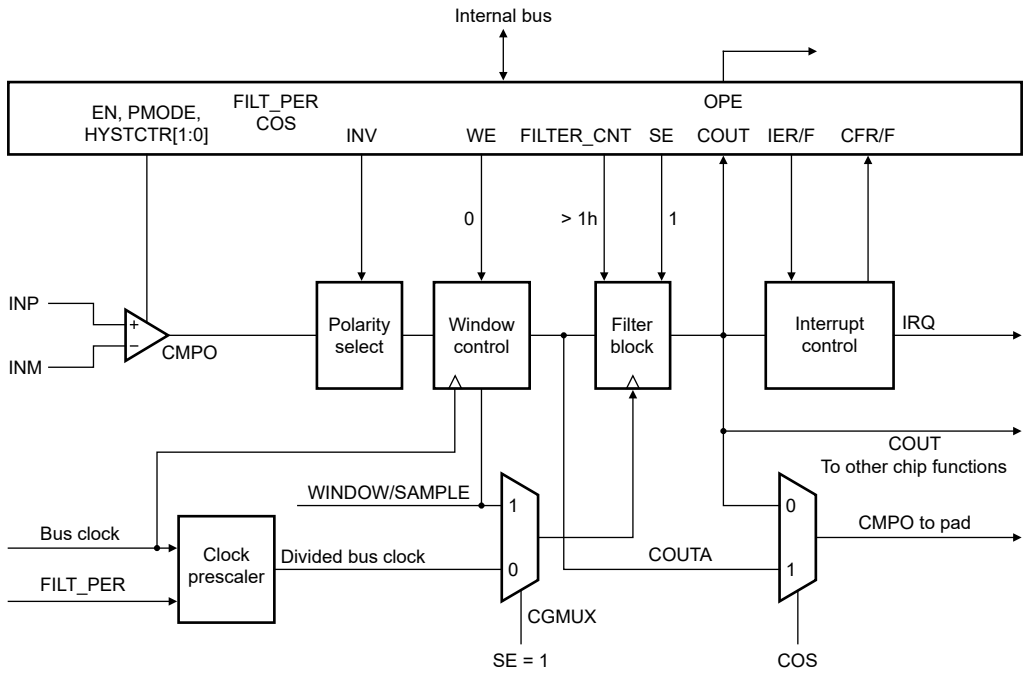

Figure 621. Sampled, Filtered (# 4A): sampling point externally driven

The only operational difference between Sampled, Nonfiltered, and Sampled, Filtered modes (3B and 4B in Table 1113) is C0[FILTER_CNT] > 1, which activates the filter operation (see Figure 622).

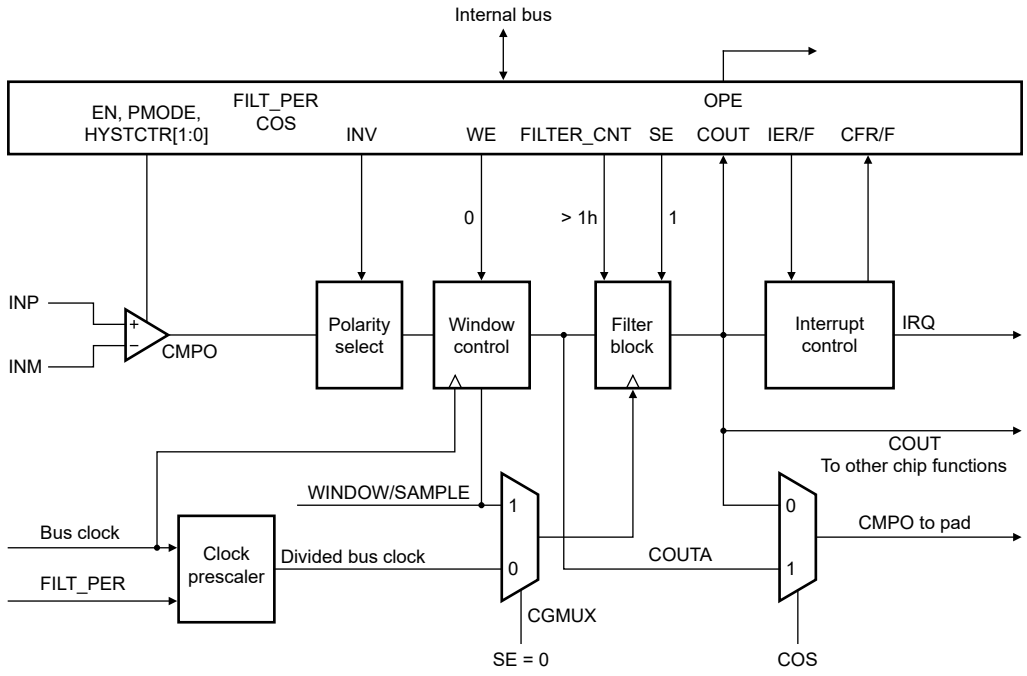

Figure 622. Sampled, Filtered (# 4B): sampling point internally derived

81.3.1.5 Windowed mode

Figure 623 shows the following:

- Comparator operation in Windowed mode
- Ignoring the latency of the analog comparator (see Latency issues)
- Polarity select
- Window control block

It also assumes that the polarity select sets to a noninverting state.

NOTE

The analog comparator output passes to COUTA only after the Window signal becomes high.

In actual operation, COUTA may lag the analog inputs by up to one bus clock cycle plus the combinational path delay through the comparator and polarity select logic.

See CMP block diagram section for control configurations that result in disabling the filter block.

When a windowed mode is active, the bus clock clocks COUTA whenever the Window signal is 1. The bus clock holds the last latched value when the Window signal is 0.

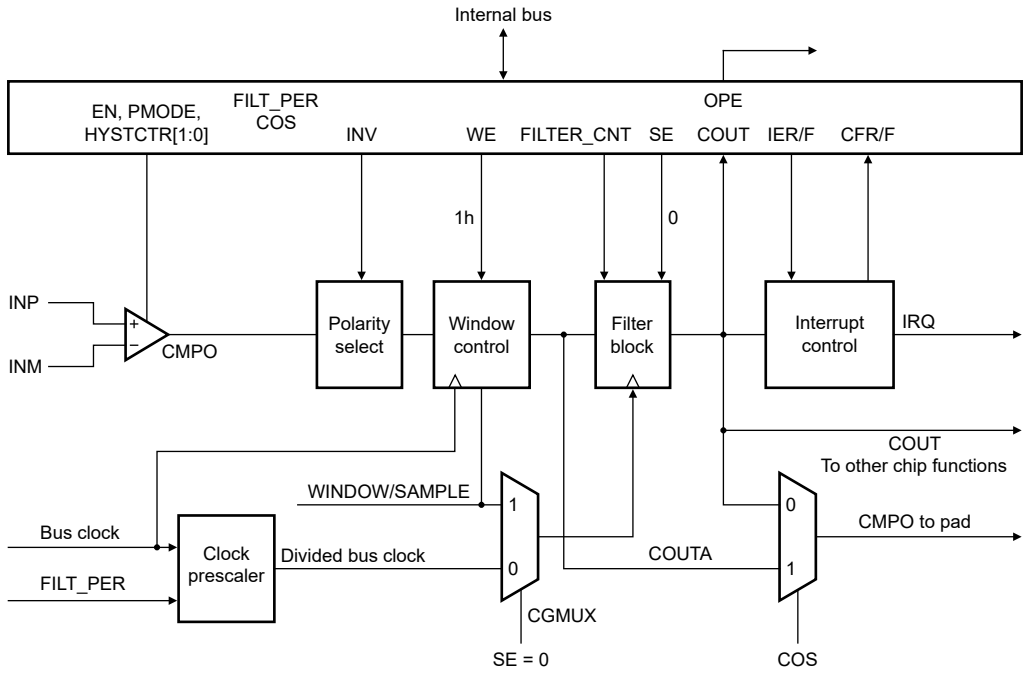

Figure 623. Windowed mode

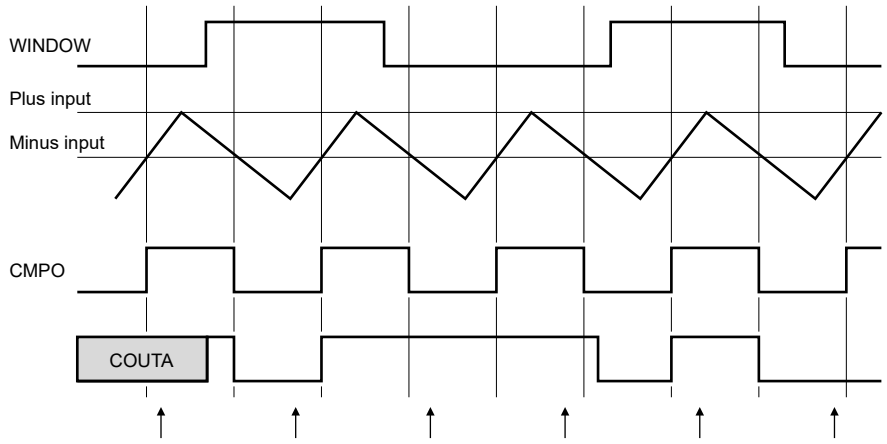

Figure 624. Windowed mode timing diagram

81.3.1.6 Windowed/Resampled mode

Figure 625 uses the same input stimulus as shown in Figure 624, and adds resampling of COUTA to generate COUT. The arrows in the figure indicate the time points at which the samples are taken. You can ignore prop delays and latency for clarity.

This example demonstrates operation of the comparator in Windowed/Resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events, which the analog comparator detects. You must carefully consider the sampling period and window placement for a given application.

This mode of operation results in an unfiltered string of comparator samples where C0[FPR] and the bus clock rate determine the interval between the samples. The next section describes that the configuration for this mode is identical to that of Windowed/Filtered mode. The only difference is that the value of C0[FILTER_CNT] must be 1.

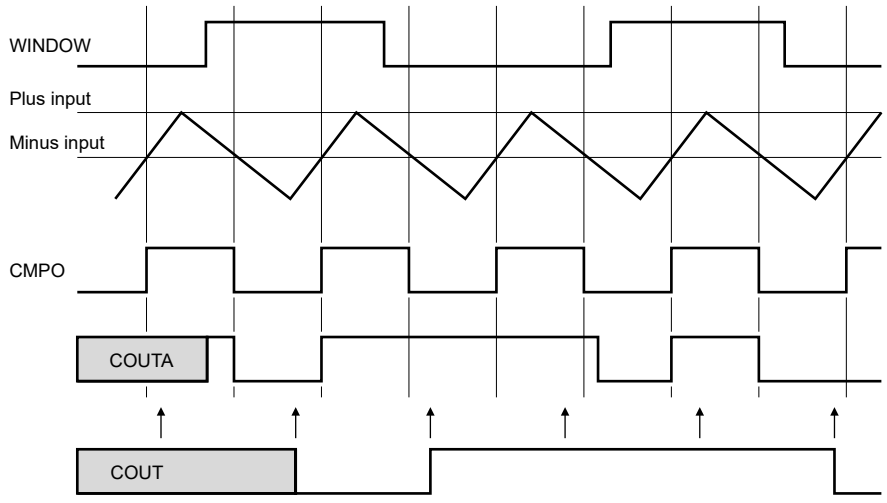

Figure 625. Windowed/Resampled mode operation

81.3.1.7 Windowed/Filtered mode

This is the most complex mode of operation for the comparator block, because this mode uses both windowing and filtering features. It also has the highest latency of any of the modes. This is approximately: up to 1 bus clock synchronization in the window function + ((C0[FILTER_CNT] × C0[FPR]) + 1) × bus clock for the filter function.

When any windowed mode is active, the bus clock clocks the COUTA whenever the Window signal is 1. The bus clock holds the last latched value when the Window signal is 0.

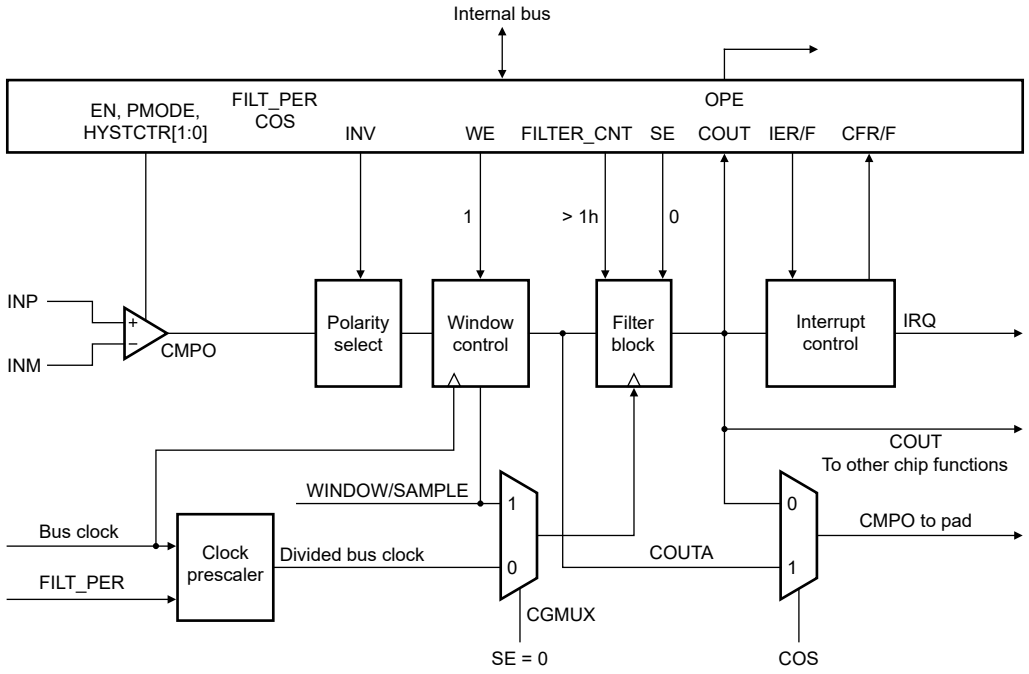

Figure 626. Windowed/Filtered mode

81.3.2 Low-pass filter

The low-pass filter operates on the unfiltered, unsynchronized, and optionally inverted comparator output, COUTA, and generates the filtered and synchronized output, COUT. You can configure both COUTA and COUT as module outputs, and use them for different purposes within the system.

Synchronization and edge detection always determine the status register bit values. They also apply to COUT for all sampling and windowed modes. You can perform filtering using an internal timebase defined by C0[FPR], or use an external sample input to determine sample time.

The need for digital filtering and the amount of filtering depends on your requirements. Filtering can become more useful in the absence of an external hysteresis circuit, without which you can generate high-frequency oscillations at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

81.3.2.1 Enabling filter modes

To enable filter modes:

1. Write a value greater than 1h to C0[FILTER_CNT].
2. Write a nonzero value to C0[FPR] or write 1 to C0[SE].

If you use the divided bus clock to drive the filter, it samples COUTA at every bus clock cycle that C0[FPR] defines.

The filter output is at logic 0 when first initialized and later changes when all the consecutive samples that C0[FILTER_CNT] specifies agree that the output value has changed. In other words, C0[COUT] is 0 for some initial period, even when COUTA is at logic 1.

Writing 0 to C0[SE], C0[FPR] and C0[FILTER_CNT] disables the filter and eliminates the switching current associated with the filtering process.

NOTE

Always switch to this setting before you make any changes in filter parameters. This resets the filter to a known state. Switching C0[FILTER_CNT] on the fly without this intermediate step can result in unexpected behavior.

If C0[SE] = 1, the filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive samples that C0[FILTER_CNT] specifies agree that the output value has changed.

81.3.2.2 Latency issues

Program the value of C0[FPR] or the sample period in a way that the sampling period is longer than the period of the expected noise. This way, a noise spike corrupts only one sample. You must choose the value of C0[FILTER_CNT] to reduce the probability of noisy samples causing an incorrect transition to recognize. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of the value in C0[FILTER_CNT].

You must trade off the values of C0[FPR] or the sample period and C0[FILTER_CNT] against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of the value in C0[FILTER_CNT].

The following table summarizes the maximum latency values for the various modes of operation in the absence of noise. Filtering latency restarts each time the noise masks an actual output transition.

Table 1114. Comparator sample or filter maximum latencies

Mode #	C0[EN]	C0[WE]	C0[SE]	C0[FILTER_CNT]	C0[FPR]	Operation	Maximum latency[1]
1	0	X	X	X	X	Disabled	N/A
2A	1	0	0	00h	X	Continuous mode	T_{PD}
2B	1	0	0	X	00h		
3A	1	0	1	01h	X	Sampled, Nonfiltered mode	$T_{PD} + T_{SAMPLE} + T_{per}$
3B	1	0	0	01h	> 00h		$T_{PD} + (C0[FPR] \times T_{per}) + T_{per}$
4A	1	0	1	> 01h	X	Sampled, Filtered mode	$T_{PD} + (C0[FILTER\_CNT] \times T_{SAMPLE}) + T_{per}$
4B	1	0	0	> 01h	> 00h		$T_{PD} + (C0[FILTER\_CNT] \times C0[FPR] \times T_{per}) + T_{per}$
5A	1	1	0	00h	X	Windowed mode	$T_{PD} + T_{per}$
5B	1	1	0	X	00h		$T_{PD} + T_{per}$
6	1	1	0	01h	01h – FFh	Windowed/ Resampled mode	$T_{PD} + (C0[FPR] \times T_{per}) + 2T_{per}$
7	1	1	0	> 01h	01h – FFh	Windowed/ Filtered mode	$T_{PD} + (C0[FILTER\_CNT] \times C0[FPR] \times T_{per}) + 2T_{per}$

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

NOTE

The delay in this table does not include the delay caused by the Discrete Mode.

81.3.3 CMP Discrete mode timing sequence

In order to support the 3 V domain input the analog comparator should be configured to work in Discrete Mode since the internal transistors are not 3 V tolerance. This section summarizes the possible configurations depending on the input range.

Note that the sample signal below means that the analog comparator samples the input analog input. It is different from the sample mode that occurs on the digital process to the final comparison result. Also, note that the cross domain round robin cycling (see Trigger mode) is not allowed.

1. When CMP_C3[PCHCTEN] and CMP_C3[NCHCTEN] are set to 1, the CMP is in continuous time operation. No special timing is required.
2. When either CMP_C3[PCHCTEN] or CMP_C3[NCHCTEN] is 0, it means at least one input comes from the 3V PAD.
   a. If CMP_C3[RDIVE] is zero, it means the input signal comes from 3V PAD, but its range still is in the range of 0 to 1.8V, no timing requirement for the generation of Phase1 and Phase2.

      In this condition, there are two modes for this comparator, high speed mode and low speed mode. Clock source may come from fast clock(16-20M)

      In Figure 627, the Analog ready indicates the analog settling time is reached and is ready for comparison. Tc is set by CMP_C3[ACSAT], in high speed mode, it is normally used as 1*T, 2*T, 4*T and 8*T where T is CLOCK period, and in low speed mode (CMP_C0[PMODE] = 0), CMP_C3[ACSAT] is normally used as 16*T, 32*T, 64*T and 256*T.

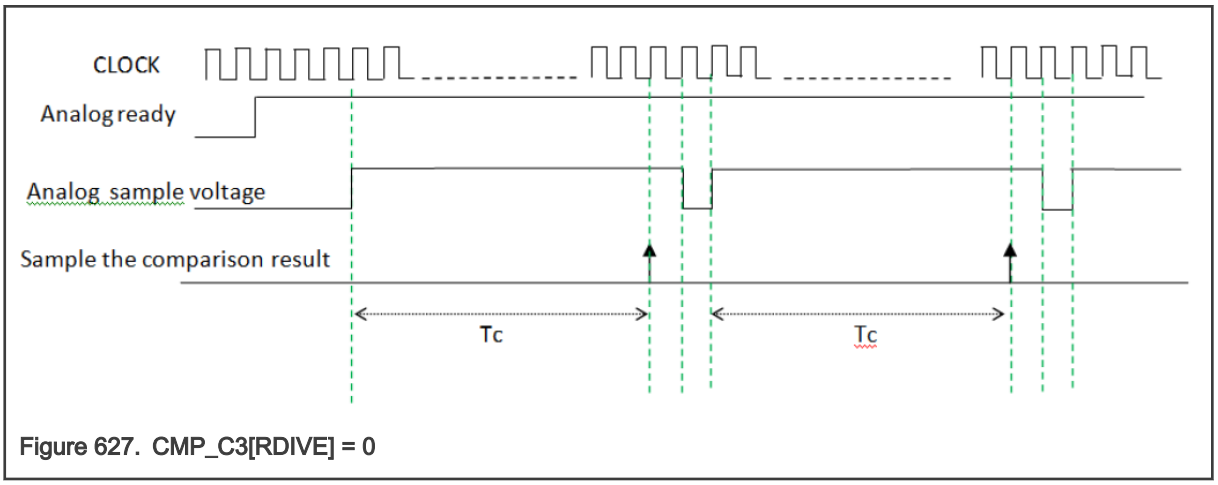

Figure 627. CMP_C3[RDIVE] = 0

   b. If CMP_C3[RDIVE] == 1, it means the signals come from the 3V PAD and it could over 1.8 V, Phase1, Phase2 will be generated.

      If CMP is in high speed mode (CMP_C0[PMODE] = 1) , Tc, Phase1, and Phase2 can be set based on the possible combinations in Table 1115.

      If CMP works in low speed mode, Phase1 is suggested to set to 1*T, Phase2 is suggested to set to 8*T, and Tc is normally set to 16*T, 32*T, 64*T and 256*T.

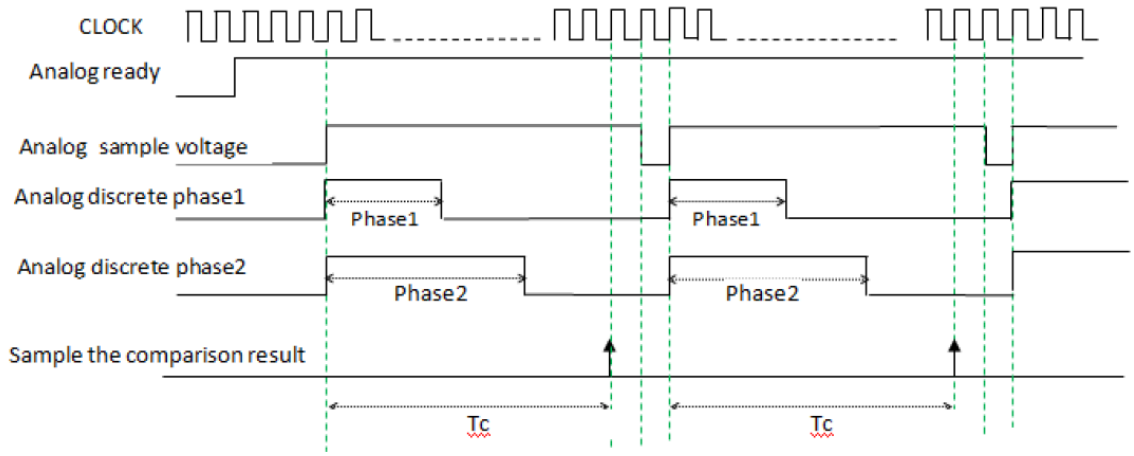

Figure 628. CMP_C3[RDIVE] = 1

Table 1115. Possible Combinations of CMP_C3[ACSAT], CMP_C3[ACPH1TC] and CMP_C3[ACPH2TC]

Tc	Phase1	Phase2
1*T	1*T	1*T
2*T	2*T	2*T
4*T	4*T	4*T
8*T	8*T	8*T
16*T	1*T	16*T
32*T	1*T	32*T
64*T	1*T	64*T
256*T	0	16*T

If the clock comes from 32KHz slow clock(CMP_C3[DMCLKSEL] = 0), both analog phase 1 and phase 2 will be driven to 0 and Tc is limited to T as shown in the figure below.

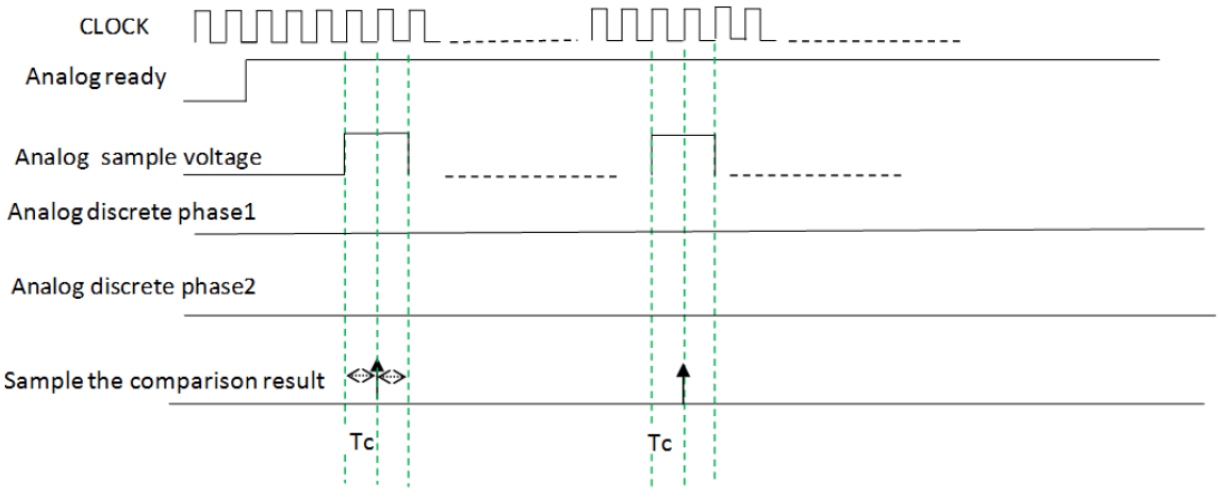

Figure 629. Slow (32 kHz) clock timing

81.3.4 CMP clocks

This module contains the following clocks:

- Bus clock for register access and window or filter operation
- Fast clock for Discrete mode
- Slow clock for Discrete mode
- Round-robin clock for Trigger mode

81.3.5 Interrupts

CMP generates an interrupt on either the rising- or falling-edge of the comparator output, or both. Assuming that C0[DMAEN] is not 1, the following table presents the conditions in which the interrupt request is asserted and deasserted.

Table 1116. CMP interrupt generations

Condition	Result
C0[IER] and C0[CFR] are 1.	The interrupt request is asserted.
C0[IEF] and C0[CFF] are 1.	The interrupt request is asserted.
C0[IER] and C0[CFR] are 0 for a rising-edge interrupt.	The interrupt request is deasserted.
C0[IEF] and C0[CFF] are 0 for a falling-edge interrupt.	The interrupt request is deasserted.

81.3.6 DMA support

CMP generates a CPU interrupt if there is a change on the COUT. The corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt after you write 1 to C0[DMAEN] to enable the DMA support, and write 1 to C0[IER], C0[IEF], or both to enable the interrupt. After the DMA completes the transfer, it sends a transfer-completing indicator signal that deasserts the DMA transfer request and clears the flags (C0[CFR] and C0[CFF]) to allow a subsequent change on the comparator output to occur and force another DMA request.

The comparator can remain functional in stop modes. The corresponding change on COUT forces a DMA transfer request to wake up the system from stop modes after you write 1 to C0[DMAEN] to enable the DMA support and write 1 to C0[IER], C0[IEF], or both, to enable the interrupt. After the data transfer has finished, the system goes back to stop modes. See the DMA chapters in this document for more information on the asynchronous DMA function.

81.4 DAC functional description

81.4.1 DAC block diagram

The following figure shows a 256-tap resistor ladder network and a 256-to-1 multiplexer. They select an output voltage from one of the 256 distinct levels that outputs from DACO.

CMP Control 1 (C1) controls DAC. You can select its supply reference source from two sources, V_{in1} and V_{in2}. Power down or disable the module when not in use. In Disabled mode, DACO is connected to the analog ground.

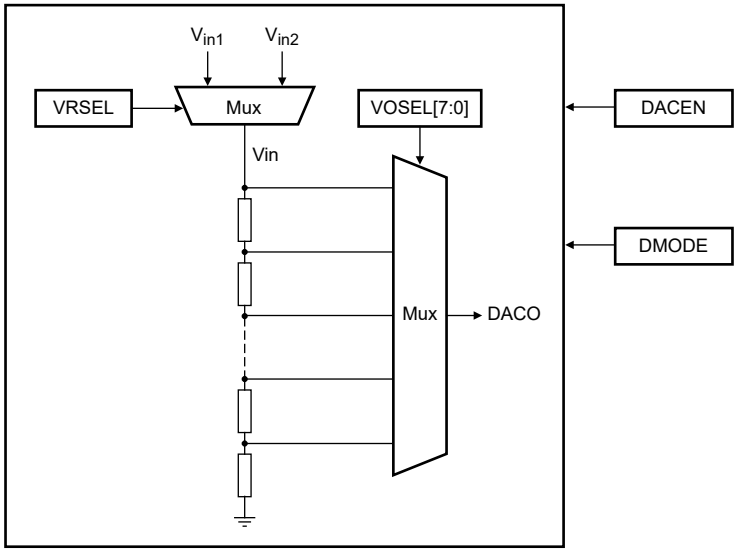

Figure 630. 8-bit DAC block diagram

81.4.2 Voltage reference source select

You must use:

- V_{in1} to connect to the primary voltage source as a supply reference of the 256-tap resistor ladder.
- V_{in2} to connect to an alternate voltage source, or primary source, if an alternate voltage source is not available.

81.4.3 DAC resets

This module contains a single reset input corresponding to the chip-wide peripheral reset.

81.4.4 DAC clocks

This module contains a single clock input—the bus clock.

81.4.5 DAC interrupts

This module contains no interrupts.

81.4.6 Trigger mode

CMP and the 8-bit DAC support the trigger mode operation, which is enabled when the MCU enters Stop mode with C0[WE], C0[SE], and C0[EN] = 1.

When this mode is enabled, the trigger events that include the operation clock and a trigger start signal initiate a compare sequence that must first enable CMP and DAC before performing a CMP operation and capturing the output. You can select a fixed channel for either the plus side mux or the minus side mux with C2[FXMP] and C2[FXMXCH]. You must set the round-robin cycling period for a longer duration than the time that all active channels take to complete the comparison cycles specified by C2[NSAM].

The active channels that C1[CHN*n*] selects route to the non fixed channel mux and compare with the reference input in a round-robin manner. To meet the comparator stabilization time, after the configurable number of operation clocks that C2[NSAM] defines, sample the comparison result for the selected channel. Write to C2[ACOn] to configure a software pre-programmed state for each channel. After you sample all the active channels, if the comparison result changes from its pre-programmed state, the corresponding flag in C2[CH*n*F] sets. An asynchronous reset asserts to bring the MCU out of Stop mode, if C2[RRIE] becomes 1.

Note that these flags do not support generating a DMA transfer event.

This mode is active when the MCU is in Stop mode, so no window or filter functions are available. A basic assumption of this mode is that the selected inputs change at a much slower rate than the operation clock. NXP recommends configuring the comparator in Low-Power Comparison mode as well. To program C2[INITMOD], you must ensure that the INITMOD × round-robin clock period must be longer than the initialization delay (see the chip data sheet for more information).

Figure 631 shows the basic flow of this mode. In the diagram, C1[CHN1], C1[CHN3], and C1[CHN4] are 1, so channels #1, #3, and #4 are selected for round-robin based on their polarity setting. When you write 1 to C2[NSAM], CMP samples the clock after one round-robin clock cycle. After you compare channel #3, the result is sampled, and round-robin ends. If any of the comparison results from channel #1, #3, or #4 deviates from its programmed value (written to C2[ACO1], C2[ACO3], and C2[ACO4]), an interrupt is generated to wake up the MCU from Stop mode. During Stop mode, you can poll C2[CH*n*F] to see the values of which channel input(s) are changed.

NOTE

In Round-Robin mode, you must ensure that the RTC_CLK period is greater than the comparison time corresponding to the value of C0[PMODE].

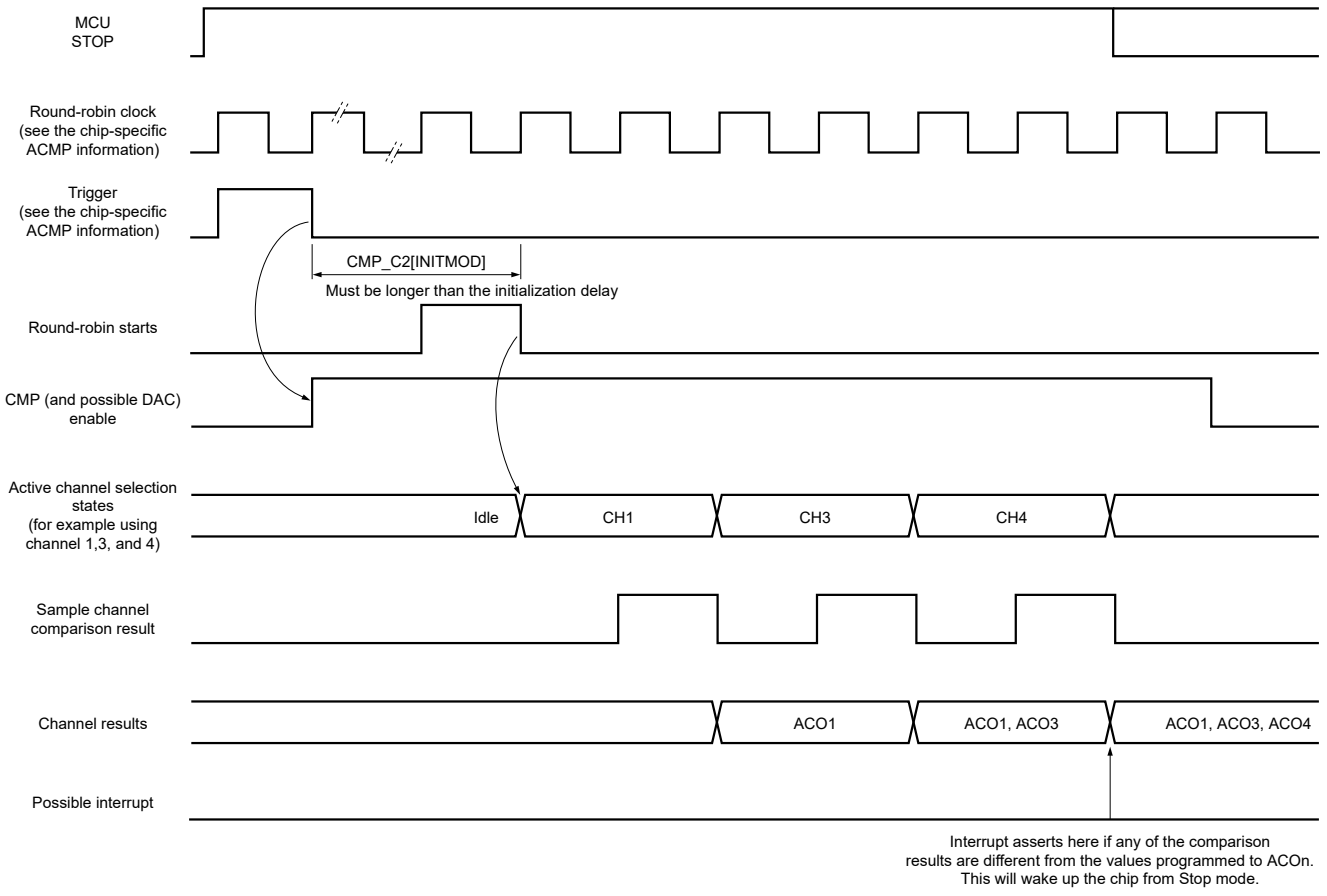

Figure 631. Trigger mode

81.5 CMP external signals

C1[PSEL] and C1[MSEL] mux the external 3V domain inputs, INA_3V[6:1] and 1.8 V domain INA_1P8 [4:1], INA_1P8_0_P, and INA_1P8_0_M, before going to the positive and negative ports of the comparator, respectively.

Table 1117. CMP external signals

Signal	Description	I/O
INA_3V[6:1]	The 3 V domain analog inputs [6:1]	I
INA_1P8 [4:1]	Analog 1.8 V input channels [4:1]	I
INA_1P8_0_P	Analog 1.8 V input channel 0 positive	I
INA_1P8_0_m	Analog 1.8 V input channel 0 minus	I

NOTE

It is not recommended to compare 3V domain channel with 1.8V domain channel. If the 3V domain channel's voltage is smaller than 1.8V, in this case, it can be compared with 1.8V domain channel by setting C3[RDIVE] to 0.

81.5.1 External pins

CMP contains two analog inputs:

- INP
- INM

Each pin can accept an input voltage that varies across the full operating range of the MCU. If the module is not enabled, you can use each pin as a digital input or output. See the specific MCU documentation for more information on what functions are shared with these analog inputs.

You can select either filtered or unfiltered comparator outputs for use on an external I/O pad.

81.6 Initialization

The time required to stabilize COUT is the power on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter. The windowing function has a maximum of one bus clock period delay. Low-pass filter specifies the filter delay.

During operation, you must always consider the propagation delay of the selected data paths. It may take many bus clock cycles for COUT and C0[CFR] or C0[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

When programmed for filtering modes, COUT initially equals 0 until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

30 DMAEN	DMA Enable Enables the DMA transfer that CMP triggers. If this field and the corresponding interrupt enable field are 1, a DMA request is asserted when C0[CFR] or C0[CFF] is set. 0b - Disable 1b - Enable
29 —	Reserved
28 IER	Comparator Interrupt Enable Rising Enables the CFR interrupt from CMP. If this field is 1, an interrupt asserts when C0[CFR] is set. 0b - Disable 1b - Enable
27 IEF	Comparator Interrupt Enable Falling Enables the CFF interrupt from CMP. If this field is 1, an interrupt asserts when C0[CFF] is set. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
26 CFR	Analog Comparator Flag Rising Detects a rising edge on COUT, when set, during normal operation. In stop mode, this field is level sensitive. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
25 CFF	Analog Comparator Flag Falling Detects a falling edge on COUT, when set, during normal operation. In Stop mode, this field is level sensitive . **NOTE** This field behaves differently for read and write operations. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
24 COUT	Analog Comparator Output Returns the current value of the analog comparator output, when read. The field resets to 0 and read as C0[INVT] when ACMP is disabled, that is, when C0[EN] = 0. Writes to this field are ignored.
23-16 FPR	Filter Sample Period Specifies the sampling period, in bus clock cycles, of the comparator output filter, when C0[SE] = 0. Writing 0h to this field disables the filter. See CMP functional description for more information on filter programming and latency. This field has no effect when C0[SE] = 1. In that case, the external sample signal determines the sampling period.
15 SE	Sample Enable Enables Sampling mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If a write to this register writes 1 both this field and C0[WE], then only Sampling mode is effective in MCU Run mode, and the round-robin cycling (Trigger mode) is enabled in MCU Stop mode. 0b - Disable 1b - Enable
14 WE	Windowing Enable Enables Windowing mode. If a write to this register writes 1 to both C0[SE] and this field, then only Sampling mode is effective in MCU Run mode, and the round-robin cycling (Trigger mode) is enabled in MCU Stop mode. 0b - Disable 1b - Enable
13 —	Reserved
12 PMODE	Power Mode Select Selects the power mode. 0b - Low-speed (LS) 1b - High-speed (HS)
11 INVT	Comparator Invert Selects the polarity of the analog comparator function. It is also driven to the COUT output (on the chip pin and as C0[COUT]) when C0[OPE] = 0. If the value of this field is 1, it inverts the comparator output. If the value of this field is 0, it does not invert the comparator output. 0b - Do not invert 1b - Invert
10 COS	Comparator Output Select Specifies whether CMPO must be set to equal COUT (filtered comparator output) or COUTA (unfiltered comparator output). 0b - COUT 1b - COUTA
9 OPE	Comparator Output Pin Enable Enables the path from the comparator output to a selected pin. If the value of this field is 0, the comparator output (after window or filter settings depending on software configuration) is not available to a packaged pin.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If the value of this field is 1 and the software configures the comparator to own a packaged pin, the comparator is available in a packaged pin. 0b - Disable 1b - Enable
8 EN	Analog Comparator Module Enable Enables ACMP. When the module is not enabled, the analog part remains in the off state, and consumes no power. When you select the same input from the analog mux to the positive and negative ports, the comparator is disabled automatically. 0b - Disable 1b - Enable
7 —	Reserved
6-4 FILTER_CNT	Filter Sample Count Specifies the number of consecutive samples that must agree prior to the comparator output filter accepting a new output state. 000b - Filter is disabled (if C0[SE] = 1, then COUT is a logic zero (this is not a legal state, and is not recommended); if C0[SE] = 0, COUT = COUTA) 001b - One consecutive sample (comparator output is simply sampled) 010b - Two consecutive samples 011b - Three consecutive samples 100b - Four consecutive samples 101b - Five consecutive samples 110b - Six consecutive samples 111b - Seven consecutive samples

82.2 Overview

The 12-bit digital-to-analog converter (DAC) is a low-power, general-purpose DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator, op-amps, or ADC.

82.2.1 Block diagram

The block diagram of the DAC module is as follows:

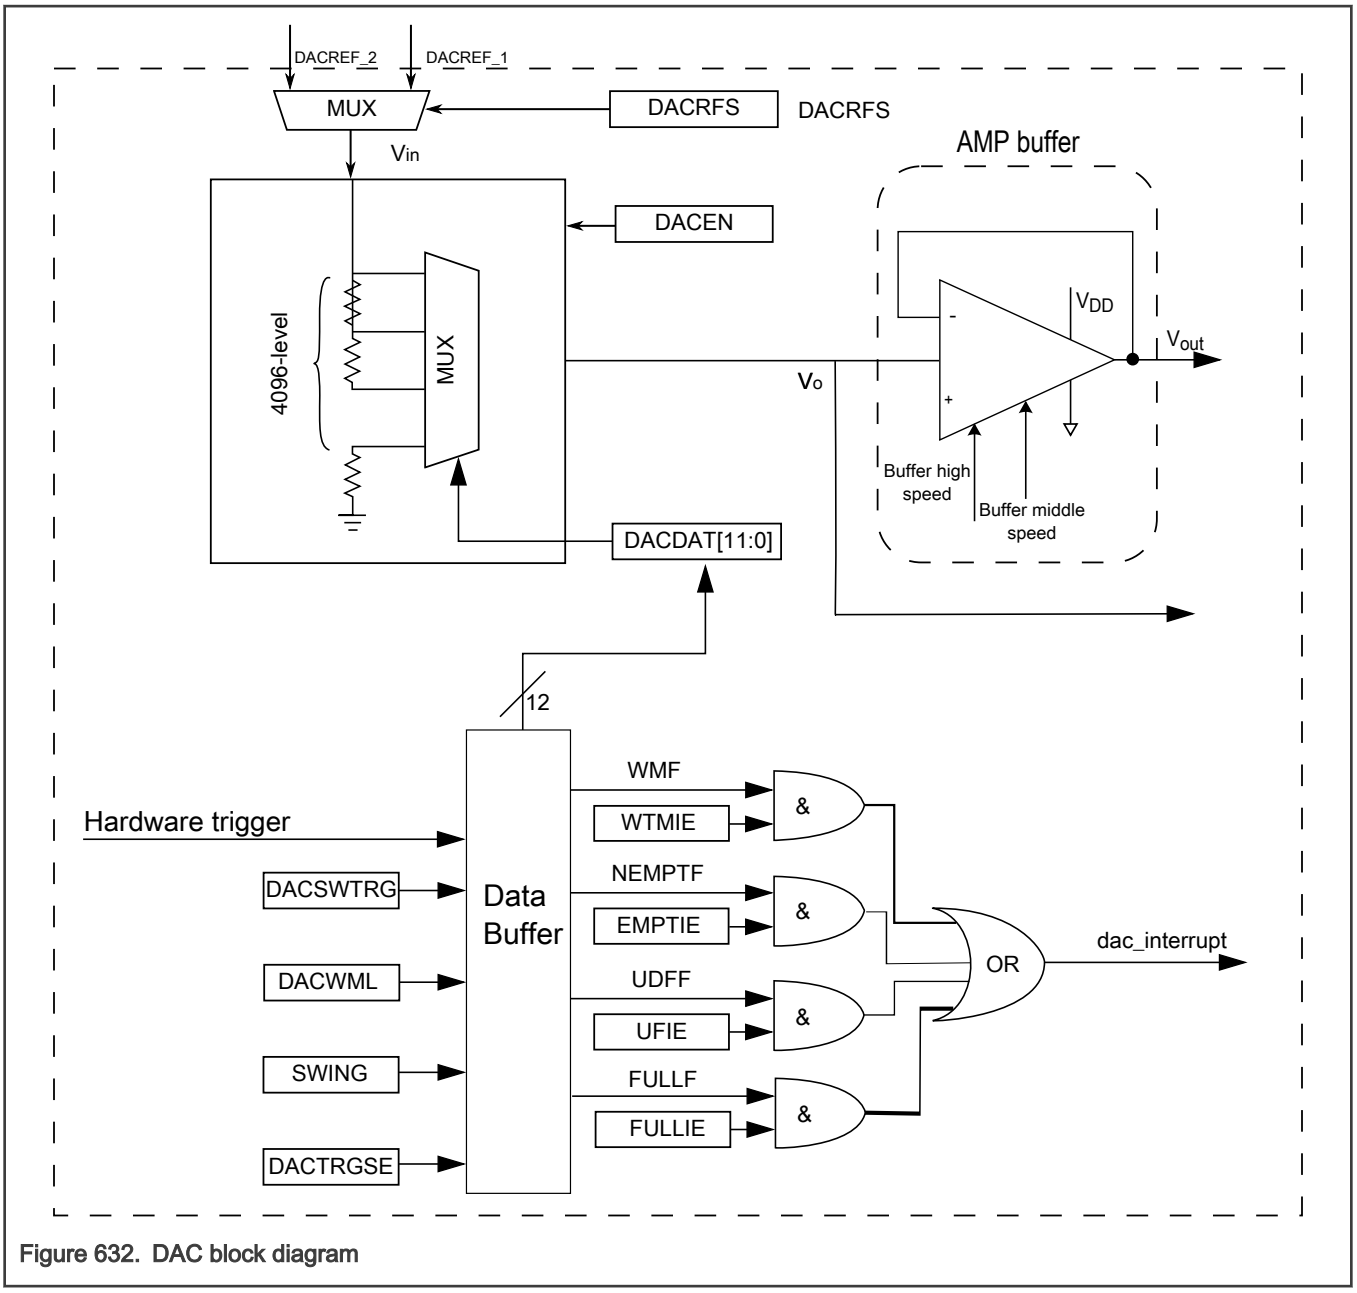

Figure 632. DAC block diagram

82.2.2 Features

The features of the DAC module include:

- On-chip programmable reference generator output. The voltage output range is from 1⁄4096 V_{in} to V_{in}, and the step is 1⁄4096 V_{in}, where V_{in} is the input voltage.
- V_{in} can be selected from two reference sources. See Chip-Specific Information section.
- 16 -word data buffer supported with configurable watermark and multiple operation modes
- DMA support

82.3 Functional description

The 12-bit DAC module can select one of the two reference inputs - DACREF_1 and DACREF_2 as the DAC reference voltage, V_{in} by C0[DACRFS]. See the chip-specific DAC information to determine the source options for DACREF_1 and DACREF_2.

When the DAC is enabled, it converts the data in DATA[11:0] or the data from the DAC data buffer to a stepped analog output voltage. The output voltage range is from V_{in} to $V_{in}/4096$, and the step is $V_{in}/4096$.

82.3.1 FIFO mode

In FIFO mode, the buffer is organized as a FIFO. For a valid write to the DATA register, the data is put into the FIFO, and the write pointer is automatically incremented. The module is connected internally to a 32-bit interface. For any 16-bit or 8-bit FIFO access, address bit[1] needs to be 0; otherwise, the write is ignored. A successful 32-bit FIFO write increases the write pointer by one.

For an 8-bit write, the LSB determines which byte lane is written to. Only if both the byte lanes are written to, will the write pointer increase. The user needs to ensure that an 8-bit access is done in pair, and both the upper and lower bytes are written. There is no priority for which byte is written to first.

FIFO mode needs to be enabled with DACCR[FIFOEN].

82.3.2 DAC data buffer operation

When the DAC FIFO is disabled, and the one entry buffer is enabled, the DAC converts the data in the buffer to analog output voltage. Any write to the DATA register will replace the data in the buffer and push data to analog conversion without trigger support.

When the IP interface bus access (IPS) is in write state, the write speed of DATA[DATA0] is high. However, the analog part of the DAC cannot convert data at the same speed. Therefore, the multi write speed limit needs to be defined in the firmware.

82.3.3 DAC interrupts

There are several interrupts and associated flags that can be configured for the DAC buffer.

FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration. This flag is set when the number of entries in any of the enabled FIFOs is less than or equal to the FIFO watermark configuration and is automatically cleared when the number of entries in FIFO is greater than the FIFO watermark configuration. The FIFO request flag can generate an interrupt or a DMA request.

FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO. The empty flag and full flags are both warning flags. The FIFO warning flag can generate an interrupt, or a DMA request (for empty flag only).

FIFO error flag

The FIFO error flag is set when overflow and underflow happens.

82.3.4 DMA operation

When DMA is enabled, DMA requests are generated instead of interrupt requests. The DMA Done signal clears the DMA request.

The status register flags are still set and are cleared automatically when the DMA completes.

82.3.5 Resets

During reset, the DAC is configured in the default mode and is disabled.

82.3.6 Low-Power mode operation

The following table shows the wait mode and the stop mode operation of the DAC module.

Table 1119. Modes of operation

Modes of operation	Description
Wait mode	The DAC will operate normally, if enabled.
Stop mode	If enabled, the DAC module continues to operate normally, with the hardware trigger initiating the conversion.

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

82.3.7 Background Debug Mode Operation

When the microcontroller is in active background debug mode, the DAC continues to operate normally.

82.4 Memory map/register definition

The DAC has registers to control analog comparator and programmable voltage divider to perform the digital-to-analog functions.

82.4.1 DAC register descriptions

82.4.1.1 DAC memory map

DAC base address: 42E2_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version Identifier Register (VERID)	32	R	0100_0000h

Ch	DAC Status and Control Register (CR)	32	RW	0000_0002h
10h	DAC FIFO Pointer Register (PTR)	32	R	0000_0000h
14h	DAC Status and Control Register 2 (CR2)	32	RW	0000_0000h

82.4.1.2 Version Identifier Register (VERID)

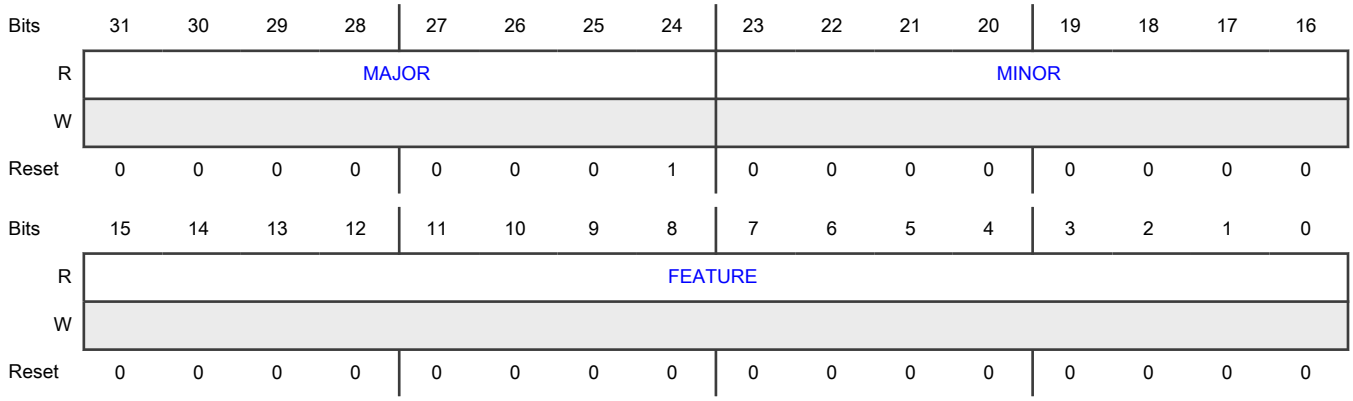
Offset

Register	Offset
VERID	0h

Function

The Version ID register indicates the version integrated for this instance on the device.

Diagram



Fields

Field	Function
31-24 MAJOR	Major version number This read-only field returns the major version number for the module specification.
23-16 MINOR	Minor version number This read-only field returns the minor version number for the module specification.
15-0 FEATURE	Feature Identification Number This read-only field returns the feature set number. 0000_0000_0000_0000b - Standard feature set 0000_0000_0000_0001b - C40 feature set 0000_0000_0000_0010b - 5V DAC feature set 0000_0000_0000_0100b - ADC BIST feature set

82.4.1.3 Parameter Register (PARAM)

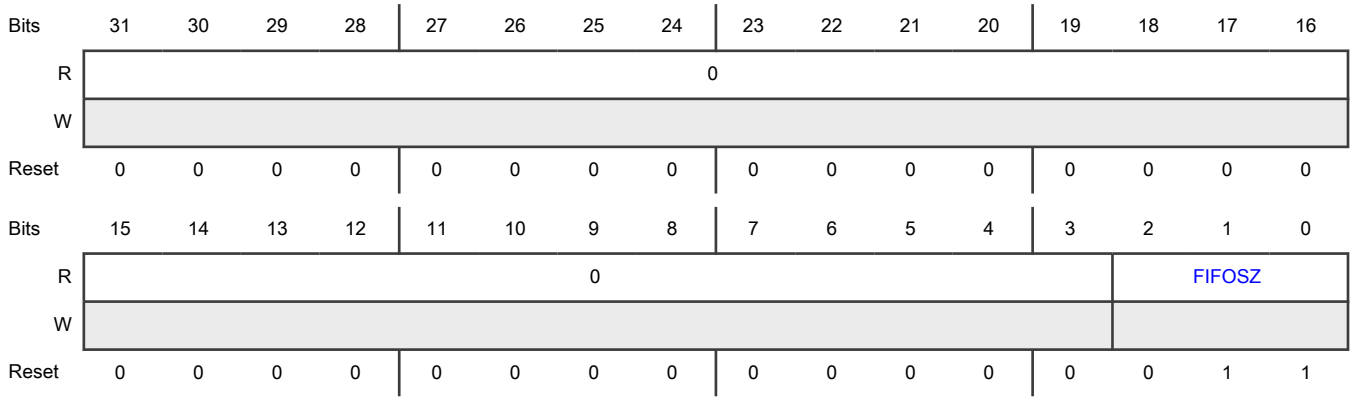
Offset

Register	Offset
PARAM	4h

Function

The Parameter register indicates the feature parameters for this instance on the device.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 FIFOSZ	FIFO size The number of words in the DAC FIFO is 2^(FIFOSZ+1). 000b - FIFO depth is 2 001b - FIFO depth is 4 010b - FIFO depth is 8 011b - FIFO depth is 16 100b - FIFO depth is 32 101b - FIFO depth is 64 110b - FIFO depth is 128 111b - FIFO depth is 256

82.4.1.4 DAC Data Register (DATA)

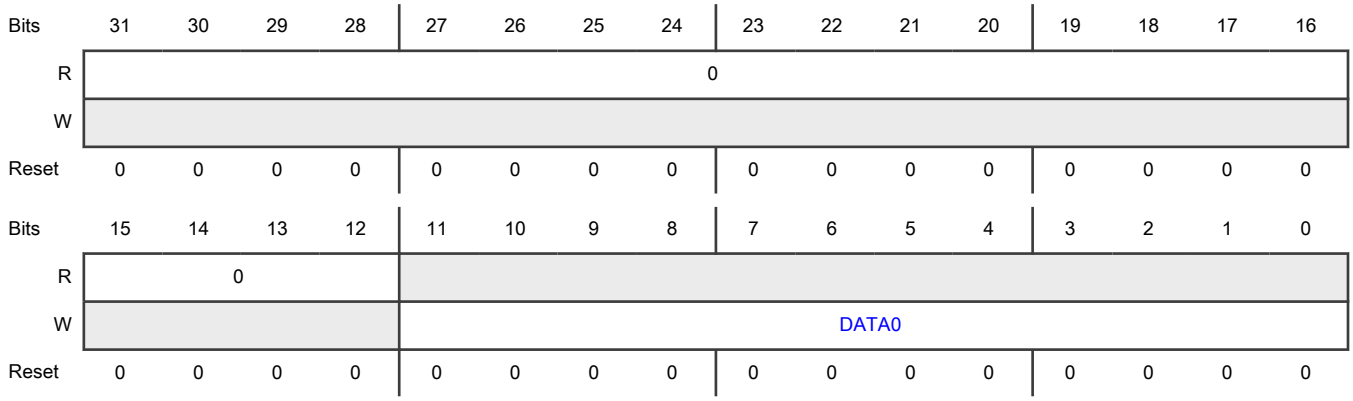
Offset

Register	Offset
DATA	8h

Function

The DAC Data Register holds the entry of FIFO in FIFO mode. It also works as the data buffer for buffer mode.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 DATA0	FIFO DATA0

82.4.1.5 DAC Status and Control Register (CR)

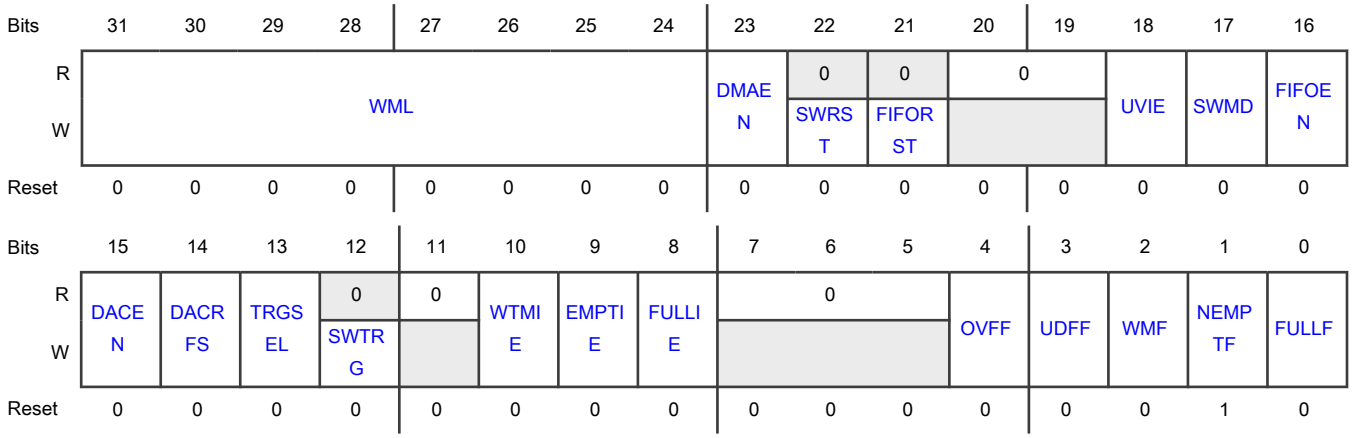
Offset

Register	Offset
CR	Ch

Function

The DAC Status and Control Register contains configuration options for the DAC operation, such as DMA and interrupt, trigger select and FIFO mode select. It also includes the FIFO status flags.

Diagram



Fields

Field	Function
31-24 WML	Watermark Level Select MAX is the FIFO size. **NOTE** If the FIFO depth is 2, then all settings are treated the same. That is, if the FIFO is not full, the watermark status bit and NEMPTF will be set. One of the status bits maybe needed for DMA or IRQ request.
23 DMAEN	DMA Enable Select 0b - DMA is disabled. 1b - DMA is enabled. When DMA is enabled, the DMA request will be generated by original interrupts. The interrupts will not be presented on this module at the same time.
22 SWRST	Software reset Resets all internal logic and registers, in case of any failure during the Low-power mode. This field is written to only to trigger reset, self clear, or read 0.
21 FIFORST	FIFO Reset Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the DAC is disabled. This field can be used to configure both pointers to the same address to reset the FIFO as empty. This field is written to only to trigger reset, self clear, or read zero. 0b - No effect 1b - FIFO reset
20-19 —	Reserved
18 UVIE	Underflow and overflow interrupt enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Underflow and overflow interrupt is disabled. 1b - Underflow and overflow interrupt is enabled.
17 SWMD	DAC FIFO Mode Select In Swing back mode, the FIFO must be set up such that the FIFO is full. In Swing back mode, a trigger changes the read pointer to make it swing between the FIFO Full and Nearly Empty state. That is, the trigger increases the read pointer till FIFO is nearly empty and decreases the read pointer till the FIFO is full, and so on. 0b - Normal mode 1b - Swing back mode
16 FIFOEN	FIFO Enable 0b - FIFO is disabled and only one level buffer is enabled. Any data written from this buffer goes to conversion. 1b - FIFO is enabled. Data will first read from FIFO to buffer then go to conversion.
15 DACEN	DAC Enable Starts the Programmable Reference Generator operation. 0b - The DAC system is disabled. 1b - The DAC system is enabled.
14 DACRFS	DAC Reference Select 0b - The DAC selects DACREF_1 as the reference voltage. 1b - The DAC selects DACREF_2 as the reference voltage.
13 TRGSEL	DAC Trigger Select 0b - The DAC hardware trigger is selected. 1b - The DAC software trigger is selected.
12 SWTRG	DAC Software Trigger Active high. This is a write-only field, which always reads 0. If DAC software trigger is selected and FIFO is enabled, writing 1 to this field will advance the FIFO read pointer once. **NOTE** It is not suggested to adopt hardware trigger and software trigger in mixed use, during continuous conversions. 0b - The DAC soft trigger is not valid. 1b - The DAC soft trigger is valid.
11 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 WTMIE	Watermark Interrupt Enable 0b - Watermark interrupt is disabled. 1b - Watermark interrupt is enabled.
9 EMPTIE	Nearly Empty Interrupt Enable 0b - FIFO Nearly Empty interrupt is disabled. 1b - FIFO Nearly Empty interrupt is enabled.
8 FULLIE	Full Interrupt Enable 0b - FIFO Full interrupt is disabled. 1b - FIFO Full interrupt is enabled.
7-5 —	Reserved
4 OVFF	Overflow Flag This is the FIFO overflow status flag. This flag indicates that more data has been written into FIFO than it can hold. This field asserts regardless of the value of UVIE. However, an interrupt is issued to the host only if UVIE is set. This flag is cleared by writing a 1 to it. 0b - No overflow has occurred since the last time the flag was cleared. 1b - At least one FIFO overflow has occurred since the last time the flag was cleared.
3 UDFF	Underflow Flag This is the FIFO underflow status flag. If this field is set, it means that there is a new trigger after NEMPTF is set. This field asserts regardless of the value of UVIE. However, an interrupt is issued to the host only if UVIE is set. This flag is cleared by writing a 1 to it. 0b - No underflow has occurred since the last time the flag was cleared. 1b - At least one trigger underflow has occurred since the last time the flag was cleared.
2 WMF	FIFO Watermark Status Flag This field is set if the remaining FIFO data is less than or equal to the watermark setting. It is cleared automatically by writing data into FIFO by DMA or CPU. Write to this bit is ignored in FIFO mode. 0b - The DAC buffer read pointer has not reached the watermark level. 1b - The DAC buffer read pointer has reached the watermark level.
1 NEMPTF	Nearly Empty Flag This is the FIFO nearly empty flag. It is set when only one data remains in FIFO. 0b - More than one data is available in the FIFO. 1b - One data is available in the FIFO.
0	Full Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
FULLF	This is the FIFO Full status bit. This means that the FIFO read pointer equals the write pointer, because of the write pointer increase. This field is cleared if any DAC trigger is making the DAC read pointer increase. Any write to this field is ignored in FIFO mode. 0b - FIFO is not full. 1b - FIFO is full.

82.4.1.6 DAC FIFO Pointer Register (PTR)

Offset

Register	Offset
PTR	10h

Function

The DAC FIFO Pointer Register contains the FIFO read pointer and write pointer.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-16 DACRFP	DACRFP This is the FIFO read pointer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The read pointer is later than the trigger for one cycle. After the conversion finishes and the next trigger comes, then the read pointer updates in the hardware trigger mode.
15-8 —	Reserved
7-0 DACWFP	DACWFP This is the FIFO write pointer. It's value is initially set to equal the read pointer value automatically, and the FIFO status is empty. Both write pointer and read pointer in FIFO mode do not change by IPS read access.

82.4.1.7 DAC Status and Control Register 2 (CR2)

Offset

Register	Offset
CR2	14h

Function

The DAC Status and Control Register 2 contains configuration options for the analog DAC.

NOTE

For CR2[6:4] (IREF, IREF1 and IREF2), it is suggested to enable one of the bits to reduce power. If more than one bit is selected, the power consumption will increase but the conversion rate will also speed up.

NOTE

IREF works in all modes, but the operation mode of IREF1 or IREF2 depends on PMC'.

Signal multiplexing	IOMUXC BLK_CTRL_AON BLK_CTRL_WAKEUP	External signals and pin multiplexing IOMUX Controller (IOMUXC) Block Control, AON Domain (BLK_CTRL_AON) Block Control, Wakeup Domain (BLK_CTRL_WAKEUP)
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

NOTE

Alternative DMA is not supported, access register C0ACFR[ADMASEL] has unpredictable results.

NOTE

Input signals INP[3:0] are not connected for RT1180, program CnCFR[IBSEL]=01b are unpredictable.

83.2 Overview

SINC converts an external ADC sigma-delta modulator bitstream to a data stream. The converters are based on:

- A maximum of 3-order sinc digital decimation filters with FastSinc support.
- A maximum selectable oversampling ratio (OSR) of 2048.

You can combine SINC functionality with additional software-based filtering.

83.2.1 Block diagram

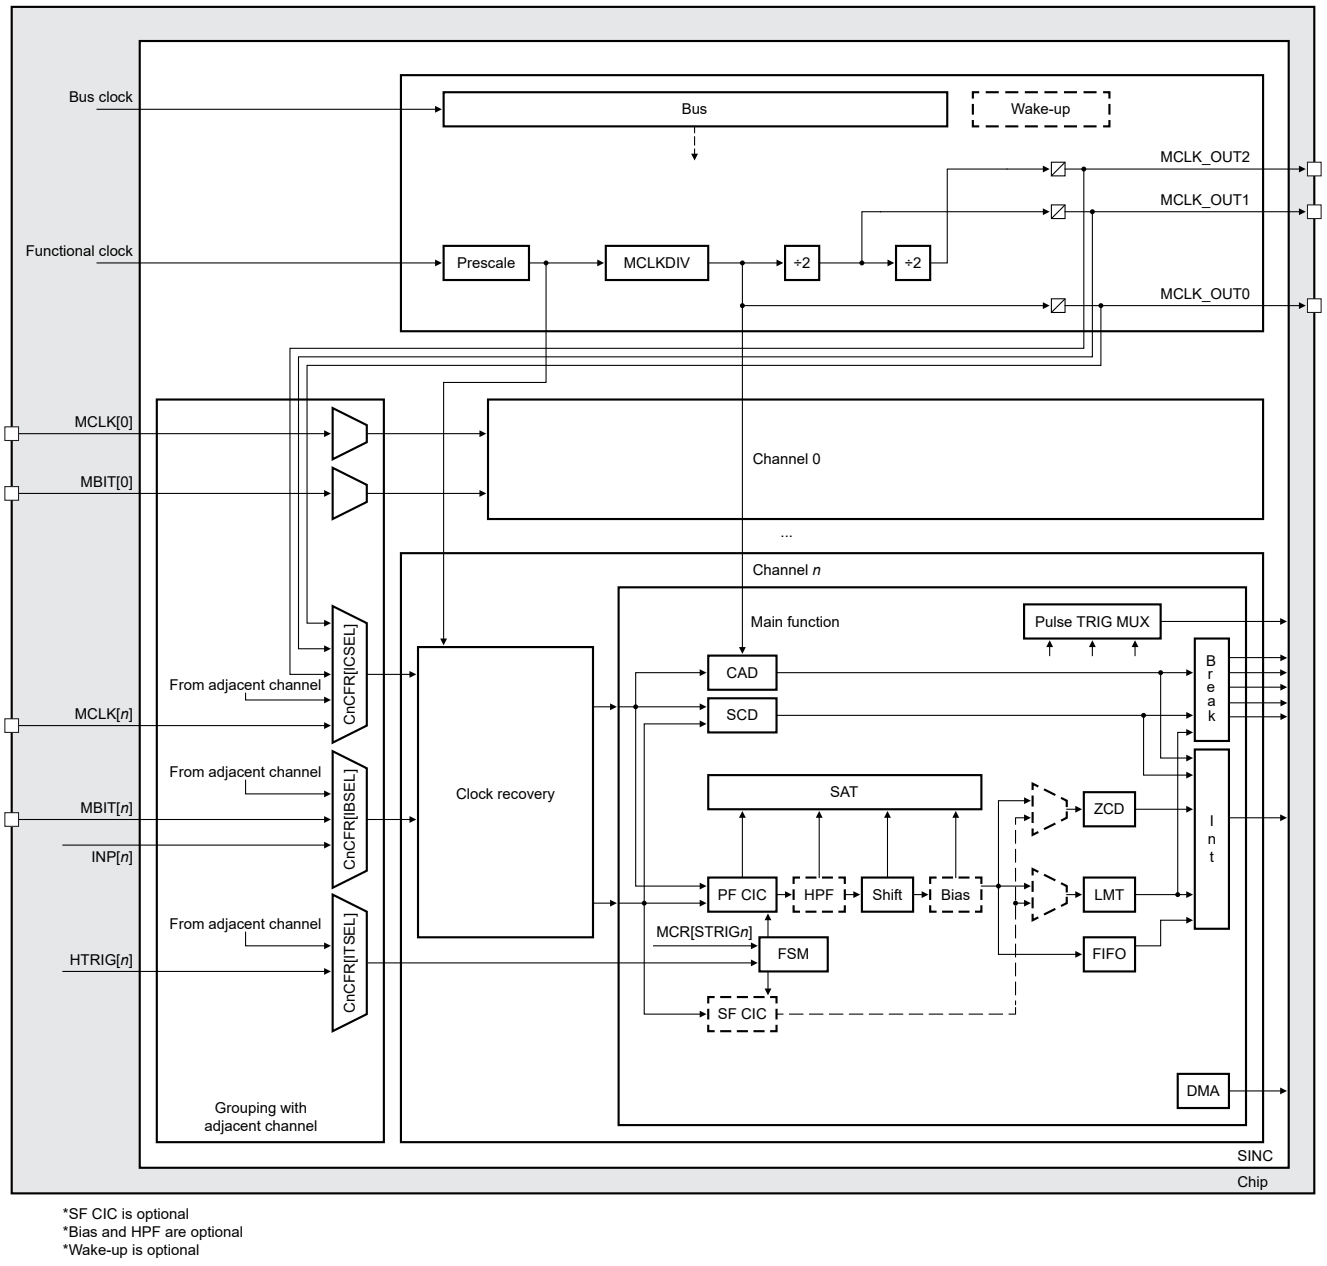

Figure 633. Block diagram

83.2.2 Features

- Filter channels with dedicated modulator clocks, bitstreams, and triggers
- Modulator clock outputs
- One software and one hardware trigger per channel
- One primary filter (PF) for each channel, with a shift and cascaded integrator comb (CIC) filter, for 24-bit precision
- Break signal outputs to turn off the external peripheral when a protection event occurs
- A 16-entry FIFO with watermark support for each channel

- Two DMA requests per channel with various event sources
- Various interrupt sources available for each channel (see Interrupts and breaks)
- Programmable high and low detection limits
- Support for short-circuit detector (SCD), clock-absence detector (CAD), and zero-cross detector (ZCD)
- Programmable shift operations
- Programmable bias (offset) operations
- high-pass filters (HPF) for DC removal
- Support for a Manchester-encoded bitstream
- Pulse-triggered output for additional control and monitoring

83.3 Functional description

83.3.1 Components

SINC includes the following two main components.

Table 1121. Components

Component	Supported functionality
Decimation filter	• A PF per channel • A high-precision 24-bit result with gain scaling • Facility for DC removal using an HPF • Offset bias compensation logic
Digital protection logic	• SCD • Hi-low limit detection (LMT) • CAD • ZCD

83.3.2 Operations

SINC performs operations based on:

- Modulator bitstream sources. See Bitstream source selection for more information.
- Conversion modes. See Modes and behaviors for more information.
- The selected PF. See PF for more information on SINC PF components, and see Calculating ORD and Equation for OSR that define the calculation for ORD and OSR, respectively, of the PF.

83.3.2.1 Calculating ORD

Use the following table to calculate ORD for the PF.

Table 1122. Calculating ORD

When C*n*DR[PFORD] is:	ORD is:
0	4
> 0	C*n*DR[PFORD]

83.3.2.2 Equation for OSR

$$OSR = C\textit{n}DR[PFOSR] + 1$$

Equation 35. Equation for OSR

83.3.2.3 Bitstream source selection

These are SINC's modulator bitstream sources:

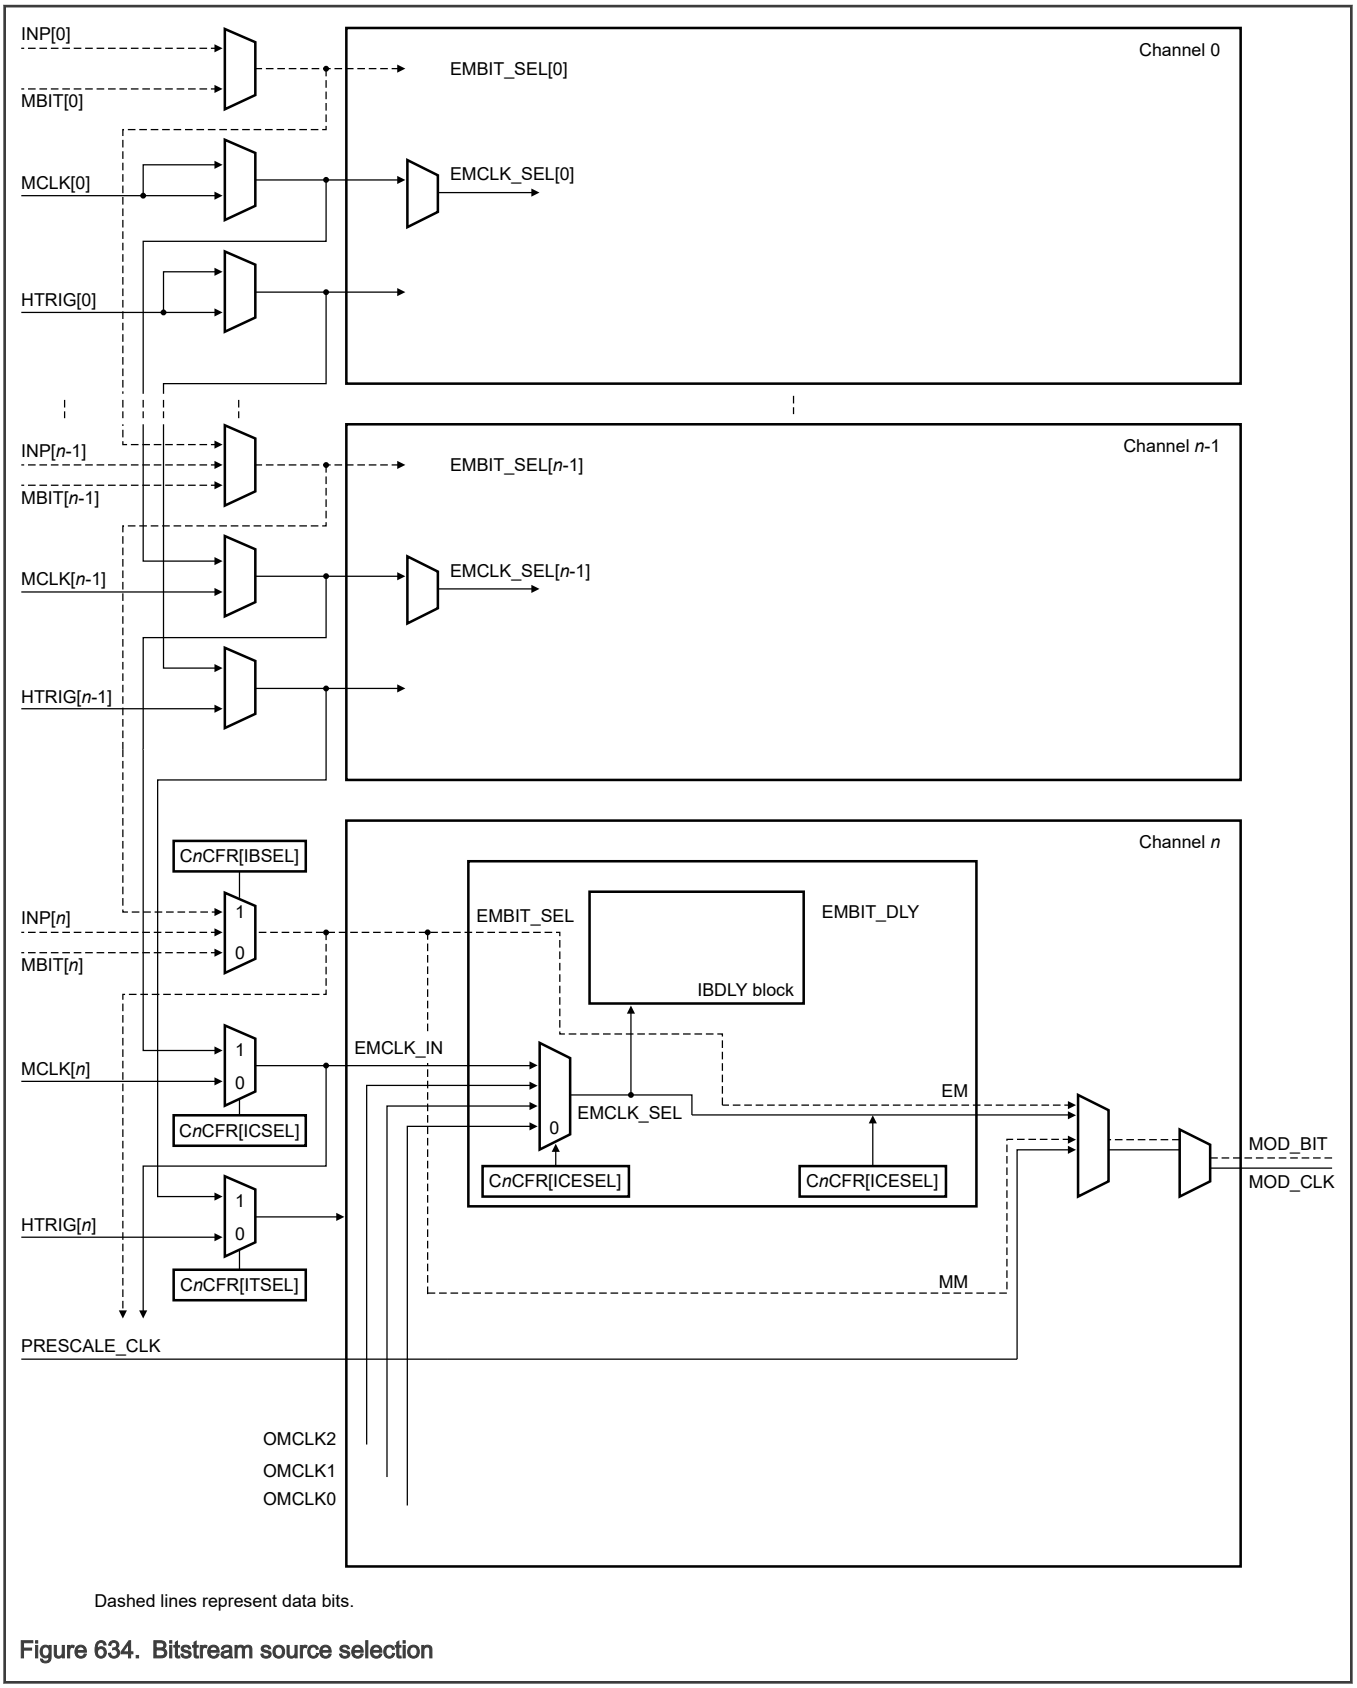
- The MBIT[3:0] signals (see External signals)
- The INP[3:0] signals (see External signals)
- Internal data from registers in Parallel or Serial mode

The following diagram shows MCLK[*n*] and MBIT[*n*] decoder circuits along with these key components:

- External modulator (EM) bitstream (see EM clock input bitstream sampling for EM clock input bitstream sampling)
- Manchester modulator (MM) bitstream (see MM clock input bitstream sampling for MM clock input bitstream sampling)
- Parallel modulator (PM) bitstream (see PM clock input bitstream sampling for PM clock input bitstream sampling)
- Serial modulator (SM) bitstream (see SM clock input bitstream sampling for SM clock input bitstream sampling)

The diagram also illustrates an example of bitstream source selection using:

- An external MCLK[*n*]
- An internal route back clock (OMCLK)
- An internal auto-generated clock for Parallel or Serial mode
- An internal auto-generated clock for Manchester format



Dashed lines represent data bits.

Figure 634. Bitstream source selection

83.3.2.3.1 Modulator bitstream and channel clock selection

Following is the modulator bitstream and clock mux configuration you could perform for each channel.

Table 1123. Modulator bitstream and channel clock selection

Use C*n*CFR[IBSEL] to	Use C*n*CFR[ICSEL] to	Use C*n*CFR[ITSEL] to
Select a modulator input bitstream (EMBIT_SEL) for channel *n* that can be either of the following: • A dedicated external modulator bitstream (MBIT[*n*]) if C*n*CFR[IBSEL] = 00b • A dedicated internal modulator bitstream (INP[*n*]) if C*n*CFR[IBSEL] = 01b • A shared group bitstream from an adjacent channel (*n*-1) if C*n*CFR[IBSEL] = 11b	Select a modulator input clock (EMCLK_SEL) for channel *n* that can be either of the following: • A dedicated modulator clock (MCLK[*n*]) if C*n*CFR[ICSEL] = 011b • A shared group clock (MCLK[*n*-1]) from an adjacent channel if C*n*CFR[ICSEL] = 111b • One of the three internal clocks routed to the chip modulator output clock if C*n*CFR[ICSEL] = 000b, 001b, or 010b	Select a modulator input trigger (HTRIG_SEL) for channel *n* that can be either of the following: • A dedicated software trigger (STRIG[*n*]) if C*n*CFR[ITSEL] = 00b • A dedicated hardware trigger (HTRIG[*n*]) if C*n*CFR[ITSEL] = 01b • A shared group hardware trigger (HTRIG[*n*-1]) from an adjacent channel if C*n*CFR[ITSEL] = 11b

83.3.2.3.2 Cross channel modulator bitstreams and clock groups

Following is the modulator bitstream and clock mux configuration you could perform with an adjacent channel.

Table 1124. Cross channel modulator bitstreams and clock groups

Write 111b to C*n*CFR[IBSEL] for	Write 111b to C*n*CFR[ICSEL] for	Write 11b to C*n*CFR[ITSEL] for
Combining the adjacent channel modulator bitstreams as groups, which: • Share the same modulator bitstreams and clocks if C*n*CFR[ICSEL] = 111b. • Can be configured to use one channel sample by rising edge and another channel sample by falling edge as a microphone use case. • Can be cascaded.	Combining adjacent channels as groups for the same clock to do either of these: • Reduce the I/O pin number. • Retain channels with the same time sequence. • Cascade, possibly.	Combining adjacent channels as groups for the same hardware trigger to: • Retain channels with the same time sequence. • Share the hardware trigger. • Cascade, possibly.

83.3.2.3.3 Modulator bitstream clock edge selection

Following are the modulator bitstream clock and trigger options you could use for each channel.

Table 1125. Modulator bitstream clock edge selection

Use C*n*CFR[ICESEL] to	Use C*n*CFR[ITLVL] to
Select a clock edge and use the selected modulator input clock (EMCLK_SEL) as either of the following:	Select a modulator input trigger event type. The selected modulator input trigger (HTRIG_SEL) can be used as either of the following:

Table continues on the next page...

Table 1125. Modulator bitstream clock edge selection

Use CnCFR[ICESEL] to	Use CnCFR[ITLVL] to
• Positive edge (by writing 001b to CnCFR[ICESEL]) • Negative edge (by writing 010b to CnCFR[ICESEL]) • Dual edge (by writing 011b to CnCFR[ICESEL]) • Every other even positive edge (by writing 101b to CnCFR[ICESEL]) • Every other odd negative edge (by writing 110b to CnCFR[ICESEL]) • Every other odd positive edge (by writing 100b to CnCFR[ICESEL]) • Every other even negative edge (by writing 111b to CnCFR[ICESEL])	• A positive edge trigger (by writing 0b to CnCFR[ITLVL]) • A high-level trigger (by writing 1b to CnCFR[ITLVL])

83.3.2.3.4 Modulator bitstream programmed delay

You can write an appropriate value to CnACFR[IBDLY] for the selected modulator bitstream to be delay sampled by the number of prescaled clock cycles. The delay number can be 0 (bypass), and extend to a maximum of 15 clock cycles.

See the following figure for a pictorial representation of the modulator bitstream programmed delay and see Modulator bitstream delay case 0, Modulator bitstream delay case 1, Modulator bitstream delay case 2, Modulator bitstream delay case 3, and Modulator bitstream delay case 4 for delay cases.

83.3.2.3.5 EM clock input bitstream sampling

See EM clock input bitstream sampling: settings for the values you need to write to SINC register fields for EM clock input bitstream sampling and see EM clock input bitstream sampling: diagram for the related bitstream sampling diagram.

83.3.2.3.5.1 EM clock input bitstream sampling: settings

Table 1126. EM clock input bitstream sampling: settings

Action	Result
Writing 00b to C*n*CFR[IBFMT]	Selects the CIC filter input from the selected modulator bitstream input (EMBIT_SEL[*n*]), which the EMCLK_SEL[*n*] clock samples to meet the I/O timing requirement and deliver for further decode.
If you write 011b to C*n*CFR[ICSEL]	The selected external clock (EMCLK_SEL) becomes a dedicated modulator clock, MCLK[*n*], for this channel.
If you write 111b to C*n*CFR[ICSEL]	The selected external clock (EMCLK_SEL) becomes a shared group clock from an adjacent channel.
If you write 000b, 001b, or 010b to C*n*CFR[ICSEL]	The selected external clock (EMCLK_SEL) becomes one of the three internal clocks that are routed as modulator clock outputs.

Table continues on the next page...

Table 1126. EM clock input bitstream sampling: settings (continued)

Action	Result
If you write 00b to CnCFR[IBSEL]	The selected external modulator bitstream (EMBIT_SEL) becomes a dedicated external modulator bitstream (MBIT[n]) for this channel.
If you write 01b to CnCFR[IBSEL]	The selected external modulator bitstream (EMBIT_SEL) becomes a dedicated internal modulator bitstream (inp[n]) for this channel.
If you write 11b to CnCFR[IBSEL]	The selected external modulator bitstream (EMBIT_SEL) becomes a shared group bitstream from an adjacent channel, n-1.
Writing an appropriate value to CnCFR[ICESEL]	Helps you select the type of edge to sample EMBIT_SEL.
Writing an appropriate value to CnACFR[IBDLY]	Helps you select the modulator bitstream delay function.

NOTE

You must configure the prescaler correctly to sample EMCLK_SEL according to CnCFR[ICESEL]. If you configure CnCFR[ICESEL] as a single-edge sample, you must program the prescaler to be 3x faster than EMCLK_SEL; if you configure CnCFR[ICESEL] as a dual-edge sample, you must program the prescaler to be 6x faster than EMCLK_SEL.

See the following for more information:

- Modulator bitstream and channel clock selection
- Modulator bitstream programmed delay
- Bitstream source selection

83.3.2.3.5.2 EM clock input bitstream sampling: diagram

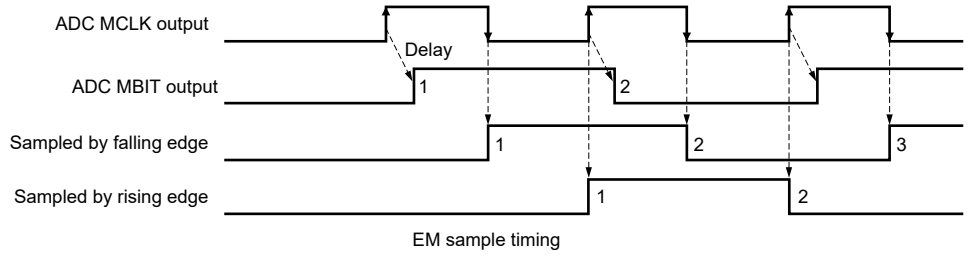

Figure 641. EM clock input bitstream sampling: diagram

83.3.2.3.6 MM clock input bitstream sampling

See MM clock input bitstream sampling: settings for the values you need to write to SINC register fields for MM clock input bitstream sampling and see MM clock input bitstream sampling: diagram for the related bitstream sampling diagram.

83.3.2.3.6.1 MM clock input bitstream sampling: settings

Table 1127. MM clock input bitstream sampling: settings

Action	Result
Writing 01b to C*n*CFR[IBFMT]	Helps you select the input bitstream format as external Manchester code. The modulator clock is recovered from the bitstream.
Writing an appropriate value to C*n*CFR[ICESEL]	Helps you select the input clock edge as rising or falling, with only 001b and 010b are valid values (see MM clock input bitstream sampling: diagram).
Writing 00b to C*n*CFR[IBSEL]	Helps you define the selected external modulator bitstream (EMBIT_SEL) as a dedicated external modulator bitstream (MBIT[*n*]) for this channel.
Writing 01b to C*n*CFR[IBSEL]	Helps you define the selected external modulator bitstream (EMBIT_SEL) as a dedicated internal modulator bitstream (INP[*n*]) for this channel.
Writing 11b to C*n*CFR[IBSEL]	Helps you define the selected external modulator bitstream (EMBIT_SEL) as a shared group bitstream from an adjacent channel, *n*-1.
Writing an appropriate value to C*n*MPDATA	Helps you define the correct threshold for the Manchester decoder. The threshold value must lie between the long pulse width and the short pulse width, and the prescaler clock counts this MBIT[*n*] pulse width. As shown in MM clock input bitstream sampling: diagram, if the previous short pulse is not recovered correctly, the first long pulse is considered as the first valid bit used for whole packet synchronization.

For more on the aforementioned settings, see the following:

- Modulator bitstream and channel clock selection
- Bitstream source selection

83.3.2.3.6.2 MM clock input bitstream sampling: diagram

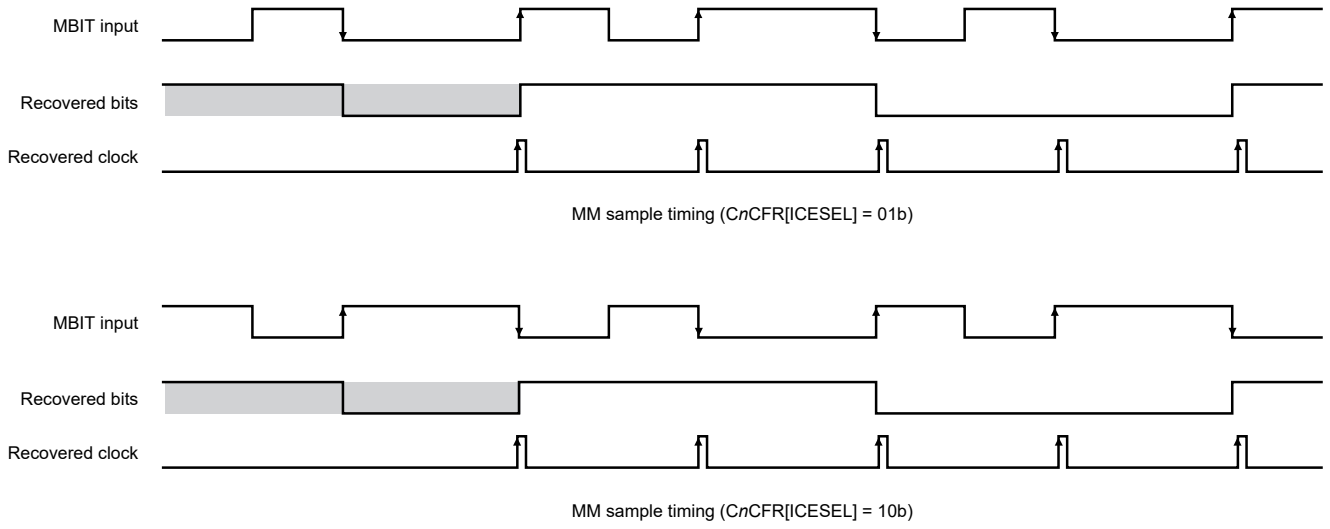

Figure 642. MM clock input bitstream sampling: diagram

83.3.2.3.7 PM clock input bitstream sampling

Table 1128. PM clock input bitstream sampling

Action	Result
Writing 10b to CnCFR[IBFMT]	Selects the CIC filter input from Channel n Multipurpose Data (C0MPDATA - C3MPDATA).
Checking the value of CnSR[PSRDY]	Helps you determine if the next write is allowed. CnSR[PSRDY] = 1 indicates that the previously written data is processed and the field is waiting for the next PM write.
Writing to CnCFR[RDFMT]	Selects PM data as signed or unsigned.
Writing to Channel n Multipurpose Data (C0MPDATA - C3MPDATA)	Sends the lower 16 bits to the CIC filter. The PM clock generates automatically after a write event; IMCLK0 decides the clock rate. If a PM write is not allowed (CnSR[PSRDY] = 0 when CnCFR[IBFMT] = 10), writing to Channel n Multipurpose Data (C0MPDATA - C3MPDATA) returns a bus error.

NOTE

Modulator clocks are automatically generated when you write data to Channel n Multipurpose Data (C0MPDATA - C3MPDATA). Because of conversion latency, you must write an extra two dummy data samples to provide extra clocks after the conversion is complete.

83.3.2.3.8 SM clock input bitstream sampling

See SM clock input bitstream sampling: settings for the values you need to write to SINC register fields for SM clock input bitstream sampling and see SM clock input bitstream sampling: diagram for the related bitstream sampling diagram.

83.3.2.3.8.1 SM clock input bitstream sampling: settings

Table 1129. SM clock input bitstream sampling: settings

Action	Result
Writing 11b to C*n*CFR[IBFMT]	Selects the CIC filter input from Channel n Multipurpose Data (C0MPDATA - C3MPDATA). The entire 32-bit serial data is shifted to the CIC filter. SM clocks are auto generated after a write event, and IMCLK0 decides the clock rate.
Checking the value of C*n*SR[PSRDY]	Determines if the next SM write is allowed. C*n*SR[PSRDY] = 1 indicates that the previously written data is processed and the field is waiting for the next SM write.
Writing to Channel n Multipurpose Data (C0MPDATA - C3MPDATA) for SM	Returns a bus error if an SM write is not allowed (C*n*SR[PSRDY] = 0), and no bitstream remains to be shifted after conversion finishes (C*n*CFR[IBFMT] = 11b).

NOTE

After conversion, the remaining bits are retained in Channel n Multipurpose Data (C0MPDATA - C3MPDATA). To reset them, you could toggle C*n*CR[CHEN] or MCR[RST].

83.3.2.3.8.2 SM clock input bitstream sampling: diagram

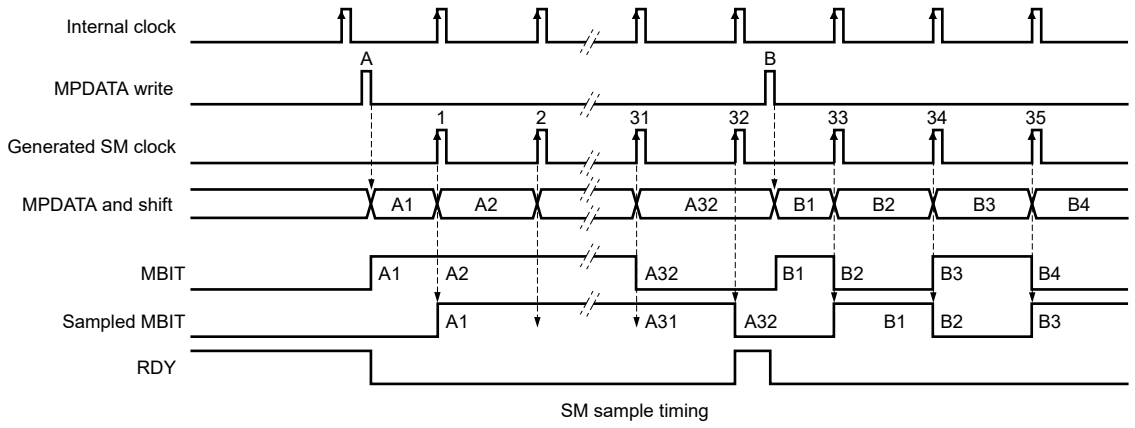

Figure 643. SM clock input bitstream sampling: diagram

83.3.2.4 Conversion process

83.3.2.4.1 Modes and behaviors

After a conversion process triggers:

- The decimation filters are activated.
- NIS[COC*n*] becomes 1 after the conversion completes.

You could use C*n*DR[PFCM] to select one of the conversion modes shown in the following table.

Table 1130. Modes and behaviors

Mode	Behavior of the conversion process in this mode
Single (C*n*DR[PFCM] = 00b)	• Each conversion requires a conversion trigger. • A single trigger starts only one conversion.
Continuous (C*n*DR[PFCM] = 01b)	• After a trigger is detected, the conversion process continues until the next trigger event. • The conversion process also continues after the first sample. You can perform a series of conversions at the rate of one sample per decimation clock cycle, which equals the value of C*n*DR[PFOSR] + 1. For details on subsequent samples, see Total conversion time. • The next trigger cancels the current conversion and restarts it.
Always (C*n*DR[PFCM] = 10b)	• After a trigger is detected, the conversion process continues until it is disabled. • Conversions also continue after the first sample. You can perform a series of conversions at the rate of one sample per decimation clock cycle, which equals the value of C*n*DR[PFOSR] + 1. For details on subsequent samples, see Total conversion time. • The next trigger event is ignored.
Fixed-Number (C*n*DR[PFCM] = 11b)	• After a trigger is detected, the conversion process continues until the required conversion number is achieved or until the next trigger event. • The conversion process stops when NIS[CHF*n*] becomes 1, so you can configure C*n*CFR[FIFOWMK] to determine the number of needed conversions. • The conversion process also continues after the first sample. You can perform a series of conversions at the rate of one sample per decimation clock cycle, which equals the value of C*n*DR[PFOSR] + 1. For details on subsequent samples, see Total conversion time. • The next trigger cancels the current conversion and restarts it.

83.3.2.4.2 Completion

Following are some of the events that take place after a conversion completes:

- The new sample value is transferred to the FIFO, and you can get the FIFO content by reading Channel n Result Data (C0RDATA - C3RDATA).
- NIS[COC*n*] becomes 1 and the FIFO data is available.
- NIS[CHF*n*] becomes 1 if the FIFO from the PF channel *n* has overflowed its watermark level and the FIFO data is available.
- A conversion complete and CHF interrupt are asserted if NIE[COCIE*n*] = 1 or NIE[CHFIE*n*] = 1.
- A DMA request and CHF are asserted if C*n*CR[DMAEN] = 1.

Additionally, you can read the current conversion data directly from Channel n Result Data (C0RDATA - C3RDATA) if FIFO is disabled.

83.3.2.4.3 Discontinuation

Conversion involves the following steps:

- CIC calculation
- Shift
- DC removal
- Bias
- Push FIFO and interrupt

You could abort a conversion by using any of these techniques:

- Disable
- Next Trigger
- Stop

This is what you could do to abort conversions, by using different register fields, modes, and triggers:

- To abort a conversion in progress, disable the PF by writing 0 to C*n*CR[PFEN]. However, in case you cancel the CIC filter by using C*n*CR[PFEN], the SCD and CAD blocks can still keep working.
- To abort a conversion along with its subfunctions (PF, CAD, and SCD), disable the channel by writing 0 to C*n*CR[CHEN].
- To abort or disable all the conversions globally, write 0 to MCR[MEN]. The FIFO retains the values of the previous conversion result that had not been read.
- In Single and Continuous conversion modes, if you select an edge trigger, a new trigger aborts the current conversion and restarts a new one.
- If you select a level trigger, a deasserted software or hardware trigger cancels the current conversion.
- In Stop mode, the current conversion is canceled.

If an abort occurs after the CIC filter has performed its function, you could:

- Use the Disable or Stop technique to cancel the current conversion immediately.
- Use the Next Trigger technique for the current conversion to continue the shift and bias operations and save the result to the FIFO. At the same time, the CIC can process the next conversion.

NOTE

For a motor use case, you must calculate the maximum speed (trigger frequency) to ensure that the required conversion number and the next trigger do not overlap. The margin must be at least two modulator clocks.

83.3.2.5 Conversion timing

83.3.2.5.1 Total conversion time

Table 1131. Total conversion time

In this mode:	The conversion time is:
Single	The value derived using this formula for a single conversion after the trigger event is over: ORD × OSR × MOD_CLK period
Continuous Always Fixed-Number	The value derived using this formula for the first 24-bit sample after the trigger event is over: ORD × OSR × MOD_CLK period However, the subsequent 24-bit samples are available after the OSR × MOD_CLK period.

where MOD_CLK period = 1 ÷ the frequency of MOD_CLK.

During a conversion, if you opt to resynchronize the conversion by providing a trigger, the first conversion result is available after the ORD × OSR × MOD_CLK period.

However, if you opt for a run-time phase compensation for a channel, SINC does not support it. You must provide a hardware trigger delay (for example, a PDB block) at the chip level. SINC does not support a software trigger delay.

83.3.2.5.2 Trigger alignment

When a trigger asserts, the recovered modulator clock samples the trigger event (see MOD_CLK in Bitstream source selection). At the same time, the modulator clock samples the MBIT[*n*] signal (see External signals). Therefore, the first valid bitstream to CIC is the clock cycle during which the trigger is asserted.

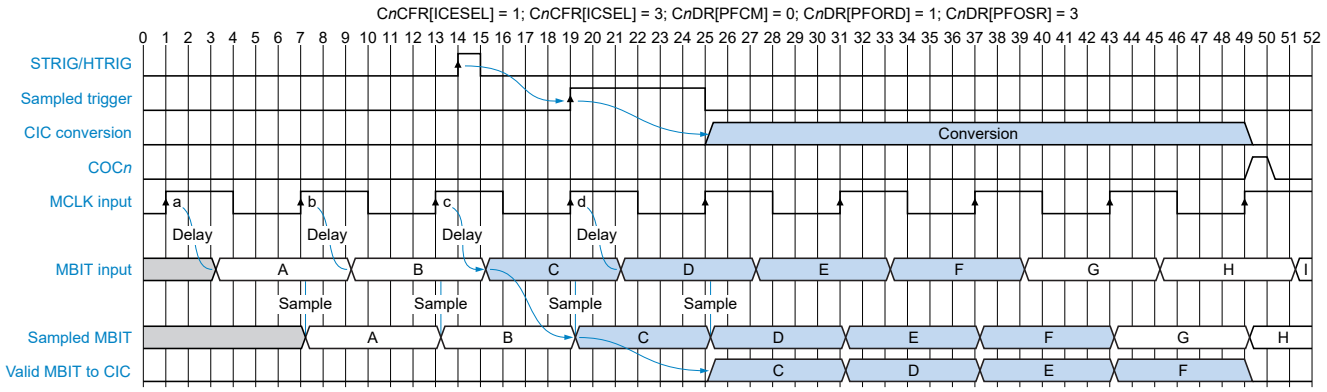

Figure 644. Trigger alignment

83.3.2.6 Trigger timing

83.3.2.6.1 Single mode software edge trigger

As illustrated in the following figure, when a software edge trigger event occurs in Single mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; trigger d starts conversion D1.
- Trigger e starts conversion e1 and trigger f cancels it before the conversion is complete. Simultaneously, trigger f starts (or resynchronizes) conversion F1.
- Trigger g starts conversion g1 but deassertion of the "Enable" signal cancels it.

See Total conversion time that defines the formula for Single mode conversion time.

NOTE

- The "Enable" signal is a combined AND logic of C*n*CR[PFEN] and SR[CHRDY*n*].
- You write 1 to MCR[STRIG*n*] and SINC writes 0 to this field for a software edge trigger case.

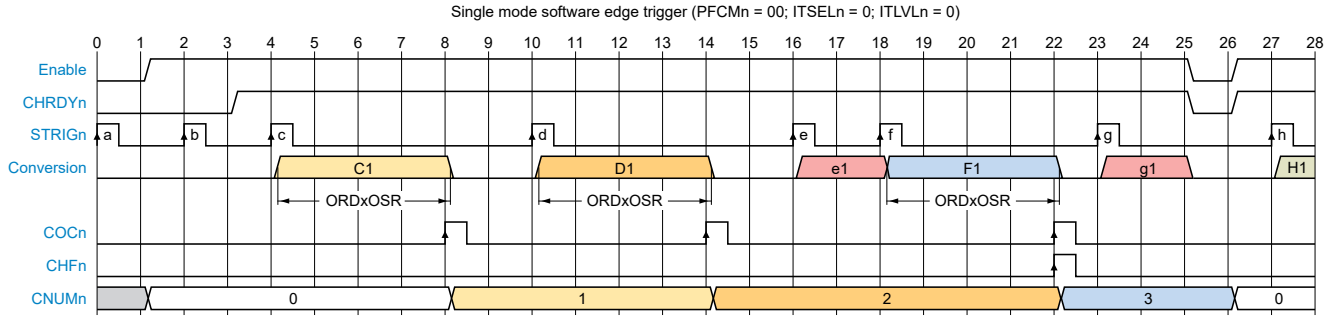

Figure 645. Single mode software edge trigger

83.3.2.6.2 Single mode hardware edge trigger

As illustrated in the following figure, when a hardware edge trigger event occurs in Single conversion mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; trigger d starts conversion D1.
- Trigger e starts conversion e1, but trigger f cancels it before completion. Simultaneously, trigger f starts (or resynchronizes) conversion F1.
- Trigger g starts conversion g1 but deassertion of the "Enable" signal cancels it.

The external hardware both asserts and deasserts the HTRIG[*n*] signal (see External signals); however, only the rising edge of the signal is accepted as the startup event for conversion. For example, trigger d exists several times, but the fall of trigger g does not cancel conversion D1.

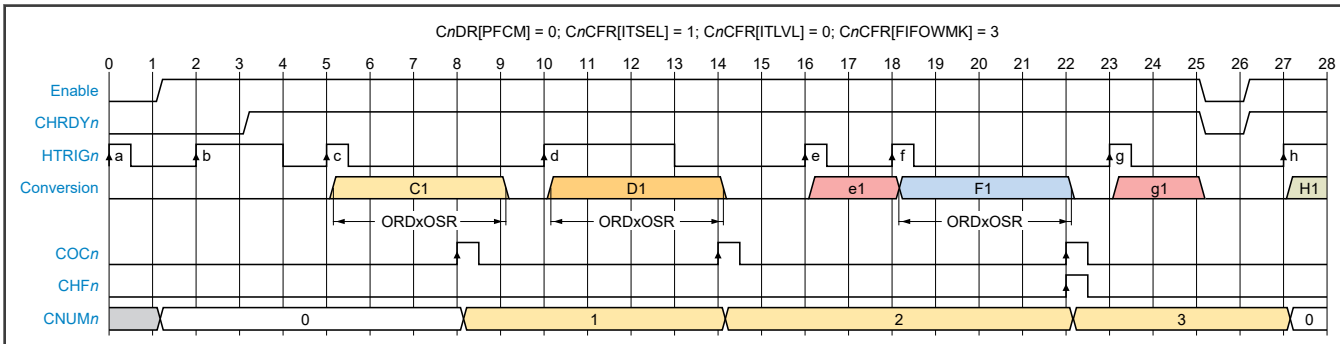

Figure 646. Single mode hardware edge trigger

83.3.2.6.3 Single mode hardware level trigger

As illustrated in the following figure, when a hardware level trigger event occurs in Single mode:

- Trigger a is ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger b starts conversion B1; trigger c starts conversion C1.
- Trigger d starts conversion d1 but the conversion cancels because trigger d deasserts before conversion completion.
- Trigger f starts conversion f1 but the conversion cancels because the "Enable" signal deasserts.

An external hardware asserts and deasserts HTRIG[*n*]. The rising of HTRIG[*n*] starts the conversion and the falling of HTRIG[*n*] cancels the conversion before its completion.

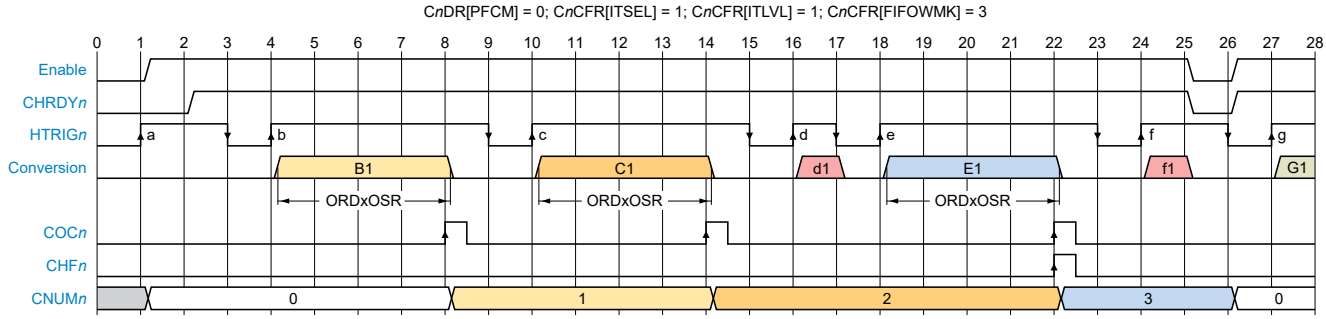

Figure 647. Single mode hardware level trigger

83.3.2.6.4 Continuous mode software edge trigger

In Continuous mode, conversions comprise a set of subconversions and continue until aborted by another event. For example, as shown in the following figure, conversion C comprises subconversions C1, C2, C3, c4, and so on; and conversion D comprises subconversions D1, D2, d3, and so on. When a software edge trigger event occurs in Continuous conversion mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1 and trigger d starts conversion D1.
- The output delay time for C1 is defined as OSR×ORD. When conversion C1 comes to an end, conversion C2 starts automatically.
- The output delay time for C2 is defined as OSR, and so is the output delay time for conversion C3.
- Trigger d cancels conversion c4 and simultaneously resynchronizes conversion D1.
- Writing 0 to C*n*CR[PFEN] cancels conversion d3.

You write 1 to MCR[STRIG*n*] and SINC writes 0 to this field for a software edge trigger event in Continuous mode.

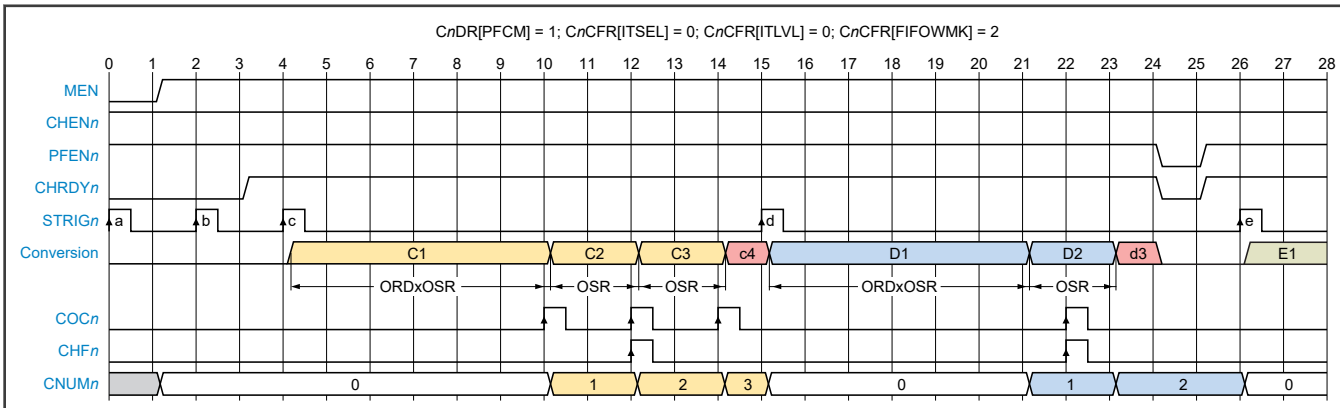

Figure 648. Continuous mode software edge trigger

83.3.2.6.5 Continuous mode hardware edge trigger

As illustrated in the following figure, when a hardware edge trigger event occurs in Continuous mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1, and hardware trigger d starts conversion D1.
- The output delay time for C1 is defined by OSR×ORD. After conversion C1 comes to an end, conversion C2 starts automatically.

- The output delay time for C2 is defined as OSR, and so is the output delay time for C3.
- Trigger d cancels conversion c4 and simultaneously resynchronizes conversion D1.
- Writing 0 to C*n*CR[PFEN] cancels conversion d4.

The external hardware asserts and deasserts HTRIG[*n*]. However, only the rising of HTRIG[*n*] starts the conversion. For example, the hardware trigger d exists several times, but the fall of trigger d does not cancel conversion D1. Hardware trigger b asserts before SR[CHRDY*n*] becomes 1 and remains asserted after SR[CHRDY*n*] becomes 1, but no conversion starts.

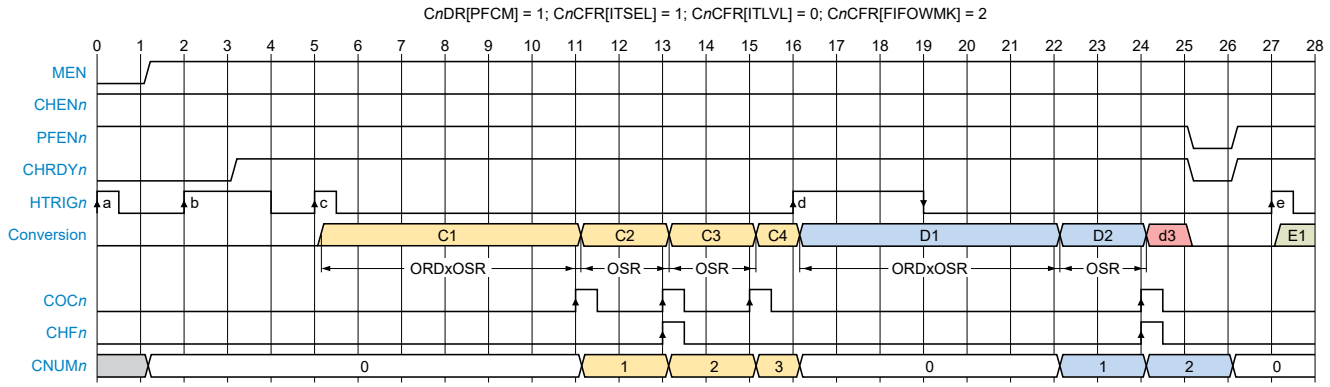

Figure 649. Continuous mode hardware edge trigger

83.3.2.6.6 Continuous mode software level trigger

As illustrated in the following figure, when a software level trigger event occurs in Continuous mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; trigger d starts conversion D1.
- The output delay time for C1 is defined as OSR×ORD. After conversion C1 comes to an end, conversion C2 starts automatically.
- The output delay time for C2 is defined as OSR, and so is the output delay time for C3.
- Trigger c deassertion cancels conversion c4.
- Signal "Enable" deassertion cancels conversion d3.

For a software level trigger event in Continuous mode, you can write both 1 (to start the conversion process) and 0 (to stop the conversion process) to MCR[STRIG*n*] if SR[CHRDY*n*] is 1. SINC can also write 0 to MCR[STRIG*n*] to cancel the conversion. The following example shows writing 0 to MCR[STRIG*n*] cancels conversion c4.

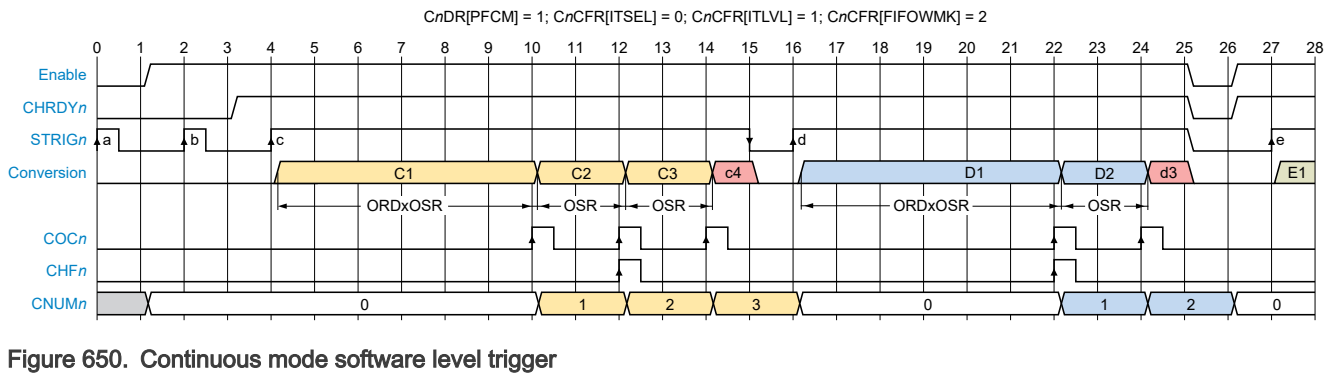

Figure 650. Continuous mode software level trigger

83.3.2.6.7 Continuous mode hardware level trigger

As illustrated in the following figure, when a hardware level trigger event occurs in Continuous mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; and trigger d starts conversion D1.
- The output delay time for C1 is defined as OSR×ORD. When conversion C1 comes to an end, conversion C2 starts automatically.
- The output delay time for C2 is defined as OSR, and so is the output delay time for conversion C3.
- Trigger c deassertion cancels conversion c4.
- Signal "Enable" deassertion cancels conversion d3.

An external hardware asserts and deasserts HTRIG[*n*]. It asserts HTRIG[*n*] to start the conversion process and deasserts it to stop the conversion process. The following example shows that HTRIG[*n*] deassertion cancels conversion c4.

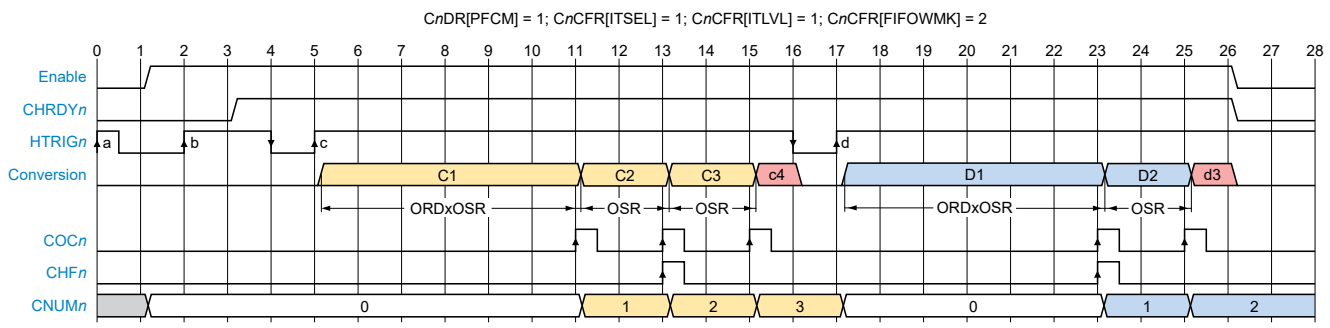

Figure 651. Continuous mode hardware level trigger

83.3.2.6.8 Always mode hardware edge trigger

As illustrated in the following figure, when a hardware edge trigger event occurs in Always mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; trigger e starts conversion D1.
- The output delay time for C1 is defined as OSR×ORD. After conversion C1 comes to an end, conversion C2 starts automatically.
- The output delay time for C2 is defined as OSR, and so is the output delay time for conversion C3.
- Trigger d is ignored.

After the conversion process starts in this mode, the only way to stop it is by writing 0 to MCR[MEN], C*n*CR[CHEN], or C*n*CR[PFEN].

An external hardware both asserts and deasserts HTRIG[*n*].

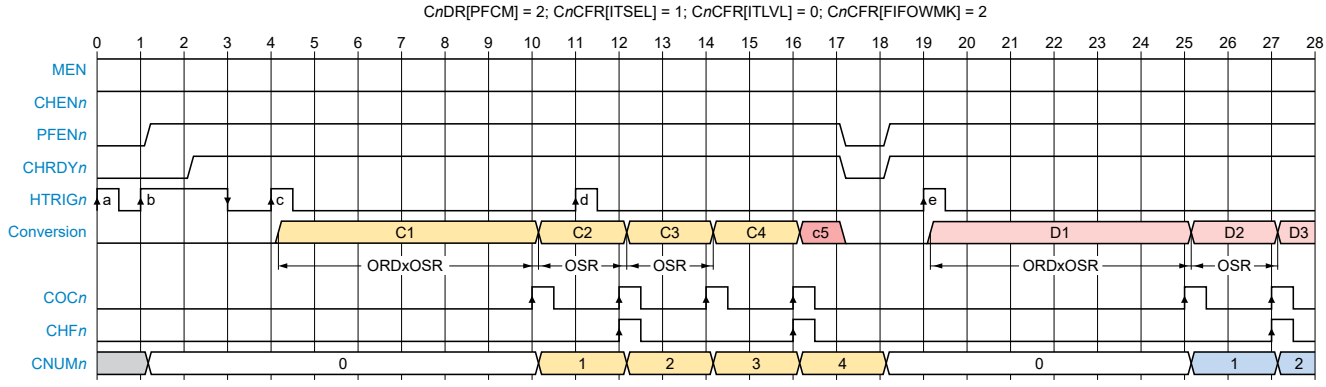

Figure 652. Always mode hardware edge trigger

83.3.2.7 PF

SINC's PF comprises the following:

- A CIC filter
- An optional HPF for DC removal operations
- A shift
- An optional bias

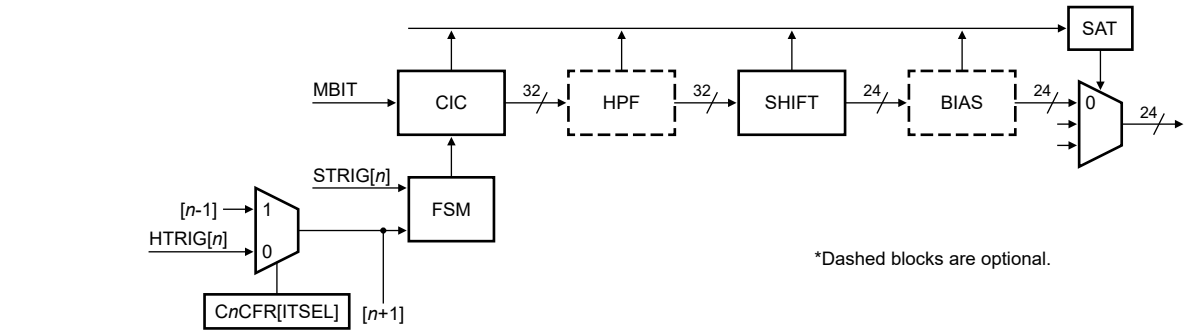

Figure 653. PF

83.3.2.7.1 CIC filter

CIC filters:

- Consist of one or more integrator and comb filter pairs.
- Represent an optimized implementation of low-pass filters (LPFs) with programmable, multiple stages.
- Are widely used because they can be implemented using just adders and subtractors.
- Output raw 32-bit data and deliver it to the HPF (or to the PF shift if HPF is not present).
- Select a CIC filter input, decode modulator bitstream, and decode modulator clock from the recovery block.

The following figure shows the architecture of a three-stage CIC filter, comprising integrator sections followed by comb sections downsampled.

See CnDR[PFORD] for information on PF order and CnDR[PFOSR] for information on PF OSR.

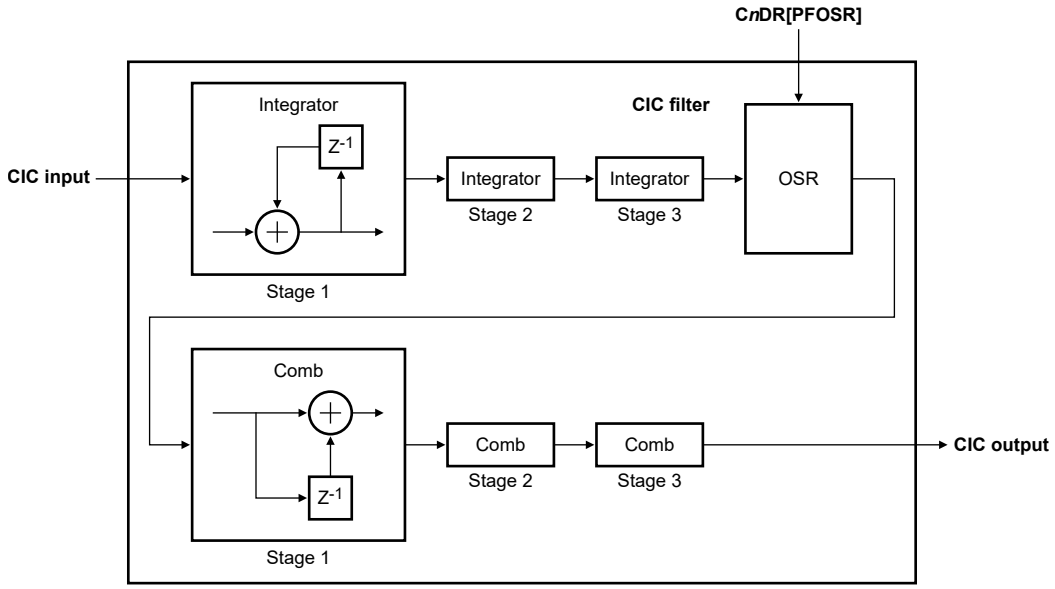

Figure 654. CIC filter

83.3.2.7.1.1 CIC filter transfer function

You can calculate the transfer function of the CIC filter, when CnDR[PFORD] is any value except 0, based on the following equation.

$$H(Z) = \frac{Y(Z)}{X(Z)} = \left[\frac{1-Z^{-OSR}}{1-Z^{-1}}\right]^{ORD}$$

Equation 36. CIC filter transfer function

You can see an example of Frequency Response in Frequency response

You can get CIC output effective data width by below equation. Where OSR are described at Equation for OSR.

when CnCFR[RDFMT]=0b(signed):

WDITH = log2(OSR^^CnDR[PFORD]+1)+1

when CnCFR[RDFMT]=1b(unsigned):

WDITH = log2(OSR^^CnDR[PFORD]+1)

Equation 37. Equation for CIC effective data width

83.3.2.7.1.2 FastSinc filter transfer function

You can calculate the transfer function of the FastSinc filter, when CnDR[PFORD] = 0, based on the following equation.

$$H(Z) = \frac{Y(Z)}{X(Z)} = \left[\frac{1-Z^{-OSR}}{1-Z^{-1}}\right]^{2} * \left[1+Z^{-2*OSR}\right]$$

Equation 38. FastSinc filter transfer function

You can get CIC output effective data width by below equation. Where OSR are described at Equation for OSR

when CnCFR[RDFMT]=0b(signed):

WDITH = log2(OSR^^2*2+1)+1

when C*n*CFR[RDFMT]=1b(unsigned):

WDITH = log2(OSR^^2*2+1)

Equation 39. Equation for CIC effective data width

83.3.2.7.1.3 CIC effective data width

You can see an example of Frequency Response in Frequency response

You can get example CIC output effective data width by Table 1132. Where OSR are described at Equation for OSR

Table 1132. data width vs OSR and ORD

OSR	C*n*CFR[RDFMT]=0b(signed)				C*n*CFR[RDFMT]=1b(unsigned)			
	PFORD=1	PFORD=2	PFORD=0 (fastsinc)	PFORD=3	PFORD=1	PFORD=2	PFORD=0 (fastsinc)	PFORD=3
16	6	10	11	14	5	9	10	13
32	7	12	13	17	6	11	12	16
64	8	14	15	20	7	13	14	19
128	9	16	17	23	8	15	16	22
256	10	18	19	26	9	17	18	25
1291	12	22	23	33(not support)	11	21	22	32
1626	12	23	24	34(not support)	11	22	23	33(not support)

83.3.2.7.2 Trigger events

The following table shows trigger cases based on the configuration of PF conversion modes (C*n*DR[PFCM]), input trigger selection (C*n*CFR[ITSEL]), and input trigger level type (C*n*CFR[ITLVL]).

NOTE

C*n*CFR[ITSEL] = 11b indicates that a grouped trigger shared with an adjacent channel behaves in the same way as a hardware trigger (01b).

Table 1133. Trigger events

C*n*DR[PFCM]	C*n*CFR[ITSEL]	C*n*CFR[ITLVL]	Case	Functioning
00	00	0	Single mode software edge trigger	• Writing 1 to MCR[STRIG*n*] starts the conversion process. In case of an ongoing conversion, writing 1 to this field cancels it and starts a new conversion. • MCR[STRIG*n*] automatically becomes 0 after the conversion starts.

Table continues on the next page...

Table 1133. Trigger events (continued)

CnDR[PFCM]	CnCFR[ITSEL]	CnCFR[ITLVL]	Case	Functioning
	00	1	Single mode software level trigger	Reserved
	01	0	Single mode hardware edge trigger	• An external hardware trigger rising edge starts the conversion process. • The next trigger during conversion cancels the current conversion and restarts a new one.
	01	1	Single mode hardware level trigger	• An external hardware trigger rising edge starts the conversion process. • The hardware trigger deasserts during conversion and cancels the current conversion.
01	00	0	Continuous mode software edge trigger	• Writing 1 to MCR[STRIGn] starts the conversion process, which continues unless the filter is disabled. In case of an ongoing conversion, writing 1 to this field cancels it and starts a new conversion. • MCR[STRIGn] automatically becomes 0 after the conversion starts.
	00	1	Continuous mode software level trigger	• Writing from 0 to 1 to MCR[STRIGn] starts the conversion process, which continues unless the channel filter is disabled. • Writing 0 to MCR[STRIGn] cancels the current conversion.
	01	0	Continuous mode hardware edge trigger	• An external hardware trigger rising edge starts the conversion process, which continues unless the channel filter is disabled. • The next trigger cancels the current conversion and restarts a new one.
	01	1	Continuous mode hardware level trigger	• An external hardware trigger rising edge starts the conversion process, which continues unless the channel filter is disabled. • The hardware trigger deasserts and cancels the current conversion.

Table continues on the next page...

Table 1133. Trigger events (continued)

CnDR[PFCM]	CnCFR[ITSEL]	CnCFR[ITLVL]	Case	Functioning
10	00	0	Always mode software edge trigger	Reserved
	00	1	Always mode software level trigger	Reserved
	01	0	Always mode hardware edge trigger	• An external hardware trigger rising edge starts the conversion process, which continues unless the channel filter is disabled. • The next trigger is ignored.
	01	1	Always mode hardware level trigger	Reserved
11	Any value	1	Always mode hardware level trigger	• Trigger behavior is the same as in Continuous mode for CnCFR[ITSEL] and CnCFR[ITLVL]. • The conversion process automatically stops when the FIFO watermark is asserted.

83.3.2.7.3 HPF transfer function for DC removal

An HPF performs the DC removal function. The CIC filter provides an input to the HPF and outputs 32-bit data, which is sent to the PF shift.

CnACFR[HPFA] specifies the HPF alpha coefficient or disables the HPF when it is 0.

The HPF restarts if CnCR[CHEN] changes from 0 to 1 (in case of a rise event) and the following transfer function specifies the HPF frequency response.

$$H(Z) = \frac{Y(Z)}{X(Z)} = \frac{1\text{-}Z^{-1}}{1\text{-}aZ^{-1}}$$

Equation 40. HPF transfer function for DC removal

NOTE

For DC removal, you can perform HPF gain compensation and use only the signed data format.

83.3.2.7.4 Shift

The CIC filter outputs raw 32-bit data. The higher part of that data is most likely to consist of zeros or sign bits. You must shift this data to attain 24-bit alignment.

If the raw CIC data contains more than 24 bits, then you must shift it right by CnCFR[PFSFT] to fill bits 23–0, and copy the result to data bits 31–8.

If the raw CIC data contains fewer than 24 bits, then you must shift it left by CnCFR[PFSFT] to fill bits 23–0, and copy the result to data bits 31–8.

For right shift, SINC rounds the result up (as if adding 0.5×LSB) before truncation.

Rounding is not necessary for a left shift. If the shift and rounding result is more than 24 bits, the result is saturated and SINC changes the corresponding saturation status field to 1.

83.3.2.7.4.1 Shift right block diagram

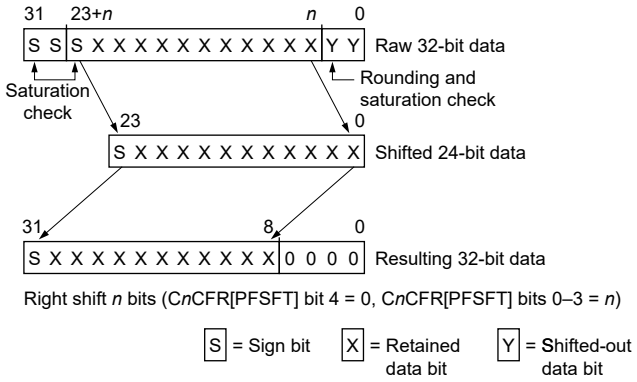

Figure 655. Shift right block diagram

83.3.2.7.4.2 Shift left block diagram

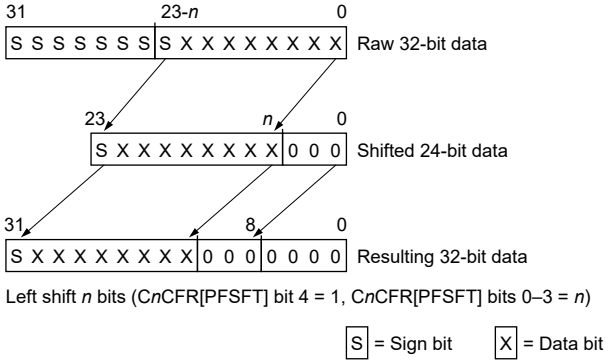

Figure 656. Shift left block diagram

83.3.2.7.5 Bias setting

Channel n Bias (C0BIAS - C3BIAS) specifies a bias offset for PF output, derives input from PF shift, and outputs the final result or value to FIFO and other compare blocks. The valid value is represented in the two's-complement format and the PF subtracts this bias value from the data.

83.3.2.8 SCD operations

An SCD is applied to each channel. Its purpose is to quickly respond if an analog signal is close to its maximum threshold value. The SCD can detect both short-circuit (overcurrent) and open-circuit (overvoltage) errors.

NOTE

An SCD does not support parallel modulator inputs.

Table 1134. SCD operations

Using	You can
C*n*CR[SCDEN]	Write 0 to disable the SCD.
EIS[SCD*n*]	Check whether SINC detected a short circuit on filter channel *n*.
Channel n Debug (C0DBGR - C3DBGR) with an appropriate value of C*n*CR[DBGSEL]	Check SCD status anytime. When an SCD event occurs, the SCD continues to count for the same field until a bit toggle occurs and holds the counter for you to read.
EIE[SCDIEn]	Enable and disable the Short Circuit Detected interrupt for filter channel *n*.
C*n*PROT[SCDBK]	Enable and disable the automatic assertion of the BREAK_SCD signal (see External signals).
C*n*PROT[SCDLMT]	Specify the threshold value of the SCD counter. There exists an upcounting counter on each input channel that counts consecutive 0s or 1s on the modulator bitstream. The counter restarts in case of a bit toggle. If this counter reaches a threshold value (C*n*PROT[SCDLMT]), a short-circuit event is invoked.
C*n*PROT[SCDOP]	Program conversion options and control detection of the bit value (0, 1, or both) that increments the SCD counter.
C*n*PROT[SCDCM]	Program conversion modes and control when the SCD operates—when C*n*CR[CHEN] = 1 or when the PF is performing a conversion.

83.3.2.9 CAD operations

A CAD is applied to each channel. You must check the modulator clock input for absence to ensure that the correct conversion process and error detection are in progress.

NOTE

When a clock absence event occurs, the data conversion process and detectors provide incorrect data. You must manage this event and discard the given data when a clock absence is reported.

Table 1135. CAD operations

Using field	You can
C*n*CR[CADEN]	Write 0 to disable CAD.
FIFOIS[CAD*n*]	Check whether SINC detected the absence of a clock on filter channel *n*. When a CAD event occurs, CAD continues to count until an overflow occurs and then latches the value until you clear the flag.
FIFOIE[CADIE*n*]	Enable and disable the Clock Absence interrupt for filter channel *n*.

Table continues on the next page...

Table 1135. CAD operations (continued)

Using field	You can
C*n*PROT[CADBK]	Enable and disable the automatic assertion of the BREAK_CAD signal (see External signals).
C*n*PROT[CADLMT]	Specify the threshold value of the CAD counter. The internal counters use IMCLK0 (see Function clock); therefore, you must program MCR[PRESCALE] and MCR[MCLKDIV] correctly to ensure that MCLK0_OUT is faster than the expected modulator clock input. However, MCLK0_OUT must not be more than 15 times faster.

83.3.2.10 ZCD operations

A ZCD asserts when a filter channel changes sign. In case of the absence of a threshold register and ripples, the ZCD asserts multiple times.

Table 1136. ZCD operations

Using field	You can
C*n*CFR[RDFMT]	Configure the field as signed for the ZCD to work correctly.
C*n*CR[ZCDEN]	Write 0 to disable ZCD.
NIS[ZCD*n*]	Check the status of ZCD.
NIE[ZCDIE*n*]	Enable and disable the Zero Cross Detected interrupt for filter channel *n*.
C*n*CFR[ZCOP]	Select the type of zero crossing—rise, fall, or both.

Various zero cross compare outputs can be sent to the pulse trigger (see Pulse trigger).

83.3.2.11 Limit detection operations

Each filter sample is compared to values in the limit registers. This comparison is based on the final conversion value with offset correction applied. C*n*HILMT[HILMT] and C*n*LOLMT[LOLMT] registers contain the corresponding values that are used to compare with the result. C*n*HILMT[HILMT] is used for result comparison with the high limit, and C*n*LOLMT[LOLMT] is used for result comparison with the low limit.

Table 1137. Limit detection operations

Using field	You can
C*n*CR[LMTEN]	Write 0 to disable limit checking.
EIS[HLMT*n*], EIS[LLMT*n*], and EIS[WLMT*n*]	Check the status of high limit flag, low limit flag, and window limit flag, respectively.
EIE[HLMTIE*n*], EIE[LLMTIE*n*], and EIE[WLMTIE*n*]	Enable or disable the High Limit interrupt, Low Limit interrupt, and Window Limit Interrupt, respectively.
C*n*ACFR[ADMASEL]	Enable an alternative DMA and select the limit flag that triggers the DMA.
C*n*PROT[HLMTBK], C*n*PROT[LLMTBK], and C*n*PROT[WLMTBK]	Program to assert break signals BREAK_HIGH, BREAK_LOW, and BREAK_WIN, respectively (see External signals).
C*n*PROT[LMTOP]	Program a limit detection option.

Various limit compare outputs can be sent to the pulse trigger block (see Pulse trigger).

83.3.2.12 Pulse trigger

A pulse trigger is used to generate various sets of additional signals for each channel. You can use C*n*ACFR[PTMUX] to select one of these signals and send them to the chip for additional control. A dedicated conversion complete signal (FILT_CC) is also sent to the chip for each channel. For more on FILT_CC, see External signals.

83.3.2.12.1 High-low limit signals to pulse trigger

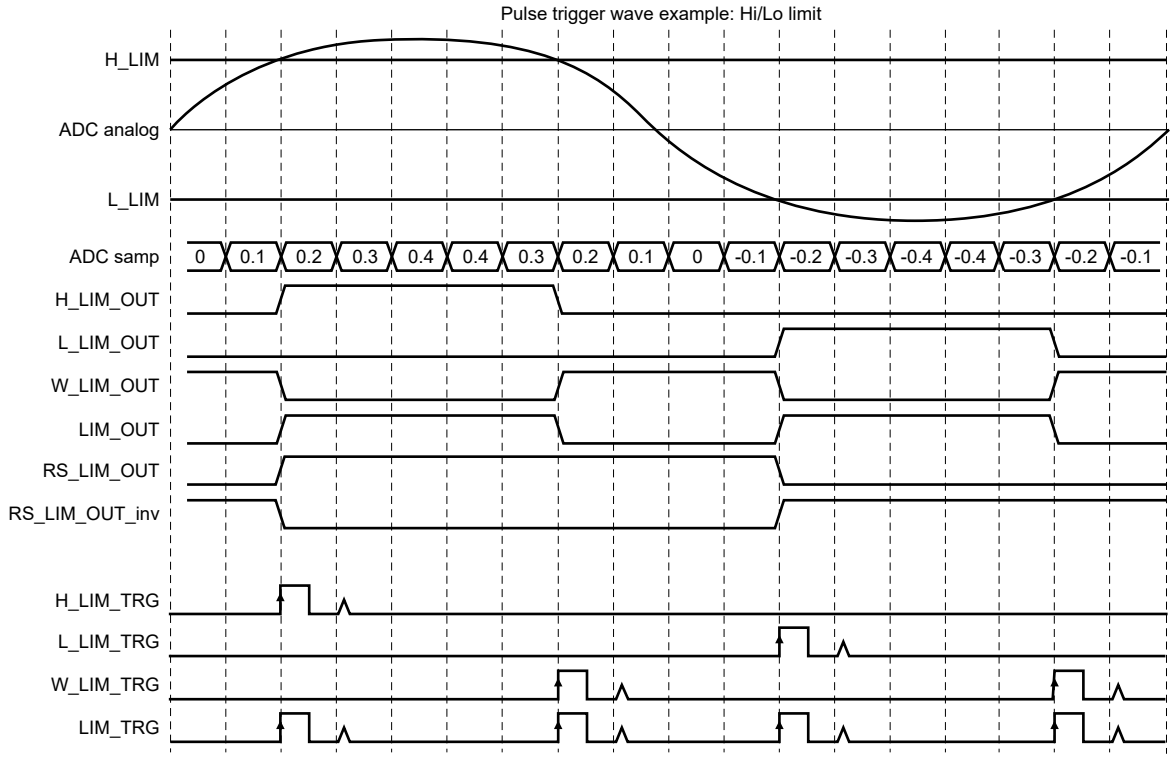

Figure 657. High-low limit signals to pulse trigger

83.3.2.12.2 ZCD output signals to pulse trigger

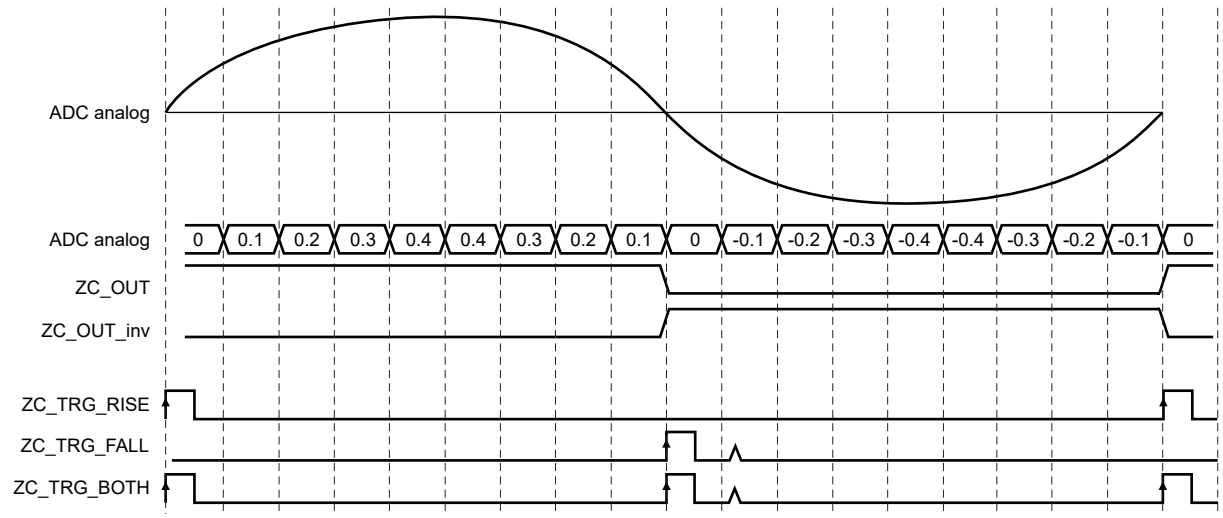

Figure 658. ZCD output signals to pulse trigger

83.3.3 FIFO

The FIFO is a first-in, first-out buffer that saves the final filtering results. Each FIFO has a depth of 16 entries, and each entry stores a 24-bit result. Each channel has one FIFO. SINC writes (pushes) data into the FIFO, and you read (pop) data from the FIFO by using Channel n Result Data (C0RDATA - C3RDATA).

The FIFO has a configurable watermark (C*n*CFR[FIFOWMK]). When the amount of data in the FIFO is greater than C*n*CFR[FIFOWMK], SINC requests a DMA, IRQ, or both, depending on NIE[CHFIE*n*] and C*n*CR[DMAEN].

When the FIFO is full, SINC discards a new filtered result and sets the overflow flag (FIFOIS[FOVF*n*]). Similarly, if you attempt a pop operation and the FIFO is empty, SINC does not return any valid data and sets the underflow flag (FIFOIS[FUNF*n*]). When an overflow or underflow occurs, SINC sets the aforementioned flags and can generate an error interrupt you write 1 to the corresponding field in FIFO And CAD Error Interrupt Enable (FIFOIE).

When FIFO is enabled (C*n*CR[FIFOEN] = 1), MCR.MEN = 1, but C*n*CR[CHEN] = 0, you can still read the FIFO to flush it.

When you reset the FIFO by writing 1 to MCR[RST], SINC fills all FIFO entries with zeros and resets the push and pop pointers to their initial position.

Only a PF can serve as the input to a FIFO.

You can use either of the following methods to determine how much data remains in a FIFO:

- Read C*n*SR[FIFOAVIL].
- Write 9d to C*n*CR[DBGSEL], then read Channel n Debug (C0DBGR - C3DBGR).

83.3.4 Wake-up

SINC does not support an asynchronous interrupt to wake up the chip.

83.3.5 Details of debug data

Table 1138. Details of debug data

When CnCR[DBGSEL] is:	CnDBGR[DBGDATA] contains:
0b	Final data from the PF (24 bits)
1b	Offset data (24 bits)
10b	Shifted data from the PF (24 bits)
11b	DC remover (HPF) data (32 bits)
100b	Raw data from the PF's CIC filter
110b	Historical data from short-circuit detection: • Bit 0 indicates the current count bit value. • Bits 1–8 indicate the current count. • Bits 9–16 indicate the previous count. • Bits 17–24 indicate the second-previous count. • Bits 25–31 are reserved.
111b	Data from the Manchester decoder: • Bits 0–7 indicate the number of decode errors (resync) that occurred after you enabled the channel. When this number exceeds 256, SINC resets it to 128. • Bits 8–18 indicate how long (in clock cycles) the current bit value has existed. • Bit 19 is the current bit value. • Bits 20–31 are reserved.
1000b	Data from CAD: • Bits 0–3 indicate the number of cycles during which SINC did not detect a modulator clock. SINC resets this number when SINC detects the modulator clock again. If it exceed the CnPROT[CADLMT], it will hold the value until software clear it. The maximum reportable number of clockless cycles is 15d (1111b). If more clockless cycles occur, the value in bits 0–3 remains 15d (1111b). • Bits 4–31 are zero.
1001b	Number of available entries in the FIFO: • Bits 0–7 indicate the number of available entries. • Bits 8–31 are zero.
1010b	Status of the parallel or serial data converter: • Bits 0–5 indicate the number of bits that SINC must still shift out as mod bits, for serial data converter. • Bits 6–7 are reserved. • Bits 8–31 are zero.

83.3.6 Modes of operation

Table 1139. Modes of operation

Mode	Description
Normal	Default operational mode in which channels perform filtering operations. An external bitstream from the MBIT[*n*] signal (see External signals) supplies the input data and the MCLK_OUT[*n*] signal (see External signals) delivers the modulator clock to the external ADC.
Low-Power	Mode in which the chip gates the CPU clock, and if MCR[DOZEN] = 1, SINC functions are canceled. If the CPU is in Wait mode, SINC filters and protects the modulator bitstream data and can generate a wake-up event through a synchronous DMA or interrupt, depending on the values of MCR[MEN], C*n*CR[CHEN], C*n*CR[PFEN], and other protection block enable fields (C*n*CR[CADEN], C*n*CR[SCDEN], or C*n*CR[ZCDEN]). If the CPU clock enters very low power stop (VLPS) mode, the CPU clock is gated and a peripheral-bus stop acknowledge signal is raised if: • MCR[MEN] = C*n*CR[CHEN] = 1. • Either C*n*CR[PFEN] or the other related protection enable fields (C*n*CR[CADEN], C*n*CR[SCDEN], or C*n*CR[ZCDEN]) are 1. You cannot generate DMAs and interrupts asynchronously to wake up the CPU clock.
Single	Mode in which you can control a typical motor using coils. For more on this mode, see Use case: Motor control with Single mode.
Continuous	Mode in which you can control audio applications and power meters, and create a sinusoidal decoder. For more on this mode, see Use case: Audio system with Continuous mode, Use case: Sinusoidal decoder with Continuous mode, and Use case: Power meter with Continuous mode.
Fixed-Number	Mode in which you can control a typical motor and enhance this control by using techniques as such: • Adding a compensation filter to achieve better precision. • Flattening the passband. • Improving roll-off. For more on this mode, see Use case: Motor control with Fixed-Number mode.

83.3.7 Clocks

83.3.7.1 Overview

SINC has these types of clocks:

- Bus (see Bus clock)
- Function (see Function clock)
- Modulator (see Modulator clock)

The following sections provide:

- A block diagram of SINC clocks.

- An overview of the functioning and special clocking requirements of SINC clock types.

83.3.7.1.1 Clocks: block diagram

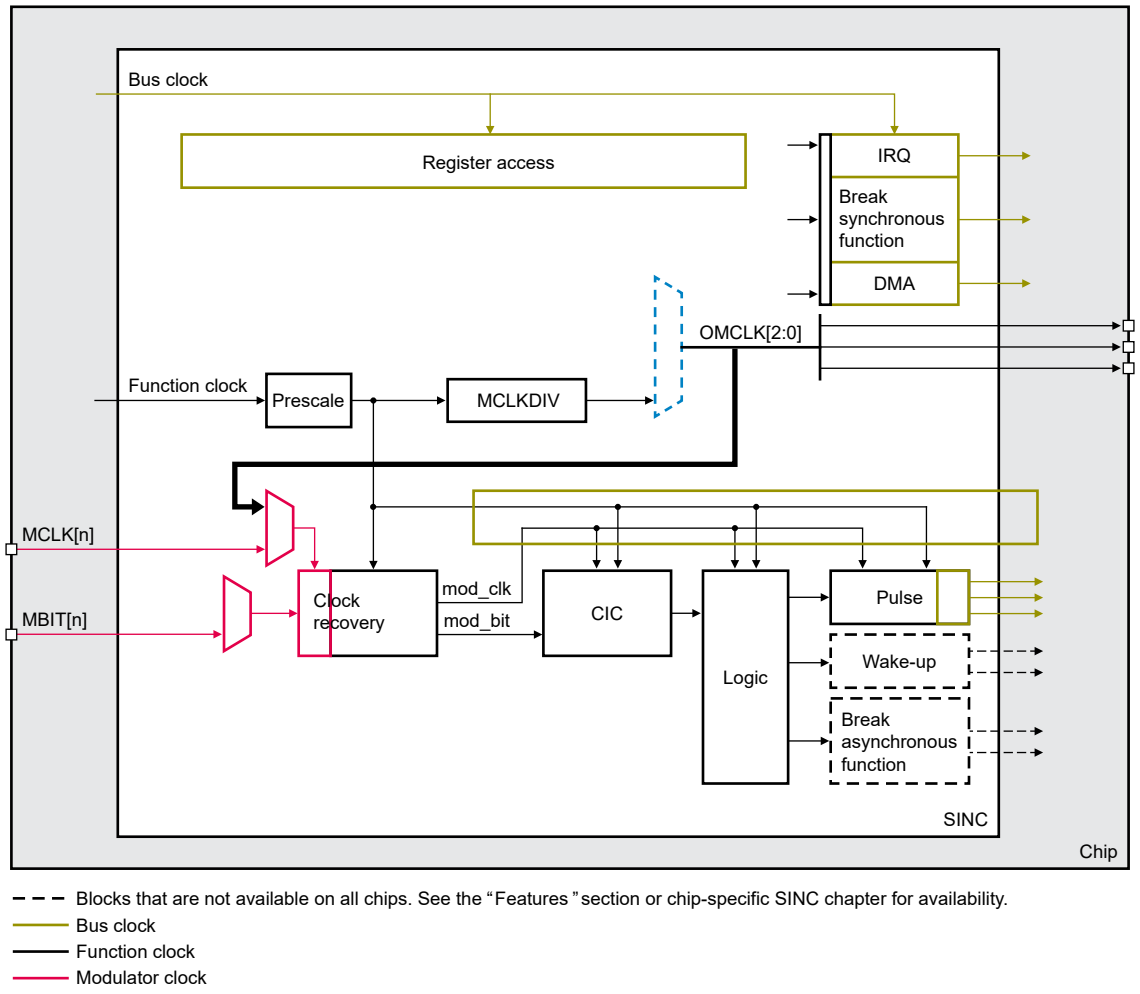

Figure 659. Clocks: block diagram

83.3.7.2 Bus clock

- Provides register access
- Allows control over low-power request signals, DMA, and interrupts

83.3.7.3 Function clock

The chip-provided function clock drives major functions, including:

- The prescaler
- The modulator clock divider (MCLKDIV)

The function clock is prescaled and divided to the correct operating range for SINC.

83.3.7.3.1 Main clock logic

The main clock logic, which is an integral part of the function clock:

- Is shared among all channels.

- Comprises a prescaler, MCLKDIV (divided by 2), and a clock output enable to external clocks.

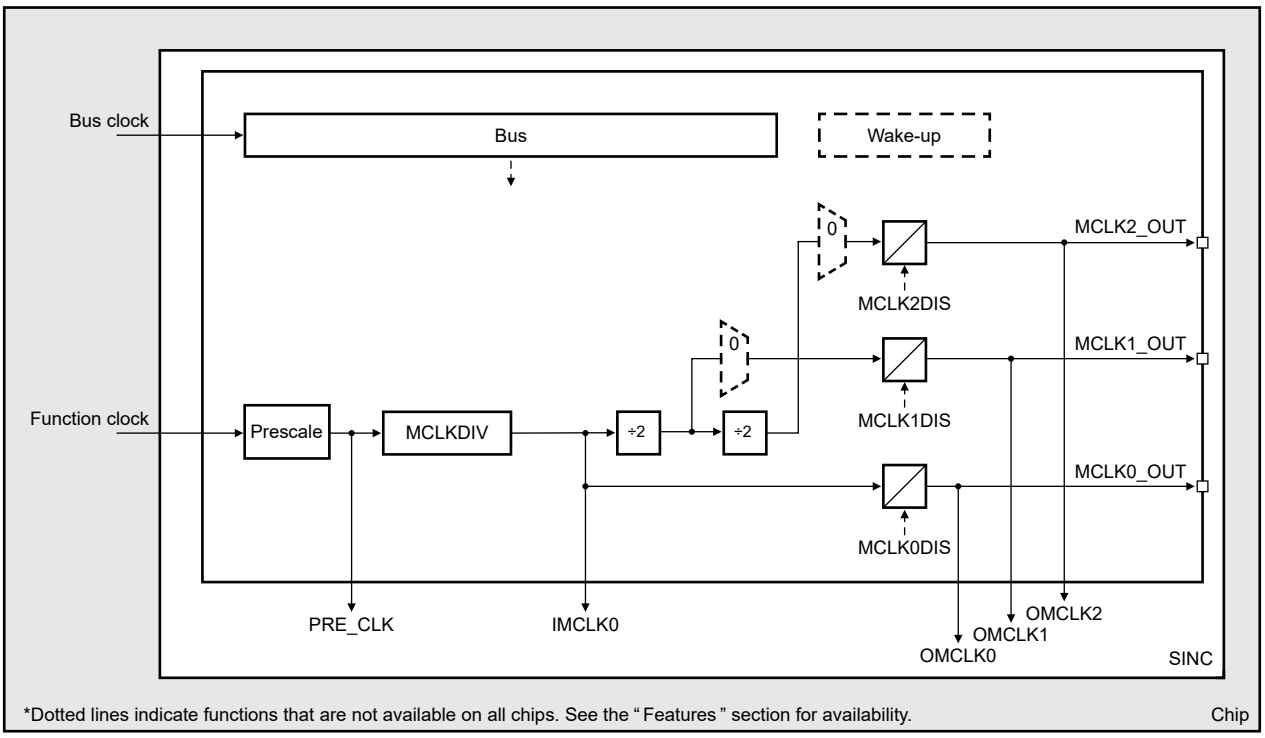

Figure 660. Main clock logic

83.3.7.3.2 Prescaler and output clocks

The prescaler supports power saving. It divides a high-frequency function clock (a major clock for other blocks) with an associated low-frequency clock. The prescaler divides the function clock by using MCR[PRESCALE], and then sends the clock to the divider and other blocks. See Main clock logic.

MCLKDIV sends the following three clocks to the chip for driving an external modulator ADC:

- MCLK_OUT0: Clock arrived at by adding 1 to the value of MCR[MCLKDIV].
- MCLK_OUT1: Clock arrived at by further dividing MCLK_OUT0 by 2.
- MCLK_OUT2: Clock arrived at by further dividing MCLK_OUT1 by 2.

These three aforementioned divided output clocks can be enabled or disabled by using MCR[MCLK0DIS], MCR[MCLK1DIS], and MCR[MCLK2DIS], respectively.

You must write an appropriate value to MCR[MCLKDIV]:

- For the target modulator clock to function properly. In some use cases, the modulator clock frequency must be certain times of the PWM frequency to use SINC's CIC filter.
- To obtain a 50% duty cycle, depending on the requirements of the external modulator ADC.

83.3.7.4 Modulator clock

A modulator clock:

- Is dedicated to each channel.
- Is provided by an external or system source.
- Can generate a digital output bitstream at a high data rate.

The SINC decimation filters reduce the sampling rate of the high-rate modulator output. Because of the latency of the decimation filters, each time a decimation filter is enabled or resynchronized, it takes one to four output samples (depending on the filter order) to reach a steady state producing valid output values.

83.3.7.4.1 Channel clock logic

The channel clock logic, which is a part of the modulator clock:

- Is dedicated to each channel individually.
- Comprises the following:
  - A normal decoder
  - A Manchester decoder
  - A clock source selection for these decoders
  - An MPDATA clock generator
- Includes the following:
  - An input asynchronous MCLK[*n*] selection, sample, or resynchronization
  - An MBIT[*n*] selection or sample
  - Manchester clock recovery
  - A clock select

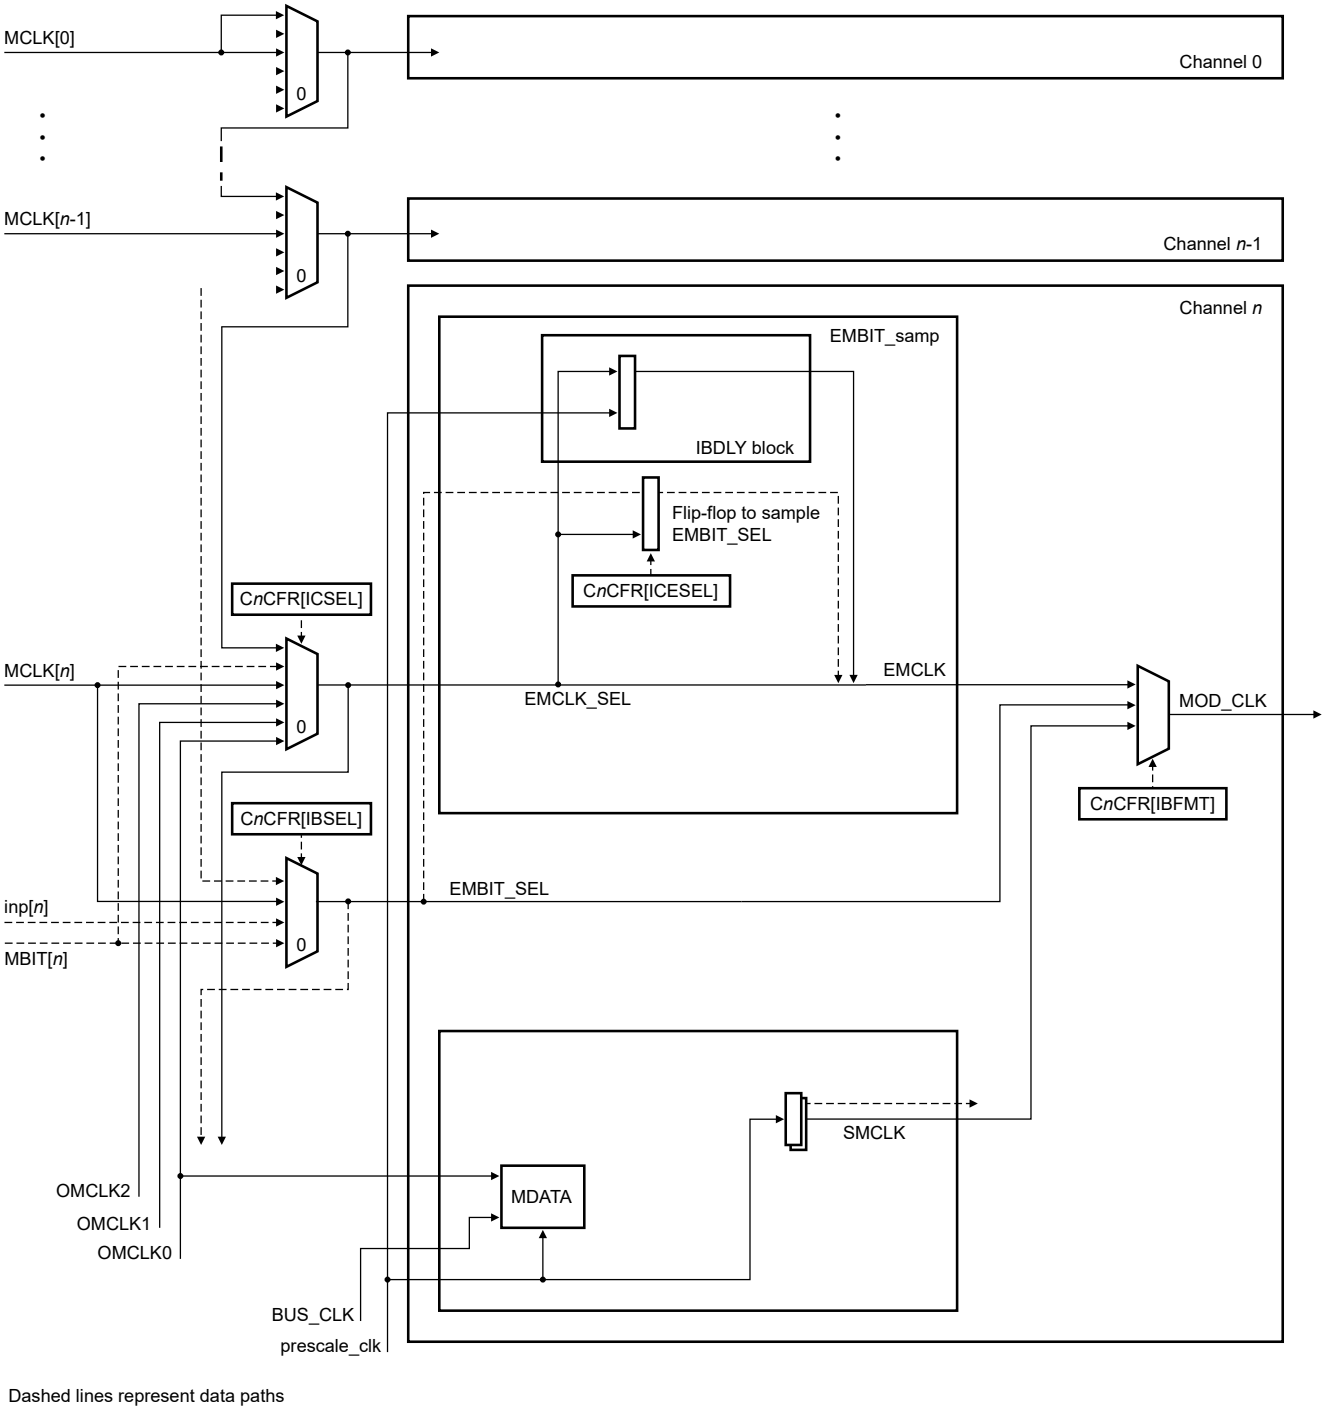

Figure 661. Channel clock logic

83.3.7.4.2 Prescaler considerations

You must program the prescaler to ensure that the predivided clock is:

- At least 3x faster than the MCLK[*n*] input for a single-edge sample.
- 6x faster than the MCLK[*n*] input for a dual-edge sample.
- 6x faster for Manchester coding, else the clock recovery block may function inappropriately.

83.3.7.4.3 Input clock configuration

To configure input clock edges and bitstream formats, you can:

- Write to C*n*CFR[ICSEL] to perform clock source selection and configure C*n*CFR[ICESEL] for the channel modulator clock to be rising edge, falling edge, or dual edge. These clock edges are used to sample the modulator bitstream.
- Write to C*n*CFR[IBFMT] for Manchester coding, when clocks are auto generated.

83.3.7.5 Clock source selection

The selected channel modulator clock input (EMCLK_SEL[*n*]) can be a dedicated external input (MCLK[*n*]), or it could be shared with an adjacent channel (MCLK[*n*-1]), if you write 111b to C*n*CFR[ICSEL]. Additionally, the shared clock can be cascaded between channels (for example, all channels share the same clock, MCLK[0]).

This is what you can do by writing appropriate values to the fields of Channel n Configuration (C0CFR - C3CFR):

- Route the output clocks OMCLK0, OMCLK1, and OMCLK2 as internal clock inputs by writing 000b, 001b, and 010b, respectively, to C*n*CFR[ICSEL]. Thus, SINC can provide output clocks to drive both the external modulator ADC and internal demodulator.
- Recover the manchester clock (MMCLK) by writing 01b to C*n*CFR[IBFMT]. You can use external modulator bitstream selection (EMBIT_SEL), which can be dedicated to each channel (external MBIT[*n*] and internal INP[*n*]) or shared with the adjacent channel (MBIT[*n*-1]), if you write 11b to C*n*CFR[IBSEL].
- Program the Manchester format by writing an appropriate value to C*n*CFR[ICESEL].

See Clock source selection settings for the values you must write to C*n*CFR[ICSEL], C*n*CFR[IBFMT], and C*n*CFR[ICESEL] for clock source selection.

83.3.7.5.1 Clock source selection settings

Table 1140. Clock source selection settings

C*n*CFR[ICSEL]	C*n*CFR[IBFMT]	C*n*CFR[ICESEL]	Source	Description
000	00	Any value	OMCLK0	Output clock 0 selected
001	00	Any value	OMCLK1	Output clock 1 selected
010	00	Any value	OMCLK2	Output clock 2 selected
011	00	Any value	MCLK	External modulator clock selected
100	00	Any value	—	—
101	00	Any value	—	Reserved
110	00	Any value		
111	00	Any value	GCLK	Group clock (a previous channel clock selected as clock source)
Any value	01	01	MMCLK_RISE	A manchester clock selected per channel in the Rise format
		10	MMCLK_FALL	A manchester clock selected per channel in the Fall format
		00	Reserved	—
		11		

Table continues on the next page...

Table 1140. Clock source selection settings (continued)

CnCFR[ICSEL]	CnCFR[IBFMT]	CnCFR[ICESEL]	Source	Description
Any value	10	Any value	PMCLK	An internal (IMCLK0), auto-generated parallel or serial modulator clock selected for clock source generation when you write a bitstream to Channel n Multipurpose Data (C0MPDATA - C3MPDATA)
	11		SMCLK	

83.3.7.6 Clock edge selection

For clock edge selection, you must program CnCFR[ICESEL] to select when to sample a modulator bitstream (EMBIT_SEL), if CnCFR[IBFMT] = 0.

See Clock edge selection settings for information about which modulator input clock (EMCLK_SEL) and clock edge you must select to sample this modulator bit (EMBIT_SEL), and see Clock edge selection diagram for a pictorial representation of these edge settings.

83.3.7.6.1 Clock edge selection settings

Table 1141. Clock edge selection settings

CnCFR[IBFMT]	CnCFR[ICESEL]	Name	Clock edge used to sample the modulator bit (EMBIT_SEL)
00	001	MCLK positive edge	EMCLK_SEL as positive edge sample—SINC uses even-numbered MCLK edges (0, 2, 4, 6, 8, and so on) to sample the selected input data.
	010	MCLK negative edge	EMCLK_SEL as negative edge sample—SINC uses odd-numbered MCLK edges (1, 3, 5, 7, 9, and so on) to sample the selected input data.
	011	MCLK dual edge	EMCLK_SEL as dual edge sample—SINC uses all MCLK edges to sample the selected input data.
	101	MCLK positive edge even	EMCLK_SEL as every other even positive edge sample—SINC uses even-numbered MCLK edges (0, 4, 8, 12, 16, and so on) to sample the selected input data.
	110	MCLK negative edge odd	EMCLK_SEL as every other odd negative edge sample—SINC uses odd-numbered MCLK edges (1, 5, 9, 13, 17, and so on) to sample the selected input data.
	000—111	Reserved	—
01	00		
	01	MMCLK_RISE	A manchester clock per channel in the Rise format—no edge sample options.
	10	MMCLK_FALL	A manchester clock per channel in the Fall format—no edge sample options.
	11	Reserved	—

Table 1141. Clock edge selection settings (continued)

CnCFR[IBFMT]	CnCFR[ICESEL]	Name	Clock edge used to sample the modulator bit (EMBIT_SEL)
10	Any value	PMCLK	An auto-generated internal clock when you write a bitstream to Channel n Multipurpose Data (C0MPDATA - C3MPDATA)—no edge sample options. IMCLK0 is selected for clock source generation.
11		SMCLK	

83.3.7.6.2 Clock edge selection diagram

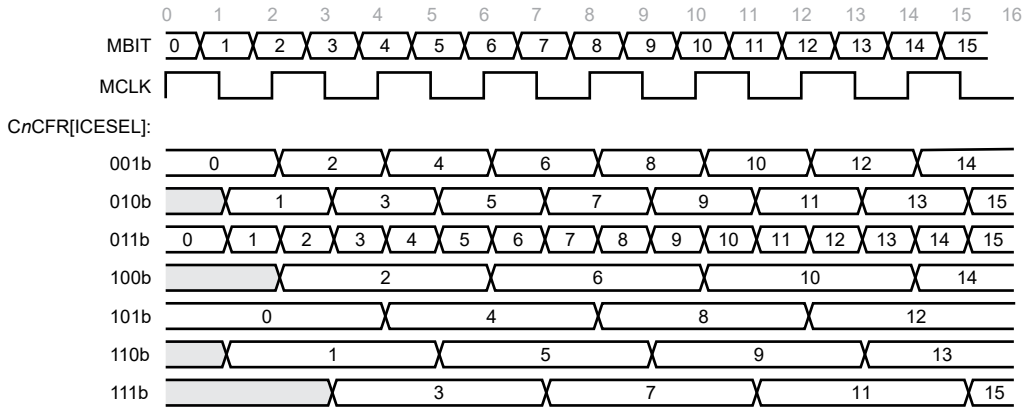

Figure 662. Clock edge selection diagram

83.3.7.7 Modulator clock frequencies and bit rates

The frequency of the function clock provided by the chip determines the minimum and maximum modulator clock frequencies.

83.3.7.7.1 Minimum clock output example

Assume the frequency of the function clock is 133 MHz. At this frequency, the minimum clock output frequency for MCLK_OUT2 is 16 kHz, and an internal or external clock can route it to SINC. Alternatively, an external ADC can divide the clock by 2. Therefore, in this example, the bit rate is 16 kbit/s or 8 bit/s in ideal scenarios.

See Minimum clock output settings for minimum clock output frequency settings of signals at different data rates and the resultant conditions.

83.3.7.7.1.1 Minimum clock output settings

Table 1142. Minimum clock output settings

Signal	Minimum frequency	Condition	CnCFR[ICESEL]	Data rate (kbit/s)	Comments
MCLK_OUT0	65 kHz (133 MHz ÷ 8 ÷ 256 = 65 kHz)	Clock routed (CnCFR[ICSEL] = 000b)	001 = positive edge 010 = negative edge	65	—
			011	130	

Table continues on the next page...

Table 1142. Minimum clock output settings (continued)

Signal	Minimum frequency	Condition	CnCFR[ICESEL]	Data rate (kbit/s)	Comments
			1xx	32	If ADC divides the clock by 2 but does not connect it
		ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 = positive edge 010 = negative edge	32	—
			011	65	
			1xx	16	
MCLK_OUT1	32 kHz (133 MHz ÷ 8 ÷ 256 ÷ 2 = 32 kHz)	Clock routed (CnCFR[ICSEL] = 001b)	001 = positive edge 010 = negative edge	32	
			011	65	
			1xx	16	
		ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 = positive edge 010 = negative edge	16	
			011	32	
			1xx	8	
MCLK_OUT2	16 kHz (133 MHz ÷ 8 ÷ 256 ÷ 2 ÷ 2 = 16 kHz)	Clock routed (CnCFR[ICSEL] = 010b)	001 = positive edge 010 = negative edge	16	
			011	32	
			1xx	8	
		ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 = positive edge 010 = negative edge	8	
			011	16	
			1xx	4	

83.3.7.7.2 Maximum clock output example

Assume the frequency of the function clock is 133 MHz. At this frequency:

- 66 MHz is the maximum clock output frequency for MCLK_OUT0. The actual frequency depends on the chip I/O timing and the specific use case.

- 44 Mbit/s is the maximum data rate that SINC can support.

Therefore, an external ADC must divide a 66 MHz clock by 2 and route it as 33 MHz. The chip's I/O timing may also limit this high-speed clock.

With an output of 44 MHz, the duty cycle cannot be 50% when the clock is divided by 3. Most external ADCs require a 50% duty cycle. Therefore, 33 MHz is a better choice for the maximum frequency.

See Maximum clock output settings for maximum clock output frequency settings of signals at different data rates and the resultant conditions.

83.3.7.7.2.1 Maximum clock output settings

Table 1143. Maximum clock output settings

Signal	Condition	C*n*CFR[ICESEL]	Maximum frequency (MHz)	Data rate (Mbit/s)	Comments
MCLK_OUT0	Clock routed (C*n*CFR[ICSEL] = 000b)	001 or 010	33	33	133 MHz ÷ 4 = 33 MHz (50% duty cycle)
			44	44	133 MHz ÷ 3 = 44 MHz (66% duty cycle, depending on the maximum data rate)
		011	22	44	133 MHz ÷ 6 = 22 MHz (depending on the maximum data rate)
		1xx	66	33	133 MHz ÷ 2 = 66 MHz
	ADC routes the clock after dividing it by 2 (C*n*CFR[ICSEL] = 011b)	001 or 010	66	33	133 MHz ÷ 2 = 66 MHz
		011	33	33	133 MHz ÷ 4 = 33 MHz (50% duty cycle)
			44	44	133 MHz ÷ 3 = 44 MHz (66% duty cycle, depending on the maximum data rate)
		1xx	66	17	133 MHz ÷ 2 = 66 MHz (SINC does not support clock division by 1)
MCLK_OUT1	Clock routed (C*n*CFR[ICSEL] = 001b)	001 or 010	17	17	133 MHz ÷ 4 ÷ 2 = 17 MHz (assuming you are also using MCLK_OUT0)
			33	33	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)
		011	17	33	133 MHz ÷ 4 ÷ 2 = 17 MHz (assuming you are also using MCLK_OUT0)
			22	44	133 MHz ÷ 3 ÷ 2 = 22 MHz (depending on the maximum output)
		1xx	17	8	133 MHz ÷ 4 ÷ 2 = 17 MHz (assuming you are also using MCLK_OUT0)
			33	17	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)
	ADC routes the clock after dividing it by 2 (C*n*CFR[ICSEL] = 011b)	001 or 010	17	8	133 MHz ÷ 4 ÷ 2 = 16 MHz (assuming you are also using MCLK_OUT0)
			33	17	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)

Table continues on the next page...

Table 1143. Maximum clock output settings (continued)

Signal	Condition	CnCFR[ICESEL]	Maximum frequency (MHz)	Data rate (Mbit/s)	Comments
MCLK_OUT2	Clock routed (CnCFR[ICSEL] = 010b)	011	17	17	133 MHz ÷ 4 ÷ 2 = 16 MHz (assuming you are also using MCLK_OUT0)
			33	33	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)
		1xx	17	4	133 MHz ÷ 4 ÷ 2 = 17 MHz (assuming you are also using MCLK_OUT0)
			33	8	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)
		001 or 010	8	8	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	17	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
		011	8	17	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	33	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
		1xx	8	4	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	8	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
	ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 or 010	8	4	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	8	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
		011	8	8	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	17	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
		1xx	8	2	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	4	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)

83.3.7.7.3 Maximum clock input example

The modulator input clock can be either routed from a SINC output clock or provided by an external ADC (see Block diagram for details).

The maximum input frequency allowed depends on:

- The maximum input data rate and use case.
- The chip's I/O timing.

Assuming that the frequency of the Function clock is 133 MHz, the maximum data rate is 44 Mbit/s (133MHz ÷ 3 = 44 Mbit/s) for a typical use case. For Manchester formats, the maximum allowed clock frequency (recovery from bit) is 22 MHz (133 MHz ÷ 6 = 22 Mbit/s).

The minimum allowed input frequency is not limited if the clock input comes from an external ADC. However, if you select the Manchester format, the limit is 133 MHz ÷ 1024 ÷ 8 = 16 kHz.

NOTE

To calculate the output sample rate, ORD = 3 in Continuous mode.

See Maximum clock input settings for maximum clock input frequency settings of signals at different data rates and the resultant conditions.

83.3.7.7.3.1 Maximum clock input settings

Table 1144. Maximum clock input settings

Case	C*n*CFR[ICESEL]	Maximum frequency (MHz)	Input data rate (Mbit/s)	OSR	Output sample rate	Comments
C*n*CFR[IBFMT] = 00	001 010	44	44	16	2.7 Mbit/s	44 MHz ÷ 16 = 2.7 Mbit/s; 14-bit CIC
				256	172 kbit/s	44 MHz ÷ 256 = 172 kbit/s; 26-bit CIC
				1290	34 kbit/s	44 MHz ÷ 1290 = 34 kbit/s; 32-bit CIC
	011	22	44	16	2.7 Mbit/s	—
				256	172 kbit/s	
				1290	34 kbit/s	
	1xx	44	22	16	1.4 Mbit/s	
				256	86 kbit/s	
				1290	17 kbit/s	
C*n*CFR[IBFMT] = 01	Any value	22	22	16	1.4 Mbit/s	For the Manchester format, recovered clocks must be a value smaller than 22 Mbit/s.
				256	86 kbit/s	—
				1290	17 kbit/s	

83.3.7.8 Modulator clock I/O timing

T_{h3}	Hold time from clock high to data valid	5	—
T_{s4}	Setup time from data valid to clock low	5	—
T_{h4}	Hold time from clock low to data valid	5	—

83.3.8 Reset

This section describes how to reset the SINC module and explains special requirements related to reset.

Writing 1 to MCR[RST] resets the following function blocks and registers:

- All function blocks (such as filters, short-circuit detectors, and so on) except for the clock
- Normal Interrupt Status (NIS)
- Error Interrupt Status (EIS)
- FIFO And CAD Error Interrupt Status (FIFOIS)
- Status (SR)

- MCR[STRIG*n*], together with related functions

83.3.9 Interrupts and breaks

This section describes all the interrupts that SINC generates.

Each channel has several interrupt sources that you can control and check with dedicated register fields.

If NIE[COCIE*n*] = 1, then an interrupt request is used to indicate that one filtering result is available in the corresponding channel's FIFO. You can then read the result in Channel n Result Data (C0RDATA - C3RDATA).

If NIE[CHFIE*n*] = 1, then an interrupt request is used to indicate that the FIFO surpassed its watermark level. In this case, SINC sets the corresponding NIS[CHF*n*] flag.

SINC can also generate an error interrupt request when an unexpected condition such as a FIFO overflow or underflow, a loss of clock, saturation, or exceeded value threshold occurs.

When an error occurs, SINC can assert break signals to deactivate an external peripheral. You control this feature by using Channel n Protection (C0PROT - C3PROT).

Table 1146. Interrupts and breaks

Status register	Status field	Enable register	Enable field	Break enable field in C*n*PROT	Description
NIS	COC*n*	NIE	COCIE*n*	—	Conversion complete
	CHF*n*		CHIE*n*	—	Data ready
	ZCS*n*		ZCIE*n*	—	Zero cross detected
EIS	SCD*n*	EIE	SCDIE*n*	SCDBK	Short circuit detected
	WLMT*n*		WLMTIE*n*	WLMTBK	Window limit reached
	LLMT*n*		LLMTIE*n*	LLMTBK	Low limit reached
	HLMT*n*		HLMTIE*n*	HLMKBK	High limit reached
FIFOIS	FUNF*n*	FIFOIE	FUNFIE*n*	—	FIFO underflow
	FOVF*n*		FOVFIE*n*	—	FIFO overflow
	CADF*n*		CADIE*n*	CADBK	Clock absence detected
	SAT*n*		SATIE*n*	—	Saturation

83.3.10 DMA

SINC has two DMAs for each channel:

- Primary DMA exclusively for the FIFO
- Alternate DMA for various sources (see C*n*ACFR[ADMASEL])

If C*n*CR[DMAEN] = 1, you read the FIFO-stored samples through DMA transactions. Each channel has dedicated DMA requests. If the FIFO of each channel reach their watermark the output interface makes a request for DMA transaction.

SINC clears the "data output ready" flags (NIS.CHFn) when a DMA transaction finishes.

SINC supports all the alternate DMA sources mentioned in C*n*ACFR[ADMASEL]. You can select only one source at a time. After an alternate DMA transaction finishes, SINC clears the related flags in Normal Interrupt Status (NIS), Error Interrupt Status (EIS), and FIFO And CAD Error Interrupt Status (FIFOIS).

83.4 External signals

Table 1147. External signals

Signal	Used for	Description
BREAK_CAD[3:0]	Output to the chip	CAD-related break signals sent to the chip for turning off other functions
BREAK_HIGH[3:0]	Output to the chip	High-limit break signals sent to the chip for turning off other functions
BREAK_LOW[3:0]	Output to the chip	Low-limit break signal sent to the chip for turning off other functions
BREAK_SCD[3:0]	Output to the chip	SCD-related break signal sent to the chip for turning off other functions
BREAK_WIN[3:0]	Output to the chip	Window-limit-related break signal sent to the chip for turning off other functions
FILT_CC[3:0]	Output to the chip	Signal acting as an output to be used by downstream modules in the signal processing chain that SINC is a component of
HTRIG[3:0]	Input from the chip	Hardware external trigger
INP[3:0]	Input from the chip	Internal modulator bitstream input
MBIT[3:0]	Input from the chip	External modulator bitstream input
MCLK_OUT0	Output to the chip	Modulator clock output 0
MCLK_OUT1	Output to the chip	Modulator clock output 1, which is MCLK_OUT0 divided by 2
MCLK_OUT2	Output to the chip	Modulator clock output 2, which is MCLK_OUT1 divided by 2
MCLK[3:0]	Input from the chip	External modulator clock input
PULSE_TRG[3:0]	Output to the chip	Pulse-triggered output sent to the chip
ipi_coc_int[3:0]	Output to the chip	Conversion complete interrupt
ipi_chf_int[3:0]	Output to the chip	Channel (FIFO) output interrupt
ipi_zcs_int[3:0]	Output to the chip	Zero cross interrupt
ipi_scd_int[3:0]	Output to the chip	Short circuit detect interrupt
ipi_low_int[3:0]	Output to the chip	Low limit interrupt
ipi_high_int[3:0]	Output to the chip	High limit interrupt
ipi_win_int[3:0]	Output to the chip	Window limit interrupt
ipi_fund_int[3:0]	Output to the chip	FIFO underflow interrupt
ipi_fover_int[3:0]	Output to the chip	FIFO overflow interrupt
ipi_sat_int[3:0]	Output to the chip	Saturation interrupt
ipi_cad_int[3:0]	Output to the chip	Clock monitor interrupt

Table continues on the next page...

Table 1147. External signals (continued)

Signal	Used for	Description
ipi_chn_ored_int[3:0]	Output to the chip	ORed together for above interrupt per channel
ipd_req_sinc[3:0]	Output to the chip	Conversion complete DMA request for SINC
ipd_done_sinc[3:0]	Input from the chip	Handshake signal from chip, indicates that DMA request is processed
ipd_req_alt[3:0]	Output to the chip	Alternative DMA request for SINC
ipd_done_alt[3:0]	Input from the chip	Handshake signal from chip, indicates that DMA request is processed

83.5 Internal signals

Table 1148. Internal signals

Signal	Used for	Description
H_LIM_OUT	Internal SINC functionality	Level signal that indicates a high limit
H_LIM_TRG	Internal SINC functionality	Pulse signal that indicates a high limit
HL_LIM_TRG	Internal SINC functionality	Pulse signal that indicates a high or low limit
L_LIM_OUT	Internal SINC functionality	Level signal that indicates a low limit
L_LIM_TRG	Internal SINC functionality	Pulse signal that indicates a low limit
LIM_OUT	Internal SINC functionality	Level signal that indicates a low or high limit
LIM_TRG	Internal SINC functionality	Pulse signal that indicates a high, low, or window limit
RS_LIM_OUT	Internal SINC functionality	Level signal that indicates a high level from an RS flip-flop or a Schmitt trigger
RS_LIM_OUT_inv	Internal SINC functionality	Level signal that indicates a low level from an RS flip-flop or a Schmitt trigger
W_LIM_OUT	Internal SINC functionality	Level signal that indicates a window limit
W_LIM_TRG	Internal SINC functionality	Pulse signal that indicates a window limit
ZC_OUT	Internal SINC functionality	Level signal that indicates a rising zero crossing
ZC_OUT_inv	Internal SINC functionality	Level signal that indicates a falling zero crossing

83.6 Initialization

83.6.1 Starting SINC

By default, SINC is disabled (MCR[MEN] = 0). To start or configure SINC, do this:

1. Configure the shared clock generation logic as described in Configure clocking-related fields before enabling SINC.

2. Configure OSR, ORD, and all other necessary options.
3. Enable the modulator clock output.
4. Enable all the required decimation filters and protection functions.
5. Write 1 to MCR[MEN] to start SINC.

The corresponding clock is generated for both the internal (IMCLK0) and external (MCLK_OUT*n*) signals (see External signals). If MCLK_OUT*n* is enabled, SINC waits for seven clock cycles before the external ADC is stable. SR[MCLKRDY*n*] fields become 1 after that.

This is how SINC behaves during and after starting up:

- For an internal clock source (if C*n*CFR[ICSEL] = 000b, 010b, or 001b), MCLK_OUT*n* checks SR[MCLKRDY*n*]. The field changes into a valid state when it becomes 1.
- If the clock source is external, Manchester, or grouped, all the three SR[MCLKRDY*n*] fields are selected and wait for a certain number of clock cycles before becoming 1.
- If MCLK_OUT*n* is disabled, SINC waits for one clock cycle for the internal logic to be stable.
- After startup, SINC waits for the conversion trigger to start conversion. The enabled channel conversions begin after SINC receives a software or hardware trigger. During startup, SINC ignores this signal.

83.6.2 Configure clocking-related fields before enabling SINC

Before you enable SINC (write 1 to MCR[MEN]), you must configure the following fields:

Table 1149. Configure clocking-related fields before enabling SINC

Register	Fields to configure
Main Control (MCR)	MCLK0DIS MCLK1DIS MCLK2DIS MCLKDIV PRESCALE

83.6.3 Configure fields before enabling channels

Before you enable a channel (write 1 to C*n*CR[CHEN]), you must configure the following fields:

Table 1150. Configure fields before enabling channels

Register	Fields to configure
Channel n Data Rate (C0DR - C3DR)	All
Channel n Configuration (C0CFR - C3CFR)	All except FIFOWMK
Channel n Protection (C0PROT - C3PROT)	All
Channel n Bias (C0BIAS - C3BIAS)	All
Channel n Low Limit (C0LOLMT - C3LOLMT)	All
Channel n High Limit (C0HILMT - C3HILMT)	All
Channel n Advanced Configuration (C0ACFR - C3ACFR)	All

83.7 Application information

This section describes several ways to use SINC.

83.7.1 Reading asynchronous data safely

1. Write 1 to C*n*SR[SRDS].
2. Wait until SINC changes C*n*SR[SRDS] to 0.
3. Read the data in Channel n Debug (C0DBGR - C3DBGR).

83.7.2 Transferring data between domains safely

To transfer data from the function-clock domain to the bus-clock domain safely, perform this procedure:

1. Choose the type of data that you want (see Details of debug data).
2. Write the corresponding value to C*n*CR[DBGSEL].
3. Write 1 to C*n*SR[SRDS].
4. Wait until C*n*SR[SRDS] becomes 0.
5. Read the data from C*n*DBGR.
6. Ensure that C*n*SR[DBGRS] = 0.

If you skip steps 1 and 2, C*n*DBGR contains the data from the last time you performed the full procedure.

Due to SINC's internal microarchitecture, the returned instantaneous data may be incomplete and invalid. Step 6 ensures that the data you read is valid.

83.7.3 Use case: Motor control with Single mode

83.7.3.1 Overview

This example uses Single mode to control a typical motor with three coils. Six on-chip PWM channels drive those three coils. Three external ADCs measure the coil current, and additional ADCs monitor total current or voltage to trigger critical events (such as overcurrent or short circuit) to shut down the motor.

The ADCs produce a high-speed bitstream and send it to SINC through MBIT signals (see External signals). Then, SINC:

1. Demodulates the bitstream.
2. Decimates the bitstream.
3. Converts the bitstream to a 24-bit result at a lower frequency.
4. Saves the result in a FIFO.

You can then:

1. Read the coil current from the FIFO.
2. Read other information (such as speed and position) from other modules on the chip.
3. Process the data to determine the parameters (on or off, PWM ratio drive strength) for the next coil-drive step.

Schematic shows the motor-control schematic.

Frequency response shows the resulting frequency response of the PF's CIC. In that diagram, pay particular attention to the following:

- Without a compensation filter, there is a drop in the passband, and roll-off (aliasing) occurs in the stop band.
- F_D (346 kHz) is near the 17th harmonic wave of the PWM switch frequency (20 kHz). This example filters out this noise more efficiently.

- A dropoff of –3 dB occurs at F_C (91 kHz). Therefore, the input signal must have a much-lower frequency—1 kHz or lower. If this is not possible, your software must compensate accordingly.

83.7.3.2 Schematic

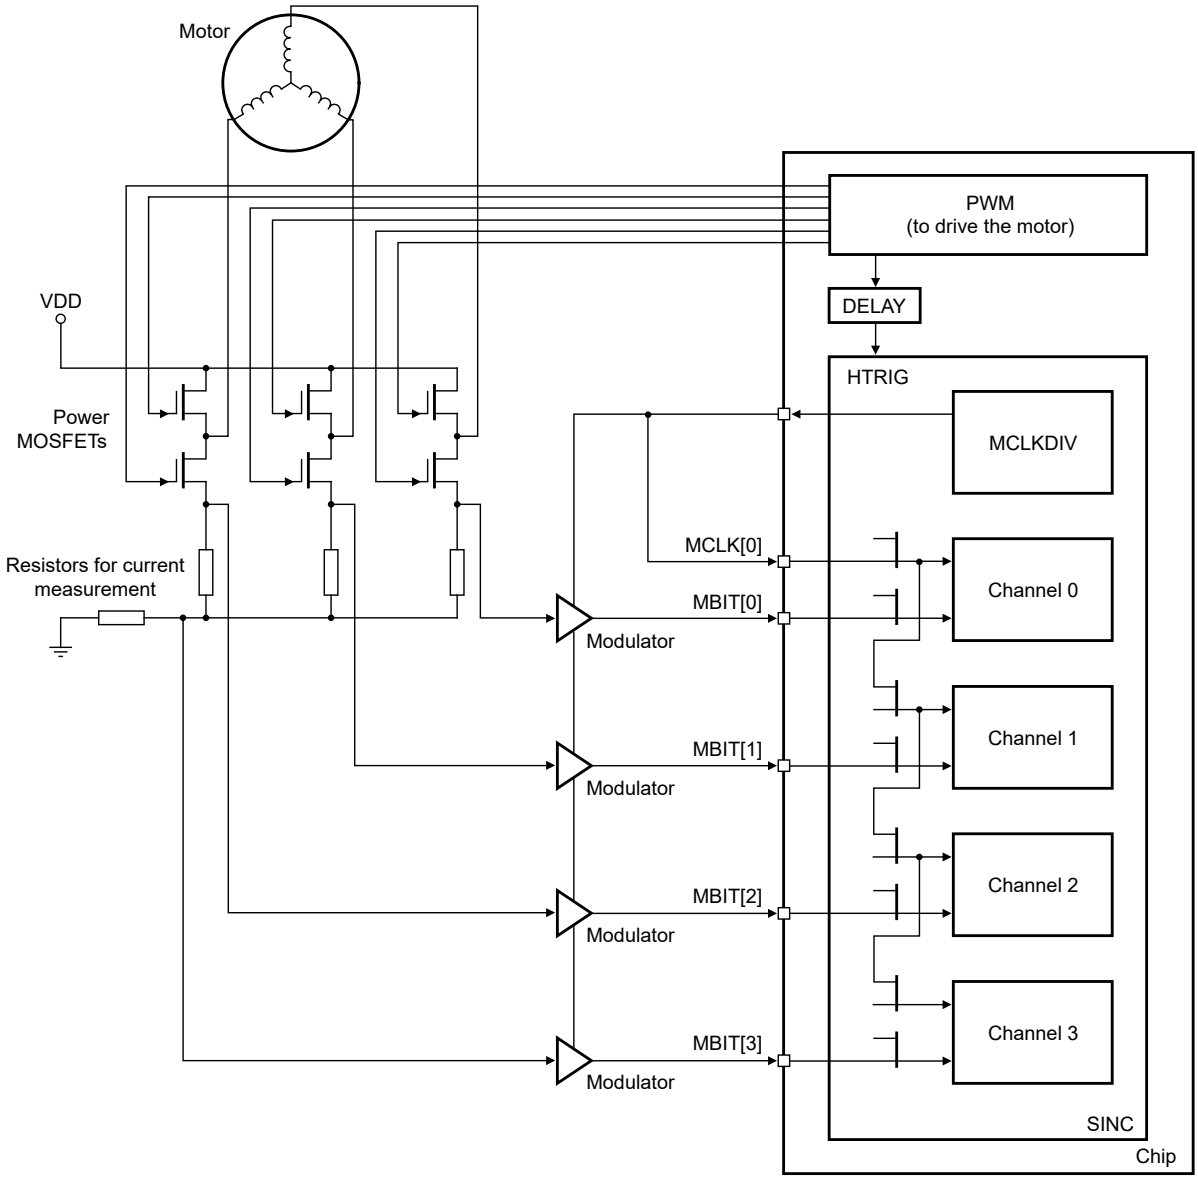

Figure 664. Schematic

83.7.3.3 Assumptions

Table 1151. Assumptions

Parameter	Value
SINC function clock	133 MHz

Table continues on the next page...

Table 1151. Assumptions (continued)

Parameter	Value
Target external modulator ADC clock (F_S)	22.2 MHz
Motor speed	6000 RPM (100 Hz)
PWM switch frequency (F_P)	20 kHz (corresponding to a 50 µs period, or 200 PWM steps per revolution)
OSR	64
Decimation frequency (F_D)	346 kHz (calculated from target external modulator ADC clock and OSR)
Cutoff frequency (F_C)	91 kHz
Signal-to-noise ratio (SNR)	79 dB
Effective number of bits (ENOB)	Approximately 12.9 (calculated using SNR)
Data width	20 bits (calculated using OSR and ORD)

83.7.3.4 Frequency response

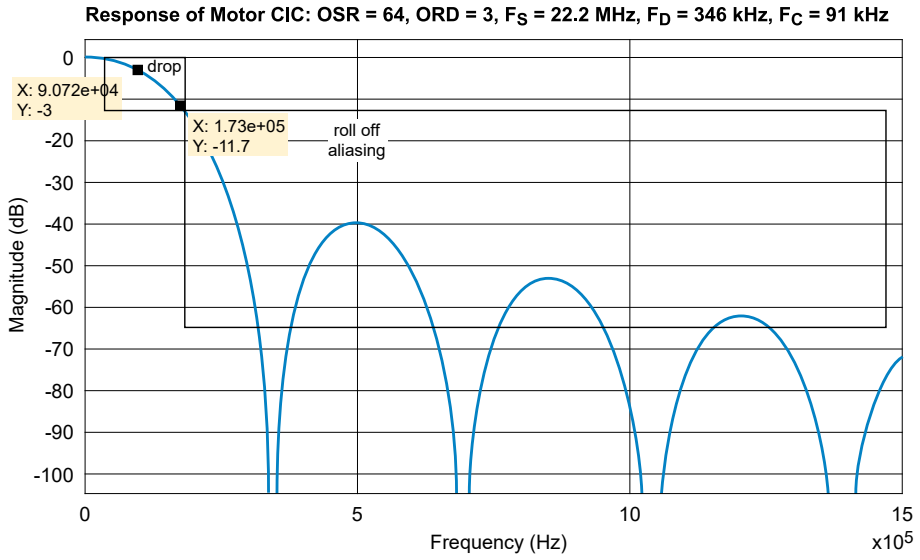

Figure 665. Frequency response

83.7.3.5 Procedure

1. Configure the related PWM and other chip modules to establish the correct pin connection with SINC. In particular, ensure that the PWM event signal connects to SINC as a hardware trigger, so that when PWM starts driving the coil, SINC can start conversion at a specific time.
2. Program the PWM event delay such that when SINC starts conversion, the coil currents are stable, as shown in Measurement time.
3. If the external ADC does not provide a clock, configure the modulator clock output. In this case, MCLK_OUT0 drives all external ADCs. To achieve MCLK_OUT0 = 22.2 MHz:
   a. Write 0 to MCR[PRESCALE].
   b. Write 5d to MCR[MCLKDIV].

4. Configure the data rate for channels 0–2 (*n* = 0–2) as follows:
    a. Write 3d to C*n*DR[PFORD].
    b. Write 63d to C*n*DR[PFOSR] to select OSR = 64.
    c. Write 0 to C*n*DR[PFCM] to select Single mode.
5. Configure the data rate for channel 3 (*n* = 3) as follows:
    a. Write 2d to C*n*DR[PFORD] to select the optional fast response.
    b. Write 63d to C*n*DR[PFOSR] to select OSR = 64.
    c. Write 10b to C*n*DR[PFCM] to select Always mode for monitoring total current.
6. Configure fields in Channel n Configuration (C0CFR - C3CFR) for data operation as follows:

Channels (value of *n*)	C*n*CFR field to write	Value to write	Purpose
0–3	ITLVL	0	Select edge triggering
0–2	ITSEL	1	Select hardware triggering
3	ITSEL	0	Select software triggering
0–3	IBSEL IBFMT	0	Select a bitstream from the MBIT signals (see External signals)
0	ICSEL	11b	Select the external modulator clock
1–3	ICSEL	111b	Group the clocks with channel 0
0–3	ICESEL	1b or 10b	Configure the clock edge that you want
0–3	FIFOWMK	0	Set the FIFO watermark
0–3	RDFMT	0	Select the signed data format
0–3	PFSFT	1_0100b	Select a left shift of 4

NOTE

For channels 0–2, the conversion time (calculated using ORD×OSR÷F_S) is 8.6 µs. This is smaller than the PWM period (50 µs) and allows enough margin to adjust sample time that Measurement time requires.

7. Enable SINC features as follows:

Channels (value of *n*)	Register and field to write	Value to write	Purpose
0–3	C*n*CR[PFEN]	1	Enable the PFs
0–3	C*n*CR[CHEN]	1	Enable the channels and their subfunctions
0–3	C*n*CR[FIFOEN]	1	Enable each PF's FIFO transfers
3	C*n*CR[SCDEN]	1	Enable SCD
3	C*n*PROT[SCDOP]	0	Specify that both repeating bit values increment the SCD counter
3	C*n*PROT[SCDBK]	1	Enable the SCD break signal
3	C*n*PROT[SCDLMT]	192d	Specify the SCD limit threshold

8. Optionally enable other subfunctions if you need them.
9. To enable interrupts for all channels (*n* = 0–3), write 1 to NIE[COCIEn].
10. To enable conversion, write 1 to MCR[MEN].
11. Wait until SR[CHRDYn] becomes 1 for all channels (*n* = 0–3).
12. Start PWM.
13. To start conversion for channel 3, write 1 to MCR[STRIG3].
14. Wait until NIS[COC*n*] = 1. This indicates conversion completion.
15. Read the ADC results from the FIFO using Channel n Result Data (C0RDATA - C3RDATA).
16. Process the motor-control data.
17. Reconfigure PWM.
18. Go to step 14 for the next loop.

83.7.3.6 Measurement time

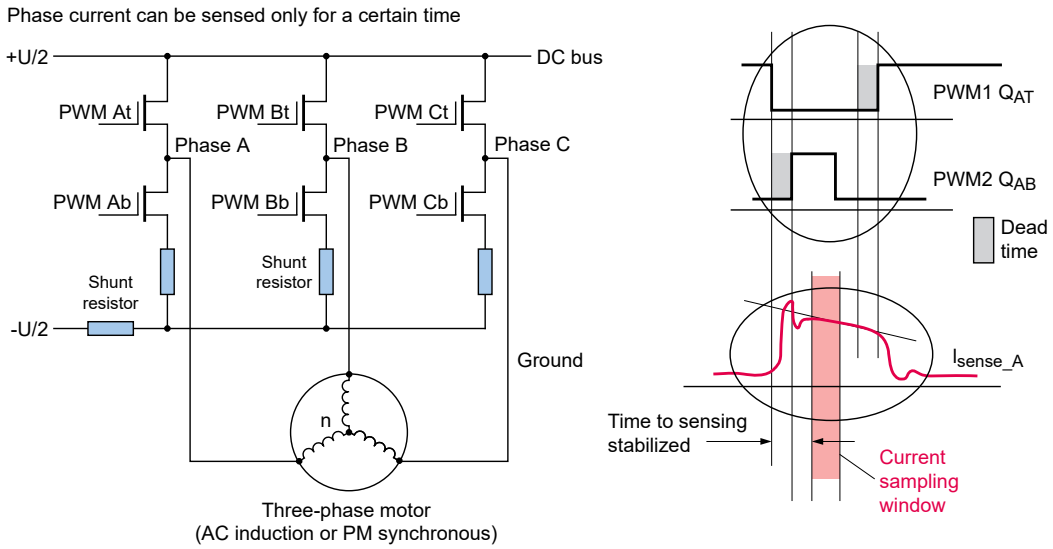

Figure 666. Measurement time

83.7.4 Use case: Motor control with Fixed-Number mode

83.7.4.1 Overview

This example improves on Use case: Motor control with Single mode by adding a compensation filter to achieve better precision, flatten the passband, improve roll-off, and so on. This method requires several samples for each PWM turn to perform filter compensation and sharpening with additional decimation. After the FIFO reaches its watermark, the conversion and filtering processes automatically stop.

NOTE

You can also achieve the same result with Continuous mode. When the FIFO reaches its watermark, you can toggle C*n*CR[PFEN] to abort conversion and wait for another trigger. The problem with this approach is that you must toggle C*n*CR[PFEN] as quickly as possible when SINC sets the corresponding NIS[CHF*n*] flag. If you disable conversion too late, it is hard to identify whether the 13th conversion had completed before you terminated conversion.

83.7.4.2 Assumptions

Table 1152. Assumptions

Parameter	Value
SINC function clock	133 MHz
Target external modulator ADC clock (F_S)	22.2 MHz
Motor speed	6000 RPM (100 Hz)
PWM switch frequency (F_P)	20 kHz (corresponding to a 50 µs period, or 200 PWM steps per revolution)
Number of samples per PWM period	12
OSR	64
Decimation frequency (F_D)	346 kHz (calculated using the target external modulator ADC clock and OSR)
Cutoff frequency (F_C)	91 kHz
Additional decimation factor	2, in software
SNR	Approximately 94 dB (see the ADC specifications in the chip data sheet)
ENOB	Approximately 15.4 (calculated using SNR)
Data width	20 bits (calculated using OSR and ORD)

83.7.4.3 Frequency response

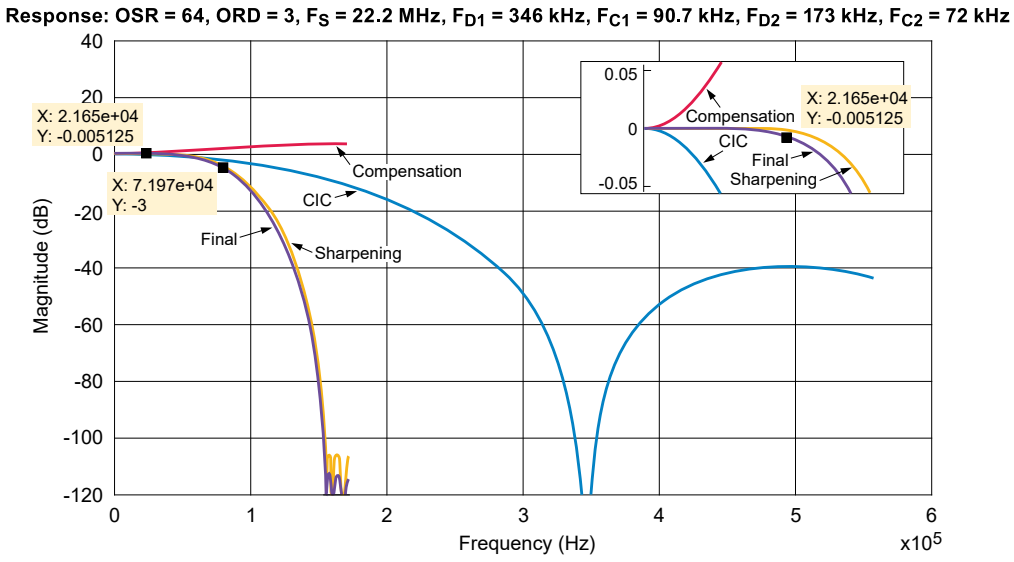

Figure 667. Frequency response

83.7.4.4 Procedure

1. Configure the related PWM and other chip modules to establish the correct pin connection with SINC. In particular, ensure that the PWM event signal connects to SINC as a hardware trigger, so that when PWM starts driving the coil, SINC can start conversion at a specific time.

2. Program the PWM event delay such that when SINC starts conversion, the coil currents are stable, as shown in Measurement time.
3. If the external ADC does not provide a clock, configure the modulator clock output. For this example, MCLK_OUT0 drives all external ADCs. To achieve MCLK_OUT0 = 22.2 MHz:
    a. Write 0 to MCR[PRESCALE].
    b. Write 5d to MCR[MCLKDIV].
4. Configure the data rate for channels 0–2 (*n* = 0–2) as follows:
    a. Write 3d to C*n*DR[PFORD].
    b. Write 63d to C*n*DR[PFOSR] to select OSR = 64.
    c. Write 11b to C*n*DR[PFCM] to select Fixed-Number mode.
5. Configure the data rate for channel 3 (*n* = 3) as follows:
    a. Write 2d to C*n*DR[PFORD] to select the optional fast response.
    b. Write 63d to C*n*DR[PFOSR] to select OSR = 64.
    c. Write 10b to C*n*DR[PFCM] to select Always On mode for monitoring total current.
6. Configure fields in Channel n Configuration (C0CFR - C3CFR) for data operation as follows:

Channels (value of *n*)	C*n*CFR field to write	Value to write	Purpose
0–3	ITLVL	0	Select edge triggering
0–2	ITSEL	1	Select hardware triggering
3	ITSEL	0	Select software triggering
0–3	IBSEL IBFMT	0	Select a bitstream from the MBIT signals (see External signals)
0	ICSEL	11b	Select the external modulator clock
1–3	ICSEL	111b	Group the clocks with channel 0
0–3	ICESEL	1b or 10b	Configure the clock edge that you want
0–3	FIFOWMK	11b	Set the FIFO watermark
0–3	RDFMT	0	Select the signed data format
0–3	PFSFT	1_0100b	Select a left shift of 4

NOTE

For channels 0–2, the conversion time for 12 samples (calculated using {[ORD+11]×OSR]}÷F_S) is 40.3 µs. This is smaller than the PWM period (50 µs) and allows enough margin to adjust sample time that Measurement time requires.

7. Enable SINC features as follows:

Channels (value of *n*)	Register and field to write	Value to write	Purpose
0–3	C*n*CR[PFEN]	1	Enable the PFs

Table continues on the next page...

Table continued from the previous page...

Channels (value of *n*)	Register and field to write	Value to write	Purpose
0–3	C*n*CR[CHEN]	1	Enable the channels and their subfunctions
0–3	C*n*CR[FIFOEN]	1	Enable each PF's FIFO transfers
3	C*n*CR[SCDEN]	1	Enable SCD
3	C*n*PROT[SCDOP]	0	Specify that both repeating bit values increment the SCD counter
3	C*n*PROT[SCDBK]	1	Enable the SCD break signal
3	C*n*PROT[SCDLMT]	192d	Specify the SCD limit threshold

8. Optionally enable other subfunctions if you need them.
9. To enable interrupts for all channels (*n* = 0–3), write 1 to NIE[COCIEn].
10. To enable conversion, write 1 to MCR[MEN].
11. Wait until SR[CHRDYn] becomes 1 for all channels (*n* = 0–3).
12. Start PWM.
13. To start conversion for channel 3, write 1 to MCR[STRIG3].
14. Wait until NIS[CHF*n*] = 1. This indicates conversion completion.
15. Read the ADC results from the FIFO using Channel n Result Data (C0RDATA - C3RDATA).
16. Optionally perform compensation:
    a. CIC gain adjust (divide 40_0000h if necessary) to get a fixed-point decimal between -1.0 and 1.0, than take part in the ADC reference voltage to get the final value in the correct format.
    b. Post-process the ADC result at a low speed, perform filter compensation and sharpening, and decimate the frequency by 2 to get the final ADC result as shown in Frequency response.
    c. If you have enough samples and don't have a hardware-delay feature, optionally perform delay compensation (for example, with a Lagrange polynomial).
17. Process the motor-control data.
18. Reconfigure PWM.
19. Go to step 14 for the next loop.

83.7.5 Use case: Audio system with Continuous mode

83.7.5.1 Overview

You can use SINC for two typical audio applications:

- Stereo recorder, using two SINC channels to sample the left and right audio channels
- Microphone array, using two or more SINC channels to sample a person's voice (based on distance from the person) and a beamforming software compensation to filter out environment noise

Schematic shows the audio schematic.

Waveforms: Audio system illustrates why you need different edges and why one MBIT input goes to two channels.

Frequency response after CIC filter shows the resulting frequency response of the PF's CIC.

Frequency response after HPF shows that HPF response is not linear and does not approach 0 dB.

83.7.5.2 Schematic

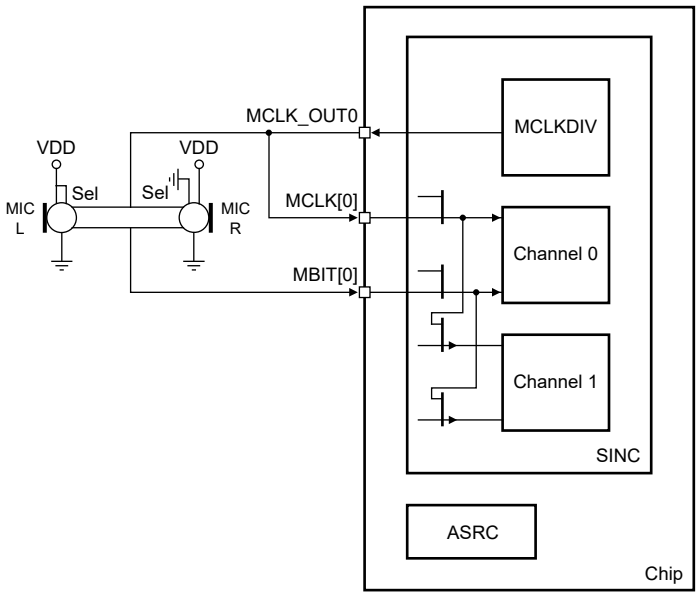

Figure 668. Schematic

83.7.5.3 Assumptions

Table 1153. Assumptions

Parameter	Value
SINC function clock	133 MHz
Target external modulator ADC clock	16.6 MHz
Target audio sample rate	44.0 kHz
Data precision	24 bits
OSR	94
Additional decimation factor	4
C*n*ACFR[HPFA]	1
Signal-to-noise ratio	Approximately 118 dB
Equivalent number of bits	Approximately 19.2
Final output frequency	44.22 kHz (calculated using the ADC clock, OSR, and additional decimation)

83.7.5.4 Waveforms: Audio system

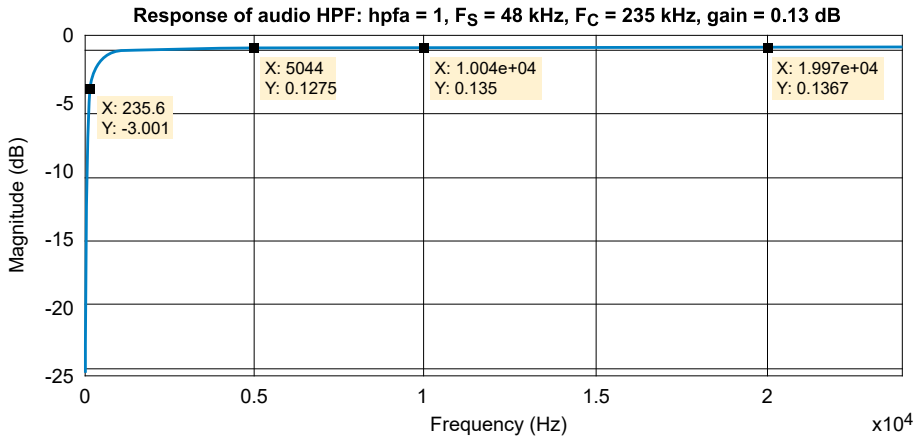

Figure 672. Frequency response after HPF

83.7.5.8 Procedure

This procedure involves only channels 0 and 1 (*n* = 0–1).

1. Configure the chip pin connections so that one MBIT goes to both SINC channels 0 and 1 (containing the left and right bitstreams, respectively).
2. If the external ADC does not provide a clock, configure the modulator clock output. For this use case, MCLK_OUT0 drives all external ADCs. To achieve MCLK_OUT0 = 16.6 MHz:
    a. Write 0 to MCR[PRESCALE].
    b. Write 7d to MCR[MCLKDIV].

3. Configure the data rate as follows:
    a. Write 3d to C*n*DR[PFORD].
    b. Write 93d to C*n*DR[PFOSR] to select OSR = 94.
    c. Write 01b to C*n*DR[PFCM] to select Continuous mode.
4. Configure fields in Channel n Configuration (C0CFR - C3CFR) for data operation as follows:

Channels (value of *n*)	C*n*CFR field to write	Value to write	Purpose
0–1	ITLVL	0	Select edge triggering
0–1	ITSEL	0	Select software triggering
0–1	IBSEL IBFMT	0	Select a bitstream from the MBIT signals (see External signals)
0	ICSEL	11b	Select the external modulator clock
1	ICSEL	111b	Group the clocks with channel 0
0	ICESEL	1	Select the left clock edge
1	ICESEL	10b	Select the right clock edge
0–1	FIFOWMK	7d	Set the FIFO watermark
0–1	RDFMT	0	Select the signed data format
0–3	PFSFT	1_0011b	Select a left shift of 3

5. Enable SINC features:
    - Optionally enable other subfunctions if you need them.

Channels (value of *n*)	Register and field to write	Value to write	Purpose
0–1	C*n*CR[PFEN]	1	Enable the PFs
0–1	C*n*CR[CHEN]	1	Enable the channels and their subfunctions
0–1	C*n*CR[FIFOEN]	1	Enable each PF's FIFO transfers
0–1	C*n*ACFR[HPFA]	1	Select the alpha coefficient

6. Optionally enable other subfunctions if you need them.
7. To enable interrupts for channels 0 and 1, write 1 to CHFIE0 and CHFIE1 in Normal Interrupt Enable (NIE).
8. To enable conversion, write 1 to MCR[MEN].
9. Wait until SR[CHRDYn] becomes 1.
10. To start conversion, write 1 to MCR[STRIGn].
11. Wait until NIS[CHF*n*] = 1. This indicates that the FIFOs are nearly full.
12. Process the audio data. This can include:
    - Adjusting the CIC gain. For example, divide the 24-bit result by OSR^{ORD} (in this case, C_AC78h) to get a fixed-point decimal value between –1.0 and 1.0. Then, account for the ADC reference voltage to get the real value.

- Using your software to perform additional compensation, low-pass filtering (sharpening), and decimation by 4. See Frequency response after LPF and compensation for results.
- Using your software to perform HPF gain compensation. Frequency response after HPF shows that you must compensate by adding 0.1367 dB.
- Using your software or another module (such as a sample-rate converter) to perform asynchronous data-rate conversion. In this use case, the final data rate is 44.22 kHz, but the audio system requires 44.000 kHz.
- Optionally performing delay compensation or beamforming. You can use a Lagrange polynomial for this.

13. Go to step 11 for the next loop.

83.7.6 Use case: Sinusoidal decoder with Continuous mode

83.7.6.1 Overview

You can use Continuous mode to create a sinusoidal decoder.

Consider a traditional quadrature encoder—an incremental encoder with two out-of-phase output channels that is used in many general automation applications for sensing the direction of rotary movement. (See Waveforms: Crude-position quadrature decoder.) Compared with such an encoder, a sinusoidal encoder provides much higher position and speed resolution. This improvement comes from a pair of quadrature sine and cosine signals as the shaft rotates. The signal typically comes from optical or magnetic sensors and typically generates approximately 1000 steps or cycles per revolution.

This example uses two external modulator ADCs to measure the sine and cosine signals. The modulator ADC results are high-speed bitstreams. The chip sends these results to SINC through MBIT signals (see External signals). Then, SINC:

1. Demodulates the bitstream.
2. Decimates the bitstream.
3. Converts the bitstream to a 24-bit lower-speed result.
4. Saves the result in a FIFO.

The internal pulse trigger generates a pulse to the quadrature decoder elsewhere on the chip. This generates the crude position. You can then read the sine and cosine wave from the FIFO and process the data to get the fine position. The crude and fine positions, combined together, can achieve an approximately 24-bit precision of position.

Schematic shows the sinusoidal-decoder schematic.

83.7.6.2 Schematic

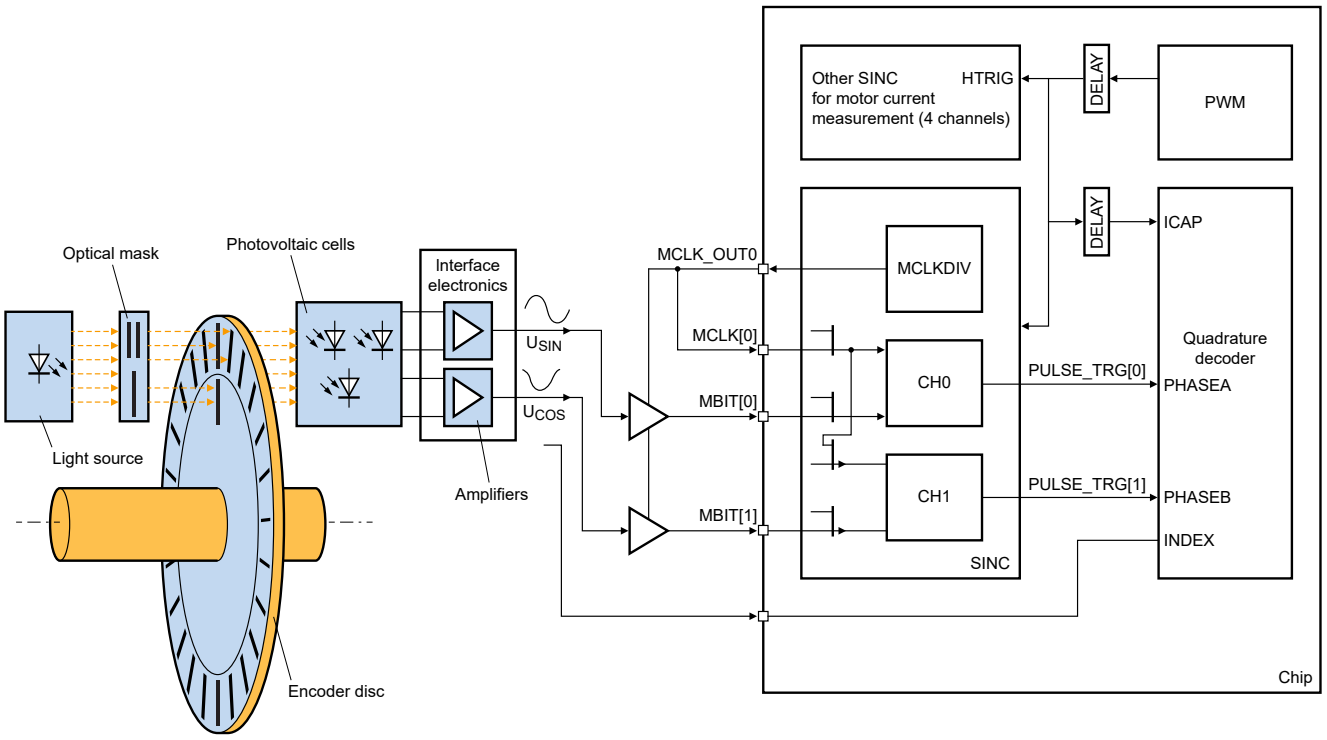

Figure 673. Schematic

83.7.6.3 Assumptions

For channels measuring motor current:

- Ensure one of the following. This helps you get the position when you measure the current.
  - OSR is the same for all channels.
  - OSR for one channel is an integer multiple of all other OSRs.
- Use the hardware trigger for both sinusoidal and current-measurement channels with different delay settings.

Table 1154. Assumptions

Parameter	Value
SINC function clock	133 MHz
Target external modulator ADC clock	22.2 MHz
Motor speed	600 RPM (10 Hz)
Encoder disk pulses per revolution	512 sine and cosine
Data precision	25 bits
ORD	3
OSR	64
Additional decimation factor	2

Table continues on the next page...

Table 1154. Assumptions (continued)

Parameter	Value
Signal-to-noise ratio	Approximately 94 dB
Equivalent number of bits	Approximately 15.4
Final output frequency	173 kHz
Final output precision	25 bits

83.7.6.4 Waveforms: Crude-position quadrature decoder

This diagram shows signals that are typical in a generic quadrature decoder.

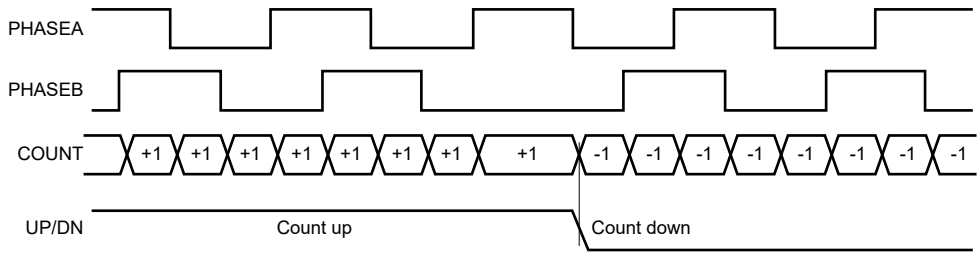

Figure 674. Waveforms: Crude-position quadrature decoder

83.7.6.5 Procedure

This procedure involves only channels 0 and 1 (*n* = 0–1).

1. Configure the chip pin connections and related modules so they match Schematic.
2. Configure the additional SINC instance shown in Schematic for motor-current measurement according to Use case: Motor control with Single mode.
3. If the external ADC does not provide a clock, configure the modulator clock output. For this example, MCLK_OUT0 drives drive all external ADCs. To achieve MCLK_OUT0 = 22.2 MHz:
    a. Write 0 to MCR[PRESCALE].
    b. Write 5d to MCR[MCLKDIV].
4. Configure the data rate as follows:
    a. Write 3d to C*n*DR[PFORD].
    b. Write 63d to C*n*DR[PFOSR] to select OSR = 64.
    c. Write 01b to C*n*DR[PFCM] to select Continuous mode.
5. Configure fields in Channel n Configuration (C0CFR - C3CFR) for data operation as follows:

Channels (value of *n*)	C*n*CFR field to write	Value to write	Purpose
0–1	ITLVL	0	Select edge triggering
0–1	ITSEL	0	Select software triggering
0–1	IBSEL	0	Select a bitstream from the MBIT signals (see External signals)

Table continues on the next page...

Table continued from the previous page...

Channels (value of *n*)	C*n*CFR field to write	Value to write	Purpose
	IBFMT		
0	ICSEL	11b	Select the external modulator clock
1	ICSEL	111b	Group the clocks with channel 0
0–1	ICESEL	1b or 10b	Configure the clock edge that you want
0–1	FIFOWMK	7d	Set the FIFO watermark
0–1	RDFMT	0	Select the signed data format
0–1	PFSFT	1_0100b	Select a left shift of 4

6. Configure the pulse trigger:
    a. Write 111b to C*n*ACFR[PTMUX].
    b. To set the high-detect margin, write 1000d to C*n*HILMT[HILMT].
    c. To set the low-detect margin, write FF_FC18h to C*n*LOLMT[LOLMT].
7. Enable SINC features as follows:

Channels (value of *n*)	Register and field to write	Value to write	Purpose
0–1	C*n*CR[PFEN]	1	Enable the PFs
0–1	C*n*CR[CHEN]	1	Enable the channels and their subfunctions
0–1	C*n*CR[FIFOEN]	1	Enable each PF's FIFO transfers

8. Optionally enable other subfunctions if you need them.
9. To enable interrupts for channels 0 and 1, write 1 to CHFIE0 and CHFIE1 in Normal Interrupt Enable (NIE).
10. To enable conversion, write 1 to MCR[MEN].
11. For channels 0–1 (*n* = 0–1), wait until SR[CHRDY*n*] becomes 1.
12. Start quadrature for crude decoder and PWM for motor drive.
13. Wait until NIS[CHF*n*] becomes 1. This indicates that the FIFOs are nearly full.
14. Process the resulting data:
    a. Read ADC results from the FIFO.
    b. Apply compensation, low-pass filtering, and additional decimation to the ADC results.
    c. Calculate position.
    d. Save results to memory.
    e. Save the timestamp or number of conversions after the hardware trigger occurred. You can use C*n*SR[CNUM] to determine how many samples SINC gathered after receiving a hardware trigger in Continuous mode.
15. Go to step 13 for the next loop.

NOTE

In your software motor control main loop (separate from the procedure above), select the memory-stored position that corresponds to the time when you measured the coil current.

83.7.7 Use case: Power meter with Continuous mode

83.7.7.1 Overview

You can use SINC for a power meter.

A typical low-cost power meter can achieve a wide dynamic range (approximately 6 mA to 60 A) using:

- A successive approximation register ADC (SAR ADC), with 12- to 16-bit resolution, to measure typical voltages (for example, 220 V or 380 V) that have a stable wave.
- A sigma-delta ADC (SD ADC), with 20- to 24-bit resolution, to measure current.

For a single-phase power meter, use one SINC channel to measure current and one SAR ADC to measure voltage.

For a three-phase power meter, use three or four SINC channels to measure current and three SAR ADCs to measure voltage. If your SAR ADC supports multiplexed channels, you can use one SAR ADC to sample three voltages at different times.

Ideally, voltage and current measurements must occur at the same time. However, in this use case, simultaneous measurement is hard to achieve. You can use SINC's FILT_CC output to synchronize the measurement time between SINC and SAR ADC.

Schematic shows the power-meter schematic.

83.7.7.2 Schematic

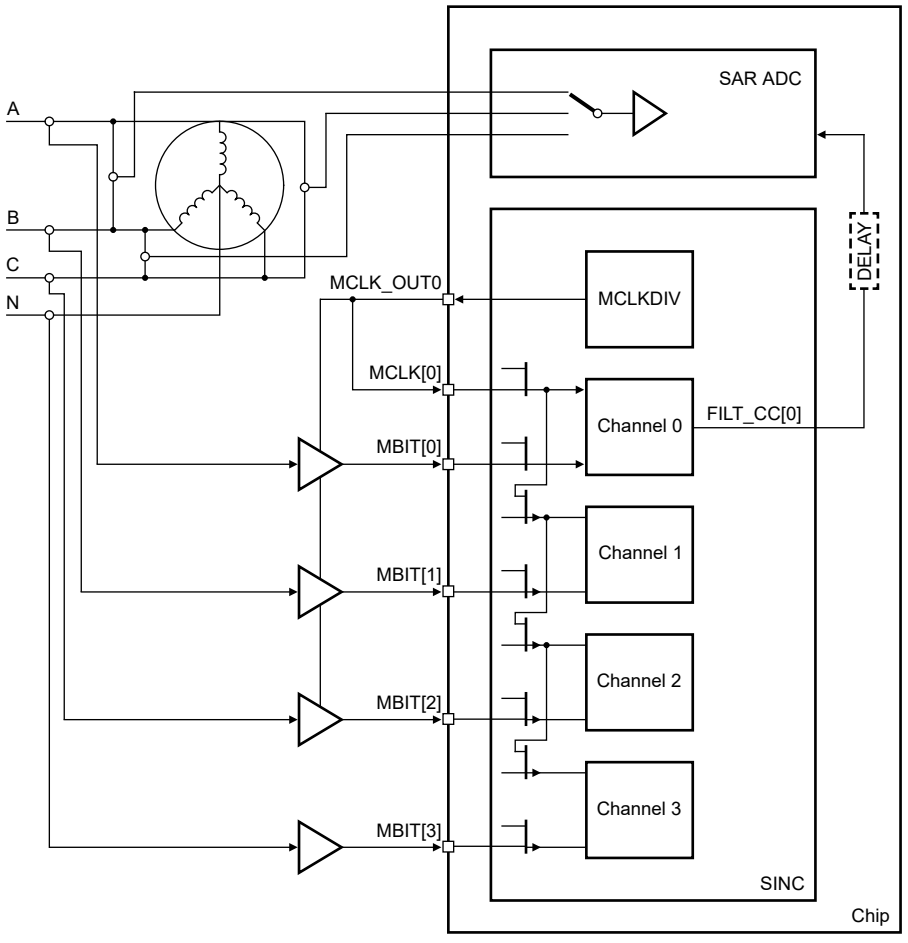

Figure 675. Schematic

83.7.7.3 Considerations

SAR ADC must support switching and must sample three voltage inputs when it receives a trigger.

This use case includes the following delays:

- From the SINC sample time to FILT_CC
- From FILT_CC to the delay block
- From the delay block to the start of SAR ADC's conversion of A in Schematic
- From the end of SAR ADC's conversion of A to the start of conversion B

You can calculate the delay, and you must compensate for that delay.

You can also manage delays by configuring the delay value to be near the SINC sample rate (0.5 × OSR), and ignore SINC's first output. In this case, when SINC completes its second conversion, SAR ADC has also just finished its first sample. Therefore, you can reduce the delay-compensation effort and improve precision by carefully configuring the delay value.

For the exact delay setting, consider SINC's CIC phase response and align it to SAR ADC's analog sample-and-hold time (not including conversion time). CIC phase response is linear, so you can convert it to a delay time, which is about half of OSR in Continuous mode.

83.8 SINC register descriptions

SINC supports a programming model for:

- Configuring the module.
- Storing the FIFO buffer.
- Enabling clock generation.
- Generating triggers.
- Protecting SINC operation.
- Using DMA.

Before you enable SINC or its channels, you must configure certain fields as described in Configure clocking-related fields before enabling SINC and Configure fields before enabling channels.

In the memory map, the following addresses are reserved and do not generate a transfer error if you access them:

- 28h
- 2Ch
- 30h
- 34h

83.8.1 SINC memory map

SINC1 base address: 42BF_0000h

SINC2 base address: 42C0_0000h

SINC3 base address: 42C1_0000h

Fields

Field	Function
31-24 —	Reserved
23-20 —	Reserved
19-16 ZCDn	Zero Cross Detected Flag Indicates whether the resulting data on filter channel *n* crossed zero and therefore changed sign. Use C*n*CFR[ZCOP] to configure the type of zero crossing that sets the Zero Cross Detected flag.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
15-12 —	Reserved
11-8 CHFn	Data Output Ready Flag Indicates whether the FIFO from PF channel *n* has overflowed its watermark level and the data is available in Channel n Result Data (C0RDATA - C3RDATA). This flag contributes to generating an interrupt or DMA request if you enabled these by using NIE[CHFIE*n*] or C*n*CR[DMAEN], respectively. SINC sets this flag according to the watermark level. If you enabled DMA requests, SINC clears the flag after the DMA controller finishes the DMA transaction. In other cases—for example, if you enabled interrupts—you clear the flag by writing 1 to it. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overflow; data not available 1b - Overflow; data available When writing 0b - No effect 1b - Clear the flag
7-4 —	Reserved
3-0 COCn	Conversion Complete Flag Indicates whether one conversion has finished and the data is available in Channel n Result Data (C0RDATA - C3RDATA). **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - Not finished; data not available 1b - Finished; data available When writing 0b - No effect 1b - Clear the flag

83.8.9 Error Interrupt Status (EIS)

Offset

Register	Offset
EIS	1Ch

Function

Contains flags for error-related interrupts on each SINC channel.

7 —	Reserved
6 RDFMT	Result Data Format Result data are 24bit width, located at CnRDATA[31:8]. This field controls the signed or unsigned format. If signed format, CnRDATA[31] indicates the negative or positive value. 0b - Left justified, signed 1b - Left justified, unsigned
5 —	Reserved
4-0 PFSFT	PF Shift Shifts the PF data for the correct 24-bit precision. See Shift for details. Bits 0–3 specify the number of bits to shift the data. Bit 4 specifies the shift direction: 0b - Right 1b - Left

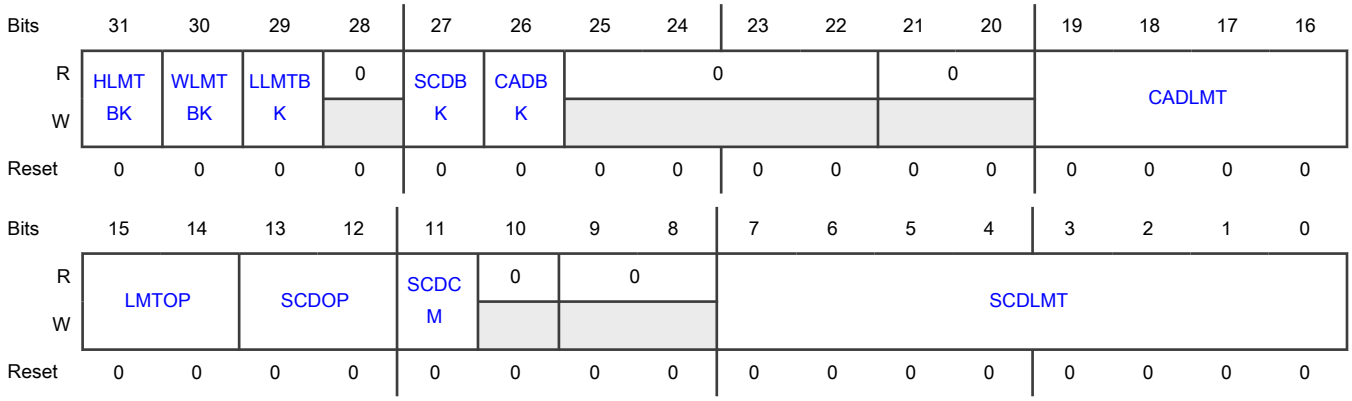
83.8.15 Channel n Protection (C0PROT - C3PROT)

Offset

Register	Offset
C0PROT	44h
C1PROT	74h
C2PROT	A4h
C3PROT	D4h

Function
Configures the SINC functions related to protection (SCD, CAD, and limits).

Diagram



Fields

Field	Function
31 HLMTBK	High Limit Break Signal Enables the automatic assertion of the BREAK_HIGH signal (see External signals) when SINC detects a high-limit event on the associated channel. 0b - Disables 1b - Enables
30 WLMTBK	Window Limit Break Signal Enables the automatic assertion of the BREAK_WIN signal (see External signals) when SINC detects a window-limit event on the associated channel. 0b - Disables 1b - Enables
29 LLMTBK	Low Limit Break Signal Enables the automatic assertion of the BREAK_LOW signal (see External signals) when SINC detects a low-limit event on the associated channel. 0b - Disables 1b - Enables
28 —	Reserved
27 SCDBK	SCD Break Signal Enables the automatic assertion of the BREAK_SCD signal (see External signals) when SINC detects an SCD event on the associated channel. 0b - Disables 1b - Enables
26	CAD Break Signal

Table continues on the next page...

Table continued from the previous page...

Field	Function
CADBK	Enables the automatic assertion of the BREAK_CAD signal (see External signals) when SINC detects a CAD event on the associated channel. 0b - Disables 1b - Enables
25-22 —	Reserved
21-20 —	Reserved
19-16 CADLMT	CAD Limit Threshold Specifies the threshold value for the CAD counter. The CAD counter tracks the number of clock cycles during which SINC does not detect a clock. If that number exceeds CADLMT, a CAD event occurs on the associated channel. You disable CAD by writing 0 to CADLMT. 0000b - Disables CAD All other values - Threshold value
15-14 LMTOP	Limit Detection Option Specifies whether SINC compares the filter sample value to: • The low limit (C*n*LOLMT[LOLMT]) • The high limit (C*n*HILMT[HILMT]) • Both the high and low limits • A window of values between the low and high limits See Limit detection operations for more information. 00b - Both high and low limits 01b - High limit 10b - Low limit 11b - Windowed value
13-12 SCDOP	SCD Option Specifies which repeating bit value increments the SCD counter. 00b - Both 0 and 1 01b - Only 1 10b - Only 0 11b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 SCDCM	SCD Conversion Mode Specifies when SCD operates. 0b - Constantly when CnCR[CHEN] = MCR[MEN] = 1 1b - Only when the PF is performing a conversion
10 —	Reserved
9-8 —	Reserved
7-0 SCDLMT	SCD Limit Threshold Specifies the threshold value for the SCD counter. The SCD counter tracks the number of received bits with the same repeating value (always 0 or always 1). If that number exceeds SCDLMT, an SCD event occurs on the associated channel. 0000_0000b-0000_0001b - Disables SCD All other values - Threshold value

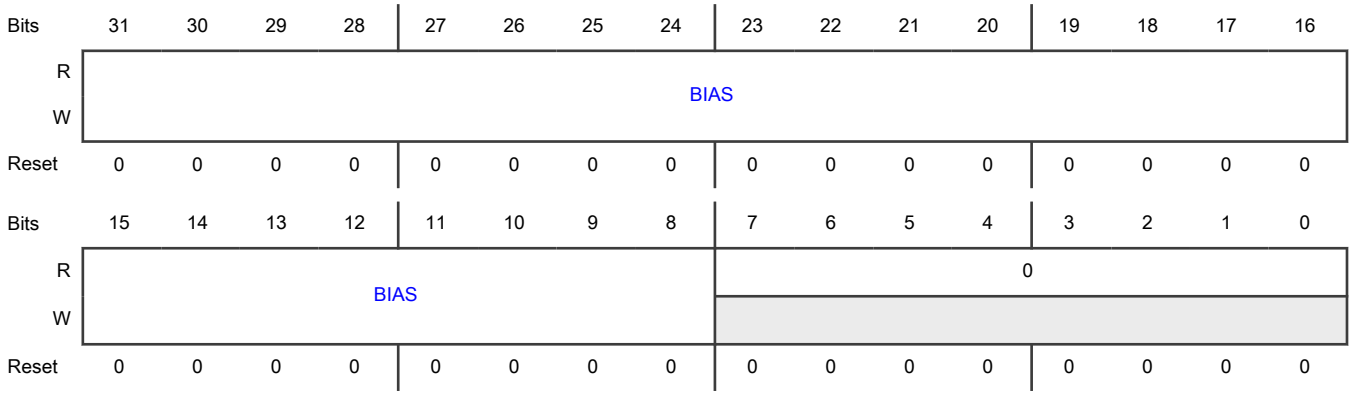
83.8.16 Channel n Bias (C0BIAS - C3BIAS)

Offset

Register	Offset
C0BIAS	48h
C1BIAS	78h
C2BIAS	A8h
C3BIAS	D8h

Function
Configures the filter bias.

Diagram



Fields

Field	Function
31-8 BIAS	Bias Value Specifies the bias offset for this channel's PF. After the PF shifts its data, the filter subtracts this bias value from the data. Bit 23 of this field (bit 31 within the register) specifies the bias sign: 0b - Positive 1b - Negative
7-0 —	Reserved

83.8.17 Channel n Low Limit (C0LOLMT - C3LOLMT)

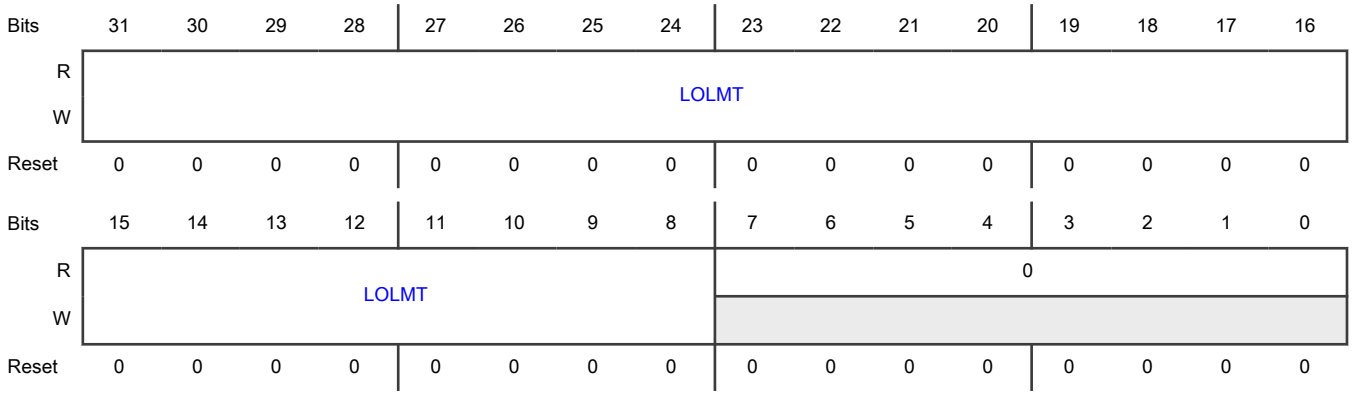
Offset

Register	Offset
C0LOLMT	4Ch
C1LOLMT	7Ch
C2LOLMT	ACh
C3LOLMT	DCh

Function

Specifies the low-limit threshold value.

Diagram



Fields

Field	Function
31-8 LOLMT	Low Limit Threshold Specifies the low-limit threshold value. When the data exceeds this threshold value, a low-limit event occurs. C*n*CFR[RDFMT] determines the limit threshold format (signed or unsigned). **NOTE** Ensure that LOLMT is lower than C*n*HILMT[HILMT]. Otherwise, the low-limit threshold does not work.
7-0 —	Reserved

83.8.18 Channel n High Limit (C0HILMT - C3HILMT)

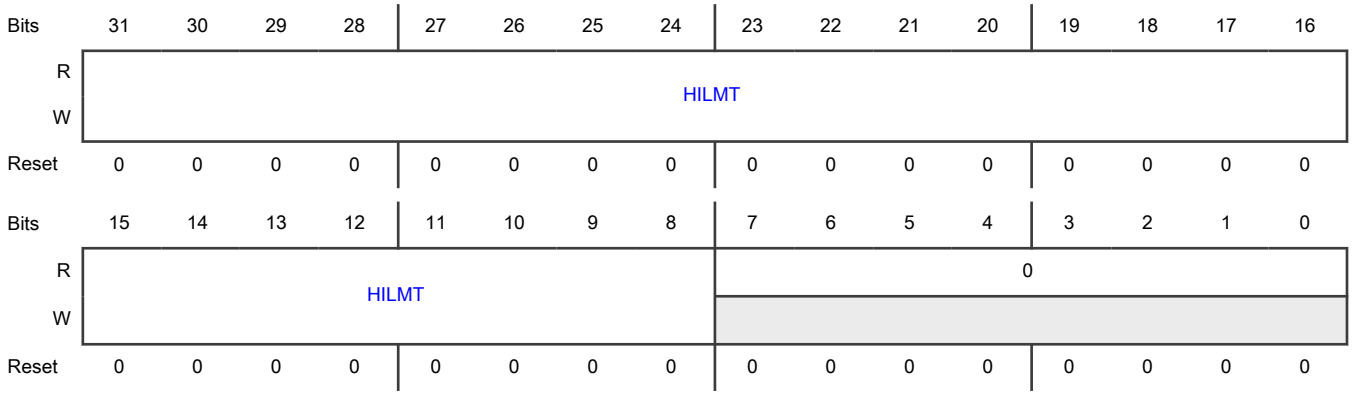
Offset

Register	Offset
C0HILMT	50h
C1HILMT	80h
C2HILMT	B0h
C3HILMT	E0h

Function

Specifies the high-limit threshold value.

Diagram



Fields

Field	Function
31-8 HILMT	High Limit Threshold Specifies the high-limit threshold value. When the data exceeds this threshold value, a high-limit event occurs. C*n*CFR[RDFMT] determines the limit threshold format (signed or unsigned). **NOTE** Ensure that C*n*LOLMT[LOLMT] is lower than HILMT. Otherwise, the low-limit threshold does not work.
7-0 —	Reserved

83.8.19 Channel n Result Data (C0RDATA - C3RDATA)

Offset

Register	Offset
C0RDATA	54h
C1RDATA	84h
C2RDATA	B4h
C3RDATA	E4h

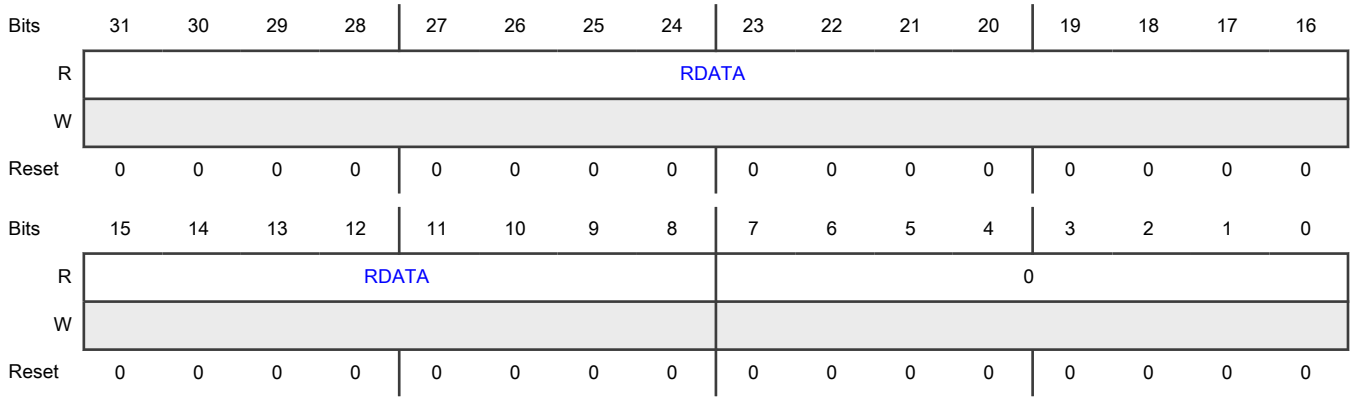
Function

Returns data from the FIFO.

NOTE

NXP recommends that you use a 32-bit access to read this register. If you use a byte access to read this register, you must read the highest byte last, and this increases the FIFO level.

Diagram



Fields

Field	Function
31-8 RDATA	Result Data Contains data from the FIFO. Bit 23 of this field (bit 31 within the register) serves as the sign bit if you specify the signed-data format (C*n*CFR[RDFMT] = 0). When you read this field, be aware of the following circumstances:
7-0 —	Reserved

Conditions when you read RDATA	Result
SINC has not yet completed the conversion	One of the following occurs: • RDATA contains all zeros. • SINC triggers a FIFO underflow error.
FIFO is disabled (C*n*CR[FIFOEN] = 0)	RDATA contains the last conversion result. You must poll the C*n*SR[SRDS] flag, and if that flag is set after you read RDATA, you must read RDATA again.

83.8.20 Channel n Multipurpose Data (C0MPDATA - C3MPDATA)

Offset

Register	Offset
C0MPDATA	58h
C1MPDATA	88h
C2MPDATA	B8h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
C3MPDATA	E8h

Function

Contains multipurpose data as specified in C*n*CFR[IBFMT].

You can use this register for a parallel bitstream, a serial bitstream, or a Manchester decoder threshold as described in the following table.

Table 1155. MPDATA content options

Data type	C*n*CFR[IBFMT]	Description
Manchester	01b	Bits 10–0 contain the Manchester decoder threshold value.
Parallel	10b	Bits 15–0 contain the parallel 16-bit data. You can write to MPDATA only when parallel or serial data is ready (C*n*SR[PSRDY] = 1). Otherwise, a transfer error occurs.
Serial	11b	Bits 31–0 contain the serial data. You can write to MPDATA only when parallel or serial data is ready (C*n*SR[PSRDY] = 1) or MPDATA is not completely full. Otherwise, a transfer error occurs. **NOTE** Allow write MPDATA when C*n*SR[PSRDY] = 0, give you the chance if keep the remain bit for next conversion or overwrite with new data. In this case, the write are only allowed one time. **NOTE** MPDATA are shift out,you can read back for debug. But in corner case, last bit does not shift out while remain bit are zero.

83.8.23 Channel n Debug (C0DBGR - C3DBGR)

Offset

Register	Offset
C0DBGR	64h
C1DBGR	94h
C2DBGR	C4h
C3DBGR	F4h

Function

Contains the instantaneous debug data and status for debugging each channel's subblocks.

You select the data by writing to C*n*CR[DBGSEL], as shown in Details of debug data. For example:

- If you write 3d to C*n*CR[DBGSEL], SINC offers you 32 bits of data from the DC remover (HPF).
- If you write 4d to C*n*CR[DBGSEL], SINC offers you raw data from the PF's CIC filter.

The instantaneous data is read-only, and the contents are for each subblock.

See Reading asynchronous data safely and Transferring data between domains safely for the procedures to manage data safely.

Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

NOTE

VREF_OUT shares same pin ADC_VREFH. In case no external VREFH is available, VREF_OUT can be used instead to save BOM cost.

84.2 Overview

The Voltage Reference provides a buffered reference voltage for use as an external reference, which can be set to 1.2 V. In addition, the buffered reference is available internally for use with on-chip peripherals (such as ADCs and DACs) . When the VREF is enabled, the reference voltage is placed on a dedicated output pin.

- The Voltage Reference output can be fine-tuning, trimmed with 0.5×(4/3) mV resolution, using the UTRIM register VREFTRIM[5:0] bitfield.

84.2.1 Block diagram

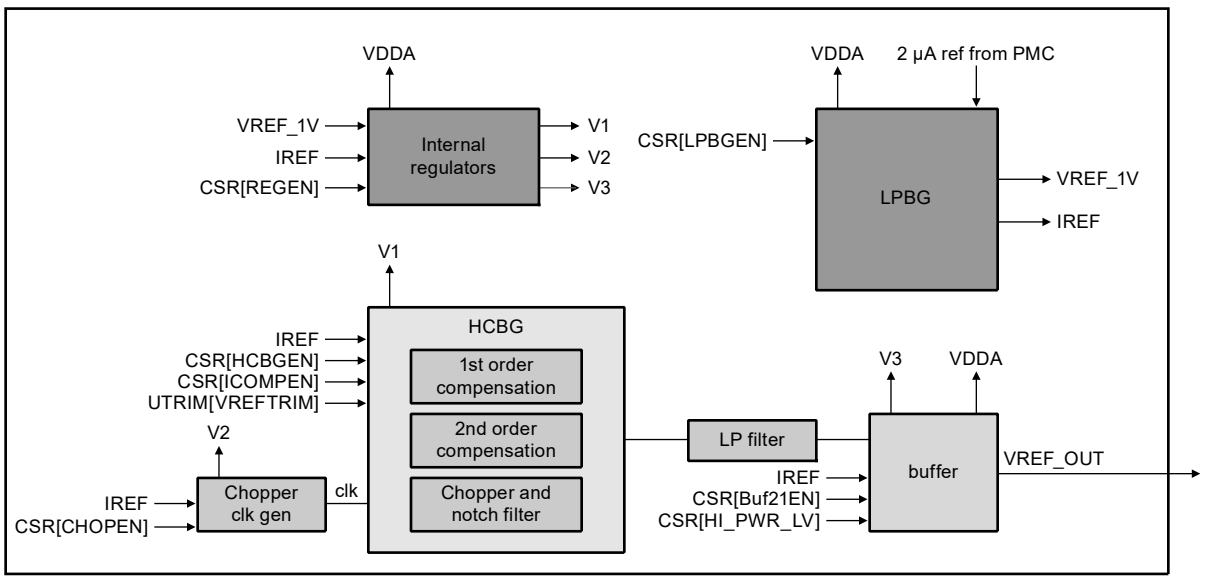

Figure 676. Voltage reference block diagram

84.2.2 Features

- Programmable trim register with 0.5×(4/3) mV steps in fine-tuning; Upon reset, the trim register is automatically loaded with a factory-trimmed value.
- Programmable buffer mode selection:
  - Off
  - Bandgap enabled/standby (output buffer disabled)
  - Low power buffer mode (output buffer enabled)
  - High power buffer mode (output buffer enabled)
- Low-Power bandgap and High-Accurate bandgap selection
- Dedicated output pin, VREF_OUT

84.3 Functional description

The Voltage Reference is a bandgap buffer system. Unity gain amplifiers are used.

The VREF_OUT signal can be used by both internal and external peripherals in low and high power buffer mode. A 220 nF capacitor must always be connected between VREF_OUT and VSS if the VREF is being used.

When CSR[LPBGEN] = 1 and CSR[HCBGEN] = 1, the Voltage Reference is enabled and different modes should be set by the bits CSR[Buf21EN] and CSR[HI_PWR_LV].

The Voltage Reference is an accurate buffered voltage 1.2 V.

84.3.1 Voltage Reference Disabled

When (CSR[LPBGEN] = 0) and (CSR[HCBGEN] = 0) and (CSR[Buf21EN] = 0), the Voltage Reference is disabled, the VREF bandgap and the output buffers are disabled. The Voltage Reference is in off mode.

84.3.2 Voltage Reference Enabled

When Voltage Reference Enabled, we have following cases:

1. Enable the CSR[LPBGEN]
2. Enable (CSR[LPBGEN]=1), (CSR[REGEN]=1), (CSR[HCBGEN]=1) and (CSR[Buf21EN]=1), this configuration enable VREF supply voltage on VREF_OUT

84.3.2.1 CSR[Buf21EN]=0,CSR[HI_PWR_LV]=X

The internal VREF bandgap is enabled to generate an accurate 0.9 V output that can be trimmed with the UTRM register's UTRIM[13:8] bitfield. The bandgap requires some time for startup and stabilization. CSR[VREFST] can be monitored to determine if the stabilization and startup is complete when the chop oscillator is not enabled.

If the chop oscillator is being used, the internal bandgap reference voltage settles within 400µs (see T_{STUP} in the device data sheet).

The output buffer is disabled in this mode, and there is no buffered voltage output. The Voltage Reference is in standby mode. If this mode is first selected and the low power or high power buffer mode is subsequently enabled, there will be a delay of 400µs before the buffer output is settled at the final value.

84.3.2.2 CSR[Buf21EN]=1,CSR[HI_PWR_LV]=1

The internal VREF bandgap is on. The high power buffer is enabled to generate a buffered voltage to VREF_OUT which is 1.2 V. The high power buffer has higher bandwidth than low power buffer. It can also be used as a reference to internal analog peripherals such as an ADC, VREF output pad and ADC VREFH are bonding to same ball in RT1180.

If this mode is entered from the standby mode (CSR[Buf21EN]=0) there will be a delay of 400µs before the buffer output is settled at the final value. If this mode is entered when the VREF module is enabled then you must wait for 400µs or until CSR[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, you must wait for 400µs to ensure the VREF output has stabilized.

In this mode, a 220 nF capacitor is required to connect between the VREF_OUT pin and VSS.

84.3.2.3 CSR[Buf21EN]=1,CSR[HI_PWR_LV]=0

The internal VREF bandgap is on. The low power buffer is enabled to generate a buffered voltage to VREF_OUT which is 1.2 V. It can also be used as a reference to internal analog peripherals such as an ADC: VREF output pad and ADC VREFH pad are bonding to the same pin in the chip.

If this mode is entered from the standby mode (CSR[Buf21EN]=0), there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (T_{STUP}) and the value is specified in the appropriate device data sheet. If this mode is entered when the VREF module is enabled, then you must wait for 400µs or until CSR[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, you must wait for 400µs to ensure the VREF output has stabilized.

In this mode, a 220 nF capacitor is required to connect between the VREF_OUT pin and VSS.

84.3.3 Internal voltage regulator

The VREF module contains an internal voltage regulator that can be enabled to provide additional supply noise rejection and internal oscillator which provide the chop clock. It is recommended that when possible, this regulator and oscillator can be enabled to provide the optimum VREF performance.

If the chop function is being used, and internal voltage regulator must also be enabled. A specific sequence must be followed when enabling the internal regulator as followings:

1. Enable (CSR[LPBGEN]=1)
2. Enable the internal regulator by setting (CSR[REGEN]=1)
3. Enable the chop oscillator(CSR[CHOPEN]=1), (CSR[ICOMPEN]=1) and (CSR[HCBGEN]=1)

84.3.4 Clocking

This module has no clocking considerations.

84.3.5 Interrupts

This module has no interrupts.

84.4 External signals

The following table shows the Voltage Reference signals properties.

Table 1157. VREF Signal Descriptions

Signal	Description	I/O
VREF_OUT	Internally-generated Voltage Reference output	O

NOTE

When the VREF output buffer is disabled, the status of the VREF_OUT signal is high-impedance.

84.5 Initialization

The Voltage Reference requires some time for startup and stabilization. After CSR[LPBGEN] = 1 and CSR[HCBGEN] = 1, CSR[VREFST] can be monitored to determine if the stabilization and startup is completed when the chop oscillator is not enabled. When the chop oscillator is enabled, the settling time of the internal bandgap reference is defined by Tstup (400µs). You must wait for 400µs after the internal bandgap has been enabled to ensure the VREF internal reference voltage has stabilized.

When the Voltage Reference is already enabled and stabilized, changing CSR[HI_PWR_LV] will not clear CSR[VREFST] but there will be some startup time before the output voltage at the VREF_OUT pin has settled. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet. Also, there will be some settling time when a step change of the load current is applied to the VREF_OUT pin. When the 1.75 V VREF regulator is disabled, the VREF_OUT voltage will be more sensitive to supply voltage variation. It is recommended to use this regulator to achieve optimum VREF_OUT performance.

The CSR[CHOPEN], CSR[REGEN] and CSR[ICOMPEN] bits must be written to 1 to achieve the performance stated in the device data sheet.

NOTE

See section "Internal voltage regulator" for details on the required sequence to enable the internal regulator.

84.6 Memory Map and Register Definition

84.6.1 VREF register descriptions

84.6.1.1 VREF memory map

VREF base address: 42E3_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0100_0000h
8h	Control and Status Register (CSR)	32	RW	0000_0000h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
10h	User Trim (UTRIM)	32	RW	0000_0000h
1Ch	Test Unlock (TEST_UNLOCK)	32	RW	0000_0000h
24h	Test Trim 0 (TRIM0)	32	RW	0000_0000h

84.6.1.2 Version ID (VERID)

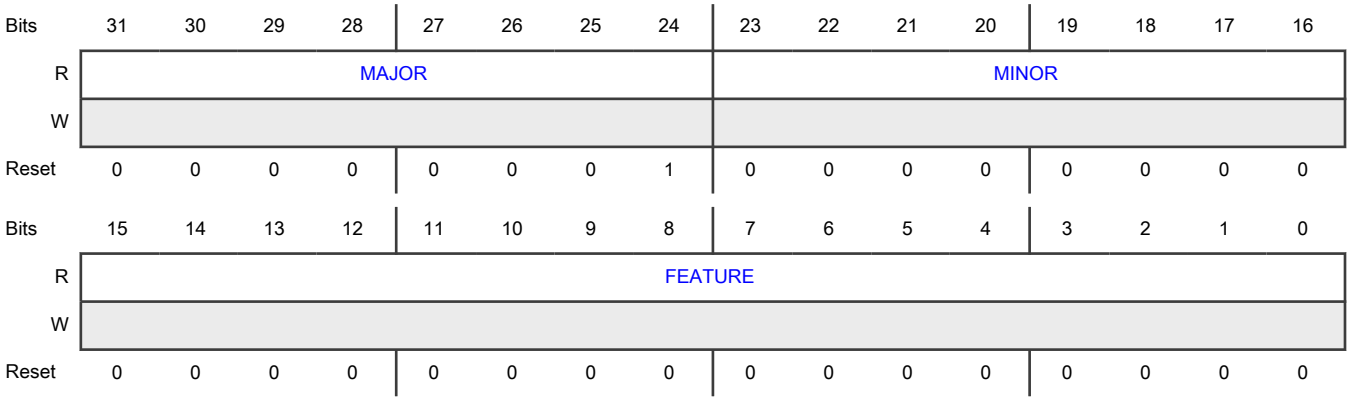
Offset

Register	Offset
VERID	0h

Function

This register contains version/feature number for VREF is read only.

Diagram



Fields

Field	Function
31-24 MAJOR	MAJOR Major Version Number: This read only field returns the major version number for the module specification.
23-16 MINOR	MINOR Minor Version Number. This read only field returns the minor version number for the module specification.
15-0 FEATURE	FEATURE Feature Specification Number. This read only field returns the feature set number.

84.6.1.3 Control and Status Register (CSR)

Offset

Register	Offset
CSR	8h

Function

This register contains the control and status bits of VREF

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	VREFST	0														Buf21EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				HI_PWR_...	0	0		0	0	REGEN	ICOMPEN	CHOPEN	0	LPBGEN	HCBGEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 VREFST	Internal High Accuracy Voltage Reference stable Indicates that the bandgap reference within the Voltage Reference module has finished its startup and stabilization. **NOTE** VREFST bit is valid only when the chop oscillator is not being used. 0b - The module is disabled or not stable. 1b - The module is stable.
30-17 —	Reserved
16 Buf21EN	Internal buffer enable Output voltage is 1.2 V 0b - buffer is disabled 1b - buffer is enabled
15-12	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
11 HI_PWR_LV	Buffer mode control 0b - buffer is in low power mode 1b - buffer is in high power mode
10 —	Reserved
9-8 —	Reserved
7 —	Reserved
6 —	Reserved
5 REGEN	Regulator enable Enables the internal 1.75 V regulator to produce a constant internal voltage supply in order to reduce the sensitivity to external supply noise and variation. REGEN bit should be written to 1 to achieve the performance stated in the data sheet. **NOTE** See section "Internal voltage regulator" for details on the required sequence to enable the internal regulator. 0b - Internal 1.75 V regulator is disabled. 1b - Internal 1.75 V regulator is enabled.
4 ICOMPEN	Second order curvature compensation enable ICOMPEN bit should be written to 1 to achieve the performance stated in the data sheet. 0b - Disabled 1b - Enabled
3 CHOPEN	Chop oscillator enable. When set, the internal chopping operation is enabled and the internal analog offset will be minimized. If the internal voltage regulator is being used (REGEN bit is set to 1), then the chop oscillator must also be enabled. If the chop oscillator will be used in very low power modes, then the High Accuracy bandgap voltage reference must also be enabled. See the chip-specific VREF information (also known as "chip configuration" details) to see how this can be achieved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Chop oscillator is disabled. 1b - Chop oscillator is enabled.
2 —	Reserved
1 LPBGEN	Low Power Bandgap enable This bit is used to enable the Low Power Bandgap. 0b - LP Bandgap is disabled 1b - LP Bandgap is enabled
0 HCBGEN	High Accuracy Bandgap enabled This bit is used to enable the High Accuracy Bandgap. **NOTE** This bit can only be enabled when LPBGEN =1. 0b - HC Bandgap is disabled 1b - HC Bandgap is enabled

84.6.1.4 User Trim (UTRIM)

Offset

Register	Offset
UTRIM	10h

Function

This register contains the trim data can be read/write in user mode

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		VREFTRIM						0				0			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-14 —	Reserved
13-8 VREFTRIM	VREF Trim bits These bits change the resulting VREF output by 0.5×(4/3) mV for each step. The trim value is stored in eFuse . 00_0000b - default–32×0.5×(4/3) mV 10_0000b - default 11_1111b - default+31×0.5×(4/3) mV All other values - see the value options above as example for calculation
7-4 —	Reserved
3-0 —	Reserved

84.6.1.5 Test Unlock (TEST_UNLOCK)

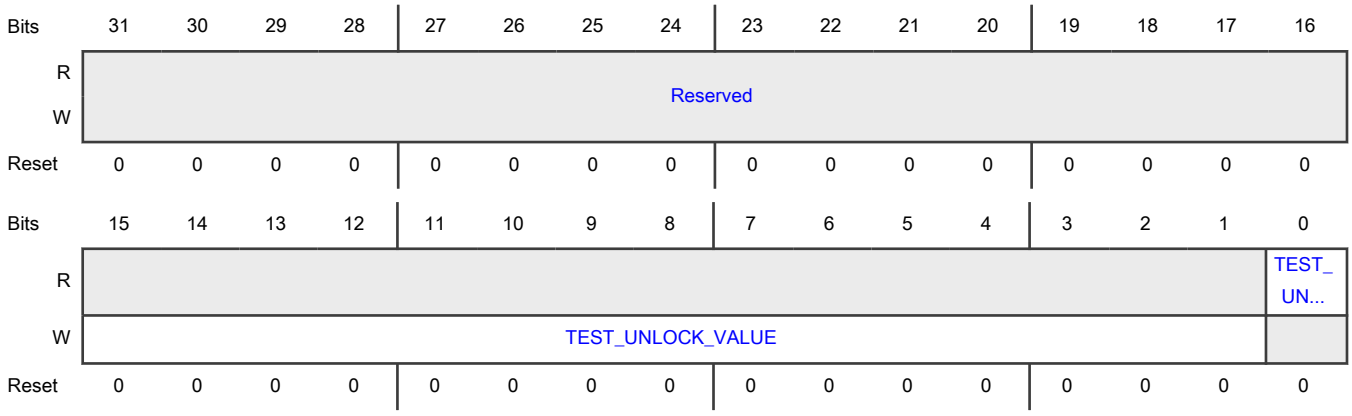
Offset

Register	Offset
TEST_UNLOCK	1Ch

Function

Unlocks read/write into test register. After reset, software cannot read/write into test register. After software writes into bit[15:1] value 0x5AA5, the read/write is unlocked.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-1 TEST_UNLOCK_VALUE	Test unlock value After reset, software cannot read/write into test register. If software writes value 0x5AA5 into this field, the read/write will be unlocked.
0 TEST_UNLOCK	Test_unlock status bit This bit will be set "1", if software writes 0x5AA5 into TEST_UNLOCK_VALUE field. 0b - Lock read/write into test register 1b - Unlock read/write into test register

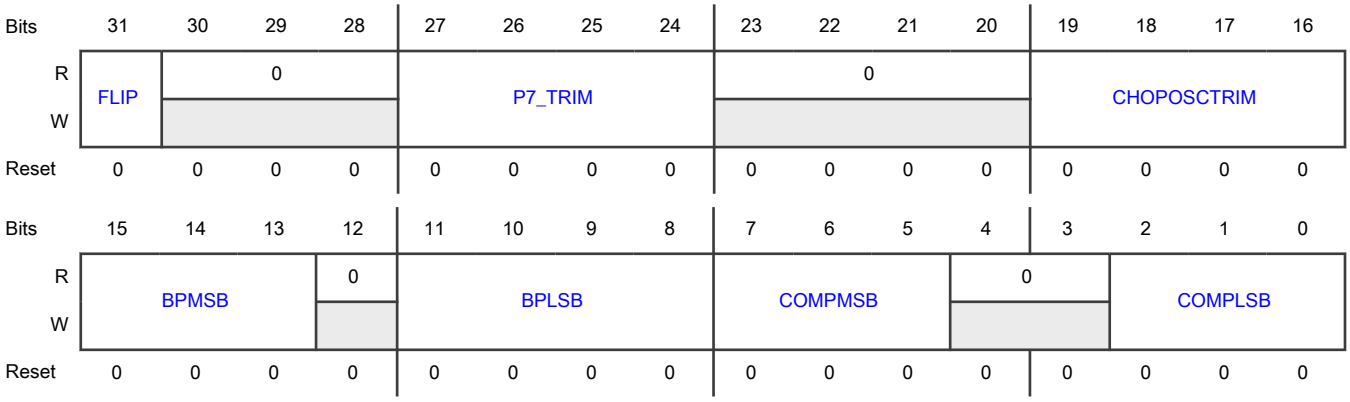
84.6.1.6 Test Trim 0 (TRIM0)

Offset

Register	Offset
TRIM0	24h

Function
This register contains the trim values read/write in functional test mode.

Diagram



Fields

Field	Function
31	Amplifier Polarity

Table continues on the next page...

Table continued from the previous page...

Field	Function
FLIP	Reverses the amplifier polarity. FLIP can be used to test bandgap amplifier offset. The trim value is stored in IFR .
30-28 —	RESERVED
27-24 P7_TRIM	P7_TRIM P7_TRIM bits are used for trimming the 0.7V for V to I at 3 mV/bit. The trim value is stored in IFR .
23-20 —	RESERVED
19-16 CHOPOSCTRIM	CHOPOSCTRIM CHOPOSCTRM bits trim the chop oscillator clock. The center frequency of the chop oscillator is 250 kHz at the trim value of 0b1000. The trim step size is 5% time domain when chop oscillator is enabled.
15-13 BPMSB	BPMSB BPMSB bits are used for thin trimming HC bandgap temperature curvature. BPMSB bits are active low and will shift the bandgap inflection point ~15 °C/bit. The trim value is stored in IFR .
12 —	RESERVED
11-8 BPLSB	BPLSB BPLSB bits are used for thin trimming HC bandgap temperature curvature. BPLSB bits are active low and will shift the bandgap inflection point ~2 °C/bit. The trim value is stored in IFR .
7-5 COMPMSB	COMPMSB COMPMSB bits are used for trimming the curvature used for the second-order temperature compensation. The trim value is stored in IFR .
4-3 —	RESERVED
2-0 COMPLSB	COMPLSB COMPLSB bits are used for trimming the curvature used for the second-order temperature compensation. The trim value is stored in IFR .

Appendix A
General Changes

A.1 Release Notes for Rev. 6

- Initial public release

Appendix B
Release Notes

B.1 Revision history

Because this is the initial release of the document, there are no changes.

Legal information

Definitions

Draft — A draft status on a document indicates that the content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included in a draft version of a document and shall have no liability for the consequences of use of such information.

Disclaimers

Limited warranty and liability — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Suitability for use — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors and its suppliers accept no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

Terms and conditions of commercial sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at https://www.nxp.com/profile/terms, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

Suitability for use in non-automotive qualified products — Unless this document expressly states that this specific NXP Semiconductors product is automotive qualified, the product is not suitable for automotive use. It is neither qualified nor tested in accordance with automotive testing or application requirements. NXP Semiconductors accepts no liability for inclusion and/or use of non-automotive qualified products in automotive equipment or applications.

In the event that customer uses the product for design-in and use in automotive applications to automotive specifications and standards, customer (a) shall use the product without NXP Semiconductors' warranty of the product for such automotive applications, use and specifications, and (b) whenever customer uses the product for automotive applications beyond NXP Semiconductors' specifications such use shall be solely at customer's own risk, and (c) customer fully indemnifies NXP Semiconductors for any liability, damages or failed product claims resulting from customer design and use of the product for automotive applications beyond NXP Semiconductors' standard warranty and NXP Semiconductors' product specifications.

Translations — A non-English (translated) version of a document, including the legal information in that document, is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

Security — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

NXP B.V. — NXP B.V. is not an operating company and it does not distribute or sell products.
