Table Description	This table stores the stream gate control lists (SGCLs). A SGCL is used to specify the time gates or time slots during which incoming frames from one more streams will be accepted. Each SGCL can have a variable number of gate control operation entries. For each Stream Gate Instance used, only two SGCLs may be allocated to the instance. It is recommended that the entry ID for each of these two SGCLs be predetermined and fixed by software, and persist till the Gate Stream Instance is no longer in use. This table is implemented as a linear array of words, accessed using an index (0, 1, 2, ..., n) that uniquely identifies a word within the array. The words are stored in a contiguous manner in the common memory. When accessing the table, the actual memory position of a word is calculated by hardware from the index based on the size of the word and the base memory address of the table. Each table entry is of variable size, and is used to hold one stream gate control list. The first word of the entry contains information specific to the entire stream gate control list. Subsequent consecutive words are contains gate control operation (or gate) specific configuration. Each word can hold 2 gate configurations. Number of words required for a stream gate control list is 1+N/2 where N is number of gates in the stream gate control list. If N is odd, only one gate configuration will be specified in the last word. The Stream Gate Control Entry ID (SGCL_EID) has to be specified in units of words such that it points to the first word in a stream gate control list. Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers; S0SGCLITMAR[NUM_WORDS] for switch and EaSGCLITMAR[NUM_WORDS] for ENETC. These allocations can also be changed when the functions are initialized through their respective base function registers SGCLITMAR[NUM_WORDS]. Table management command operations are performed using Add, Delete or Query operations. Note that the Update operation is not supported for this table. Memory fragmentation may occur if stream gate control lists of different sizes are repeatedly added/deleted. There is no hardware assist to manage such memory fragmentation, software must take care of this situation.

Table continues on the next page...

Table 685. Table ID 37 - Stream Gate Control List Table Common Attributes (continued)

	Following are the behavior of operations: • Add operation: This operation adds a stream gate control list to the Stream Gate Control List table. Hardware will perform the following checks to determine if the Add operation is valid before executing the Add operation. — Checks if the specified stream gate control list is within the allocated region to the Stream Gate Control List table in common memory. — Checks if the common memory locations for the stream gate control list are not already allocated. — Checks if the cumulative gate time in the stream gate control list is <2^30. If above conditions are not met the operation will be rejected. • Delete operation: This operation deletes a stream gate control list from the Stream Gate Control List table. The SGCL_EID must point to the first word of the stream gate control list that is to be deleted. Following checks are performed before executing the Delete operation. — Checks if SGCL_EID is in valid range of words for this table. — Checks if the stream gate control list has already been added by software. — Checks if stream gate control list is not in use (that is,. stream gate control list is not operational nor installed as an administrative list. Note that REF_COUNT is non zero if the stream gate control list is in use. — If above conditions are not met the operation will be rejected. • Query operation: This operation queries a stream gate control list. The following checks are performed before executing the Query operation. — Checks if SGCL_EID is in valid range of words for this table. — Checks to see if the stream gate control list has already been added. — If above conditions are not met the operation will be rejected. Note that due to dynamic size of stream gate control lists that get added/deleted can cause memory fragments.		
Number of Entries	Maximum number of entries is indicated in SGCLITCAPR[NUM_WORDS]. Number of entries in-use is indicated in SGCLTMOR[NUM_ENTRIES]. Number of words required for a stream gate control list is 1+N/2 where N is number of gate time slots in the stream gate control list.		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x4 = Query. 0x8 = Add.

Table 691. Table ID 37 - Stream Gate Control List Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
31-0	32	CYCLE_TIME	Cycle Time This field specifies the cycle time of the stream gate control list. This is the period of time over which the sequence of operations in a stream gate control list repeats. The time is expressed in units of nanoseconds. Only least significant 30 bits are valid. Upper two bits are ignored. This value has to be a non-zero value else operation will be rejected. It is also required that ADMIN_CYCLE_TIME + ADMIN_CYCLE_TIME_EXT must be < 2^30 -1.
39-32	8	LIST_LENGTH	List Length This field indicates the number of entries in the stream gate control list. Software must set this value to the size of the list being configured minus one. Valid values are 0 (one entry) to 255 (256 entries). The operation will be rejected if list length is invalid.
47-40	8	--	Reserved.
48	1	EXT_OIPV	Extension Override Internal Priority Value This field specifies whether to override the frame IPV after the stream gate control list ends and before CYCLE_TIME restarts. 0b = Don't override frame IPV. 1b = Override frame IPV with the value configured in the EXT_IPV field of this entry.
52-49	4	EXT_IPV	List Extension Internal Priority Value This field specifies the IPV to be assigned to frames after the stream gate control list ends and before CYCLE_TIME restarts. Valid if the EXT_OIPV field of this entry is set to 1. The least significant 3 bits are used, most significant bit is reserved.
53	1	EXT_CTD	Extension Cut Through Disabled This field specifies whether to disable cut-through for frames received after the stream gate control list ends and before CYCLE_TIME restarts. 0b = No action. 1b = Cut-through disabled. Note: Not applicable to ENETC function.
54	1	EXT_GTST	Extension Gate State This field specifies the gate state that will be applied after the stream gate control list ends and before CYCLE_TIME restarts. List started. 0b = Closed. 1b = Open.
63-55	9	--	Reserved.
(127 + 64i)	32	TIME_INTERVAL_GE_i	Time Interval for Gate Entry i, where i = 0, ..., N-1 This field specifies the time interval for a gate entry. The time is expressed in units of nanoseconds. Only least significant 30 bits are valid. Upper two bits are ignored.

Table continues on the next page...

Table 691. Table ID 37 - Stream Gate Control List Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
- (64 + 64i)			This field has to be a non-zero value and the cumulative TIME_INTERVAL amount in a Gate List must not exceed 2^30-1. Cumulated TIME_INTERVAL amount in a Gate List is allowed to be greater than CYCLE_TIME, in such case the CYCLE TIME restarts before Gate List completes.
	24	IOM_GE_i	Interval Octets Maximum for Gate Entry i, where i = 0, ..., N-1 This field specifies the maximum bytes (octets) allowed to pass (open) gate entry i when IOMEN is enabled.
	4	IPV_GE_i	Internal Priority Value for Gate Entry i, where i = 0, ..., N-1 This field specifies the Internal Priority Value (IPV) that will be assigned to frames. Valid if OIPV_GE_i field of this entry is set to 1. The least significant 3 bits are used, most significant bit is reserved.
	1	OIPV_GE_i	Override Internal Priority Value for Gate Entry i, where i = 0, ..., N-1 0b = Don't override frame IPV. 1b = Override frame IPV with the value configured in IPV_GE_i of field this entry.
	1	CTD_GE_i	Cut Through Disable for Gate Entry i, where i = 0, ..., N-1 This field specifies whether to disable cut-through for frames received in this gate. 0b = No action. 1b = Cut-through is disabled. Note: Not applicable to ENETC function.
	1	IOMEN_GE_i	Interval Octet Maximum Enabled for Gate Entry i, where i = 0, ..., N-1 This field specifies whether to track the number of bytes (octets) received in the gate when the gate is permanently closed; if OEXEN=1 and octets received in this gate exceeds IOM_GE. 0b = Don't track count. 1b = Track count.
	1	GTST_GE_i	Gate State for Gate Entry i, where i = 0, ..., N-1 0b = Closed. 1b = Open. Frames received in this gate are dropped if gate state is closed.

Table 693. Table ID 37 - Stream Gate Control List Table SGCLSE_DATA Description

Bits	Width [bits]	Name	Description
0	8	REF_COUNT	Reference Count Indicates whether a stream gate control list (SGCL) is in-use in a Stream Gate Instance (SGI). An SGCL becomes in-use when it is added to an SGI (as the administrative SGCL), and remains in-use when it is installed as the operational SGCL. An administrative SGCL is no longer considered in-use when if it is removed from an SGI. An operational SGCL is no longer in-use when it is replaced with a new SGCL or when the SGI is deleted. 0x00 = Not in-use by an SGI. 0x01 = In-use by an SGI. All other values reserved. Note: An attempt to delete an SGCL with a Reference Count set to 1 will result in an error response; in this case, the SGCL is not deleted from the Stream Gate Control List table.

53.4.2.4.7.17 Ingress Stream Count Table

Table 694. Table ID 38 - Ingress Stream Count Table Common Attributes

TABLE_ID	38		
TABLE_VERSION	0		
Table Type	Dynamic bounded index table		
Table Description	Ingress stream related statistics are maintained in this table. The Ingress Stream Count table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. The entries are stored in contiguous manner in a common memory. Ingress Stream Counter Entry ID (ISC_EID) is used as an index to an entry in this table. The ISC_EID is specified in the Ingress Stream table. For this table, each table entry occupies 1 word. Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers; S0ISCITMAR[NUM_WORDS] for switch and EaISCITMAR[NUM_WORDS] for ENETC. These allocations can also be changed when the functions are initialized through their respective base function register ISCITMAR[NUM_WORDS]. Table management operations Add, Delete, Update and Query are supported.		
Number of Entries	Maximum number of entries is indicated in ISCITCAPR[NUM_ENTRIES]. Number of entries in-use is indicated in ISCITOR[NUM_ENTRIES].		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete.

53.4.2.4.7.19 Frame Modification Table

Table 708. Table ID 40 - Frame Modification Table Common Attributes

TABLE_ID	40		
TABLE_VERSION	0		
Table Type	Dynamic bounded index table		
Table Description	Ingress and egress frame modification actions are specified in this table if Frame Modification entry ID (FM_EID) is used as an index. This table is implemented as a linear array of words, accessed using an index (0, 1, 2, ..., n) that uniquely identifies a word within the array. The words are stored in a contiguous manner in the common memory. When accessing the table, the actual memory position of a word is calculated by hardware from the index based on the size of the word and the base memory address of the table. For this table, each table entry occupies one word (one to one corresponding between words and entries). Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) register S0FMITMAR[NUM_WORDS]. This allocation can also be changed when the function is initialized through its respective base function register FMITMAR [NUM_WORDS].		
Number of Entries	Maximum number of entries is indicated in FMITCAPR[NUM_ENTRIES]. Number of entries in-use is indicated in FMITOR[NUM_ENTRIES].		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete.

Table 714. Table ID 40 - Frame Modification Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
0	1	L2_ACT	Layer 2 Actions 0b = L2 actions are specified in L2 header action fields of this entry; i.e. MAC_HDR_ACT, VLAN_HDR_ACT and SQT_HDR_ACT 1b = The entire L2 PDU (or frame) is replaced with new L2 PDU of length FMD_BYTES specified by FMD_EID (FCS not present in the new L2 PDU). No L2 header actions or payload action in this entry should be specified. Note: Code point L2_ACT = 1b is not applicable for ingress frame modifications; if set to 1b, it will result in a misconfiguration event handled according to the port's PFMCR register. Note: This field must be set to 0 for traffic destined to a pseudo link. Note: This field must be set to 0 for any device with ASIL-B safety requirements.
3-1	3	MAC_HDR_ACT	Layer 2 Header MAC Actions 000b = no action 001b = Reserved. 010b = Replace SMAC with the contents of the PMAR0/1 register where port=SMAC_PORT 011b = Replace SMAC with the contents of the PMAR0/1 register where port=SMAC_PORT, and DMAC by specified DEST_MAC_ADDR field value. 100b = Replace SMAC with the contents of the PMAR0/1 register where port=SMAC_PORT, and DMAC by frame's SMAC 101b = Replace DMAC with specified DEST_MAC_ADDR field value 110b = Swap DMAC and SMAC 111b = Reserved. Note: MAC_HDR_ACT = 000b, 101b are the only valid code points for ingress frame modifications, any other code points

Table continues on the next page...

Table 714. Table ID 40 - Frame Modification Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			specified will result in a misconfiguration event handled according to the port's PFMCR register.
5-4	2	VLAN_HDR_ACT	Layer 2 VLAN Actions 00b = No action 01b = Delete outer VLAN header 10b = Add outer VLAN header. A new VLAN header is to be inserted in the outer position immediately following the SMAC address. The following action fields of this entry specify how to select the VID, PCP, DEI and TPID values that are to be used to construct the VLAN header. - OUTER_VID_ACT for VID - OUTER_PCP_ACT for PCP - OUTER_DEI_ACT for DEI - OUTER_TPID_ACT for TPID 11b = Replace outer VLAN header. The VLAN header in the outer position immediately following the SMAC address is to be modified. The following action fields of this entry specify how to select the VID, PCP, DEI and TPID values that are to be used to construct the VLAN header. - OUTER_VID_ACT for VID - OUTER_PCP_ACT for PCP - OUTER_DEI_ACT for DEI - OUTER_TPID_ACT for TPID Egress frame modifications assume that any ingress frame modifications specified have been applied to the frame prior to applying egress frame modifications. For example, if a frame is received with no VLAN tag, and a VLAN tag has been added as a result of ingress frame modification action, any references to the outer VLAN header of the frame in a egress frame modification action will use the VLAN header that was added by the ingress frame modification action. Similarly, if a frame is received with both outer and inner VLAN tags as being present and valid, and the outer VLAN tag has been deleted as a result of an ingress frame modification action, any references to the outer VLAN header in a egress frame modification action will use the inner VLAN header of the received frame. Note: For a Delete or Replace action, if no outer VLAN header is present, then a misconfiguration event will be generated and handled according to the port's PFMCR register. The outer VLAN header in a received frame is considered present if VLAN classification has deemed the outer VLAN header valid.

Table continues on the next page...

Table 714. Table ID 40 - Frame Modification Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
7-6	2	OUTER_VID_ACT	Outer VID Actions This field specifies how to select the VID value that is to be used to construct or modify the VLAN header. 00b = Use the VID from the outer VLAN header of the frame; in the case of a replace VLAN header action, this has the net effect of preserving the VID since the VID is being replaced by the same value. If no outer VLAN header is present then an misconfiguration event will be generated and handled according to the port's PFMCR register. The outer VLAN tag in a received frame is considered present if VLAN classification has deemed the outer VLAN tag valid. 01b = Use the VID specified in the OUTER_VLAN_VID field of this entry. 10b,11b = Reserved This field must be set to a non reserved value when VLAN_HDR_ACT field of this entry is set to 10b or 11b.
10-8	3	SQT_ACT	Sequence Tag Action 000b = No action. 001b = Remove R-TAG/draft 2.0 R-TAG/HSR tag; If R-TAG/draft 2.0 R-TAG/HSR tag not present, then a misconfiguration event will be generated and handled according to the port's PFMCR register, packet processing moves to the next function. 010b-111b: Reserved Note: Not applicable for ingress frame modifications; any code point other than 000b will result in a misconfiguration event handled according to the port's PFMCR register.
15-11	5	SMAC_PORT	Source MAC Address Register Port Specifies the port from which the MAC Address Register PMAR0/1 is to be read to obtain the Source MAC address. Valid if MAC_HDR_ACT=010b,011b,100b
63-16	48	DMAC	Destination MAC Address This field is defined in network byte order (big-endian). Most significant byte of the destination MAC address is stored at the lowest byte offset of this field. Valid if MAC_HDR_ACT = 011b,101b.
75-64	12	OUTER_VLAN_VID	Outer VLAN VID This field specifies the VID to be used in the outer VLAN header to be added or replaced when OUTER_VID_ACT field of this entry is set 01b.

Table continues on the next page...

Table 714. Table ID 40 - Frame Modification Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
78-76	3	OUTER_VLAN_PCP	Outer VLAN PCP This field specifies the 3-bit PCP to be used in the outer VLAN header to be added or replaced when OUTER_PCP_ACT field of this entry is set 001b.
79-79	1	OUTER_VLAN_DEI	Outer VLAN DEI This field specifies the 1-bit DEI to be used in the outer VLAN header to be added or replaced when OUTER_DEI_ACT field of this entry is set 01b.
82-80	3	OUTER_TPID_ACT	Outer TPID action Specifies the TPID value to be used to construct or modify the VLAN header. 000b = Use TPID from outer VLAN header, if no outer VLAN header is present then a misconfiguration event will be generated and handled according to the port's PFMCR register. The outer VLAN header in a received frame is considered present if VLAN classification has deemed the outer VLAN header valid. 001b = Set TPID to 0x8100 010b = Set TPID to 0x88A8 011b = Set TPID to C-VLAN as defined by CVLANR1[ETYPE] 100b = Set TPID to Custom S-VLAN as defined by CVLANR2[ETYPE] 101b-111b = Reserved This field must be set to a non reserved value when VLAN_HDR_ACT field of this entry is set to 10b or 11b.
85-83	3	OUTER_PCP_ACT	Outer PCP action This field specifies how to select the PCP value that is to be used to construct or modify the VLAN header. 000b = Use PCP value from outer VLAN header of the frame. 001b = Set to the PCP value specified in the OUTER_VLAN_PCP field of this entry. 010b = Use the PCP from outer VLAN header of the frame to access the PCP to PCP mapping profile specified in the port register PPCPDEIMR[IPCPMP/EPCPMP], to set the new PCP value. The actual PCP to PCP mapping is specified in register PCP2PCPMPaR, where a identifies the profile. For ingress modifications, port register PPCPDEIMR[IPCPMP] is used to select the mapping profile whereby for egress frame modifications, port register PPCPDEIMR[EPCPMP] is used to select the mapping profile. 011b = Use internal QoS associated with frame (IPV, DR) to access the QoS to PCP mapping profile specified in the egress port to set the new PCP value. The actual QOS to PCP mapping is specified in register QOSVLANMPaR0/1/2/3 where a identifies

Table continues on the next page...

Table 714. Table ID 40 - Frame Modification Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			the profile. 100b-111b: Reserved This field must be set to a non reserved value when VLAN_HDR_ACT field of this entry is set to 10b or 11b. Note: Code point OUTER_PCP_ACT = 011b is not applicable for ingress frame modifications; if set to 011b, it will result in a misconfiguration event handled according to the port's PFMCR register. Note: If access to the outer VLAN header is required (OUTER_PCP_ACT = 000b or 010b) and no outer VLAN is present, a misconfiguration event will be generated and handled according to the port's PFMCR register. The outer VLAN header in a received frame is considered present if VLAN classification has deemed the outer VLAN header valid. Note: If the PCP to PCP mapping profile specified in the port register PPCPDEIMR[IPCPMP/EPCPMP] is not valid, it will result in a misconfiguration event handled according to the port's PFMCR register.
87-86	2	OUTER_DEI_ACT	Outer DEI action This field specifies how to select the DEI value that is to be used to construct or modify the VLAN header. 00b = Use DEI value from outer VLAN header of the frame, if no outer VLAN header is present then a misconfiguration event will be generated and handled according to the port's PFMCR register. The outer VLAN header in a received frame is considered present if VLAN classification has deemed the outer VLAN header valid. 01b = Set to the DEI value specified in the OUTER_VLAN_DEI field of this entry. 10b = To construct the VLAN header, use internal DR associated with frame to access the DR to DEI mapping specified in the egress port register PPCPDEIMR[DRnDEI], to set new DEI value. To replace the VLAN header, preserve DEI if PPCPDEIMR[DRME]=0 or use the internal DR associated with frame to access the DR to DEI mapping specified in the egress port register PPCPDEIMR[DRnDEI], to set new DEI value, if PPCPDEIMR[DRME]=1. 11b = Reserved This field must be set to a non reserved value when VLAN_HDR_ACT field of this entry is set to 10b or 11b. Note: Code points OUTER_DEI_ACT = 10b is not applicable for ingress frame modifications; will result in a misconfiguration error according to the port's PFMCR register.

Table continues on the next page...

Table 714. Table ID 40 - Frame Modification Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
90-88	3	PLD_ACT	Payload Actions 000b = None 001b = Remove entire Ethernet payload including the payload Ethertype and insert with FMD_BYTES of data specified in FMD_EID. The the Ethernet payload (including the payload Ethertype) begins in the received frame immediately after source MAC address or VLAN tag(s) (up to 2) or R-TAG/HSR tag (if any). 010b = Replace FMD_BYTES of raw data in the Ethernet payload starting at PLD_OFFSET. Data is specified in FMD_EID. The maximum number of bytes that can be replaced is 128 bytes. If the frame is too short to replace all of the bytes specified by this replacement action, the Ethernet payload of the frame is replaced up to its last byte, and then the new calculated FCS is appended to the frame. The transmission of the frame completes without error. 011b-111b: Reserved Note: L2 header modification actions can be specified in combination to Ethernet payload modification actions. Ingress and egress L2 header modifications have no effect on the Ethernet payload modifications. When specifying an Ethernet payload modification action, the VLAN Ethertypes (2 standards, up to 2 customs) used to recognize a VLAN tag by the Ingress Packet Processing Parser must be set as acceptable Ethertypes for both the outer and inner VLAN tags (PTAR register). Note: Not applicable for ingress frame modifications; any value other than 000b will result in a misconfiguration event handled according to the port's PFMCR register. Note: This field must be set to 0 for traffic destined to a pseudo link. Note: This field must be set to 0 for any device with ASIL-B safety requirements.
95-91	5	--	Reserved.
103-96	8	PLD_OFFSET	Payload Offset Refer to PLD_ACT for more details Specifies the offset from the beginning of the payload Ethertype where replacement of FMD_BYTES starts. Valid if PLD_ACT= 010b.
127-104	24	--	Reserved.
143-128	16	FMD_BYTES	Frame Modification Bytes

Table continues on the next page...

Table 714. Table ID 40 - Frame Modification Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			Specifies the number of bytes contained in the Frame Modification Data table for this entry, starting at word specified in FMD_EID. Valid if PLD_ACT = 001b,010b or L2_ACT = 1b. If L2_ACT = 1b, then the minimum number of bytes that can be specified in FMD_BYTES is 14 bytes.
159-144	16	--	Reserved.
191-160	32	FMD_EID	Frame Modification Data Entry ID FMD_EID is a pointer to a word in Frame Modification Data table for data replacement/insertion bytes. Must be valid if PLD_ACT = 001b, 010b or L2_ACT = 1b FMD_EID[15:0]*24 + FMD_BYTES has to be <= (FMDITCAPR[NUM_WORDS]*24) L2_ACT and PLD_ACT fields are ignored if this field is set to a null pointer (ffff). Note that if FMD_EID is not set to null the valid range of bits for FMD_EID are [15:0]. Bits [31:16] are not used and will be ignored.

53.4.2.4.7.20 Frame Modification Data Table

Table 715. Table ID 44 - Frame Modification Data Table Common Attributes

TABLE_ID	44
TABLE_VERSION	0
Table Type	Static bounded index table
Table Description	The Frame Modification Data table is a contiguous memory space in the common memory composed of 24-byte words. The number of 24-byte words in the Frame Modification Data table is defined in the register FMDITCAPR. The Entry ID is used to address a word within this memory space. Thus, Entry IDs are sequential from 0, 1, 2,..., N-1, where N is the number of 24-byte words. Neither the Add or Delete operation is supported for this table. All words are initialized and zeroed out of reset, and thus they may only be updated or queried. When updating, it is possible to update any number of bytes, which can span multiple words. The ENTRY_ID specifies the "base" word and the REQUEST_LENGTH field in the Table ID Request Message Header is used to implicitly specify the number of bytes to update. Since REQUEST_LENGTH includes the entire length of the request data buffer, including the four bytes of ACCESS_KEY and the four bytes of actions fields, the number of bytes to update will be interpreted as REQUEST_LENGTH minus these eight bytes. An Update operation must specify a number of bytes greater than zero to update, otherwise an error is returned.

Table continues on the next page...

Table 715. Table ID 44 - Frame Modification Data Table Common Attributes (continued)

	When updating, only the number of data bytes indicated by the REQUEST_LENGTH will be updated. For example, if REQUEST_LENGTH=d'12, then this indicates four data bytes to update and therefore only the first 4 bytes of the word specified by ENTRY_ID will be updated. Updates at an arbitrary location within a word, are not supported; updates are performed from the first byte in the word for as many bytes as were specified by the command. As mentioned earlier, an update may span multiple words. For example, if a command requests 50 bytes to be updated (REQUEST_LENGTH=d'58), the word at ENTRY_ID will be updated with the first 24 bytes of the request configuration data (see the Configuration Element Data definition), the word at ENTRY_ID + 1 will be updated with next 24 bytes, and the first two bytes of the word at ENTRY_ID + 2 will be updated with the last 2 bytes of the request configuration data. The remaining 22 bytes of the word at ENTRY_ID + 2 are undefined. When querying, it is possible to query any number of bytes, The ENTRY_ID specifies the "base" word and the RESPONSE_LENGTH field in the Table ID Request Message Header is used to specify the number of bytes to query. Since the RESPONSE_LENGTH field indicates the length of the entire response data buffer, including four bytes of ENTRY_ID, the number of bytes to query is the RESPONSE_LENGTH minus these four bytes. For example, if RESPONSE_LENGTH=d'12, then this indicates a request for eight data bytes to be queried, and the hardware will return the first eight data bytes at the word specified by ENTRY_ID in the query request message. Queries at an arbitrary location within a word are not supported; queries are performed from the first byte in the word for as many bytes as were specified by the command. A query may span multiple words. For example, if a command requests 50 bytes to be queried (RESPONSE_LENGTH=d'54), the word at ENTRY_ID will be will be returned in the first 24 bytes of the response configuration data (see the Configuration Element Data definition), the word at ENTRY_ID + 1 will be returned in bytes 24-47,and the first two bytes of the word at ENTRY_ID + 2 will be returned in bytes 48-49 of the response configuration data. A Query operation must specify a number of bytes greater than zero to query, otherwise an error is returned. It is possible to perform the query and update operations in the same command, and in this case, there is no requirement that the number of bytes to query be equal to the number of bytes being updated. When updating and/or querying, an error will be returned by any command which attempts to access (either reading or writing) memory which is outside the space allocated for this table. That is to say, the following must always be satisfied: numBytes + ENTRY_ID <= 24*N where N is the number of words in the Frame Modification Data table, specified in register FMDITCAPR; and where numBytes is the number of bytes on which to operate (whether for an update or query). Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) register S0FMDITMAR[NUM_WORDS]. This allocation can also be changed when the function is initialized through its respective base function register FMDITMAR[NUM_WORDS].
Number of Entries	Number of entries/words is indicated in FMDITCAPR[NUM_WORDS].

Table 721. Table ID 44 - Frame Modification Data Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
Variable-0	Variable	DATA	Data Frame data that is used as payload data when frame data modification s performed. Data has to be aligned to word boundary and has to be specified in network byte order (big-endian).

53.4.2.4.7.21 Buffer Pool Table

Table 722. Table ID 41 - Buffer Pool Table Common Attributes

TABLE_ID	41			
TABLE_VERSION	0			
Table Type	Static bounded index table			
Table Description	The Buffer Pool table contains buffer pool configuration and operational information. Each entry corresponds to a buffer pool. The Entry ID value represents the buffer pool ID to access. See Switch Shared Internal Buffer Memory Management for a description of buffer pools. Buffer pools are always present and enabled.			
Number of Entries	Each Entry ID corresponds to a buffer pool ID. See BPCAPR[NUM_BP] register for the number of buffer pools.			
Default Reset Behavior	After reset all table fields are cleared to 0			
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**	
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x2 = Update. 0x4 = Query.	
	Exact Match Key Element Match (KEY_ELEMENT)	No	--	
	Ternary Match Key Element Match (KEY_ELEMENT)	No	--	
	Search (SEARCH_CRITERIA)	No	--	
Data Buffer Component Attributes	**Name**	**Description**	**Size [bytes]**	**Alignment [bytes]**
	ENTRY_ID	Entry Id (BP_EID)	4	4
	ACCESS_KEY	Access Key	4	4
	CFGE_DATA	Configuration Element	20	4
	BPSE_DATA	Buffer Pool State Element	9	4
Entry Alignment [bytes]	4			
Entry ID Management	Software assigns entry IDs.			
Response STATUS Applicable	No

--				FC_OFF_THRESH								--				FC_ON_THRESH																0x4
--												--				SBP_THRESH																0x8
SBP_EID																																0xC
FC_PORTS																																0x10

Table 728. Table ID 41 - Buffer Pool Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
0	1	SBP_EN	Shared Buffer Pool Enable 0b = No shared buffer pool is associated with this buffer pool. 1b = A shared buffer pool is associated with this buffer pool. The ID of the shared buffer pool is specified in the SBP_EID field of this entry. This setting should only be changed when the BP is first initialized, changing it when BP usage is non-zero may result in corrupted SBP usage count.
2-1	2	FC_CFG	Flow Control (FC) Configuration 00b = FC disabled. 01b = FC enabled using only buffer pool FC state. 10b = FC enabled using only shared buffer pool FC state. 11b = FC enabled using both buffer pool (BP) and shared buffer pool (SBP) FC state, the combined FC state of both BP and SBP must be 1 to assert FC ON, if either FC state is 0, FC OFF is asserted. Enabling flow control using the SBP is only valid if SBP_EN is set to 1. Setting FC_CFG = 10b or 11b and SBP_EN = 0 will result in undefined flow control behavior.

Table continues on the next page...

Table 728. Table ID 41 - Buffer Pool Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
7-3	5	--	Reserved.
15-8	8	PFC_VECTOR	Priority Flow Control (PFC) Vector When a flow control (FC) notification is sent (FC ON), this vector indicates which priorities are to be flow controlled for this buffer pool, one bit per PFC priority level. If the MAC is configured in link pause mode, this field is ignored. Valid if FC_CFG is not set 0. Not supported in NETC 3.0 and 3.1.
27-16	12	MAX_THRESH	Maximum Threshold The default setting of 0 disables maximum threshold checking, in which case all accounting update requests for this buffer pool (BP) will be accepted. If the threshold is non-zero, and BP usage is greater than or equal to this threshold, accounting update requests for this BP will be denied. This in turn, will result in discarding the frames associated with these denied accounting update requests. The threshold is in number of internal memory words (average of 20 bytes each), and is expressed as MANT = bits 11:4, EXP = bits 3:0, and threshold = MANT*2^{EXP}. Note that the maximum size of a buffer pool may go one maximum frame size beyond the value configured in this field as the datapath memory availability check for the buffer pool is performed without considering the length of the frame.
31-28	4	--	Reserved.
43-32	12	FC_ON_THRESH	Flow Control On Threshold If the buffer pool usage crosses this threshold, and if FC_ON_THRESH is greater than FC_OFF_THRESH, the flow control state of the buffer pool is set to 1. Valid if FC_CFG = 01b or 11b. The threshold is in number of internal memory words (average of 20 bytes each), and is expressed as MANT = bits 11:4, EXP = bits 3:0, and threshold = MANT*2^{EXP}.
47-44	4	--	Reserved.
59-48	12	FC_OFF_THRESH	Flow Control Off Threshold If buffer pool usage drops to this threshold or below, the flow control state of the buffer pool is set to 0. Valid if FC_CFG = 01b or 11b. The threshold is in number of internal memory words (average of 20 bytes each), and is expressed as MANT = bits 11:4, EXP = bits 3:0, and threshold = MANT*2^{EXP}.
63-60	4	--	Reserved.
75-64	16	SBP_THRESH	Shared Buffer Pool Threshold If buffer pool usage exceeds this threshold, the excess contribution is tracked in the shared buffer pool. Valid only if SBP_EN = 1. The threshold is in number of internal memory words (average of 20 bytes each), and is expressed as MANT = bits 11:4, EXP = bits 3:0, and threshold = MANT*2^{EXP}.

Table continues on the next page...

Table 728. Table ID 41 - Buffer Pool Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			This setting should only be changed when the BP is first initialized, changing it when BP usage is non-zero may result in corrupted SBP usage count.
95-76	20	--	Reserved.
127-96	32	SBP_EID	Shared Buffer Pool Entry ID This field indicates the shared buffer pool ID to which this buffer pool is associated with. Valid if SBP_EN = 1. This setting should only be changed when the BP is first initialized, changing it when BP usage is non-zero may result in corrupted SBP usage count.
159-128	32	FC_PORTS	Flow Control Ports When a flow control notification is sent (FC ON), this is a per-port bitmap indicates which ports are to be flow controlled for this buffer pool. Each bit of the bitmap corresponds to a port on the switch. Least significant bit of the bitmap corresponds to the smallest port number. The port(s) to be flow controlled, are identified by having their corresponding bit set to 1 in the bitmap Valid if FC_CFG is not set to 0.

Table 729. Table ID 41 - Buffer Pool Table BPSE_DATA Format

53.4.2.4.7.23 ETM Congestion Group Table

Table 740. Table ID 43 - ETM Congestion Group Table Common Attributes

TABLE_ID	43		
TABLE_VERSION	0		
Table Type	Static bounded index table		
Table Description	The ETM Congestion Group table contains congestion group configuration and operational information. Each entry corresponds to a congestion group on given switch port. Each class queue within a port is mapped to a single congestion group, and each congestion group can have 0 or more class queues as members (n to 1 mapping). By default each class queue is mapped to a separate congestion group, see the ETM Class Queue Table for details of the mapping. Congestion groups are always present and enabled.		
Number of Entries	The number of congestion groups is equal to the number of class queues in the switch, see "ETM Class Queue Table".		
Default Reset Behavior	After reset all table fields are cleared to 0, all tail drop thresholds disabled.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x2 = Update. 0x4 = Query.

53.4.2.4.7.24 Frame Modification Entry Definition

The Entry ID for the Frame Modification table can be one of three distinct overlaid encodings. The first option (option 1 below) has the Entry ID encoded as an index into the Frame Modification table. The other two encoding options have the modification actions encoded in the Entry ID itself, allowing the configuration of basic frame modification actions without needing to configure (or add) a Frame Modification table entry. Format and description of the Frame Modification Entry ID are detailed in the tables below.

Table 749. Frame Modification Entry ID Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset
0	0	0	Index													0x0

Bits	Width (Bits)	NAME	Description
			VID and TPID are preserved. Uses the PCP from outer VLAN header of the frame to access the PCP to PCP mapping profile specified in the port register PPCPDEIMR[IPCPMP/EPCPMP], to set the new PCP value. The actual PCP to PCP mapping is specified in the register PCP2PCPMPaR, where *a* identifies the profile. For ingress modifications, port register PPCPDEIMR[IPCPMP] is used to select the mapping profile whereby for egress frame modifications, port register PPCPDEIMR[EPCPMP] is used to select the mapping profile. Preserves DEI if PPCPDEIMR[DRME]=0 or uses the internal DR associated with frame to access the DR to DEI mapping specified in the egress port register PPCPDEIMR[DRnDEI], to set new DEI value, if PPCPDEIMR[DRME]=1. 10b = Delete Outer VLAN Tag. 11b = Reserved. This field is valid when bits 15-12 are set to 0010b; i.e. the Frame Modification Entry ID is encoded as basic VLAN/R-TAG/HSR tag modification actions. Note: Misconfiguration error if replace or delete action is specified and if VLAN tag is not present in frame.
4-2	3	SQTA	Sequence Tag Action 000b = No Action. 001b = Remove R-TAG/HSR tag; If R-TAG/HSR tag not present, misconfiguration error. 010b .. 111b = Reserved. This field is valid when bits 15-12 are set to 0010b; i.e. the Frame Modification Entry ID is encoded as basic VLAN/ R-TAG/HSR tag modification actions. Note: SQTA must be set to 000b for Ingress frame modification, otherwise misconfiguration error.
11-0	12	VID	VLAN ID This field is valid when bits 15-14 are set to 01b; i.e. the Frame Modification Entry ID is encoded as basic VLAN modification actions.
13-12	2	VARA	VLAN Add/Replace Action 00b = Add VLAN with VID and PCP/DEI updated as described below. TPID=0x8100 01b = Add VLAN with VID and PCP/DEI updated as described below. TPID=0x88A8 10b = Replace VLAN with VID. The tag's original PCP, DEI and TPID are preserved. 11b = Replace VLAN with VID and PCP/DEI updated by port's PPCPDEIMR. The tag's original TPID is preserved. Uses the PCP from outer VLAN header of the frame to access the PCP to PCP mapping profile specified in the port register PPCPDEIMR[IPCPMP/EPCPMP], to set the new PCP value. The actual PCP to PCP mapping is specified in the register PCP2PCPMP*a*R, where *a* identifies the profile. For ingress modifications, the port register PPCPDEIMR[IPCPMP] is used to select the mapping profile whereby for egress frame modifications, the port register PPCPDEIMR[EPCPMP] is used to select the mapping profile. Preserves DEI if PPCPDEIMR[DRME]=0 or uses the internal DR associated with frame to access the DR to DEI mapping specified in the egress port register PPCPDEIMR[DRnDEI], to set new DEI value, if PPCPDEIMR[DRME]=1. For ingress frame modification with 00b or 01b, use the ingress port to select PCP and DEI from the Bridge port default VLAN register (BPDVR). For egress frame modification with 00b or 01b, use the internal QoS associated with the frame (IPV, DR) to access the QoS to PCP mapping profile to set the new PCP value. The profile

Table continues on the next page...

Table 750. Frame Modification Entry ID Description (continued)

Bits	Width (Bits)	NAME	Description
			is determined in the PQOSMR[QVMP] register corresponding to the egress port being used. The actual QOS to PCP mapping is specified in register QOSVLANMPaR0/1/2/3 where 'a' corresponds to the profile selected. Use internal DR associated with frame to access the DR to DEI mapping specified in the register PPCPDEIMR[DRnDEI] corresponding to the egress port being used, to set new DEI value. This field is valid when bits 15-14 are set to 01b; i.e. the Frame Modification Entry ID is encoded as basic VLAN modification actions. Note: Misconfiguration error if replace action is specified and if VLAN tag is not present in frame. Note: For the option 11b, if the PCP to PCP mapping profile specified in the port register PPCPDEIMR[IPCPMP/EPCPMP] is invalid, it results in a misconfiguration event handled according to the port's PFMCR register.

53.4.2.5 IEEE 1588 timer module

53.4.2.5.1 Overview

The (IEEE 1588) Timer module provides the current time with nanosecond resolution, precise periodic pulse, Pulse on timeout (alarm), and time capture on external pulse support. This blocks capabilities support implementing time synchronization as required for IEEE 1588 and IEEE 802.1AS-2020.

53.4.2.5.1.1 Block diagram

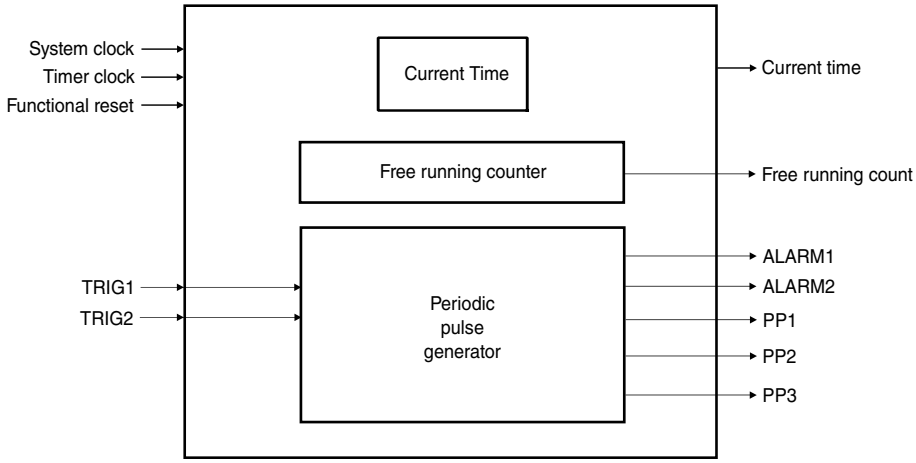

Figure 361. Block diagram

53.4.2.5.1.2 Features

The Timer module includes the following features:

- 64-bit running time with nanosecond resolution
- 64-bit free running time (NETC clock ticks)
- Software selectable clock
- 64-bit time offset to allow adjustment of local time to global time

- Software adjustable tick generation to allow adjustment for clock error and drift
- Time stamp capture from external GPIO input
  - Programmable input pulse polarity
  - Maskable interrupt on event
- Alarms generated at a future time
  - Programmable pulse to GPIO
  - Maskable interrupt
- Periodic pulse generation
  - Programmable pulse to GPIO
  - Maskable interrupt

53.4.2.5.2 Functional description

Note that the Timer has different hardware clock domains. Some registers are clocked by the standard system clock and are accessible whenever the Timer Function's PCIe Memory System Enable (MSE) bit is set. Other registers are clocked by the selected Timer clock and are only accessible when an active clock has been selected by setting TMR_CTRL[CK_SEL] and the module has been enabled by setting TMR_CTRL[TE]. See Table 751 for the list of registers which are in the timer clock domain. Table 752 lists some relevant registers in the normal clock domain.

Table 751. Timer Clock Domain Register List

Register Name
TMR_CNT_H - timer counter high register
TMR_CNT_L - timer counter low register
TMR_ADD - Timer drift compensation addend register
TMR_ACC - Timer accumulator register
TMR_PRSC - timer prescale
TMROFF_H - Timer offset high
TMROFF_L - Timer offset low
TMR_ALARM1_H - Timer alarm 1 high register
TMR_ALARM1_L - Timer alarm 1 low register
TMR_ALARM2_H - Timer alarm 2 high register
TMR_ALARM2_L - Timer alarm 2 low register
TMR_FIPER1 - Timer fixed period interval
TMR_ECTRL - Extended timer control register
TMR_CUR_TIME_L - Timer current time low register
TMR_CUR_TIME_H - Timer current time high register
TMR_TIME_CTRL - Timer time control register
TMR_FIPER2 - Timer fixed period interval
TMR_FIPER3 - Timer fixed period interval

Table continues on the next page...

Table 751. Timer Clock Domain Register List (continued)

Register Name
TMR_ETTS1_H - Time-stamp of general purpose external trigger
TMR_ETTS1_L - Time-stamp of general purpose external trigger
TMR_ETTS2_H - Time-stamp of general purpose external trigger
TMR_ETTS2_L - Time-stamp of general purpose external trigger

Table 752. Platform Clock Domain Register List

Register Name
TMR_ID - Module ID and version register
TMR_ID2 - Module ID and configuration register
TMR_CTRL - Timer control register
TMR_TEVENT - time-stamp event register
TMR_TEMASK - Timer event mask register
TMR_STAT - Timer Status
TMR_MSIVEC - Timer MSI-X vector register

53.4.2.5.2.1 Normal mode with drift and error adjustment

During normal operation, TMR_CNT increments by the value of TMR_CTRL[TCLK_PERIOD] and TMR_ACC increments by the value of TMR_ADD[ADDEND] every timer clock cycle. When TMR_ACC overflows, TMR_CNT increments by 1 to account for fractional part of the clock frequency. Software may update TMR_ADD to compensate for drift in timer clock.

The Timer module provides current time to other functions in the SoC such as time gate scheduling, time specific departure scheduling, stream gating and rate policing, and the Ethernet MAC for timestamp generation. Current time is equal to the 64-bit time in TMR_CNT_H/L plus the 64-bit offset in TMROFF_H/L, and also available in TMR_CUR_TIME_H/L.

53.4.2.5.2.2 Slave mode

In certain circumstances there may be other timers available in the system which provide 64-bit time values, perhaps multiple Timer modules. The Timer module can accept the time value from these other sources by putting it in slave mode by setting TMR_CTRL[SLV]. In this case the alarm, periodic pulse, and time stamp capture functionality of the Timer module is available, but the Timer module's 64-bit time and the timer clock adjust circuitry is not used.

53.4.2.5.2.3 Bypass mode

In some cases, an external phase, drift, and error adjusted clock is available. This clock may be selected by setting TMR_CTRL[CK_SEL] and used to directly update the 64-bit time by setting TMR_CTRL[BYP]. In this case the Timer module timer clock adjust accumulator is not used.

Note that TMR_CTRL[SLV] must be cleared ("master" mode selected) for bypass mode to work.

The time (in TMR_CNT) is updated by TMR_CTRL[TCLK_PERIOD] on each external clock.

53.4.2.5.2.4 Default counter mode

There is a Default nanosecond (ns) counter that can be used in a system that does not use 1588. This default ns counter is not dependent on configuring any of the 1588 functions.

The following three fields, inputs to the Timer block from the IERB, control the behaviour of this default counter:

1. ierb_load - which is the enable for the Default counter.

2. NETCCLKCR[FREQ], functionally equivalent to TMR_CTRL[TCLK_PERIOD], which is the clock frequency setting

3. NETCCLKFR[FRAC], functionally equivalent to TMR_ADD, that represents the fractional part of the clock period

There is a mux that chooses between Default ns counter and 1588 ns counter (TMR_CNT/TMR_CUR_TIME). When ierb_load is asserted and TMR_CTRL[TMR_TE] is 0, the Default counter starts counting and is the source for the ns output. If user configures 1588 and sets TMR_CTRL[TMR_EN]=1, then mux switches to choose 1588 ns counter and Default ns counter goes to 0 and stops counting

Please note that if 1588 function is required, user should configure all Timer registers before using any feature that depends on Default ns counter, else there could be a discontinuity in time of +/- 1 sec when the mux switches

Default counter value can be read from dedicated read only registers, TMR_DEF_CNT_L and TMR_DEF_CNT_H

When Default counter is enabled,and 1588 Timer is disabled (TMR_CTRL[TMR_TE]=0), TMR_CNT and TMR_CUR_TIME are not updated.

53.4.2.5.2.5 Clocking

This module works on two clocks; System clock and a separate Timer clock. Timer clock has two sources; the System clock and an externally connected clock. Timer clock selection is done by setting TMR_CTRL[CKSEL].

53.4.2.5.2.6 Reset

Table 753. Reset

Reset source	Description
Functional reset	Hardware reset for all registers.

53.4.2.5.2.7 Interrupts

Table 754 lists the various sources of 1588 timer related interrupts.

When an interrupt occurs TMR_TEVENT indicates the cause(s) of interrupts. Reading of TMR_TEVENT clears these indications.

Table 754. 1588 Module Interrupts

Interrupt	Description	Action taken by the 1588 module
ETS*n*	External trigger caused a time-stamp to be sampled.	None.
ALM*n*	Current time equaled the programmed alarm time.	The alarm output pin will be continuously driven asserted until TMR_ALARM*n* is disarmed.
PP*n*	Periodic pulse has been generated.	The FIPER*n* will continue pulsing until disabled.

53.4.2.5.2.8 Hardware assist for IEEE 1588/PTP compliant time keeping

IEEE 1588/802.1AS-2020 specify a mechanism for synchronizing multiple network connected nodes to the same clock based on external clock inputs from, for instance, GPS receivers. The Timer module provides functionality to support that and the following sections describe this functionality.

53.4.2.5.2.8.1 Timestamping of packets

The actual time stamping of packets is implemented by the Ethernet MAC using the time value provided by the Timer module.

The MAC is capable of recording the timestamp at the time of arrival of the frame at the MAC.

On transmit two types of timestamping are supported:

- "two-step" timestamping where the time of transmission of frame is recorded and provide to software
- "one-step" timestamping where the "Correction" field of a packet is updated based on the current time and the timestamp provided

Note that the one step form of Tx timestamping directly modifies the packet in a way which is compliant with the Precision Time Protocol (PTP). It does not simply insert the timestamp into the packet.

53.4.2.5.2.8.1.1 Rx timestamping

Each time a frame is received by the Ethernet MAC the current time is captured by the MAC at the start of the Start-of-Frame-Delimiter (SFD) for the frame. This timestamp is reported by the MAC with the packet and the lower 32b will be provided to software if the BD ring which the frame is directed to uses Extended RX Buffer Descriptor Format.

Rx timestamping of this form can be applied to any type of packet not just PTP packets.

53.4.2.5.2.8.1.2 Tx two-step timestamp

Two step Tx timestamping is the transmit equivalent of the Rx timestamping.

The main use case for Tx Timestamp is PTP (Precision Time Protocol) where it requires the Tx Timestamp when the frame was transmitted on the ethernet interface relative to the SFD.

There are multiple reasons why PTP protocol requires the Tx Timestamp information.

- For PTP two-step operation software utilizes the Tx Timestamp of the initial PTP frame (i.e.: sync, Pdelay_Resp) to update the correction field of the follow-up frame (i.e.: follow-up, Pdelay_Resp_Follow_Up).
- For Pdelay PTP frames, software utilizes the Tx Timestamp to calculate the peer delay.

This capability may also be used for non-PTP traffic if so desired.

When ENETC transmit a frame on an extended BD Ring with Extended Flags (E_FLAG) two-step timestamp offload set, the timestamp information is updated in the Transmit Descriptor buffer after successful transmit.

For ENETC connected attached to an Ethernet MAC, the timestamp is captured when the frame's SFD is transmitted by the Ethernet MAC.

For ENETC connected attached to a pseudo MAC, the timestamp is captured when the frame is dequeued and sent across the pseudo-link to the switch.

When ENETC is connected to the switch via pseudo MAC and software wants to capture the timestamp when the frame's SFD is transmitted by the switch's Ethernet MAC, the following procedure is followed:

1. ENETC Tx buffer descriptor has FL=00b, FLQ=10b, SMSO=1b (indicating direct switch enqueue), EGR_PORT set to the switch's port number and TSR=1b (Timestamp Reference Request).
2. After the frame is enqueued to the switch egress port, the Timestamp Identifier (TXTSID) is updated in the transmit descriptor.
3. After the switch dequeues and transmit the frame, it sends a transmit timestamp reference response message to ENETC's Rx BD Ring with Receive buffer descriptor containing the TXTSID, Timestamp value and a Host Reason of 0x3 for Timestamp response.
4. Since multiple timestamp reference requests may be sent prior to receiving a transmit timestamp reference response, the ENETC's Tx BD TXTSID is used to correlate with the receive transmit timestamp reference response to determine the correct response message.

NOTE

It is possible that a transmit timestamp reference response is never received due to an integrity fault within NETC.

53.4.2.5.2.8.1.3 Tx one-step timestamp

For one-step Tx timestamping the Ethernet MAC performs the following steps:

- Captures the current time as it sends the SFD for the frame

- Reads the 48b Correction field from the packet at the offset in the frame configured in PM*a*_SINGLE_STEP[OFFSET]
- Subtracts the timestamp provided by software with the packet from the SFD transmit time and adds that to the value read from The Correction field
- Writes the computed value back into the Correction field before transmission

One-step timestamping is used only with PTP frames.

Extended Tx BDs must be used, one-step timestamping must be enabled by setting the bit in the Extended Flags (E_FLAGS) field of the BD, and the packet specific timestamp must be supplied in the extended BD.

For use with the PTP protocol the timestamp provided is the lowest 30b of the time, read from the Timer modules time value, and placed in the PTP time field of the packet. Normally the Correction field of the packet is initialized to 0. This provides the receiver with the time at creation of the packet and a correction factor representing the time spent before transmission in a single message thus the name "one-step".

Note that the MAC is also capable of writing a correction word for the UDP checksum in the PTP packet, if the PTP in UDP is in use. This is enabled by setting PM*a*_SINGLE_STEP[CH].

Note that IEEE 1588 PTP one-step timestamping is not supported on the pseudo MAC.

53.4.2.5.2.8.2 Local synchronization of time

The Timer module supports synchronization of it's time with other, local (i.e. not network attached), time aware hardware. This includes the ability to take timestamps for external pulses (e.g. 1PPS inputs), and generate both periodic pulses (e.g. 1PPS outputs) and non-periodic pulses at specific future times.

53.4.2.5.2.8.2.1 Generating pulses at a specific future time (alarms)

The timer module is capable of generating a pulse on a GPIO and/or an interrupt at some future time. Two such alarms are supported and the 64-bit time is set in the appropriate TMR_ALARM*a*_H/L registers. Both alarms may not be assigned external GPIO pins in some SoCs.

The 64-bit alarm time is compared to the current time on each update and when the to match the alarm is triggered.
The comparison is for exact equivalence, so care must be taken that the alarm value is set to an integer multiple of the TMR_CTRL[TCLK_PERIOD] plus the offset and any initial value in the time otherwise the match will never occur.

The alarm can generate an interrupt to the host, if it is unmasked. It can also generate a pulse on an external GPIO. The polarity of the output signal is controlled with TMR_CTRL[ALM*a*P].

53.4.2.5.2.8.2.2 Generating periodic pulses

The Timer module can generate a periodic (Fixed Period - FIPER) pulse on a GPIO pin and/or an interrupt to the host. Three such periodic pulse sources are supported, and the period is set by programming the TMR_FIPER*a* registers.

The period is programmed as a number clock periods (TMR_CTRL[TCLK_PERIOD]). After that number of clock periods has passed, the pulse is generated, and the periodic timer starts over. In addition to generating a pulse an interrupt may also be generated if it is unmasked. Not all three periodic pulses may have GPIOs assigned on some SoCs.

It is possible to use ALARM1 to trigger the start of FIPER by setting TMR_CTRL[FS]. This allows having the periodic pulses occur at specific, controlled times.

53.4.2.5.2.8.2.3 Timestamping externals pulses

The Timer is capable of recording the timestamp on receipt of an external pulse on a GPIO pin. Up to two such external triggers may be supported, depending on the SoC.

The recorded value is saved in a 16 entry FIFO accessed through TMR_ETTS*a*_H/L. An interrupt can be generated when the trigger occurs, when the FIFO reaches a threshold, and if the FIFO overflows.

The polarity of the external trigger can be set using TMR_CTRL[ETEP*a*].

53.4.2.5.3 Initialization

Software must initialize the Timer module after cold boot. The following steps should be followed:

1. Set TMR_CTRL including CK_SEL. TE (Timer enable) should be enabled at this point and the clock selected must be active
2. Initialize TMR_TMASK
3. Initialize TMR_ADD
4. Set TMR_CTRL including TMR_CTRL[TCLK_PERIOD]

It is worth noting, again, that the clock selected must be active otherwise registers listed in Table 751 will not be accessible.

Setting of other registers, for instance alarm, periodic pulse (Fixed interval periodic pulse or FIPER), or external trigger registers, during this phase is permitted but optional.

53.4.2.5.3.1 Re-initialization

Re-initializing the Time module will disrupt the time produced by it which is used by various blocks throughout the system.

Users of the time include:

- Ethernet MACs for timestamping
- TSN related functionality such as Time gate scheduling (802.1Qbv) and Per-stream Filtering and Policing (PSFP)
- Media clock generation and recovery

Before re-initializing the Time module these users should be disabled or the time stamps they produce should be ignored.

Once use of the time is curtailed the following steps should be followed:

1. Disable Timer module by clearing TMR_CTRL[TE]
2. Perform a Function Level Reset (FLR) on the 1588 Function
3. Clear/disable any previously configured/enabled periodic pulse (FIPER), alarms, or time stamp capture settings
4. Clear outstanding events in TMR_TEVENT
5. Mask interrupts in TMR_TEMASK
6. Reconfigure the Timer modules as needed
7. Set TMR_CTRL including TMR_CTRL[TE]=1 to enable the Timer; both the synchronized timer and the free running timer are enabled

Users of the 64-bit time can then be re-enabled.

53.4.2.6 PHY Management Interface (MDIO)

The MDIO interface is a two-wire management interface. It provides a standardized method to access the management registers of PHY devices. NETC provides the following internal and external MDIO interfaces :

- One external master MDIO interface for managing external devices (PHYs). The external MDIO interface is controlled by EMDIO_* registers. EMDIO supports both Clause 22 and 45 protocols. The EMDIO provides a means for different software modules to share a single set of MDIO signals to access their PHYs. Each user can access its set of registers to initiate accesses on the MDIO and the EMDIO arbitrates between them, completing one access before proceeding with the next. It is required that each user of the EMDIO have exclusive access and control of its PHY.
- One internal MDIO interface per external link for managing Reverse Mode.
- One slave MDIO interface per RevMII-capable external link for managing Reverse Mode.

Depending on the PCI functions enabled in the system, the MDIO access points are determined as shown in the figure below.

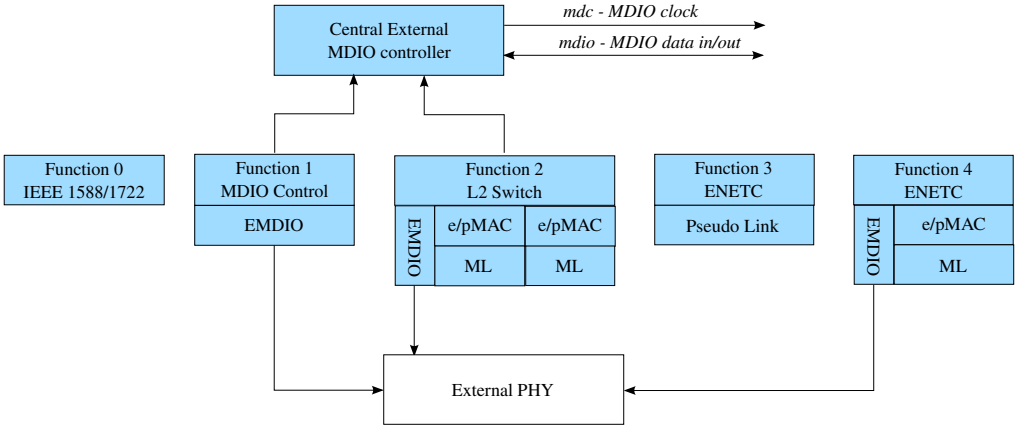

Figure 362. MDIO Access Points

53.4.2.6.1 Clause 22 External MDIO

A complete Clause 22 frame has a length of 64 bits, consisting of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change and 16-bit data. Depending on the value of EMDIO_CFG[NEG], each bit is transferred on the rising or falling edge of MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

Table 755. MDIO Clause 22 Frame Structure

ST	OP	PHYADDR	REGADDR	TA	DATA
2 bits	2 bits	5 bits	5 bits	2 bits	16 bits

Table 756. MDIO Clause 22 Frame Field Description

Field	Description
ST	Start indication. Value is 2'b01 for Clause 22 MDIO.
OP	Type of operation. 2'b01 for write, 2'b10 for read.
PHYADDR	PHY device address.
REGADDR	Register address.
TA	Turnaround time. Two bit-time is reserved for read operations to switch the data bus from write to read. PHY device will present its register contents in the data phase and drives the bus from the 2nd bit of the turnaround phase.
DATA	Data written to or read from PHY device.

EMDIO_CFG register should be configured before issuing any MDIO transactions.

- To generate a Clause 22 read transaction, follow these steps.
  1. Wait for EMDIO_CFG[BSY] = 0.
  2. Write EMDIO_CTL register with proper PHY_ADDR and REG_ADDR, with EMDIO_CTL[READ] set to 1 and EMDIO_CTL[POST_INC] cleared.
  3. Wait for EMDIO_CFG[BSY] = 0.
  4. Check EMDIO_CFG[MDIO_RD_ER]. If the addressed PHY does not respond, then EMDIO_CFG[MDIO_RD_ER] will be set.
  5. If no error, data is available in EMDIO_DATA register.

- To generate a Clause 22 write transaction, follow these steps.
  1. Wait for EMDIO_CFG[BSY] = 0.
  2. Write EMDIO_CTL register with proper PHY_ADDR and REG_ADDR, with EMDIO_CTL[READ] and [POST_INC] cleared.
  3. Write EMDIO_DATA register with proper data.

53.4.2.6.2 Clause 45 External MDIO

Clause 45 MDIO frame structure introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will write the 16-bit data in EMDIO_DATA register to the device, or retrieve the register contents from the external device.

Table 757. MDIO Clause 45 Frame Structure

ST	OP	PORTADDR	DEVADDR	TA	DATA
2 bits	2 bits	5 bits	5 bits	2 bits	16 bits

Table 758. MDIO Clause 45 Frame Field Description

Field	Description
ST	Start indication. Value is 2'b00 for Clause 45 MDIO.
OP	Type of operation. 2'b00 for address write, 2'b01 for data write, 2'b10 for read, 2'b11 for read increment.
PORTADDR	MDIO port address.
DEVADDR	Device address (within a port).
TA	Turnaround time. Two bit-time is reserved for read operations to switch the data bus from write to read. PHY device will present its register contents in the data phase and drives the bus from the 2nd bit of the turnaround phase.
DATA	Data written to or read from PHY device.

EMDIO_CFG register should be configured before issuing any MDIO transactions.

- To generate a Clause 45 read transaction, follow these steps. Note that steps 2-4 can be skipped for subsequent accesses to the same PHY register.
  1. Wait for EMDIO_CFG[BSY] = 0.
  2. Write EMDIO_CTL register with proper PORT_ADDR and DEV_ADDR, with EMDIO_CTL[READ] and [POST_INC] cleared.
  3. Write EMDIO_ADDR register with proper device register address REG_ADDR.
  4. Wait for EMDIO_CFG[BSY] = 0.
  5. Write EMDIO_CTL register with proper PORT_ADDR and DEV_ADDR and read command set to 1. For normal read, set EMDIO_CTL[READ] to 1. For read and post-increment of PHY device register address, set EMDIO_CTL[POST_INC] to 1.
  6. Wait for EMDIO_CFG[BSY] = 0.
  7. Check EMDIO_CFG[MDIO_RD_ER]. If the addressed PHY does not respond, then EMDIO_CFG[MDIO_RD_ER] will be set.
  8. If no error, data is available in EMDIO_DATA register.

- To generate a Clause 45 write transaction, follow these steps. Note that steps 2-4 can be skipped for subsequent accesses to the same PHY register.
    1. Wait for EMDIO_CFG[BSY] = 0.
    2. Write EMDIO_CTL register with proper PORT_ADDR and DEV_ADDR, with EMDIO_CTL[READ] and [POST_INC] cleared.
    3. Write EMDIO_ADDR register with proper device register address REG_ADDR.
    4. Wait for EMDIO_CFG[BSY] = 0.
    5. Write EMDIO_DATA register with proper data.

53.4.2.6.3 Clause 22 PHY STATUS

EMDIO_CFG register should be configured before initiating PHY STATUS transactions.

- To initiate Clause 22 automatic read transactions, follow these steps.
    1. Wait for PHY_STATUS_CFG[BSY] = 0.
    2. Write PHY_STATUS_CTL register with proper PHY_ADDR and REG_ADDR.
    3. Write PHY_STATUS_MASK register with proper STATUS_MASK_LH and STATUS_MASK_HL.
    4. Write PHY_STATUS_CFG register with proper value of STATUS_INTERVAL.
    5. Wait for PHY_STATUS_CFG[BSY] = 0.
    6. Check PHY_STATUS_CFG[MDIO_RD_ER]. If the addressed PHY does not respond, then PHY_STATUS_CFG[MDIO_RD_ER] will be set.
    7. If no error, status information is available in PHY_STATUS_DATA register.
    8. Repeat steps 5,6,7 for successive reads of PHY STATUS.

53.4.2.6.4 Clause 45 PHY STATUS

EMDIO_CFG register should be configured before initiating PHY STATUS transactions.

- To initiate Clause 45 automatic read transactions, follow these steps.
    1. Wait for PHY_STATUS_CFG[BSY] = 0.
    2. Write PHY_STATUS_CTL register with proper PHY_ADDR and DEV_ADDR.
    3. Write PHY_STATUS_MASK register with proper STATUS_MASK_LH and STATUS_MASK_HL.
    4. Write PHY_STATUS_ADDR register with proper REGADDR.
    5. Wait for PHY_STATUS_CFG[BSY] = 0.
    6. Write PHY_STATUS_CFG register with proper value of STATUS_INTERVAL.
    7. Wait for PHY_STATUS_CFG[BSY] = 0.
    8. Check PHY_STATUS_CFG[MDIO_RD_ER]. If the addressed PHY does not respond, then PHY_STATUS_CFG[MDIO_RD_ER] will be set.
    9. If no error, status information is available in PHY_STATUS_DATA register.
    10. Repeat steps 7,8,9 for successive reads of PHY STATUS.

53.4.2.6.5 Clause 22 Internal MDIO

Clause 22 internal MDIO is used to access the RevMII controls. It is controlled via the eMAC MDIO registers for the respective port.

MDIO_CFG register should be configured before issuing any MDIO transactions.

- To generate a Clause 22 read transaction, follow these steps.
  1. Wait for MDIO_CFG[BSY] = 0.
  2. Write MDIO_CTL register with proper PHY_ADDR and REG_ADDR, with MDIO_CTL[READ] set to 1 and MDIO_CTL[POST_INC] cleared.
  3. Wait for MDIO_CFG[BSY] = 0.
  4. Check MDIO_CFG[MDIO_RD_ER]. If the addressed PHY does not respond, then MDIO_CFG[MDIO_RD_ER] will be set.
  5. If no error, data is available in EMDIO_DATA register.
- To generate a Clause 22 write transaction, follow these steps.
  1. Wait for MDIO_CFG[BSY] = 0.
  2. Write MDIO_CTL register with proper PHY_ADDR and REG_ADDR., with MDIO_CTL[READ] and [POST_INC] cleared.
  3. Write MDIO_DATA register with proper data.

53.4.2.7 Reverse Mode (RevMII)

In Reverse Mode, the link acts as a PHY rather than a MAC. The key differences between a MAC and a port acting as a PHY via Reverse Mode are:

- Instead of using an EMDIO port as a master, a PHY has an MDIO slave interface that supports Clause 22 operation.
- The PHY contains two sets of Clause 22 registers for PHY configuration, called the RevMII registers.
- In MII mode, the device drives MII_TXCLK and MII_RXCLK
- In RGMII mode, the PHY delays RGMII_TXC and RGMII_RXC relative to data as per RGMII specification for PHYs

The device configuration of the port in Reverse Mode is indicated by PIOCAPR[REVMII]=1. If PaIOCAPR[REVMII]=1, and LaMCAPR[MII_PROT]=0b000, then the speed of the interface is indicated by PaIOCAPR[REVMII_RATE]. Software must set the corresponding configuration bits in the MAC IF_MODE register. Reverse mode is supported in all interface modes.

The two sets of Clause 22 registers in the RevMII block contain the PHY configuration settings for PHY-side (representing internal device) and MAC-side (representing the link partner). The two sets of Clause 22 registers represent two virtual PHYs, with a virtual link between them, as shown in the following figure:

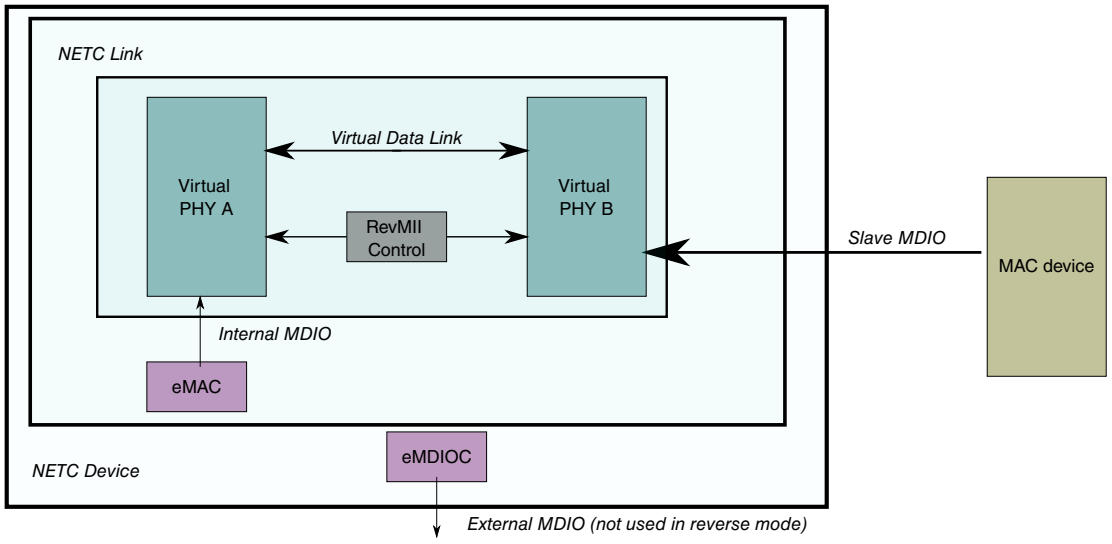

Figure 363. Reverse Mode

Accesses to PHY-side RevMII registers is over the internal MDIO interface from eMAC, using Clause 22 MDIO accesses with PHY Address 0h1F. Accesses to MAC-side RevMII MDIO space is via a per-link slave MDIO interface which supports Clause 22. When a link is configured for Reverse Mode, EMDIO is not supported for the link, and LaBCR[MDIO_PHYAD_PRTAD] determines the PHY address of the slave MDIO interface.

Application information:

- Half duplex is not supported for Reverse Mode.
- Reverse mode includes support for far-end loopback via MDIO CONTROL[14] on the MAC-side registers. If far-end loopback is enabled, received data is sent back out on the transmit interface without being sampled by the MAC reconciliation sublayer. Far-end loopback is supported for all modes, but for RGMII the link must be in synchronous operation (RGMII_TXC and RGMII_RXC from same clock source)
- Reverse mode includes support for link powerdown, via MDIO CONTROL[11], in which the interface transmit and receive functions are gated. Power down must be set to 0 for normal operation
- There is some asymmetry in the RevMII registers between MAC-side and PHY-side:
  - The MS_CTL[11] (MS_CFG_VALUE) is a RO bit. It will always read 0 for the MAC-side and 1 for the PHY-side. This also affects the state of MS_STA[14] (MS_CFG_RES) which is a read only copy of MS_CTL[11].
  - CONTROL[14] (LOOPBACK) is RW on the MAC-side and RO on the PHY-side.

53.4.2.7.1 Clause 22 Internal RevMII MDIO

The internal eMAC MDIO is used to access the REVMII registers.

For access to the RevMII register the PHY_ADDR must be set to 0h1f for both read and write transactions.

MDIO_CFG register should be configured before issuing any MDIO transactions.

- To generate a Clause 22 read transaction to the RevMII, follow these steps.
  1. Wait for MDIO_CFG[BSY] = 0.
  2. Write MDIO_CTL register with PHY_ADDR=0h1f and REG_ADDR, with MDIO_CTL[READ] set to 1 and MDIO_CTL[POST_INC] cleared.
  3. Wait for MDIO_CFG[BSY] = 0.

4. Check MDIO_CFG[MDIO_RD_ER]. If the addressed PHY does not respond, then MDIO_CFG[MDIO_RD_ER] will be set.
5. If no error, data is available in MDIO_DATA register.

- To generate a Clause 22 write transaction, follow these steps.
  1. Wait for MDIO_CFG[BSY] = 0.
  2. Write MDIO_CTL register with PHY_ADDR=0h1f and REG_ADDR, with MDIO_CTL[READ] and [POST_INC] cleared.
  3. Write MDIO_DATA register with proper data.

53.4.2.7.2 AN Theory of Operation

For AN enabled, initialization sequence is

- SW programs:
  1. AN advertisement register (offset 4)
  2. AN Next Page transmit register (offset 7)
  3. MASTER-SLAVE Control register (offset 9)
  4. CONTROL (offset 0), with AN enable = 1
- HW compares the values in offset 4,7,9 versus 5,8,10 to determine highest common speed mode
  - Speed is 1 Gbps if both 9.9 and 10.11 are set
  - else speed is 100 Mbps if both 4.9 and 5.9 are set
  - else speed is 10 Mbps if both 4.6 and 5.6 are set
  - If there is a common mode, then HW sets
    - STATUS[AN complete]=1
    - STATUS[Link Status]=1
  - If there is no common mode, HW does nothing (SW has to poll for AN complete and time out)
- PHY reset or setting CONTROL[Restart AN] re-trigger above speed calculation. Speed does not change if registers change without reset or restart AN.

For AN disable, initialization sequence is

- CONTROL (offset 0)[SPEED] with AN enable=0
  - Speed is 1 Gbps if CONTROL[SPEED]=10
  - else speed is 100 Mbps if CONTROL[SPEED]=01
  - else speed is 10 Mbps if CONTROL[SPEED]=00

53.4.2.7.2.1 AN Link Down Scenario: MAC initiated

MAC and PHY both go through regular initialization advertising support for 10/100/1000 speeds, and negotiate to 1 Gbps. MAC driver later decides to drop down to 100 Mbps, and changes advertised capability to remove 1000, then sets Restart AN=1

- MAC-side:
  - AN HW sets link down as a result of Restart AN
  - AN HW sees that highest common speed has changed to 100 Mbps, and changes its speed to 100 Mbps, setting AN done and link up
  - SW polls MDIO link state until it sees AN done and link up. Link up state is LL, so SW has to read it twice after AN done to see it set to 1

- SW changes MAC:IFMODE to match to match to new data link speed

- PHY-side:
  - PHY-side doesn't know about MAC-side's AN restart, but the HW sees that its speed choice is no longer matches what AN would choose, so it sets link down
  - SW polls MDIO link state and sees it's link down, and so sets AN restart
  - HW changes its speed to 100 Mbps and sets AN done and link up
  - SW polls MDIO link state until it sees AN done and link up. Link up state is LL, so SW has to read it twice after AN done to see it set to 1
  - PHY-side SW changes MAC:IFMODE to match to change actual data link speed

53.4.2.7.2.2 AN Link Down Scenario: PHY initiated

MAC and PHY both go through regular initialization advertising support for 10/100/1000 speeds, and negotiate to 1 Gbps. PHY driver later decides to drop down to 100 Mbps, and changes advertised capability to remove 1000, then sets Restart AN=1

- PHY-side:
  - AN HW sets link down as a result of Restart AN
  - AN HW sees that highest common speed has changed to 100 Mbps, and changes its speed to 100 Mbps, setting AN done and link up
  - SW polls MDIO link state until it sees AN done and link up. Link up state is LL, so SW has to read it twice after AN done to see it set to 1
- MAC-side:
  - MAC-side doesn't know about PHY-side's AN restart, but the HW sees that its speed choice is no longer matches what AN would choose, so it sets link down
  - SW polls MDIO link state and sees it's link down, and so sets AN restart
  - HW changes its speed to 100 Mbps and sets AN done and link up
  - SW polls MDIO link state until it sees AN done and link up. Link up state is LL, so SW has to read it twice after AN done to see it set to 1
  - SW changes MAC:IFMODE to match to match to new data link speed

53.4.2.8 Power Management

53.4.2.8.1 Power States

The PCIe Specification defines function power states (D-states) that enable the platform to establish and control power states for NETC ranging from fully on to fully off (drawing no power) and various in-between levels of power-saving states, annotated as D0-D3. Similarly, PCIe defines a series of link power states (L-states) that work specifically within the link layer. Since NETC is an integrated endpoint it does not have a PCIe link layer , and thus, there is no need to support link power states (L-states). In subsequent discussions mainly PCIe functions mastering transactions are considered, i.e. ENETC and switch. Other supporting NETC functions such as EMDIO and timer do not require any additional preparation to enter sleep state.

NETC only supports the required DO and D3 power states. These device states also indirectly reflect the states of the Ethernet link.

- $D0_{uninitialized}$ - a sub-state of D0
- $D0_{active}$ - a sub-state of D0
- $D3_{hot}$ - a sub-state of D3
- $D3_{cold}$ - a sub-state of D3

The table below describes the power states and transitions for a mastering NETC functions.

Table 759. Device Power State Description

Current State	Next States	Action	Power
$D0_{uninitialized}$ Uninitialized.			
$D0_{uninitialized}$	$D0_{uninitialized}$	During POR, all functions enter the $D0_{uninitialized}$ state. When a function completes a function level reset (FLR) it also enters the $D0_{uninitialized}$ state.	Main=On/Off
$D0_{uninitialized}$	$D0_{active}$	After configuration is complete, the function enters the $D0_{active}$ state, the fully operational state for a PCI Express function. A function enters the $D0_{active}$ state whenever the Bus Master Enable bit has been set.	Main=On
$D0_{active}$ Active. Normal functionality.			
$D0_{active}$	$D3_{hot}$	Prepare for sleep. **ENETC device driver**: Software must ensure that NETC's transmit is idle or quiesced. Either disable all ENETC station interfaces, disable all associated ENETC transmit rings or wait for ENETC transmit rings to drain.If connected to a switch, poll the switch port transmit busy bit, PSR[TX_BUSY] and the ENETC port transmit busy bit. Poll the port transmit busy bit, PSR[TX_BUSY], if connected to a MAC port. For ENETC functions not participating in wake-on event detection, external receive port should be disabled and software should wait for PSR[RX_BUSY]=0. ENETC functions connected directly to a switch port, should wait for switch function to quiesce first. Software creates Wake-on-LAN filters for ENETC in the Ingress Port Filter table to enable wake-on condition(s). Enabling wake-on mode by setting LPMR[WME]=1, activates the search for wake-on events. **Switch device driver**: Disable all external Ethernet receive ports and wait for PSR[RX_BUSY]=0. Receive ports connected to a remote ENETC function through a pseudo link should wait for remote ENETC function to quiesce the transmit path before disabling the port. Poll the transmit path busy bit for all ports, PSR[TX_BUSY], and wait for idle. **PCIe driver**: Saves PCIe configuration and requests the device to enter D3 power state by writing 11b to the Power State field in PCI-PM register PMCSR. Poll PCI-PM power state in PMCSR after a minimum of 10ms to determine if state transition was successful.	Main=On
$D3_{hot}$ Primary power is maintained. The system can keep NETC in this state for an arbitrary amount of time. This state can be used to achieve the following:			

Table continues on the next page...

Table 759. Device Power State Description (continued)

Current State	Next States	Action	Power
• prepare to transition the system into sleep or while the system sleeps • wake up the system if Wake-on-LAN events and PME is enabled • quiesce device before disabling LAN or removing clocks If enabled, NETC may generate PM_PME messages in this state to notify PM software that it needs to return to full active state. NETC is only capable to respond to PCIe configuration requests and will not be capable of mastering on the system bus or receiving device configurations. NETC will not forward any received frames to software; see L2 Filtering with Wake-on-LAN, for more details on how frames are filtered when operating in the Wake-on-LAN (WoL) mode.			
$D3_{hot}$	$D3_{cold}$	Transition to deep sleep. OS saves system state. Main power is off.	Main->Off
$D3_{hot}$	$D0_{uninitialized}$	Configuration software writes a value of 00b to the Power State field in the PCI PM registers while the No_Soft_Reset field in the PMCSR is clear. NETC PCI configuration space is not required to be maintained and as a result software is required to fully re-initialize the function.	Main=On
$D3_{hot}$	$D0_{active}$	Configuration software writes a value of 00b to the Power State field in the PCI PM registers while the No_Soft_Reset field in the PMCSR is set. NETC PCI configuration space is maintained.	Main=On
$D3_{hot}$	$D3_{hot}$	Wake event during sleep. Wake-on-LAN packet received by ENETC function. ENETC sets the PME status bit and sends a PM_PME message to Root Complex Event Collector (RCEC) which sets the PME status bit in the Root Status register. If software has set the PME interrupt enable bit in the Root Control register to 0b1, the Root Port then generates a level-sensitive interrupt to wake the system. **PCIe driver**: Reads configuration register Association Bitmap for Root Complex Integrated Endpoints in the event collector to determine device IDs for PME sources. Scans associated devices looking for any with a set PME status bit. For each device, it disables PME and informs the device driver that it is asserting wake up. The PCIe driver stops scanning for wake devices when it has made a complete pass through all PCIe devices in the list. Optionally clears the event collector PME interrupt enable bit in the Root Control register. Clears the event collector PME status bit in the root status register to deassert the PME interrupt signal. **Device driver**: Requests the device be put in D0 power state and sets any ENETC registers required to handle the Wake-on-LAN event. ENETC will return the frame associated with the Wake-on-LAN event, if such exist, when Wake-on-LAN mode is disabled.	Main=On
$D3_{cold}$ Primary power is not maintained. NETC does not operate on auxiliary power, hence it is not operational in this state which is equivalent to asserting HRESET.			

53.4.2.8.2 Energy Efficient Ethernet (EEE)

The IEEE 802.3 standard, Clause 78 and related, defines procedures to implement energy efficient Ethernet (EEE). It allows end stations to exchange low power idle (LPI) indications to indicate the link is not used and may be allowed to power down.

The MAC provides mechanisms to allow this signaling of low-power idle indications. It is then the responsibility of the application and management to use the information and implement power modes as necessary.

Transmitting LPI sequence to remote partner

To transmit LPI sequence to the remote partner, software needs to set PM0_COMMAND_CONFIG[TX_LOWP_ENA] to 1. MAC will start transmitting the sequence when current ongoing frame is completed. User is advised to inspect PM0_IEVENT[TX_EMPTY] before enabling LPI.

53.4.2.8.3 Wake-on-LAN Mode

Wake-on-LAN mode allows the NETC device and system to enter a low-power state and be woken when a specific event is detected on the Ethernet link. When operating in an active Wake-on-LAN mode, i.e. PCI-PM power state $D3_{hot}$, and a pre-programmed ENETC ingress port filter with a Wake-on-LAN trigger action (WOLTE), has been matched, the system can return to full operational mode when detecting such an event. In Wake-on-LAN mode, ENETC will not accept frames from upper layer software for transmission but assumes that device software has disabled transmit and made sure transmit pipeline is idle by checking transmit busy status bit. When Wake-on-LAN mode is enabled, ENETC will save the Wake-on-LAN frame to aid the system to respond more quickly and avoid dropping virtual connections. Additional frames may be saved based on the receive buffer capability and frame sizes received. It is recommended that traffic be differentiated appropriately based on Drop Resilience (DR) so that more discardable traffic is dropped first when internal memory congestion is detected.

The Wake-on-LAN events supported are:

- **Ingress Port Filter table entry match.**

  Wake-on-LAN trigger action as a result of Ingress Port Filter table entry match. An Ingress Port Filter table entry can match frames based on a mix of L2, L3, and L4 header fields including arbitrary fields (e.g. fields not identified by parsing).

  It can also match frames that have been identified by the MAC, as "magic packets". A magic packet consists of a specific pattern that can be found anywhere within the payload of an Ethernet frame. The pattern consists of 6 octets of 0xFF immediately followed by 16 times the MAC address of the station. The MAC address in the magic packet pattern, must match the MAC address configured in the PM*a*_MAC_ADDR_0/1 registers. Any data before or after this pattern is ignored. Therefore, any frame destination address, protocol-layer payload can be used to transport a magic packet pattern. magic packet detection is enabled by setting PM*a*_COMMAND_CONFIG[MG] to 1.

To enter Wake-on-LAN mode, the following steps should be considered.

1. Disable all other ports not participating in Wake-on-LAN.
   a. Disable the *Bus Master Enable* bit in the PCIe Command Register. This will disable the network controller and stop further transmissions.
   b. Disable MAC receive function.
   c. Transition the function to $D3_{hot}$ state. The reaction should be immediate for functions not supporting Wake-on-LAN. Note, all functions are required to support at a minimum D0 and D3 states.
2. Disable transmit of all ports participating in Wake-on-LAN event detection, by disabling all of their transmit BD rings, TB*a*MR[EN]=0.
3. Configure ENETC to report power management events to Event Collector by setting PCI_CFC_PCIPM_CTL_STAT[PME_EN]=1.
4. Configure the Wake-on-LAN trigger events in the ingress port filter table, including magic packet. Magic packet detection is enabled by setting PM*a*_COMMAND_CONFIG[MG] to 1.
5. Enable Wake-on-LAN for the port by setting LPMR[WME]=1. Setting of this bit (0b1) arms the search for a new event in the ingress port filter table.

a. Forces quiescing of ENETC

b. ENETC will drop received frames not matching the Wake-on-LAN frame. If a Wake-on-LAN frame is encountered before PCI-PM $D3_{hot}$ state is entered, the PWOSR[WOLA] signal is cleared (0b0) and subsequent frames are processed normally.

6. Software requests ENETC to enter PCI-PM $D3_{hot}$ state by writing 0b11 to the Power State field in PCI-PM register PCI_CFC_PCIPM_CTL_STAT.

   a. PCI-PM $D3_{hot}$ state will not be entered if PWOSR[WOLA]=0. Wake-on-LAN mode LPMR[WME] must be reenabled to again arm the ingress port filter function.

7. Hardware captures the request for PCI-PM power state change and waits for ENETC to quiesce before entering $D3_{hot}$ state.

   a. If a Wake-on-LAN event is detected, as indicated by PWOSR[WOLA]=0, the request for low-power mode is aborted.

8. When $D3_{hot}$ state is entered the Wake-on-LAN function continues the search for received frames matching any one of the Ingress Port Filter table entry with a Wake-on-LAN trigger action (WOLTE) . The received frames are dropped until the Wake-on-LAN event is detected after which frames (including the Wake-on-LAN frame event) are stored locally in ENETC.

   a. ICM stops forwarding frames to the host transfer agent.

9. Software waits a minimum of 10ms before polling the Power State field in PCI-PM register PCI_CFC_PCIPM_CTL_STAT. If the Power State is 0b11, then the transition was successful and the system may enter a low-power state where clocks are disabled or power removed, except for NETC. ENETC will not forward any traffic to BD rings in memory until software returns ENETC to PCIPM power state $D0_{active}$. If the Power State remains 0b00, one of the following has occurred:

   a. A quiesce state was never reached; software may poll the *Transaction Pending* bit in the PCIe Device Status Register.

   b. Wake-on-LAN was not enabled or an event not selected.

   c. Wake-on-LAN event was detected, as seen by PWOSR[WOLA]=0, before low-power mode was reached.

10. When a Wake-on-LAN event has occurred in low-power mode, ENETC sets the PME status bit in register PCI_CFC_PCIPM_CTL_STAT and sends a PME message to Root Complex Event Collector (RCEC) which sets the PME status bit in the Root Status register PCI_CFC_PCIE_ROOT_STAT. If software has set the PME interrupt enable bit in the Root Control register PCI_CFC_PCIE_ROOT_CTL to 0b1, the Event Collector then generates a level-sensitive interrupt to wake the system.

    a. A Wake-on-LAN frame may have its drop resilience modified, by the ingress port filter, to guarantee system delivery when internal memory congestion is detected.

11. Software wakes up from low-power mode and services the PME interrupt.

12. Software brings ENETC into PCI-PM D0 state by writing 0b00 to the Power State field in PCI-PM register PCI_CFC_PCIPM_CTL_STAT.

    a. At this time software may be required to re-initialize receive BD rings.

13. ENETC (ICM) will start forwarding frames to BD rings in main memory when LPMR[WME] is cleared (0b0). See L2 Filtering with Wake-on-LAN, for more details.

53.4.2.9 Clocking

This module has no clocking considerations.

53.4.2.10 Reset

NETC supports multiple types of reset, listed below in order of highest scope to smallest:

- Hard reset, also known as Power-on-Reset (POR)
- Soft reset
- Warm reset
- Function Level Reset (FLR)

Hard Reset

Hard reset restores all NETC state bits to a Power-on-State. This type of reset is issued at SoC level.

Soft Reset

Soft reset targets all functions as well as any shared or common infrastructure blocks, making this equivalent to a device reset. The use of soft reset would be in a scenario where an unrecoverable event has occurred which required a reset of NETC and a full chip level reset is not desirable.

Software should follow these steps prior to initiating a soft reset to avoid hanging any outstanding transactions in the system.

1. Software disables MAC receive function(s).
2. Software sets the soft reset bit NETCRR[SR]=1.
   - NETC stops further prefetching of BDs
   - NETC stops scheduling transmit frames
   - NETC completes any in-flight transmit frames processing.
     - If there is use of time gating or credit based shaping, worst case wait time is SaTGSLR/EaTGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET] + Transmit(MAX_SDU) + Writeback BD.
     - If there is no use of time gating or credit based shaping, worst case wait time is Transmit(MAX_SDU) + Writeback BD.
3. Software waits for either:
   - 100 ms (as per PCIe specification).
   - Shortest possible reset time as defined by IERB register NETCFLRCR.
   - NETCRR[SR] bit to clear by polling.
4. Software reconfigures NETC.

Warm Reset

Warm reset is similar to a soft reset but does not reset any of the IERB register values. The following steps generate a warm reset:

1. Software disables MAC receive function(s).
2. Software unlocks the IERB registers, currently in a locked state (i.e. NETCRR[LOCK]=1 and NETCSR[STATE]=0), by clearing (0b0) the NETCRR[LOCK] bit.
   - NETC stops further prefetching of BDs
   - NETC stops scheduling transmit frames
3. Software waits for NETC to complete any in-flight transmit frames
   - If there is use of time based scheduling, worst case wait time is SaTGSLR/EaTGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET] + Transmit(MAX_SDU) + Writeback BD.
   - If there is no use of time gating or credit based shaping, worst case wait time is Transmit(MAX_SDU) + Writeback BD.
4. Software either:
   - waits 100 ms (as per PCIe specification).
   - waits shortest possible reset time as defined by IERB register NETCFLRCR.
   - waits for NETCRR[LOCK] bit to clear by polling.

5. Software reconfigures NETC.

Function Level Reset

Function level reset is generated through the PCIe Function Level Reset (FLR) bit, or indirectly through warm or soft reset. There are two types of FLR reset; reset which occurs through the PCIe physical function (PF) and virtual interface reset, which is a reset of the PCIe virtual function (VF). FLR that targets a virtual function (VF), resets a single VF. Reset that targets a physical function (PF), resets a PF and all its associated VFs. An FLR that targets a VF does not affect the VFs existence or any address mapping assigned to it (VFs BAR*n* values and MSE). VF reset is a destructive process and must be avoided while the function is in use. It is expected it will be used as PCI functions change owners (and all existing configuration and state must be reverted to power-on defaults).

The Timer is a support function for other NETC critical functions such as time gating and Ethernet MAC timestamping. Due to these dependencies, the Timer cannot be reset by FLR alone, and requires a soft reset. Errors occurring for the Timer are reported as global.

Software should follow these steps when initiating a Function Level Reset:

1. Software initiates the FLR.
2. Software either:
   - waits 100 ms (as per PCIe specification).
   - waits PCIE_CFC_RTR_RTR2[FLR_TIME], if PCIE_CFC_RTR_RTR1[VALID]=1 in PCIe function.
   - polls PCI_CFC_PCIE_DEV_CTL[INIT_FLR] and waits for b0. If bit has not cleared within specified waiting time, there may be a potential HW failure and software is recommended to issue a soft reset for the device.
3. Software reconfigures the Function and enables it for normal operation.

NOTE

When a reset is triggered it will instruct the function to quiesce (drain pending frames and pipelines) for an extended period of time, followed by a reset of registers and finally clearing of table entries. The length of this entire sequence is controlled by IERB register NETCFLRCR.

53.4.2.10.1 Function Reset

Function reset applies to switch and ENETC instances which have physical or pseudo MAC port-links attached.

53.4.2.10.1.1 ENETC Function Reset

Reset of the ENETC function is equivalent to a PCIe Function Level Reset (FLR) of the Physical Function (PF), which includes the port and any station interface bound to the ENETC instance. The function reset is generated by writing to the PCI header Device Control Register.

Hardware will set the following register bits while trying to quiesce:

- PM*a*_COMMAND_CONFIG[RX_EN]=0b and PM*a*_COMMAND_CONFIG[TX_FLUSH]=1b if physical port present
- POR[RXDIS/TXDIS]=1b

The PCIe function number mapping for the ENETC instance can be found in IERB register E*a*BCR0[FN]. An FLR that targets a PCIe PF resets the PF's SR-IOV extended capabilities, the VFs (VSIs) are no longer allocated or enabled. The effects of the port reset are as follows:

- MSI configuration (stops any pending MSIs)
- In-flight frames in the Ethernet Rx I/F block are discarded.
- In the case of the Ethernet MAC, reception of the current frame from the Ethernet link will continue till the end of the frame, and then the frame will be discarded. Afterwards, no more frames from the Ethernet MAC are expected.
- In the case of the pseudo MAC, the other end of the pseudo link (switch) may continue sending frames, these frames received from the pseudo MAC will be discarded. Additionally, switch management frames with Host Reason set to non-zero which by-pass the pseudo MAC, will also be discarded.

- In-flight frames in the Ingress Port Processing block and the Host Transfer Agent Receive block will be drained and discarded.
- Both ICM queues are drained as fast as possible. Frames dequeued/drained from the ICM queues are immediately discarded.
- In-flight frames in the Host Transfer Agent Transmit block, Egress Port Processing block and Ethernet Tx I/F block are drained and discarded, with the error "frame dropped due to port reset" reported in their transmit buffer descriptor. Transmission of frames is stopped.
- Transmit BD rings are no longer serviced.
- Processing of in-flight table management commands will be completed. However no new table management commands will be accepted.
- Once there are no more frames in the ENETC instance and processing of in-flight table management commands is completed, all of the ENETC instance registers and tables are reset.
- Reset mailbox between VSI and associated PSI
- Flush port-link bound Ethernet MAC(s) (through the same mechanism as PM*a*_COMMAND_CONFIG[TX_FLUSH]) and reset of config and control registers. Note: FLR does not clear MAC statistics registers.

Since management registers for buffer descriptor rings will be reset, it could cause loss of unprocessed packets. To avoid loss of data, software should perform the following steps prior to reset:

1. Disable the network controller by setting bit SIMR[EN]=0, disable the receive link and wait for controller to be idle, PSR[TX_BUSY/RX_BUSY]=0
2. Save descriptor ring information (base address, size, consumer/producer indices)

NOTE

The IERB registers are unaffected by FLR. Setting the PCI_CFH_CMD[MEM_ACCESS]=1 for the function will copy register values from IERB after the FLR.

53.4.2.10.1.2 Switch Function Reset

Reset of the switch function is equivalent to a PCIe Function Level Reset (FLR), which includes all port-links bound to the switch instance (pseudo links as well). The function reset is generated by writing to the PCI header Device Control Register. The PCIe function number mapping for the switch instance can be found in IERB register S*a*BCR[FN].

Hardware will set the following register bits while trying to quiesce:

- PM*a*_COMMAND_CONFIG[RX_EN]=0b and PM*a*_COMMAND_CONFIG[TX_FLUSH]=1b if physical port present
- POR[RXDIS/TXDIS]=1b

The effects of the switch function reset is as follows:

- MSI configuration (stops any pending MSIs)
- In-flight frames in the Ethernet Rx I/F block are discarded.
- In the case of the Ethernet MAC, reception of the current frame from the Ethernet link will continue till the end of the frame, and then the frame will be discarded. Afterwards, no more frames from the Ethernet MAC are expected.
- In the case of the pseudo MAC, the other end of the pseudo link (ENETC) may continue sending frames, these frames received from the pseudo MAC will be discarded.
- In-flight frames in the Ingress Packet Processing block and the Replication and Egress Packet Processing block will be drained and discarded, with the exception of switch management frames with Host Reason set to non-zero, in which case, they will be delivered to ENETC (enqueued directly inside ENETC (ICM)); these frames are not discarded.
- All ETM class queues are drained as fast as possible. Frames dequeued/drained from the ETM class queues are immediately discarded.

- In-flight frames in the Ethernet Tx I/F datapath processing pipeline are discarded. Transmission of frames is stopped.
- Processing of in-flight table management commands will be completed. However no new table management commands will be accepted.
- Once there are no more frames in the switch and processing of in-flight table management commands is completed, all of the switch registers and tables are reset.
- Flush port-link bound Ethernet MAC(s) (through the same mechanism as PM*a*_COMMAND_CONFIG[TX_FLUSH]) and reset of config and control registers. Note: FLR does not clear MAC statistics registers.

NOTE

Note that the IERB registers are unaffected by FLR. Setting the PCI_CFH_CMD[MEM_ACCESS]=1 for the function will copy register values from IERB after an FLR.

53.4.2.10.2 VSI Function Reset

This is a reset of the Virtual Station Interfaces (VSIs). It is equivalent to PCIe Function Level Reset (FLR) of a VF, generated by writing to the PCI header Device Control register. The effects of the VF reset are as follows:

- MSI configuration (stops any pending MSIs)
- In-flight frames in the Host Transfer Agent Receive block for the VSI being reset will be drained and discarded.
- Transmit BD ring(s) for the VSI being reset, are no longer serviced.
- In-flight frames in the transmit datapath pipeline for the VSI being reset, will be drained and transmitted out the link. No frame discards are expected unless an error is detected.
- Processing of in-flight table management commands will be completed. However no new table management commands will be accepted for the VSI being reset.
- Once there are no more frames and processing of any in-flight table management commands is completed, for the VSI being reset, all of the VSI registers/fields and tables/entries are reset. The PSI's VSI registers (e.g. PSIaPMAR0/1) are also reset . These registers will need to be re-initialized after the VSI FLR operation completes, if these registers were updated prior to the completion of the VSI FLR.
- SIIDR[FLR*n*] is set to 1 in the PSI to indicate which interface is being reset.

Since management registers for buffer descriptor rings will be reset, it could cause loss of unprocessed packets. To avoid loss of data, software should perform the following steps prior to resetting the interface:

1. Disable the interface by setting bit SIMR[EN]=0 and wait for interface to be idle, SISR[TX_BUSY]=0
2. Save descriptor ring information (base address, size, consumer/producer indices)

53.4.2.10.3 EMDIO Controller Reset

Reset of the EMDIO controller can be achieved by issuing a Function Level Reset (FLR), generated by writing the PCI header Device Control register. Software should follow these steps:

1. Stop issuing MDIO transactions to external PHY.
2. Wait for any outstanding MDIO transactions to complete by reading the busy bit.
3. Issue the FLR.
4. Wait for the appropriate amount of time, as specified in the PCIe specification, before reinitializing the EMDIO controller.

53.4.2.10.4 Timer Reset

Function level reset is not applicable to timer as a supporting function and requires a soft reset.

53.4.2.11 Interrupts

53.4.2.11.1 Message Signaled Interrupt (MSI-X)

NETC supports generating MSI-X messages when an interrupt event occurs. These are functional interrupts that occur during the normal operation of NETC and usually signifies that there is data to process by the receiving entity, but it is also used for timer events.

An interrupt is generated whenever an interrupt event is detected by a NETC function and the associated interrupt enable bit is also set. An interrupt has a corresponding interrupt vector register which defines the index used during lookup of the address and data in the MSI-X Table. For interrupt grouping, two or more vector registers can share the same vector table index value. The address and data from the table is then used to generate a (32-bit) DWORD size posted memory write, which normally is routed towards the system interrupt controller.

System software initializes the message address and message data (from here on referred to as the “vector”) during device configuration, allocating a vector table to each MSI-X capable function. MSI-X supports the ability for software to control aliasing when fewer vectors are allocated than requested, plus the ability for each vector to use an independent address and data value, specified by a table that resides in Memory Space. Note that there is a mapping between NETC function and PCIe function defined by the binding configuration registers in the IERB space.

For an MSI-X to occur, the MSI-X generation must be enabled by setting PCI_CFC_MSIX_MSG_CTL[MSIX_EN]=1. MSI-X supports per-function masking and per-vector masking. Per-function masking, when set, masks all of the vectors associated with a function. See PCI_CFC_MSIX_MSG_CTL[FUNC_MASK], for more details. Per-vector masking is managed through a MSI-X Table entry. An MSI-X vector is masked when its associated MSI-X Table entry Mask bit or the MSI-X Function Mask bit is set. While a vector is masked, the function is prohibited from sending the associated message, and the function must set the associated Pending bit whenever the function would otherwise send the message. When software unmasks a vector whose associated Pending bit is set, the function must schedule sending the associated message, and clear the Pending bit as soon as the message has been sent.

The PCI MSI-X capability structure points to an MSI-X Table structure and a MSI-X Pending Bit Array (PBA) structure, each residing in Memory Space. Each structure is address mapped by an entry in the PCI Enhanced Allocation (EA) capability structure. The MSI-X BAR Indicator register field (BIR) indicates which EA entry used for the base address. A QWORD aligned MSI-X Offset indicates where the structure begins relative to the EA base address.

The MSI-X Table structure is illustrated in Table 760, typically contains multiple entries, each consisting of several fields: Message Address, Message Upper Address, Message Data, and Vector Control. Each entry is capable of specifying a unique vector. The Pending Bit Array (PBA) structure, illustrated in Table 765, contains the function’s Pending Bits, one per Table entry, organized as a packed array of bits within (64-bit) QWORDs. The last QWORD will not necessarily be fully populated.

NOTE

This implementation supports a reduced number of address bits. Total address bits available in each table entry for reading/writing are 32 bits.

Table 760. MSI-X Table Structure

DWORD 3	DWORD 2	DWORD 1	DWORD 0		
Vector Control	Msg Data	Msg Upper Addr	Msg Addr	Entry 0	Base
Vector Control	Msg Data	Msg Upper Addr	Msg Addr	Entry 1	Base + 1*16B
Vector Control	Msg Data	Msg Upper Addr	Msg Addr	Entry 2	Base + 2*16B
...	...	...	...	...	
Vector Control	Msg Data	Msg Upper Addr	Msg Addr	Entry (N-1)	Base + (N-1)*16B

Table 761. Message Address for MSI-X Table Entries

Bits	Name	Description
31-2	Message Address	System-specified message lower address. For MSI-X messages, the contents of this field from an MSI-X Table entry specifies the lower portion of the (32-bit) DWORD-aligned address (ADDR[31:2]) for the memory write transaction. This field is read/write.
1-0	Message Address	For proper DWORD alignment, the state of these bits after reset must be 0. These bits are read only.

Table 762. Message Upper Address for MSI-X Table Entries

Bits	Name	Description
31-0	Message Upper Address	System-specified message upper address. For MSI-X messages, the contents of this field from an MSI-X Table entry specifies the upper portion of the (32-bit) DWORD-aligned address (ADDR[63:32]) for the memory write transaction. This field is read/write. **NOTE** This implementation supports a reduced number of address bits. Total address bits available in each table entry for reading/writing are 32 bits.

Table 763. Message Data for MSI-X Table Entries

Bits	Name	Description
31-0	Message Data	System-specified message data. For MSI-X messages, the contents of this field from an MSI-X Table entry specifies the data driven on DATA[31:0] during the memory write transaction's data phase. This field is read/write.

Table 764. Vector Control for MSI-X Table Entries

Bits	Name	Description
31-1	Reserved	After reset, the state of these bits must be 0. However, for potential future use, software must preserve the value of these reserved bits when modifying the value of other Vector Control bits. If software modifies the value of these reserved bits, the result is undefined.
0	Mask Bit	When this bit is set, the function is prohibited from sending a message using this MSI-X Table entry. However, any other MSI-X Table entries programmed with the same vector will still be capable of sending an equivalent message unless they are also masked. This bit's state after reset is 1 (entry is masked). This bit is read/write.

Table 765. MSI-X PBA Structure

Pending Bits 0 through 63	QWORD 0	Base
Pending Bits 64 through 127	QWORD 1	Base + 1*8B

Table continues on the next page...

Table 765. MSI-X PBA Structure (continued)

...	...	...
Pending Bits ((N-1) div 64)*64 through N-1	QWORD ((N-1) div 64)	Base + ((N-1) div 64)*8B

To request service using a given MSI-X Table entry, a function performs a DWORD memory write transaction using the contents of the Message Data field entry for data, the contents of the Message Upper Address field for the upper 32 bits of address, and the contents of the Message Address field entry for the lower 32 bits of address. A memory read transaction from the address targeted by the MSI-X message produces undefined results.

Table 766. Interrupt Classes

Description	Interrupt Handling	
Virtual Station Interface message transmitted to PSI.	**Device Detect**	VSIIDR[MS]
	Device Enable	VSIIER[MSIE]
	MSI-X Table Vector	SIMSIVR[VECTOR]
	PCIe Function Binding	Determined by E*a*VBCR and ENETC SR-IOV capability
	Comments VSI has completed message transfer to the PSI through a memory partition copy. VSIMSGSR[MS/MC] may provide additional information about the success of the transfer.	
Virtual Station Interface message received from PSI.	**Device Detect**	VSIIDR[MR]
	Device Enable	VSIIER[MRIE]
	MSI-X Table Vector	SIMSIVR[VECTOR]
	PCIe Function Binding	Determined by E*a*VBCR[NUM_VSI] and ENETC SR-IOV capability
	Comments VSI has received a 16-bit message from the PSI.	
Physical Station Interface received message from VSI *a*, where *a* is the VSI number	**Device Detect**	PSIIDR[MR*a*]
	Device Enable	PSIIER[MR*a*EN]
	MSI-X Table Vector	SIMSIVR[VECTOR]
	PCIe Function Binding	E*a*BCR0[FN]
	Comments PSI has received a message from one of its VSIs through a memory partition copy.	
Physical Station Interface detected FLR by VSI *a*, where a is the VSI number	**Device Detect**	PSIIDR[FLR*a*]
	Device Enable	PSIIER[FLR*a*EN]

	Device Enable	TCCR[ARM], TCIER[TIMEOUT], TCIER[TRANSMIT]
	MSI-X Table Vector	TCMSIVR[VECTOR]
	PCIe Function Binding	S*a*BCR[FN]
	Comments	

Table continues on the next page...

Table 766. Interrupt Classes (continued)

Description	Interrupt Handling
	A receive or transmit timestamp has been captured by the switch or a timeout has occurred. Port for receive timestamp is indicated in the register TCRPSR[RX_PORT]. Port of transmit timestamp is determined by TCIDR[TX_PORTS]. Latency values are captured in P*a*TCMINLR/P*a*TCMAXLR.

NOTE

Wake up interrupt is a power management event and is handled by the Root Complex Event Collector.

The internal/external MDIO controllers are considered embedded functions within NETC. This implies that legacy interrupts are converted to MSI-X events. Legacy interrupts are edge detected to set the port/global interrupt detect register.

53.4.2.11.2 Wired Interrupt

NETC requires the use of a single wired signal for error interrupts which is provided by the iEP-RC (INTA) by means of the Event Controller. All error interrupt events are reported to the Event Controller by internal messaging from NETC operating as an integrated endpoint. The Root Complex Event Collector will assert the PCI INTA pin when properly configured, see Error Reporting.

53.4.2.12 Weighted Bandwidth Fair Scheduling (WBFS) Algorithm

Weighted Bandwidth Fair Scheduling (WBFS) is a method of scheduling packets from queues to a link such that each of the queues get their fair share bandwidth that is proportionate to a weight value assigned to a queue. This algorithm also applies to non-leaf nodes in a hierarchical scheduler structure. The term "class" is used to refer to the input to the WBFS scheduler which can be the queue itself (e.g. ETM class queue) or an aggregation of queues (e.g. channel).

WBFS is used to schedule packets from classes within a group such that each class gets a "fair amount of bandwidth made available to that group. Bandwidth (transmit opportunities) that is made available to a group is fair shared among the classes of that group in proportion to a weight value configured for that class. For example, if class "X" has a weight of 5 and class "Y" has a weight of 1, class "X" has a fair share that is 5 times the fair share of class "Y". The weight values for each class can range from 1 to 248 (in 255 pseudo logarithmic steps), which can be configured differently for each group.

The premises for fairness, follow a max-min weighted fairness principle:

1. available bandwidth is divided and offered to their classes in proportion to their weight
2. offered bandwidth in excess of a class's demand is to be re-offered to classes with unsatisfied demands proportion to their weight

The algorithm classifies classes as underweight classes and overweight classes. Underweight classes are presumed to be classes where their bandwidth demands are satisfied. Overweight classes are presumed to be classes where their bandwidth demands are unsatisfied.

The algorithm:

- Maintains three lists of indices of classes; non-active underweight list, active underweight list and overweight list. The non-active/active underweight lists contain indices of classes that have been determined to be underweight and the overweight list contains indices of classes that have been determined to be overweight.
- The active underweight list is a FIFO ordered list of classes that became non-empty since the last scheduling opportunity. This list is sorted in the order in which the class became non-empty, from the first class becoming active to the last class becoming active.
- The non-active underweight list contains classes with no packets waiting to be transmitted.
- For each overweight class, a debt/deficit value in bytes is maintained. The overweight list is sorted based on the debt value, from the lowest debt value to the highest debt value.

- Confirms all classes as underweight upon initialization or re-initialization; i.e. all classes are put in the non-active underweight list.
- Once a class in the non-active underweight list becomes non-empty, it is moved to the end of the active underweight list.
- Select packets from the classes in the active underweight list before any packets from classes in the overweight list. Within a list (active underweight or overweight), the first element (or class) is selected.
- After selecting a packet from a class in the active underweight list, the class becomes overweight and as a result is moved to the overweight list with a debt value of P where P is equal to the number bytes in the packet transmitted divided by the weight assigned to the class.
- After selecting a packet from a class in the overweight list, the class remains overweight with a debt value of P where P is equal to the number bytes in the packet transmitted divided by the weight assigned to the class. To be fair, for all other classes in the overweight list, P is credited to the debt level of each of these classes down to 0 (debt value doesn't go negative). Once all classes have been updated with their new debt value, the overweight list is sorted based on the debt value, from the lowest debt value to the highest debt value.
- If the selected class from the overweight list is empty, the class is skipped and the next element (or class) in the overweight list is selected.
- A class in the overweight list where its debt becomes completely erased, and is without packets waiting to be transmitted, is moved to the non-active underweight list.
- If all classes are without packets at any point in time the algorithm is re-initialized such that all classes are considered underweight.

53.4.2.13 Hash Table Algorithm

The exact match hash table uses a novel approach when distributing entries to attempt to reduce the number of hash collisions. Any entry inserted into the hash table has 6 possible locations that it could be placed in. The algorithm involved in this attempts to minimize chain length overall, without impacting query time by providing many more possible starting locations for collisions.

When adding a new entry, the lookup key is hashed with a series of bit shifts, swaps and XORs. This hash result will map the lookup key to a specific hash root location in a 3D row x column x plane space. The row directly corresponds to a specific address in the exact match table space. The plane specifies independently addressable parallel portions of external memory[1]. Each plane holds 3 locations for a row. The column then identifies 1 of the 3 locations in that scope. Each location holds a 32b structure that contains the billeting [2] state, the chain length and the root pointer to the exact match table entry. If the location is empty (chain length 0), the new entry is added here. If the location is not empty (chain length >0), the alternate column locations are tested to find which column has the smallest chain length[3] which has not already hosted a billet[2]. If testing an alternate column location results in a lower chain length, it is chosen in place of the predetermined location and the entry is prepended to the chain stored there. The alternate location's billeting state is updated accordingly to capture the hash result indicating where the billet originated. If no lower chain length choice is found, the entry is appended at the end of the chain stored at the predetermined location. If there are no locations available because the chain length has reached the configured maximum (HBTCR[MAX_COL]) then the new entry will not be added.

When searching for an entry, the lookup key is hashed with the same series of bit shifts, swaps and XORs. Again, the hash result maps to a specific row x column x plane hash root location. It is not known if the entry had been placed in an alternate location, so at this time, the 5 alternate columns on the row[3] are first tested for the presence of a matching billeting state value. If found in any of the alternates, the entry will exist as the first entry in the chain. If not found in the alternate columns, the chain at the predetermined location (based on row,column,plane) is traversed to find a matching entry (or confirmation that it is not found).

This algorithm provides a much improved collision distribution compared to a simple single entry collision chain, resulting an a much higher hash space utilization, without sacrificing a maximum bounds to query time (when considering the maximum collision chain value HBTCR[MAX_COL]).

1. The memory holding the hash table entries is physically stored in 2 parallel memory instances, and this allows for even better entry distribution explained below.
2. Billeting here refers to the process by which an entry is placed in a location that is not it's native location.

3. Two alternate column locations exist on the same plane at the same row and 3 alternate column locations exist on the alternate plane at a transformed row. The transformation is based on the hash result, which further 'mixes' the possible locations for any added entry.

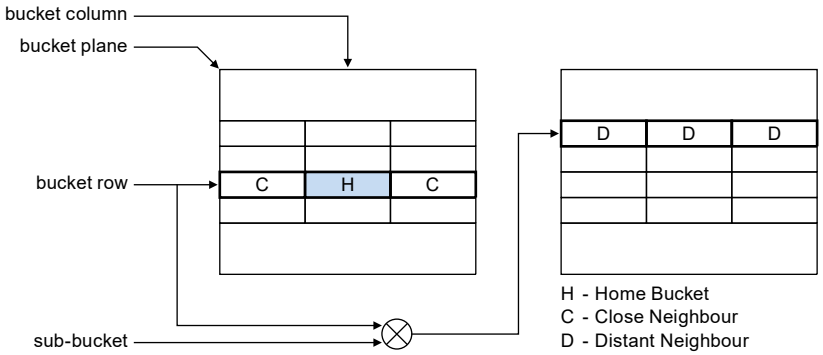

Figure 364. Hash root memory organization

53.4.3 External Signal Description

Table 767. External Signals

Signal Name	Description	I/O
Ethernet		
The MII, RMII and RGMII interfaces are supported on Ethernet (link) 0-4. The GMII interface is supported on Ethernet (link) 3 and 4. Each Ethernet (link) can be configured to connect either to a parallel interface (MII, RMII and RGMII) or a serial (SerDes) interface, using a configuration register on the device. The NETC Ethernet (link) signal mapping to the external parallel interface, is given in Table 768. The NETC Ethernet (link) signal mapping to the on chip SerDes module, is given in Table 769.		
MII_TXCLK	MII transmit clock supplied by the PHY.	I
MII_TXEN	MII Transmit Enable.	O
MII_TXD[3:0]	MII transmit data bus.	O
MII_TXER	Indicates to the PHY that the current transmission data is corrupted, or the transmit is in a low power state.	O
MII_RXCLK	MII receive clock supplied by the PHY.	I
MII_RXDV	Indicates the receive data bus is valid. Asserted beginning with the first preamble byte and lasting until the last CRC byte.	I
MII_RXD[3:0]	MII receive data bus.	I
MII_RXER	Error indication from the PHY, that the current frame contains erroneous data, or the line is in low power state.	I
MII_CRS	Carrier sense. Used for half-duplex mode only.	I
MII_COL	Collision detect. Used for half-duplex mode only.	I
GMII_TXCLK_ENA	Transmit clock enable	I
GMII_TXEN	GMII Transmit Enable.	O
GMII_TXD[7:0]	GMII transmit data bus.	O

Table continues on the next page...

Table 767. External Signals (continued)

Signal Name	Description	I/O
GMII_TXER	Indicates to the PHY that the current transmission data is corrupted, or the transmit is in a low power state.	O
GMII_RXCLK_ENA	Receive clock enable	I
GMII_RXDV	Indicates the receive data bus is valid. Asserted beginning with the first preamble byte and lasting until the last CRC byte.	I
GMII_RXD[7:0]	GMII receive data bus.	I
GMII_RXER	Error indication from the PHY, that the current frame contains erroneous data, or the line is in low power state.	I
RMII_REF_CLK	RMII 50MHz reference clock input	I
RMII_TXEN	RMII Transmit Enable.	O
RMII_TXD[1:0]	RMII transmit data bus.	O
RMII_RXD[1:0]	RMII receive data bus.	I
RMII_RXER	Error indication from the PHY, that the current frame contains erroneous data, or the line is in low power state.	I
RMII_CRS_DV	Carrier sense and receive data valid.	I
RGMII_TXD[3:0]	RGMII transmit data bus [3:0] on rising edge of RGMII_TXC, byte data [7:4] on falling edge.	O
RGMII_TXCTL	RGMII transmit data enable on rising edge of RGMII_TXC, transmit error on falling edge.	O
RGMII_TXC	RGMII transmit clock (output)	O
RGMII_RXD[3:0]	RGMII receive data bus [3:0] on rising edge of RGMII_RXC, byte data [7:4] on falling edge.	I
RGMII_RXCTL	RGMII receive data valid on rising edge of RGMII_RXC, receive error on falling edge.	I
RGMII_RXC	RGMII receive clock (input)	I
ETHn_MDIO		
The Ethernet slave MDIO interface is used for an external MAC to access and configure the PHY features of the external port, when the port is operating in the RevMII mode (IF_MODE[REVMII]=1). There is one slave MDIO interface per external port that supports RevMII. The RevMII mode is supported on Ethernet (link) 2, 3 and 4.		
ETHn_MDC	Input clock, where n represents Ethernet (link) 2, 3 and 4.	I
ETHn_MDIO	Bidirectional data, clocked by ETHn_MDC, where n represents Ethernet (link) 2, 3 and 4.	I/O
EMDIO		
The EMDIO interface is used for access to and configuration of external Ethernet PHYs. Use of this interface is via the global EMDIO function (PF1) or by virtual EMDIO per external port.		
NETC_EMDIOC	Output clock.	O
NETC_EMDIO	Bidirectional data, clocked by EMDIOC. The device supports adding delay on EMDIO data output (command and write data), controlled by EMDIO_CFG[EHOLD] and [MDIO_HOLD].	I/O
IEEE 1588 Timer		

Table continues on the next page...

Table 767. External Signals (continued)

Signal Name	Description	I/O
NETC_TMR_CLK	1588 clock in. External high precision timer reference clock input (chip external input pin). Max 200MHz.	I
NETC_TMR_TRIG1	1588 trigger in 1. External timer trigger input 1.This is an asynchronous general purpose input (chip external input pin).	I
NETC_TMR_TRIG2	1588 trigger in 2. External timer trigger input 2.This is an asynchronous general purpose input (chip external input pin).	I
NETC_TMR_GCLK	1588 clock out. Phase aligned timer clock divider output (chip external output pin).	O
NETC_TMR_PP1	1588 pulse out 1. Timer pulse per period 1. It is phase aligned with 1588 timer clock (chip external output pin).	O
NETC_TMR_PP2	1588 pulse out 2. Timer pulse per period 2. It is phase aligned with 1588 timer clock (chip external output pin).	O
NETC_TMR_PP3	1588 pulse out 3. Timer pulse per period 3. It is phase aligned with 1588 timer clock (chip external output pin).	O
NETC_TMR_ALARM1	Timer current time is equal to or greater than alarm time comparator register. User deactivate this output by writing to the TMR_ALARM1_L register. After deactivating it, the user can rearm the alarm by writing to the TMR_ALARM1_H, enabling the triggered alarm to assert the output (chip external output pin).	O
NETC_TMR_ALARM2	Timer current time is equal to or greater than alarm time comparator register. User deactivate this output by writing to the TMR_ALARM2_L register. After deactivating it, the user can rearm the alarm by writing to the TMR_ALARM2_H, enabling the triggered alarm to assert the output (chip external output pin).	O

In the table below, *n* represents the Ethernet link number (0-4).

Table 768. NETC Ethernet link mapping to parallel interface

53.4.4 Initialization

This section covers the basic steps to configure NETC for basic operation. It is not intended to provide a complete setup of the device as there are many features and parameters that are optional.

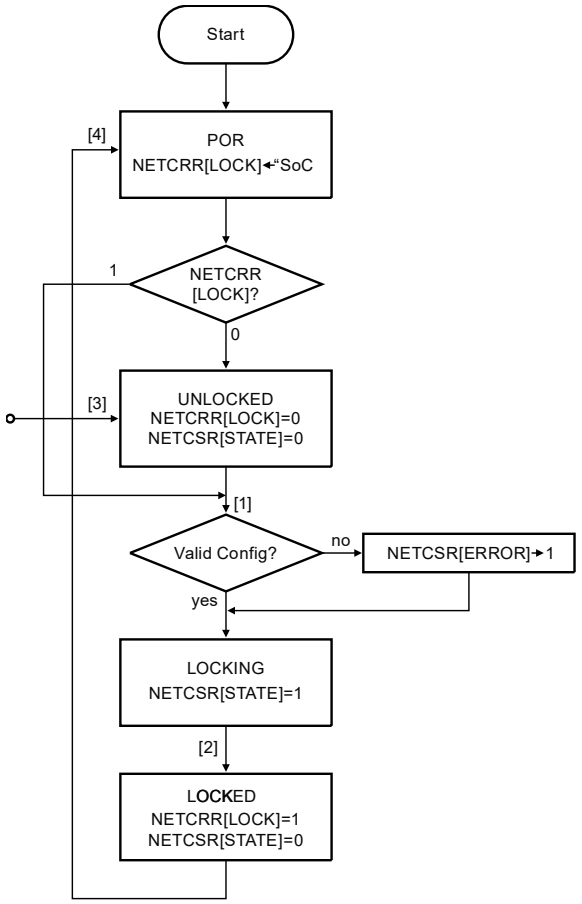
The NETC initialization consists of two initialization stages:

1. Global initialization
2. Functions initialization

53.4.4.1 Global Initialization

Global initialization starts from the device reset state, and involves setting the IERB registers and initializing components that are not associated to one specific function (for example, common memory, Ingress Port Filter TCAM, Time Gate Scheduling Memory, and so on).

The global initialization sequence (or state machine) is shown in the figure below.



POR State
NETCRR[LOCK] reset value is taken from SoC, once SoC releases internal hard reset signal to NETC

UNLOCKED State
In this state IERB registers have normal write access.

LOCKING State
In this state the following occurs:
- Global registers where their PoR values are coming from the IERB registers, are loaded with IERB values
- Free list initialization, etc
- NETCSR[STATE] = 1
  OSR[STATE] = 1 for the switch function and all of the ENETC physical functions.

Write access not allowed to IERB registers, except NETCRR.

LOCKED State
NETC is ready (operational state).
Write access not allowed to IERB registers, except NETCRR.

Transitions
[1] NETCRR[LOCK]←1 **or** PCI_CFH_CMD[MEM_ACCESS]←1(one or more functions).
If IERB is misconfigured while locking, the NETCSR[ERROR] bit is set. This bit is mainly for S/W debug as no trusted entity should initialize IERB incorrectly. Operating while in an error state can cause undefined results.

[2] Initialization completed..

[3] NETCRR[LOCK]←0: Warm Reset (Unlock)
Moving from a locked state to an unlocked state for reconfiguration of IERB registers, forces FLR to all functions, while IERB state remains. See Reset section for details of FLR behavior.

[4] NETCRR[SR]←1: Soft Reset
Return NETC to PoR state, see Reset section for more details.

Figure 365. NETC Global Initialization State Machine

The first part of the global initialization involves setting the IERB registers, which can be set to the PoR IERB values or the updated values from the boot-time software. The latter requires that the IERB be put in the “UNLOCKED” state, before the IERB registers can be updated by the boot-time software. When the IERB enters the LOCKING state, the initialization of global resources starts, which also includes copying of the IERB register values that are used to determine the reset values of the global NETC registers, into their respective global NETC registers.

The global initialization sequence completes when the IERB transitions to the “LOCKED” state, including setting NETCSR[STATE] to 0, which is used to indicate to the boot-time software that the global initialization is completed. Once the global initialization is completed, the initialization of each NETC function can then start.

Below are more details on how IERB registers are initialized during the global initialization sequence.

- **Hard reset** - SoC signals the PoR value of NETCRR[LOCK], before releasing NETC from a hard reset (or PoR).
  - If the PoR value of NETCRR[LOCK] is set 1b, then after NETC is released from the hard reset, the IERB registers are set to their PoR values, and the IERB is transitioned to the LOCKING state.
  - If the PoR value of NETCRR[LOCK] is set 0b, then after NETC is released from the hard reset, the IERB registers are set to their PoR values, and the IERB is transitioned to the UNLOCKED state. The boot-time software then can update the IERB registers. Once the update of the IERB registers is completed, the boot-time software should read NETCSR[ERROR] to ensure the configuration is valid. If valid, then it must set NETCRR[LOCK] to 1b, which then will cause the IERB to transition to the LOCKING state.
- **Soft reset –** A soft reset is initiated by setting NETCRR[SR] to 1. The PoR value of NETCRR[LOCK] comes from PoR value signaled by the SoC, at the time the NETC executes the soft reset sequence.

— If the PoR value of NETCRR[LOCK] is set 1b, then the IERB registers are set to their PoR values, and the IERB is transitioned to the LOCKING state.

— If the PoR value of NETCRR[LOCK] is set 0b, then the IERB registers are set to their PoR values, and the IERB is transitioned to the UNLOCKED state. The boot-time software can poll NETCRR[SR] until it returns 0b, which indicates that the soft reset sequence is completed. It then can proceed with updating the IERB registers. Once the update of the IERB registers is completed, boot-time software should read NETCSR[ERROR] to ensure that the configuration is valid. If valid, then it must set NETCRR[LOCK] to 1b, which will cause the IERB to transition to the LOCKING state.

- **Warm reset –** A warm reset is initiated by setting NETCRR[LOCK] to 0b. This triggers the IERB to transition to the UNLOCKED state, with the IERB register retaining their values. The boot-time software can poll NETCRR[LOCK] until it returns 0b, which indicates that the warm reset sequence is completed. It then can proceed with updating the IERB registers. Once the update of the IERB registers is completed, the boot-time software should read NETCSR[ERROR] to ensure that the configuration is valid. If valid, then it must set NETCRR[LOCK] to 1b, which will cause the IERB to transition to the LOCKING state.

53.4.4.2 Functions Initialization

The initialization of each function must be invoked after global initialization completes. A function initialization must also be invoked after its function level reset.

After the global initialization is completed, and prior to start the initialization of each NETC function, standard PCIe enumeration and discovery techniques can be used to find out the capabilities/functions supported by NETC. This includes timer, EMDIO, switch and ENETC functions. If SR-IOV capability is supported, number of VFs (virtual station interfaces) can be discovered. Base addresses for accessing device registers are determined by the PCIe Enhanced Allocation Capability structure. However, it is not necessary to discover these addresses through PCIe enumeration because these addresses are fixed and known for a given SoC address map. The BARs in ECAM are not used.

53.4.4.2.1 Common Function Initialization

The common function initialization procedures are illustrated in the figure below.

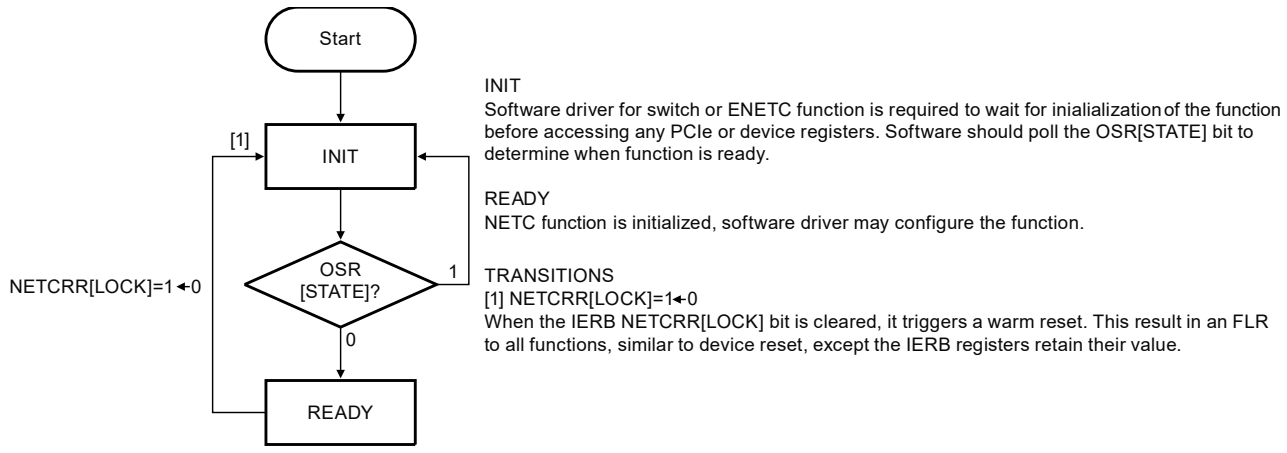


Figure 366. NETC function initialization

Perform the following initialization steps for each NETC function (non-virtual and virtual functions).

1. **Enable the function** – The initialization steps is dependent on whether the function is non-virtual or virtual. Enabling the function will load the IERB register values into the function registers, and then start the initialization of the function.

    a. **Non-virtual function** - Enable the function to master memory transaction requests by setting PCI_CFH_CMD[BUS_MASTER_EN] to 1b, and to respond to memory space accesses (register accesses), by setting PCI_CFH_CMD[MEM_ACCESS] to 1b.

b. **Virtual function** - VFs must be enabled in their corresponding PF's ECAM registers by setting VF_ENABLE and VF_MSE in the PF's PCIE_CFC_SRIOV_CTL register, to 1b. Each VF must then be enabled by setting their PCI_CFH_CMD[BUS_MASTER_EN] to 1b.

2. **Ensure the function is operationally ready** – For the switch or ENETC physical function where initialization may take some time, poll the OSR[STATE] bit to determine when the function is ready for configuration. When OSR[STATE] returns 0b, the function is operationally ready, and can now be configured. Before proceeding with configuration, OSR[ITM_STATE] should be checked to ensure that the sum of all index tables do not exceed the allotted memory size.
3. **Enable MSI-X interrupt** – If interrupt is going to be supported for a function, perform the following steps. See Message Signaled Interrupt (MSI-X), for more information.
    a. For each ENETC function, set/assign PSInCFGR2[NUM_MSIX] (where n is the SI number) based on the maximum MSI-X number indicated in ECAPR1[NUM_MSIX].
    b. Read PCI_CFC_EA_PE1_BASE (ENETC/timer/EMDIO/switch) or PCI_CFC_EA_PE3_BASE (virtual function) to determine the base address of the functions MSI-X table.
    c. Write the table vector entry, as selected by register specified by "MSI-X Table Vector" in Interrupt Classes, with address and data information (ensure that the per-vector mask bit is set to 0b).
    d. Enable MSI-X table by setting PCI_CFC_MSIX_MSG_CTL[MSIX_EN] to 1b and unmask interrupt generation by setting PCI_CFC_MSIX_MSG_CTL[FUNC_MASK] to 0b.
    e. Set the corresponding function vector registers and enable the selected interrupt using the register defined by "Device Enable" in Interrupt Classes.

53.4.4.2.2 ENETC Physical Function Basic Configuration

Perform the following configuration steps for each ENETC physical function:

1. **Discover ENETC physical function capabilities** – Software can read the ENETC capability registers to determine such things as number of Rx/Tx BD rings available, index table sizes, port features and Ethernet links bound to the ENETC instance, and so on. Then follow with the required port configuration (for example, MAC port speed, interface mode) and feature configuration.
2. **Index table memory configuration -** An ENETC instance may resize its index tables as needed within the index table memory size, specified by ITMCAPR[NUM_WORDS]. Afterwards, the OSR[ITM_STATE] must be read to ensure that the sum of all index tables do not exceed the allotted memory size. The function will not be able to configure any index table memory entries unless memory is properly configured.
3. **Tx/Rx BD ring assignment to SIs -** Distribute the Tx/Rx BD rings as necessary among SIs enabled for the ENETC instance. By default, all Tx/Rx BD rings available to the ENETC instance are assigned to the PSI.
4. **Configure the ENETC primary MAC addresses** – Set register PMAR0/1 for SI 0 and PSIaPMAR0/1 for SI 1, 2 .. a (optionally pre-configured in IERB).
5. **Allow SIs to be enabled** – Set PMR[SIaEN] to 1b for every SI present under the ENETC instance. By default, the PSI (SI 0) is set to 1b.
6. **Enable the PSI** - Enable the PSI to operate by setting SIMR[EN] to 1b. By default, the PSI (SI 0) is enabled.
7. **Configure Command BD ring** - Configure Command BD ring for the PSI. For more details, see Table Management Commands.
8. **Configure Tx/Rx BD rings** - Configure Tx/Rx BD rings for the PSI. For more details, see Transmit Buffer Descriptor Rings and Receive Buffer Descriptor Ring.
9. **Enable Tx MAC datapath**
    a. Set PM0_COMMAND_CONFIG[TX_EN] to 1b; this step is not applicable for a pseudo MAC.
    b. Set POR[TXDIS] to 0b.
10. **Enable Rx MAC datapath**

a. Set POR[RXDIS] to 0b.

b. Set PM0_COMMAND_CONFIG[RX_EN] to 1b; this is step is not applicable for a pseudo MAC.

53.4.4.2.3 ENETC Virtual Function Basic Configuration

Perform the following configuration steps for each ENETC virtual function:

1. **Discover ENETC virtual function capabilities** – Software can read the ENETC SI capability registers to determine such things as number of Rx/Tx BD rings available, offload features present, and so on. Then follow with the required feature configuration.
2. **Enable the VSI** - Enable the VSI to operate by setting SIMR[EN] to 1b.
3. **Configure Command BD ring** - Configure Command BD ring for the PSI. See Table Management Commands for more details.
4. **Configure Tx/Rx BD rings** - Configure Tx/Rx BD rings for the VSI. See Transmit Buffer Descriptor Rings and Receive Buffer Descriptor Ring, for more details.

53.4.4.2.4 Switch Basic Configuration

Perform the following configuration steps for each switch basic function:

1. **Discover switch function capabilities** – Software can read switch capability registers to determine such things as index table sizes, port features and Ethernet links bound to the switch, features present, and so on. Then follow with the required port configuration (for example, MAC port speed, interface mode) and feature configuration.
2. **Index table memory configuration -** A switch may resize its index tables as needed within the index table memory size, specified by ITMCAPR[NUM_WORDS]. Afterwards, the OSR[ITM_STATE] must be read to ensure that the sum of all index tables do not exceed the allotted memory size. The function will not be able to configure any index table memory entries unless memory is properly configured.
3. **Configure Command BD ring(s)**- Configure command BD ring(s) for the switch. See Table Management Commands, for more details.
4. **Enable switch for basic forwarding** - Currently, after power-on-reset, switch configuration is such that no packets are forwarded to the egress ports. So, the following basic configuration is needed to enable switch to forward packets:
    a. **Configure the VLAN filter hash table default entry configuration register 0 (VFHTDECR0)** – By default, to enable forwarding to all ports, set port bitmap in VFHTDECR0[PORTn] to 01b for every switch port.
    b. **Configure the VLAN filter hash table default entry configuration register 2 (VFHTDECR2**) - Out of reset, hardware MAC learning is enabled and FDB lookup (Table ID 15) is performed, and therefore, while transmitting a frame if there is no match, the frame is flooded. This configuration can be changed using the VLAN filter hash table default entry configuration registers 2 (VFHTDECR2).
    c. **Configure the Bridge port spanning tree group state register (BPSTGSR**) - BPSTGSR is configured for all supported switch ports. Set the BPSTGSR[STG_STATE] to 2 (forwarding) for all the STG groups.
5. **Enable Tx MAC datapath**-For every switch port, perform the following steps:
    a. Set PM0_COMMAND_CONFIG[TX_EN] to 1b; this is step is not applicable for a pseudo MAC.
    b. Set POR[TXDIS] to 0b.
6. **Enable Rx MAC datapath**-For every switch port, perform the following steps:
    a. Set POR[RXDIS] to 0b.
    b. Set PM0_COMMAND_CONFIG[RX_EN] to 1b; this step is not applicable for a pseudo MAC.

53.4.4.2.5 Timer Basic Configuration

For the timer initialization steps, refer to Initialization.

53.4.4.2.6 EMDIO Basic Configuration

For the EMDIO initialization steps, refer to PHY Management Interface (MDIO).

53.4.5 Application Information

This section describes the usage models for the following functional areas:

1. Forwarding Database (FDB) entry aging, and
2. Spanning Tree Protocol (STP) support

53.4.5.1 FDB Entry Aging Usage Model

53.4.5.1.1 NETC Aging Support

Aging of the FDB entries refers to the process of deleting the entries in the FDB table that have not been used for some time. An FDB entry is not used if no frames are forwarded to the MAC address stored in the FDB entry. If an FDB entry has not been used during a period of the aging time, the entry is eligible to be deleted. A typical aging time is in the order of 300 seconds or 5 minutes. However, the aging time is normally configurable, and the exact value used may depend on many factors.

It is worth noting that in most applications, it is not overly important for the aging procedure to age the entries at precisely the times they are expected to be aged. This is why the aging times are normally expressed in the units of seconds or minutes and not, for example, in milliseconds. In other words, it is often acceptable to delete the aged FDB entries with a lower time accuracy.

In NETC, FDB entries can be added to the FDB table (table ID 15) either by software or autonomously by hardware. If enabled, hardware can add or update FDB entries while processing a frame. While software can add either static or dynamic FDB entries, hardware can only add dynamic FDB entries. In normal circumstances the process of aging of the FDB entries applies only to the dynamic entries. The static FDB entries are normally never aged; they are intended to stay in the FDB table for longer periods of time, i.e., until they are explicitly removed by the application.

In NETC the process of aging of the FDB entries does not happen autonomously in hardware; software needs to be involved in order to implement the FDB entry aging function. NETC hardware does not delete the aged entries automatically nor it determines directly if an entry has aged or not. However, the following hardware mechanisms are available and can be used to assist software and make it relatively easy to implement the FDB entry aging function:

1. FDB entry activity flag - when hardware matches on an FDB entry (based on the DMAC) while processing a frame, it sets the activity flag in the entry to indicate that the entry has been used by hardware.
2. FDB entry activity counter - when hardware processes an activity update management command for an entry in the FDB table and the entry does not have its activity flag set, the activity counter is incremented. If, however, the activity flag is set, then both the activity flag and activity counter are reset. Software can issue the activity update management commands at predefined times and the value of the activity counter can then be used to estimate the period of how long an FDB entry has been inactive.
3. Management command search access method - while issuing an activity update management command for the FDB table, software can use the search access method to update the activity element of multiple FDB entries with a single management command. For example, a single activity update management command could be used to process all the dynamic entries in the FDB table. Similarly, a single delete management command could be used to delete all the FDB entries that match certain search criteria. Being able to use a single activity update or delete command instead of multiple commands can make the associated software logic much simpler.

An important factor in developing the aging strategy is the number of the FDB entries, in particular the number of the dynamic entries, that are supported in the system. In NETC the entries of the FDB table are stored in a dedicated internal memory together with the entries of all the other hash-based tables. The number of the memory entries allocated to all the hash-based tables in a switch is controlled through the IERB switch 0 hash table memory allotment register (S0HTMAR).

The number of the dynamic entries that can be created in the switch is controlled by the value of the DYN_LIMIT field of the FDB hash table memory configuration register (FDBHTMCR). Naturally, the switch entry limit should not be larger than the number of entries available in the hash table memory. The per switch port number of the dynamic entries that can be created is controlled by the value of the DYN_LIMIT field of the bridge port configuration register (BPCR). Again, any of the port entry limits should not be larger than the overall switch entry limit.

The above memory and entry limits have power on default values that are suitable for most of the typical applications. These power on default values can be modified if needed.

53.4.5.1.2 NETC Usage Model Overview

In NETC, software has flexibility in how it may implement the aging of the FDB table entries. In this section we provide an overview of one possible implementation and also point out some alternations and modifications to this implementation that could be exploited.

In general, the aging process involves two main procedures. One is to identify the FDB entries that have aged and the other one is to delete the aged entries. We consider these procedures one by one.

53.4.5.1.2.1 Aging of FDB Entries

To decide if an FDB entry has aged or not one must measure the time of how long the entry has not been used and compare it with the desired aging time. In NETC, the FDB table entries do not feature any entry creation or usage timestamps or autonomous counters, however, each entry features, the mentioned earlier, activity counter. Therefore, software can issue an FDB activity update management message which, if the entry continues to be unused, results in incrementing the FDB activity counter. Issuing such activity update management messages at specific times or with a specific period can provide a good estimate of how long an FDB entry has been inactive.

For example, if the activity update management messages were issued every minute, then an entry with an activity counter with a value of 5 would indicate that the entry has not been used in the last 5 to 6 minutes. If such activity update management commands used the search access method set to match the dynamic entries, then each such command would update the activity counter for all the dynamic FDB entries currently present in the FDB table.

In other words, a single activity update management command issued periodically with a relatively large period, e.g., one minute or more, could be used to update the activity counters in all the dynamic entries present in the FDB table providing inactivity time estimates for all these entries.

53.4.5.1.2.2 Deleting of Aged FDB Entries

With the inactivity time estimates available through the values stored in the activity counters, what is left to complete the FDB entry aging process is to delete the FDB entries that are considered to have aged. This could be done with a delete management command using the search access method set to match on the dynamic entries with a specific value of the activity counter. For example, such a delete management command could be issued periodically, e.g., every minute, and delete all the dynamic FDB entries with the activity counter having the value of 5.

53.4.5.1.2.3 Usage Model Summary

To sum up, in order to implement the FDB aging function, software can periodically issue an FDB table activity update and entry delete management commands. The aging time can be adjusted by modifying the period of how often the management commands are issued and also by choosing the activity count value, used as a search criterion in the delete command.

Consider the example depicted in the figure below. As shown, software periodically issues multi-entry search activity update and delete management commands. There are six such activity update and delete management commands shown. Each of the activity update commands processes all the dynamic FDB entries present in the table. Each of the delete commands attempts to delete all the dynamic FDB entries with the activity counter value of four (4). This means that the aging time in the example is equivalent to the time needed for the activity counter to reach the value of four.

Each of the triangle, square and circle symbols on the horizontal time axis in the middle of the figure indicates a time when a frame arrives at a switch port. Each of the three shapes indicates frames with a distinct destination MAC address. In other words, the triangle shape indicates one destination MAC address value, the square shape indicates another MAC address value, and the circle shape indicates a third MAC address value. There is one triangle frame, three circle frames and four square frames shown.

The FDB entries associated with the triangle, square and circle addresses are shown below the time axis. The states of these FDB entries are shown at times t_1, t_2, t_2, t_3, t_4, t_5, and t_6.

At time t_1 there are three dynamic entries present in the FDB table. The three entries correspond to the mentioned above triangle, square and circle MAC addresses. All three entries have their activity flag (F) reset (0) and the activity counter value (C) of zero

(0). Though it is not shown in the figure, it could be assumed that the triangle, square and circle entries were created by hardware when the frames with the triangle, square and circle source MAC addresses arrived at the switch prior to time t_1.

During the (t_1, t_2) time interval one triangle, one square and one circle frame arrive at the switch. The arrival of these frames results in setting the activity flags in all three entries. However, at time t_2 the three FDB entries look the same as they did at time t_1. This is because the activity update command issued before time t_2 resulted in resetting the activity flags and counters in all three entries.

During the (t_2, t_3) time interval one circle frame arrives at the switch before the activity update command is issued. Therefore, at time t_3 the FDB entry with the circle address has the activity flag and counter reset. The other two entries are not active (F=0), and their activity counter values are incremented to 1.

During the (t_3, t_4) time interval one square frame arrives before the activity update command is issued and one circle frame arrives after the activity command is issued. Therefore, at time t_4 the square FDB entry has the activity flag and counter reset. The circle FDB entry has the activity counter incremented to 1 by the activity update command and the activity flag set when the frame is received. The triangle entry continues to be inactive, so its activity counter value is incremented to 2.

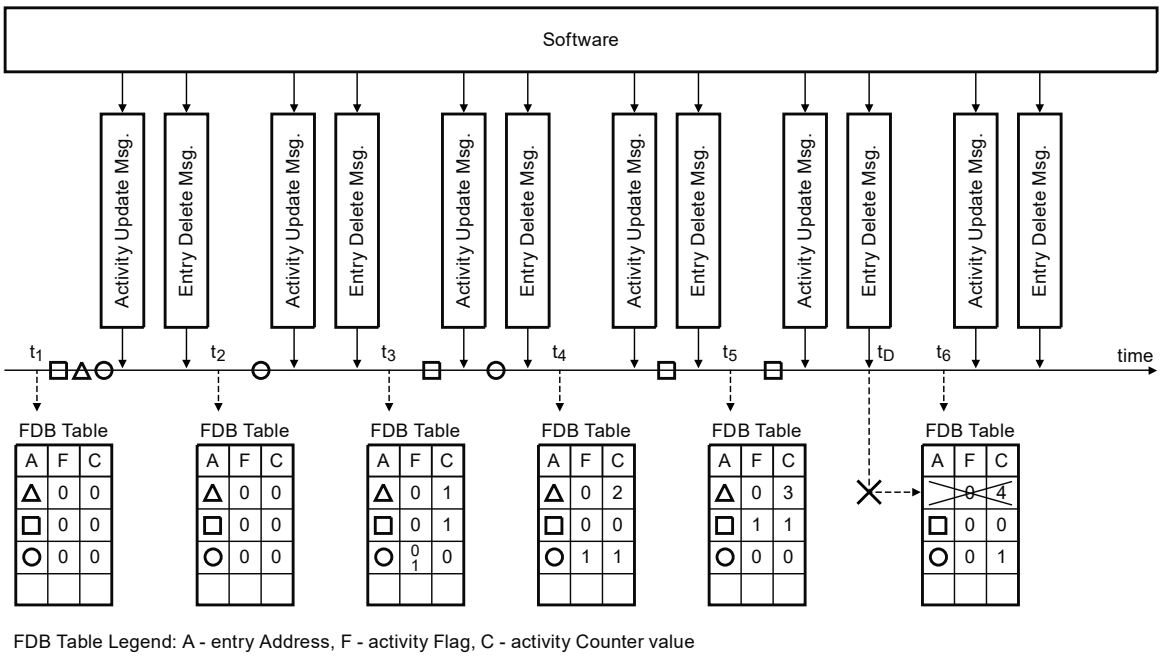

Figure 367. FDB Entry Aging Usage Model

During the (t_4, t_5) time interval one square frame arrives at the switch after the activity update command is issued. Therefore, at time t_5 the FDB entry with the square address has the activity counter value incremented to 1 by the activity update command and the activity flag set by the arrival of the frame. The previously active circle entry has its activity flag and counter reset by the activity update command. The triangle entry continues to be inactive and its activity counter value increments to 3.

During the (t_5, t_6) time interval one square frame arrives at the switch before the activity update command is issued. Therefore, at time t_6 the FDB entry for the square address has the activity flag and counter reset. The circle entry is inactive, so its activity counter value is incremented to 1. The triangle entry continues to be inactive and its activity counter value increments to 4 when processing the activity update message. The triangle entry has aged, and it became eligible for deletion. The delete command arriving at time tD results in deleting the triangle FDB entry so that at time t_6 the triangle entry is not present in the table anymore.

The procedure described in this section is an introduction into how software may implement the aging of the FDB entries in NETC.

53.4.5.1.3 Implementation Consideration

53.4.5.1.3.1 Exact Match of the FDB Activity Count Value

The value of the FDB entry activity counter can be used as the search criterion in search management commands such as multi-entry update, delete or query commands. In NETC, hardware matches on the exact activity counter value specified in the command. For example, if the specified activity counter value is 10, hardware will match on the value 10 and not on any other value, including values greater than 10. This in turn means that if an FDB entry is to be processed, e.g., queried or deleted, when its activity counter reaches the value of 10, the entry needs to be processed before the counter value increments. If the counter value is allowed to increment to 11 or a higher value, the activity counter value match criterion of 10 would result in no match for this entry.

As mentioned before, in the context of aging of the FDB entries, the activity counter match criterion can be used in the multi-entry delete management commands. In order to reliably delete the FDB entries with a certain value of the activity counter, software must ensure that the entries are deleted before their activity counter value could be incremented. One way to achieve this is to issue the aging activity update and delete management commands with the same frequency or the same period. In other words, each aging activity update command is always followed by an aging delete command which is followed by the next activity update command, etc. This ensures that the FDB activity counter values are not incremented beyond the value at which they are to be deleted.

53.4.5.2 Spanning Tree Protocol Usage Model

53.4.5.2.1 Usage Model Overview

The switch component of the NETC provides support for the Spanning Tree Protocol (STP) and the Multiple Spanning Tree Protocol (MSTP). STP variants such as the Rapid Spanning Tree Protocol (RSTP) are also supported. The STP support allows for basic interconnect of multiple Ethernet switches with redundant paths, without forwarding loops. Currently, NETC supports up to 16 concurrently active STP groups.

In NETC, the STP support takes place in the context of ingress and/or egress VLAN frame processing. During the VLAN processing of a frame, hardware first establishes which STP group the frame being processed is associated with. Once this is done, hardware retrieves the current STP port state for the established STP group and, depending on the STP port state value, the frame is either allowed to ingress or egress the system or it is dropped.

Note that the VLAN frame processing is not applied to frames being "stream forwarded". When the stream forwarding function is selected, the 802.1Q bridge forwarding function (includes VLAN frame processing) is by-passed.

The initial STP group ID to use is stored by software in the spanning tree group member ID (STG_ID) field of the switch VLAN filter table default entry configuration register (S0VFHTDECR0). This initial STP group ID is associated with all the frames ingressing into the switch. The STP group ID to use may then be modified depending on the result of the ingress VLAN filter table lookup. If the VLAN filter table lookup resulted in a match, then the STP group ID in the found entry is used. If the VLAN filter table lookup resulted in a miss, then the initially determined STP group ID is used. The STP group ID values stored in the VLAN filter table entries are, of course, controlled by software.

Once the STP group ID to use has been determined, hardware uses it to retrieve the current STP state of the port to decide how to process the frame. The port STP state values for all the supported STP groups are stored in the bridge port spanning tree group state registers (BPSTGSRs). The port STP state values for all the supported STP groups are, of course, controlled by software.

On ingress, after determining the STP state of the ingress port, the decision is made if the frame should trigger the learning action, be dropped, or processed further. On egress, the STP state of the egress port is used to decide if the frame should be dropped or transmitted. Note that at any given time, different egress ports may have different STP state values associated with them. This means that if a frame is replicated it could, depending on the port STP state value, successfully egress on some ports and be dropped on other egress ports.

In summary, the NETC STP support in a switch is controlled by software through the spanning tree group member ID (STG_ID) field of the switch VLAN filter table default entry configuration register, the bridge port spanning tree group state registers and the VLAN filter table entries. Software can modify the STP related fields in these registers and table entries and hardware uses these software supplied values while processing the frames.

The figure below illustrates this graphically. The figure shows the STP processing steps during the ingress frame processing. Initially, STG_ID* is assigned to the frame using the value found in the switch VLAN filter table default entry configuration register. Then a lookup is performed into the ingress VLAN filter table. If the lookup results in a match, the STG_ID found in the table entry is

used. The final STG_ID value is used to retrieve the STG group state for the port of interest and the frame is processed according to this STG group state value.

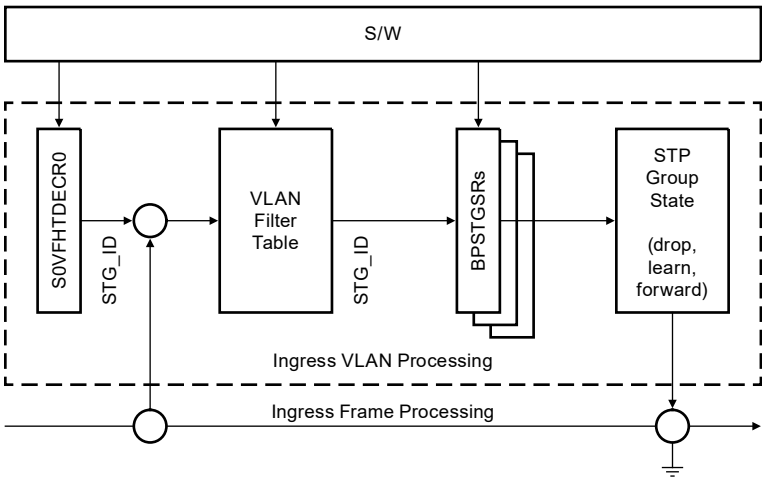

Figure 368. NETC Frame Ingress STP Processing

During the egress processing of the frame, the frame STG ID determined during the ingress processing is used once more to retrieve the current STG group state for the egress port of interest. This takes place for each egress port the frame egresses on.

53.4.5.2.2 Implementation Considerations

The STG_STATE fields in the bridge port spanning tree group state register (BPSTGSR) are 2 bits in size. Out of the 4 possible combinations available with the 2 bits, 3 are used to define STP states and the 4th one is reserved.

While RSTP protocol uses three states, the original STP protocol uses five states. While software can maintain all the five STP states, only three state values can be stored in the BPSTGSR register. In order to represent the five STP states with only the three available states in the STG_STATE field, the state mapping shown in the table below is recommended:

Table 770. Mapping of STP Protocol States to STG_STATE Field States

STP Protocol States	STG_STATE Field States
Disabled	Disabled
Blocking	Disabled
Listening	Disabled
Learning	Learning
Forwarding	Forwarding

The suggested state mapping results in the expected STP protocol behavior in which frames are dropped in the Disabled, Blocking, Listening and Learning STP states, learning takes place only in the Learning STP state and forwarding of frames takes place only in the Forwarding STP state.

53.4.6 Register Descriptions

NOTE

Systems may have software which runs at different privilege levels. In this document the term privileged or privileged software refers to the most privileged software layer, which could be Virtual Memory Manager (VMM) an operating system or software hypervisor.

This section provides a detailed description of all accessible NETC memory and registers. Virtualization and isolation is accomplished through the separation of registers using different PCI BARs. The overall mapping of these spaces, within the PCI Express memory allocated for NETC, can be seen in table Table 356. Features surrounding a multiple port implementation may have asymmetric capabilities, i.e. VSIs and transmit/receive rings.

PCIe register are byte accessible, while device registers are 32-bit only. Transactions larger than 32-bit to NETC memory mapped space are not supported, and will result in transaction error. 64-bit counters are represented as two 32-bit registers with a lower index 0 and upper index 1. For a consistent reading of a 64-bit counter, the lower index 0 must be read first, followed by index 1.

Reserved bits should be written with 0 and ignored on read. Unimplemented registers within a switch, ENETC and VSI function's address space reads as zero and returns a transaction error, while writes have no effect and may return error for some register implementations. A write to read-only register return an error only if specifically noted in the register description. For all other functions and mapped address spaces, including EMDIO, timer and PCIe, unimplemented registers return zero and will not generate an error, while writes have no effect. All other accesses to unmapped address space (not covered by a functions BARs) will result in a transaction error.

Dynamic Resource Allocation

Transmit and receive buffer descriptor rings is a generic resource which is bound to an ENETC instance through IERB registers at pre-boot time. The ENETC device driver is then allowed to allocate rings per station interface prior to enabling access to virtual station interfaces. Virtual Station Interfaces (VSIs) follow the same generic resource scheme as buffer descriptor rings, and are bound to an ENETC instance through IERB registers at pre-boot time. The ENETC device driver is then allowed to allocate MSI-X vectors to virtual station interfaces, prior to enabling them.

Switch Instance Memory Map

The switch memory map is 1MB. It includes the mapping of link specific port registers into the address space. The port registers are only present if there is a link bound to the switch port. The type of port depends on the link capability register L*a*CAPR and the link binding register L*a*BCR. The table below shows the register layout of the switch address space.

Table 771. Switch Instance Memory Mapping

Address Offset	Registers
0x0_0000 - 0x0_0FFF	Switch Specific Registers
0x0_1000 - 0x0_1FFF	Switch / ENETC Common Registers
0x0_2000 - 0x0_2FFF	Switch Service Registers
0x0_4000 - 0x0_7FFF (+ 0x4000*p)	Ethernet or Pseudo Link Port *p* (see Table 773)
0x1_0000 - 0x1_FFFF	NETC Global (Read-Only)

ENETC Instance Memory Map

The ENETC memory map is 256KB. It includes the mapping of port-link registers into the address space. The port registers are only present if there is a link bound to the ENETC instance. The type of port depends on the link capability register L*a*CAPR and the link binding register L*a*BCR. The table below shows the register layout of the ENETC address space.

Table 772. ENETC Instance Memory Mapping

Address Offset	Registers
0x0_0000 - 0x0_FFFF	Station Interface Registers (see Table 774)
0x1_0000 - 0x1_0FFF	ENETC Specific Registers
0x1_1000 - 0x1_1FFF	Switch / ENETC Common Registers
0x1_2000 - 0x1_2FFF	ENETC PSI Registers

Table continues on the next page...

Table 772. ENETC Instance Memory Mapping (continued)

Address Offset	Registers
0x1_4000 - 0x1_7FFF	Ethernet or Pseudo linkPort (see Table 773)
0x2_0000 - 0x2_FFFF	NETC Global (Read-Only)

The NETC architecture has a set of links that are bound to either an ENETC or a switch function. There are two types of links supported; Ethernet-link which attaches to either an ENETC or switch port, and a pseudo link which connects an ENETC and switch port together. These links and the corresponding ENETC/switch ports has physical registers associated with them. As these links are bound to an ENETC/switch function, these port-link registers will appear in the functions memory map. The table below shows the layout of registers within the 16KB port-link address space. See the ENETC and switch base memory map for the location of the port-link registers.

Table 773. Generic Port-Link Memory Mapping

Address Offset	Registers
0x0000-0x03FF	Common port registers
0x0400-0x0FFF	ENETC / Switch specific port registers
0x1000-0x13FF	Pseudo MAC registers [Pseudo link type only]
0x1000-0x13FF	Port Express MAC [Ethernet link type only]
0x1400-0x17FF	Port Preemptable MAC [Ethernet link type only]
0x1800-0x1BFF	Port MAC Merge Registers [Ethernet link type only w/ frame preemption support]
0x1C00-0x1CFF	EMDIO PHY Access Registers [Ethernet link type only]
0x1D00-0x3FFF	Reserved

The ENETC station interface memory map is 64KB and is part of the 256KB ENETC instance memory map. All transmit and receive BD rings are by default bound by IERB register to station interface 0. These can be assigned to other station interfaces, if available, for the ENETC instance during the configuration process.Note that the physical station interface (PSI/SI0) differs slightly from the virtual station interface(s) (VSI/SI1+) register definition.

Table 774. ENETC Station Interface Memory Mapping

Address Offset	Registers
0x0000-0x00FF	General config/status
0x0100-0x01FF	VLAN config

0x1_0000 - 0x1_FFFF	NETC Global (Read-Only)

IERB Memory Map

Within the 16MB address space allocated to the Integrated Endpoint Root Complex by the SoC, a 64KB Integrated Endpoint Register Block (IERB) exists for each endpoint. This is used for pre-boot initialization, debug and non-customer configuration. The table below shows how the IERB memory space is organized.

Table 777. Integrated Endpoint Register Block Memory Map

Address Offset	Registers
0x0000-0x000C	NETC capability
0x0020-0x007F	Memory Capability
0x0080-0x01FF	Memory and Table Configuration
0x0200 + 0x10*r	Root Complex Instance r Configuration
0x0300-0x03FF	EMDIO Instance Configuration
0x0400 + 0x40*t	Timer Instance t Configuration
0x0800 + 0x20*l	Link l Capability and Binding
0x1000 + 400*w	Switch Instance w Configuration
0x2000 + 0x100*e	ENETC Instance e Configuration
0x4000 + 0x100*v	VSI Instance v Configuration

Privileged Memory Map

Within the 16MB address space allocated to the Integrated Endpoint Root Complex by the SoC, a 64KB Reserved Register Block exists for each endpoint. This is used for reset control and error handling during functional operation. The table below shows how the privileged memory space is divided.

Table 778. Privileged Register Block Memory Map

Address Offset	Registers
0x0100-0x01FF	NETC reset control and configuration status

53.4.6.1.2 PCI device ID and vendor ID register (PCI_CFH_DID_VID)

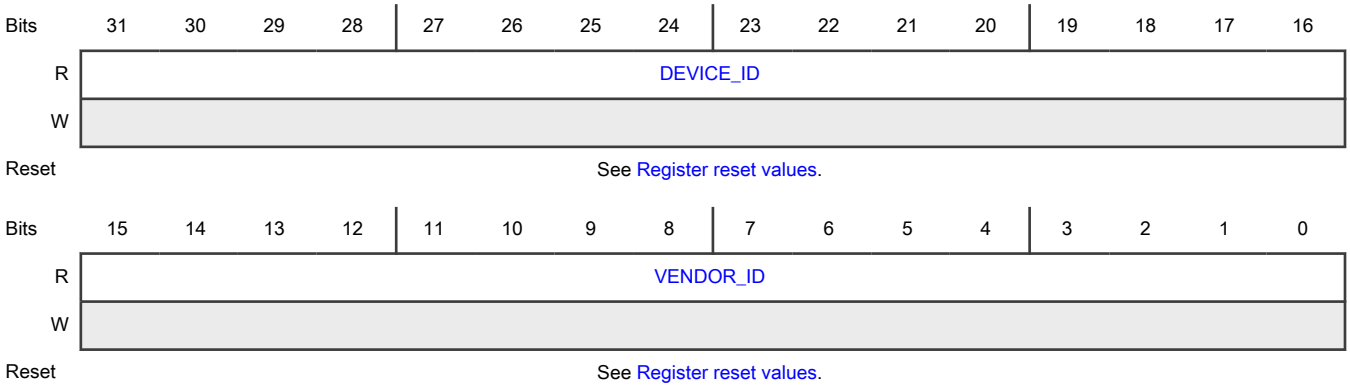
Offset

Register	Offset
PCI_CFH_DID_VID	0h

Function

This is the PCI config header device and vendor ID register. The value read is taken from IERB register <FUNC>__CFH_DIDVID.

Diagram



Register reset values

Register	Reset value
PCI_CFH_DID_VID	NETC_F0_PCI_HDR_TYPE0: EE02_1957h NETC_F1_PCI_HDR_TYPE0: EE00_1957h NETC_F2_PCI_HDR_TYPE0: EEF2_1957h NETC_F3_PCI_HDR_TYPE0: E101_1957h NETC_F4_PCI_HDR_TYPE0: E110_1957h

Fields

Field	Function
31-16 DEVICE_ID	Device ID This field identifies the device ID of the device. This field in all VFs returns FFFFh when read. For SR-IOV the VF device ID is determined from the VF Device ID field in the SR-IOV capability register.
15-0 VENDOR_ID	Vendor ID This field identifies the manufacturer of the device.

53.4.6.1.3 PCI command register (PCI_CFH_CMD)

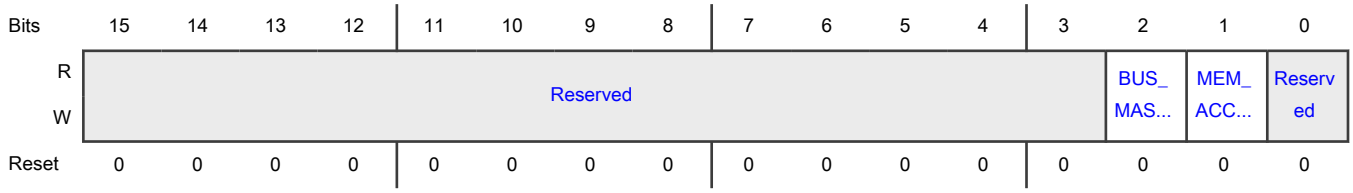
Offset

Register	Offset
PCI_CFH_CMD	4h

Function

This is the PCI config header command register.

Diagram



Fields

Field	Function
15-3 —	Reserved
2 BUS_MASTER_EN	Bus master enable Controls the ability of a PCI Express Endpoint to issue Memory and I/O Read/Write Requests. When this bit is Set, the PCI Express Function is allowed to issue Memory or I/O Requests. When this bit is Clear, the PCI Express Function is not allowed to issue any Memory or I/O Requests. Note that as MSI/MSI-X interrupt Messages are inband memory writes, setting the Bus Master Enable bit to 0b disables MSI/MSI-X interrupt Messages as well.
1 MEM_ACCESS	Controls a device's response to memory space accesses. 0 Disabled 1 Enabled
0 —	Reserved

53.4.6.1.4 PCI status register (PCI_CFH_STAT)

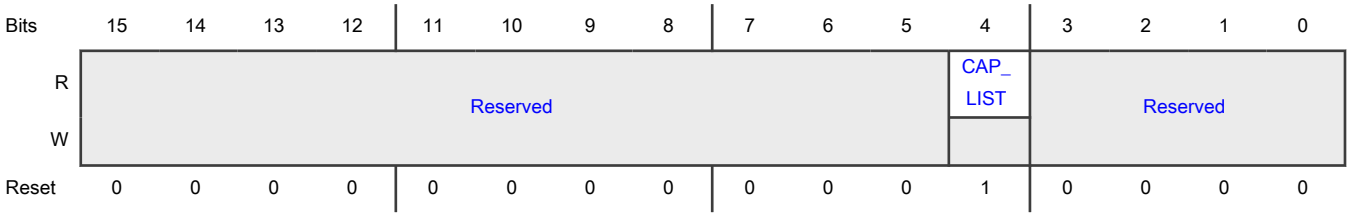
Offset

Register	Offset
PCI_CFH_STAT	6h

Function

This is the PCI config header status register.

Diagram



Fields

Field	Function
15-5 —	Reserved
4 CAP_LIST	Capabilities List Indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, this bit must be hardwired to 1b.
3-0 —	Reserved

53.4.6.1.5 PCI revision ID and classcode register (PCI_CFH_REVID_CLASSCODE)

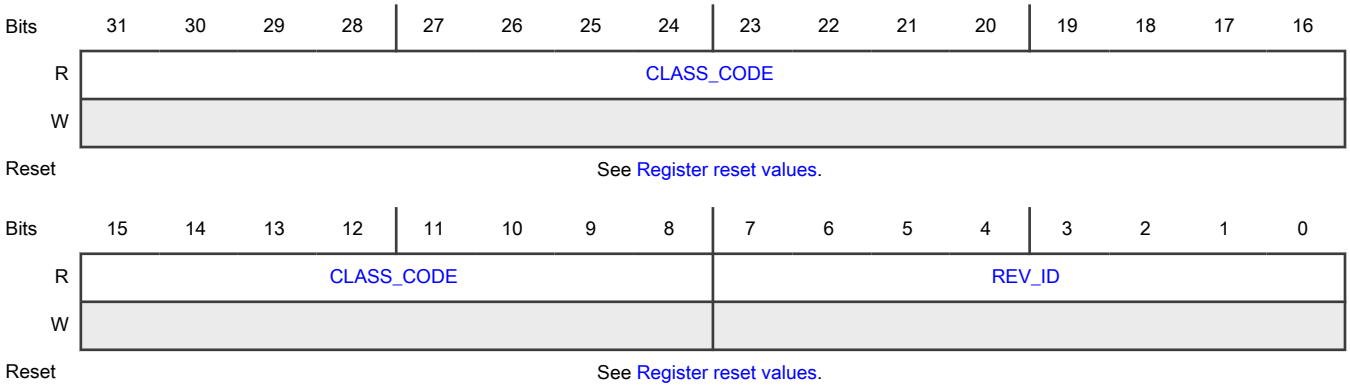
Offset

Register	Offset
PCI_CFH_REVID_CLASSCODE	8h

Function

This is the PCI config header revision ID and classcode register.

Diagram



Register reset values

Register	Reset value
PCI_CFH_REVID_CLASSCODE	NETC_F0_PCI_HDR_TYPE0,NETC_F1_PCI_HDR_TYPE0: 0880_0103h NETC_F2_PCI_HDR_TYPE0–NETC_F4_PCI_HDR_TYPE0: 0200_0103h

Fields

Field	Function
31-8 CLASS_CODE	Class code The Class Code register is read-only and is used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. The field in the PF and associated VFs must return the same value when read. For Ethernet Controllers, the class code is 02h and the sub-class code is 00h. The register interface values must be 00h for Root Complex and 01h for Integrated Endpoint.
7-0 REV_ID	Revision ID This register specifies a device specific revision identifier and is a vendor defined extension to the Device ID. This field will match IPBRR0[MAJOR] setting.

53.4.6.1.6 PCI cache line size register (PCI_CFH_CL_SIZE)

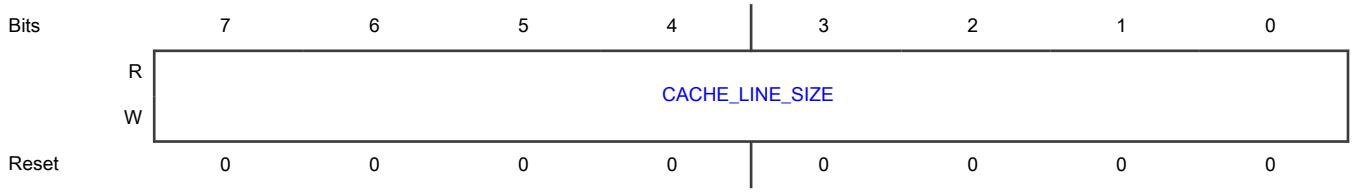
Offset

Register	Offset
PCI_CFH_CL_SIZE	Ch

Function

This is the PCI config header cache line size register.

Diagram



Fields

Field	Function
7-0 CACHE_LINE_SIZE	Cache line size The Cache Line Size register is set by the system firmware or the operating system to system cache line size. This field is implemented by PCI Express devices as a read/write field for legacy compatibility purposes but has no effect on any PCI Express device behavior.

53.4.6.1.7 PCI header type register (PCI_CFH_HDR_TYPE)

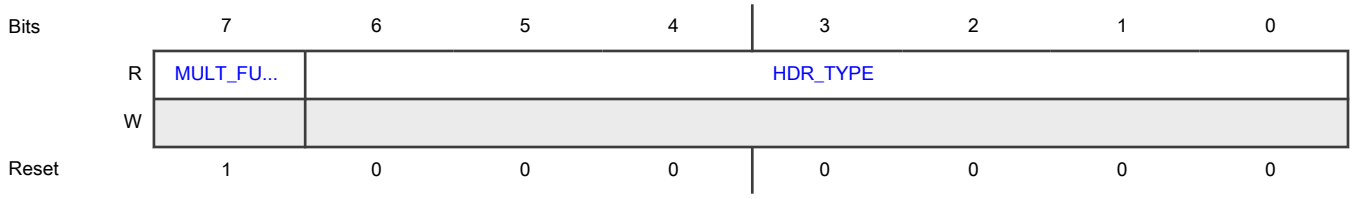
Offset

Register	Offset
PCI_CFH_HDR_TYPE	Eh

Function

This is the PCI config header header type register.

Diagram



Fields

Field	Function
7 MULT_FUNC_DEV	Multi-function device When set, indicates that the device may contain multiple functions, but not necessarily. Software is permitted to probe for functions other than function 0. When clear, software must not probe for functions other than function 0 unless explicitly indicated by another mechanism, such as an ARI or SR-IOV Capability structure. Except where stated otherwise, it is recommended that this bit be set if there are multiple functions, and clear if there is only one function.
6-0	Header type

Table continues on the next page...

Table continued from the previous page...

Field	Function
HDR_TYPE	This field identifies the layout of the second part of the predefined header (beginning at byte 10h in Configuration Space). This register is hardwired to 00h (Type 0 header for both PFs and VFs).

53.4.6.1.8 PCI base address register 0 (PCI_CFH_BAR0)

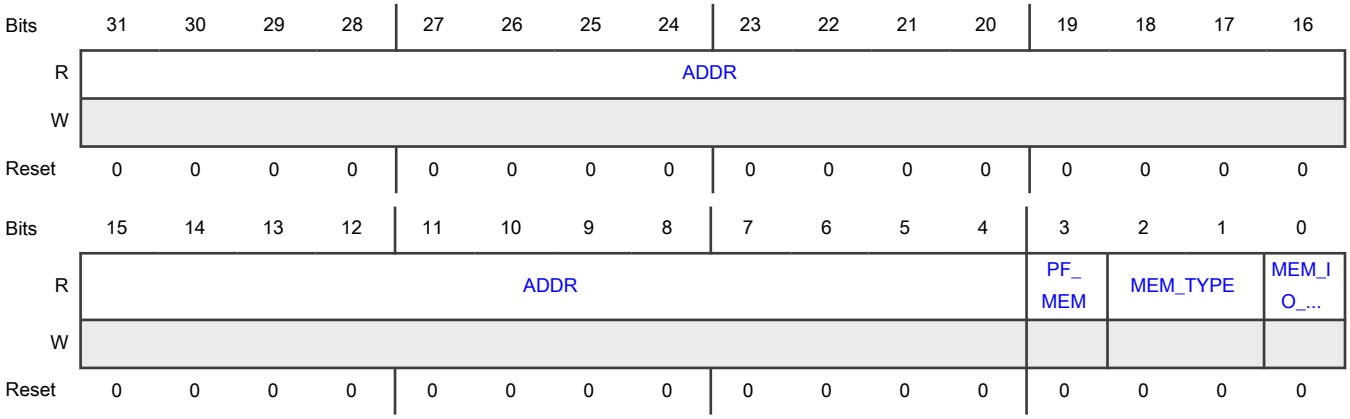
Offset

Register	Offset
PCI_CFH_BAR0	10h

Function

This is the PCI config header base address register 0.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.1.9 PCI base address register 1 (PCI_CFH_BAR1)

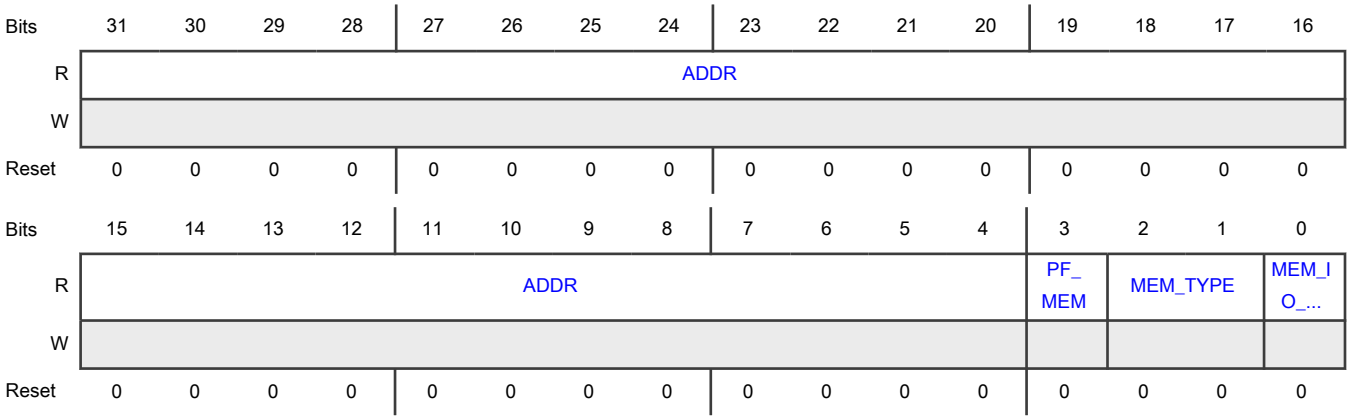
Offset

Register	Offset
PCI_CFH_BAR1	14h

Function

This is the PCI config header base address register 1.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.1.10 PCI base address register 2 (PCI_CFH_BAR2)

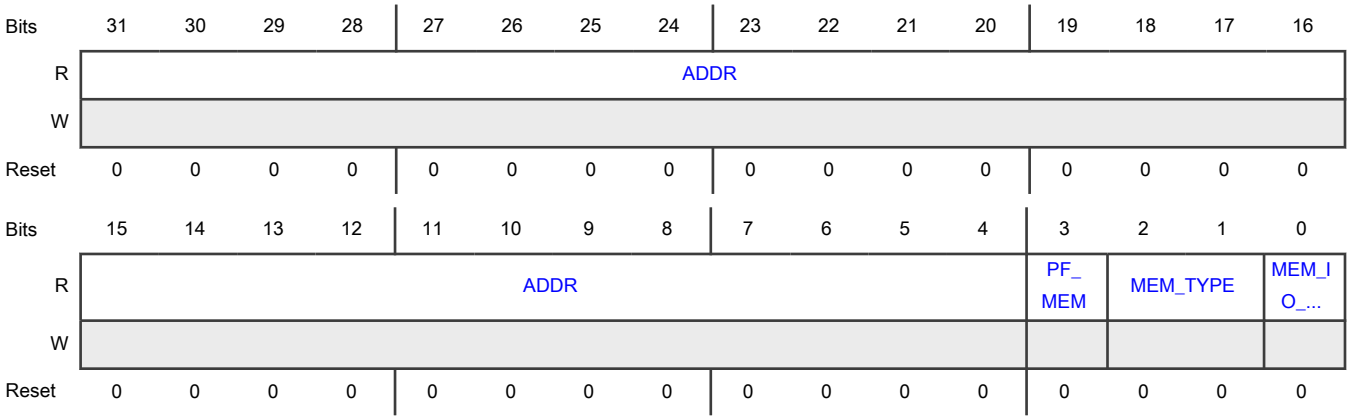
Offset

Register	Offset
PCI_CFH_BAR2	18h

Function

This is the PCI config header base address register 2.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.

0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.1.11 PCI base address register 3 (PCI_CFH_BAR3)

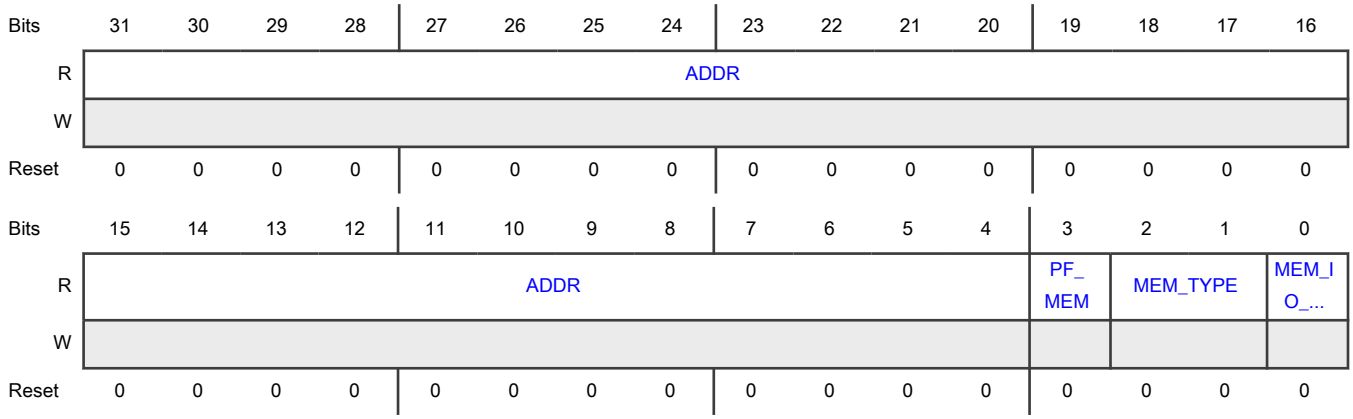
Offset

Register	Offset
PCI_CFH_BAR3	1Ch

Function

This is the PCI config header base address register 3.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.1.12 PCI base address register 4 (PCI_CFH_BAR4)

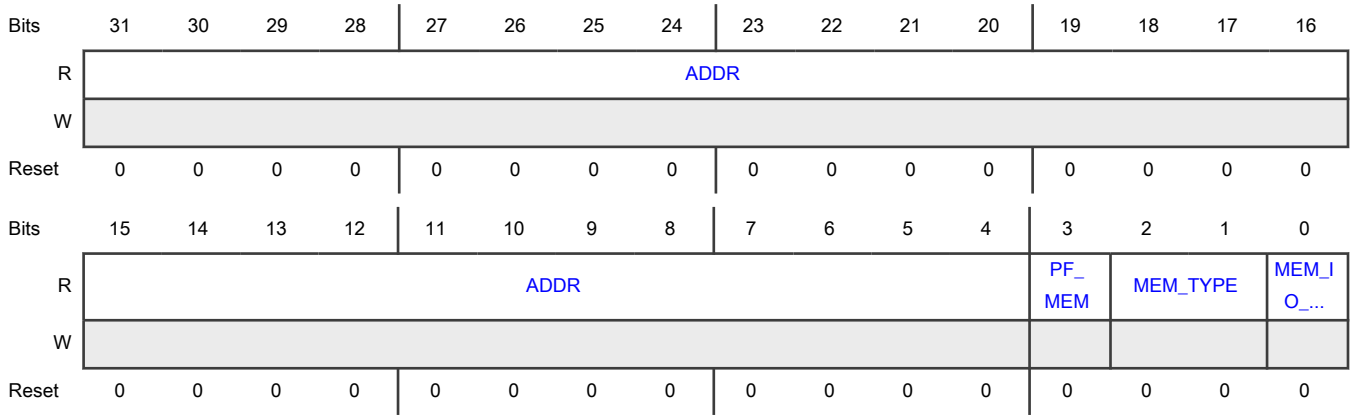
Offset

Register	Offset
PCI_CFH_BAR4	20h

Function

This is the PCI config header base address register 4.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.1.13 PCI base address register 5 (PCI_CFH_BAR5)

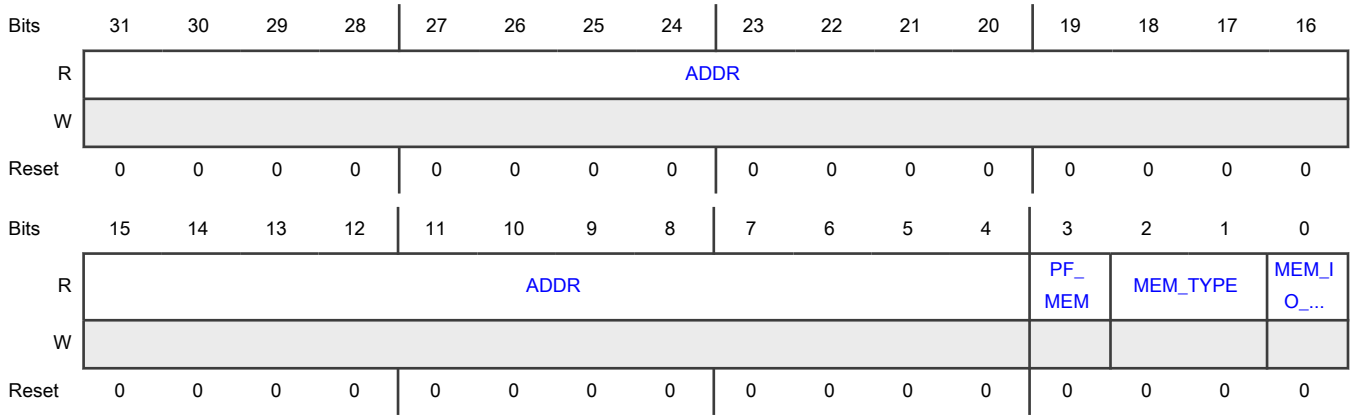
Offset

Register	Offset
PCI_CFH_BAR5	24h

Function

This is the PCI config header base address register 5.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.1.14 PCI subsystem vendor ID register (PCI_CFH_SUBSYS_VID)

Offset

Register	Offset
PCI_CFH_SUBSYS_VID	2Ch

Function

This is the PCI config header subsystem vendor ID register. The value read is taken from IERB register <FUNC>_CFH_SIDSVID.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PCI_CFH_SUBSYS_ID	NETC_F0_PCI_HDR_TYPE0: EE02h NETC_F1_PCI_HDR_TYPE0: EE00h NETC_F2_PCI_HDR_TYPE0: EEF2h NETC_F3_PCI_HDR_TYPE0: E101h NETC_F4_PCI_HDR_TYPE0: E110h

Fields

Field	Function
15-0 SUBSYSTEM_ID	This Read Only field identifies the particular subsystem. The Device may have a different value in the PF and the VF.

53.4.6.1.16 PCI capabilities pointer register (PCI_CFH_CAP_PTR)

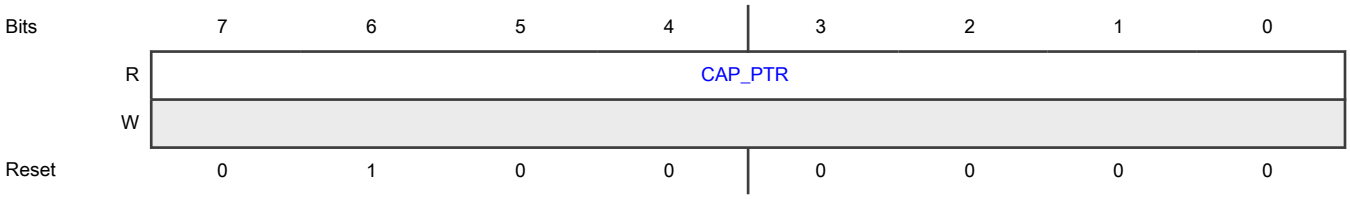
Offset

Register	Offset
PCI_CFH_CAP_PTR	34h

Function

This is the PCI config header capabilities pointer register.

Diagram



Fields

Field	Function
7-0 CAP_PTR	This register is used to point to a linked list of new capabilities implemented by this device. This register is only valid if the “Capabilities List” bit in the Status Register is set. If implemented, the bottom two bits are reserved and should be set to 00b. Software should mask these bits off before using this register as a pointer in Configuration Space to the first entry of a linked list of new capabilities. Hardwired to 40h.

53.4.6.1.17 PCI PCIe capabilities list register (PCI_CFC_PCIE_CAP_LIST)

Offset

Register	Offset
PCI_CFC_PCIE_CAP_LIST	40h

Function

This is the PCI config capability PCIe capabilities list register.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	NEXT_CAP_PTR								CAP_ID							
W																
Reset	1	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Fields

Field	Function
15-8 NEXT_CAP_PTR	This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of capabilities. Hardwired to 80h.
7-0 CAP_ID	Indicates the PCI Express Capability structure. Hardwired to 10h.

53.4.6.1.18 PCI PCIe capabilities register (PCI_CFC_PCIE_CAP)

Offset

Register	Offset
PCI_CFC_PCIE_CAP	42h

Function

This is the PCI config capability PCIe capabilities register.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	1	0	0	1	0	0	1	0

Fields

Field	Function
15-14 —	Reserved
13-9	Interrupt message number

Table continues on the next page...

Table continued from the previous page...

Field	Function
INT_MSG_NUM	This field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this capability structure. For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant. If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined. Errors for ENETC are handled through the Event Collector. Hardwired to 00h.
8 —	Reserved
7-4 DEV_PORT_TYPE	Device/Port type Indicates the specific type of this PCI Express Function. Hardwired to 9h to indicate Root Complex Integrated Endpoint.
3-0 CAP_VER	Capability Version Indicates PCI-SIG defined PCI Express Capability structure version number. Hardwired to 2h.

53.4.6.1.19 PCI PCIe device capabilities register (PCI_CFC_PCIE_DEV_CAP)

Offset

Register	Offset
PCI_CFC_PCIE_DEV_CAP	44h

Function

This is the PCI config capability PCIe device capabilities register.

3-0	Completion Timeout Ranges Supported

Table continues on the next page...

Table continued from the previous page...

Field	Function
CMPL_TO_RNG_SUPP	Completion Timeout programming not supported, the Function assumes a timeout value in the range 50 us to 50 ms.

53.4.6.1.23 PCI PCIe device control 2 register (PCI_CFC_PCIE_DEV_CTL2)

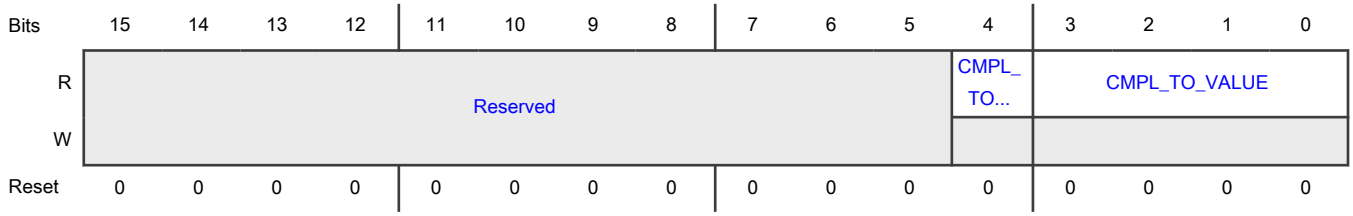
Offset

Register	Offset
PCI_CFC_PCIE_DEV_CTL2	68h

Function

This is the PCI config capability PCIe device control 2 register.

Diagram



Fields

Field	Function
15-5 —	Reserved
4 CMPL_TO_EN	Completion Timeout Enable Not supported. Hardwired to b0.
3-0 CMPL_TO_VALUE	Completion Timeout Value Completion Timeout programming not supported – the Function assumes a timeout value in the range 50 us to 50 ms. Hardwired to b0000.

53.4.6.1.24 PCI MSI-X capabilities list register (PCI_CFC_MSIX_CAP_LIST)

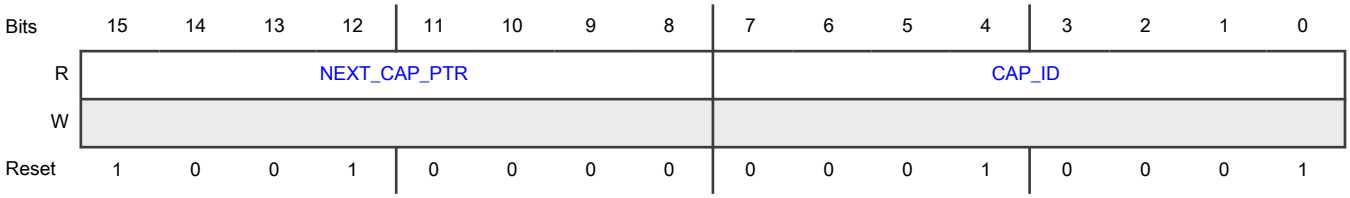
Offset

Register	Offset
PCI_CFC_MSIX_CAP_LIST	80h

Function

This is the PCI config capability MSI-X capabilities list register.

Diagram



Fields

Field	Function
15-8 NEXT_CAP_PTR	This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of capabilities. Hardwired to 90h.
7-0 CAP_ID	Indicates the MSI-X Capability structure. Hardwired to 11h.

53.4.6.1.25 PCI MSI-X message control register (PCI_CFC_MSIX_MSG_CTL)

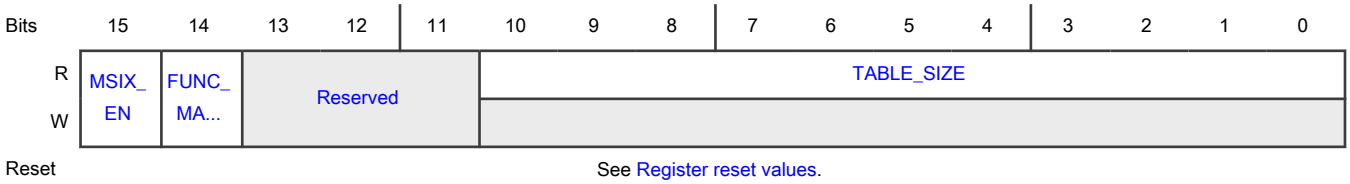
Offset

Register	Offset
PCI_CFC_MSIX_MSG_CTL	82h

Function

This is the PCI config capability MSI-X message control register.

Diagram



Register reset values

Register	Reset value
PCI_CFC_MSIX_MSG_CTL	NETC_F0_PCI_HDR_TYPE0,NETC_F1_PCI_HDR_TYPE0: 0000h NETC_F2_PCI_HDR_TYPE0: 0005h NETC_F3_PCI_HDR_TYPE0: 000Bh NETC_F4_PCI_HDR_TYPE0: 0017h

Fields

Field	Function
15 MSIX_EN	MSI-X enable If set, the function is permitted to use MSI-X to request service. System configuration software sets this bit to enable MSI-X. A device driver is prohibited from writing this bit to mask a function's service request. If 0, the function is prohibited from using MSI-X to request service. This bit's state after reset is 0 (MSI-X is disabled).
14 FUNC_MASK	Function mask If 1, all of the vectors associated with the function are masked, regardless of their per-vector Mask bit states. If 0, each vector's Mask bit determines whether the vector is masked or not. Setting or clearing the MSI-X Function Mask bit has no effect on the state of the per-vector Mask bits. This bit's state after reset is 0 (unmasked).
13-11 —	Reserved
10-0 TABLE_SIZE	Table size System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1. For example, a returned value of "00000000011" indicates a table size of 4. **NOTE** ENETC function table size is defined by PSI0CFGR2[NUM_MSIX] and is immediately reflected here. All other functions use IERB register *MCR[NUM_MSIX].

53.4.6.1.26 PCI MSI-X table offset/BIR register (PCI_CFC_MSIX_TABLE_OFF_BIR)

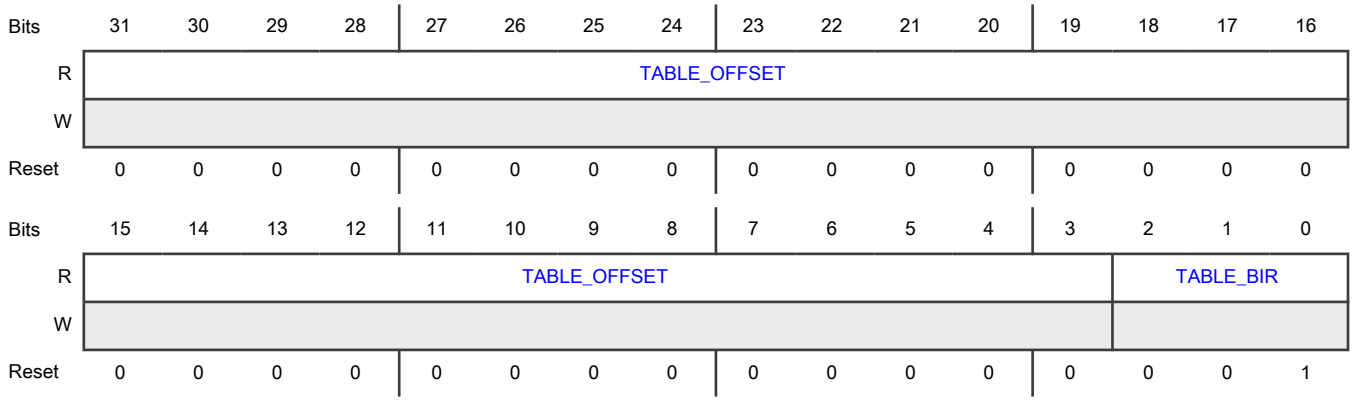
Offset

Register	Offset
PCI_CFC_MSIX_TABLE_OFF_BIR	84h

Function

This is the PCI config capability MSI-X table offset/BIR register.

Diagram



Fields

Field	Function
31-3 TABLE_OFFSET	Table Offset Used as an offset from the address contained by one of the function's Base Address registers to point to the base of the MSI-X Table. The lower 3 Table BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset.
2-0 TABLE_BIR	Table BIR Indicates which entry in the Enhanced Allocation capability with a matching BEI, is used to map the Function's MSI-X Table into Memory Space. For a 64-bit Base Address register, the Table BIR indicates the lower DWORD. Physical functions hardwires this field to 001b (PE entry 1) for MSI-X table.

53.4.6.1.27 PCI MSI-X PBA offset/BIR register (PCI_CFC_MSIX_PBA_OFF_BIR)

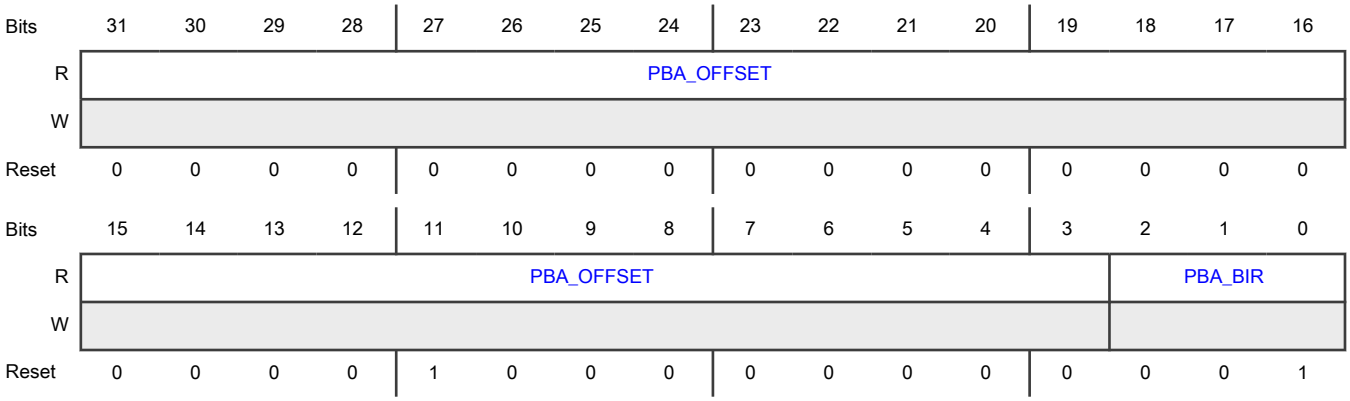
Offset

Register	Offset
PCI_CFC_MSIX_PBA_OFF_BIR	88h

Function

This is the PCI config capability MSI-X PBA offset/BIR register.

Diagram



Fields

Field	Function
31-3 PBA_OFFSET	PBA Offset Used as an offset from the address contained by one of the function's Base Address registers to point to the base of the MSI-X PBA. The lower 3 PBA BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset. The PBA structure directly follows the maximum possible MSI-X table size (2KB).
2-0 PBA_BIR	PBA BIR Indicates which entry in the Enhanced Allocation capability with a matching BEI, is used to map the Function's MSI-X PBA into Memory Space. For a 64-bit Base Address Register, the PBA BIR indicates the lower DWORD. Physical function hardwires this field to 001b (PE entry 1) for MSI-X PBA.

53.4.6.1.28 PCI PCI-PM capabilities list register (PCI_CFC_PCIPM_CAP_LIST)

Offset

Register	Offset
PCI_CFC_PCIPM_CAP_LIST	90h

Function

This is the PCI config capability PCI-PM capabilities list register.

Field	Function
	When set (“1”), this bit indicates that when NETC transitions from $D3_{hot}$ to $D0_{active}$ because of modifying Power State bits in the PCI_CFC_PCIPM_CTL_STAT register, no internal reset is issued and Configuration Context is preserved. Upon transition from the $D3_{hot}$ to the $D0_{active}$ state, no additional operating system intervention is required to preserve PCIe Configuration Context beyond writing the Power State bits. When clear (“0”), NETC performs an internal reset upon transitioning from $D3_{hot}$ to $D0_{uninitialized}$ via software control of the Power State bits in the PCI_CFC_PCIPM_CTL_STAT register. Configuration Context is lost when performing the soft reset. Upon transition from the $D3_{hot}$ to the $D0_{uninitialized}$ state, full re-initialization sequence is needed to return the device to $D0_{active}$. Regardless of this bit, NETC preserves the PME context when PME is enabled.
2 —	Reserved
1-0 PWR_STATE	Power state This field is used to set and report the power state of a function as follows: 00b = D0 01b = D1 (not supported by NETC) 10b = D2 (not supported by NETC) 11b = D3 If, for any reason, the operating system software attempts to put a function into a power management state that the function does not support, the function should handle this gracefully and remain in whatever state it was in before the request. The PWR_STATE bits will reflect the current state of the function not the intended invalid state which was written.

53.4.6.1.31 PCI PCI-PM capabilities data register (PCI_CFC_PCIPM_DATA)

Offset

Register	Offset
PCI_CFC_PCIPM_DATA	97h

Function

This is the PCI config capability PCI-PM data register. Not supported by ENETC since AUX power not supported in $D3_{cold}$.

Function

This is the PCIe config capability Advanced Error Reporting uncorrectable error mask register. The Uncorrectable Error Mask register controls reporting of individual errors by the device Function to the PCI Express Root Complex Event Collector via a PCI Express error Message. A masked error (respective bit set in the mask register) is not recorded or reported in the Header Log or First Error Pointer, and is not reported to the PCI Express Root Complex Event Collector by this Function. There is a mask bit per error bit of the Uncorrectable Error Status register.

Diagram

21-0 —	Reserved

53.4.6.1.48 PCIe AER uncorrectable error severity register (PCIE_CFC_AER_UCORR_ERR_SEV)

Offset

Register	Offset
PCIE_CFC_AER_UCORR_ERR_SEV	10Ch

Function

This is the PCIe config capability Advanced Error Reporting uncorrectable error severity register. The Uncorrectable Error Severity register controls whether an individual error is reported as a Non-fatal or Fatal error. An error is reported as fatal when the corresponding error bit in the severity register is Set. If the bit is Clear, the corresponding error is considered non-fatal.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

53.4.6.1.49 PCIe AER correctable error status register (PCIE_CFC_AER_CORR_ERR_STAT)

Offset

Register	Offset
PCIE_CFC_AER_CORR_ERR_STAT	110h

Function

This is the PCIe config capability Advanced Error Reporting correctable error status register. The Correctable Error Status register reports error status of individual correctable error sources on a PCI Express device Function. When an individual error status bit is Set, it indicates that a particular error occurred; software may clear an error status by writing a 1b to the respective bit.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-5 —	Reserved
4-0 FIRST_ERR_PTR	First error pointer The First Error Pointer is a field that identifies the bit position of the first error reported in the Uncorrectable Error Status register. **NOTE** This field is “sticky” and will be preserved across function level resets.

53.4.6.1.52 PCIe ACS capability header (PCIE_CFC_ACS_CAP_HDR)

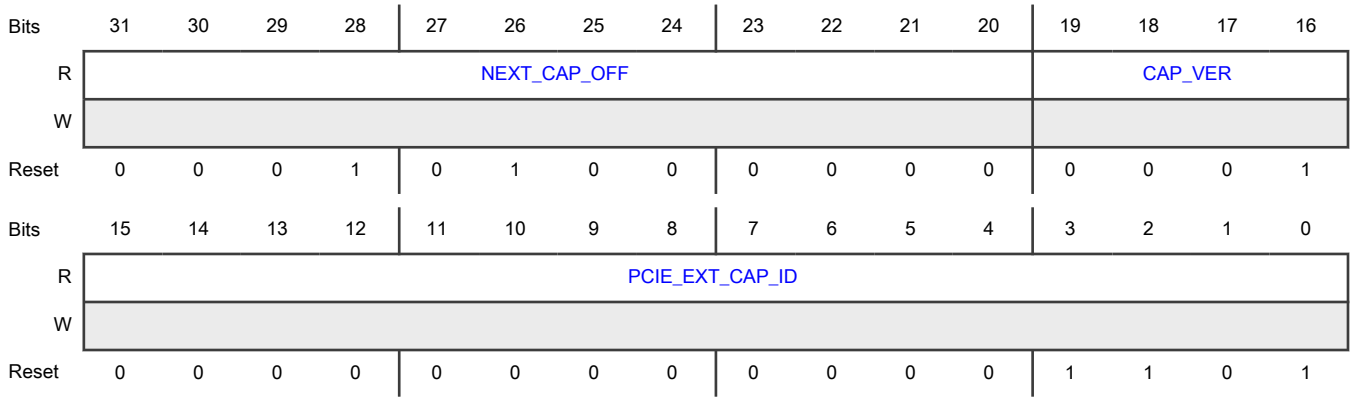
Offset

Register	Offset
PCIE_CFC_ACS_CAP_HDR	130h

Function

This is the PCIe config capability Access Control Services (ACS) capability header.

Diagram



Fields

Field	Function
31-20 NEXT_CAP_OFF	Next capability offset This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of capabilities.
19-16 CAP_VER	Capability version Must be 1h for this version of the specification.
15-0 PCIE_EXT_CAP_ID	The Extended Capability ID for the ACS Extended Capability is 000Dh.

53.4.6.1.53 PCIe ACS capability register (PCIE_CFC_ACS_CAP)

Offset

Register	Offset
PCIE_CFC_ACS_CAP	134h

Function

This is the PCIe config capability Access Control Services (ACS) capability register.

Diagram

Fields

Field	Function
15-7 —	Reserved
6 ACS_DIR_TRANS_P2P	ACS direct translated P2P (T) Set to indicate that the Function supports direct translated peer-to-peer.
5-3 —	Reserved
2 ACS_P2P_REQ_REDIR	ACS P2P request dedirect (R) Set to indicate that the Function supports peer-to-peer request redirection.
1 ACS_TRANS_BLOCK	ACS translation blocking (B) Set to indicate that the Function supports Translation Blocking.
0 —	Reserved

53.4.6.1.54 PCIe ACS control register (PCIE_CFC_ACS_CTL)

Offset

Register	Offset
PCIE_CFC_ACS_CTL	136h

Function

This is the PCIe config capability Access Control Services (ACS) control register.

Diagram

Fields

Field	Function
15-7 —	Reserved
6 ACS_DIR_TRANS_P2P_EN	ACS direct translated P2P enable (T) When set the Function determines how to direct peer-to-peer requests based on ATS Ignored if ACS Translation Blocking Enable is set. This bit is read-only if the functionality is not implemented.
5-3 —	Reserved
2 ACS_P2P_REQ_REDIR_EN	ACS P2P request dedirect enable (R) When set the Function directs peer-to-peer requests to the SoC interconnect. This bit is read-only if the functionality is not implemented.
1 ACS_TRANS_BLOCK_EN	ACS translation blocking enable (B) When set the Function directs peer-to-peer requests to the SoC interconnect. This bit is read-only if the functionality is not implemented.
0 —	Reserved

53.4.6.1.55 PCIe readiness time reporting capability header (PCIE_CFC_RTR_CAP_HDR)

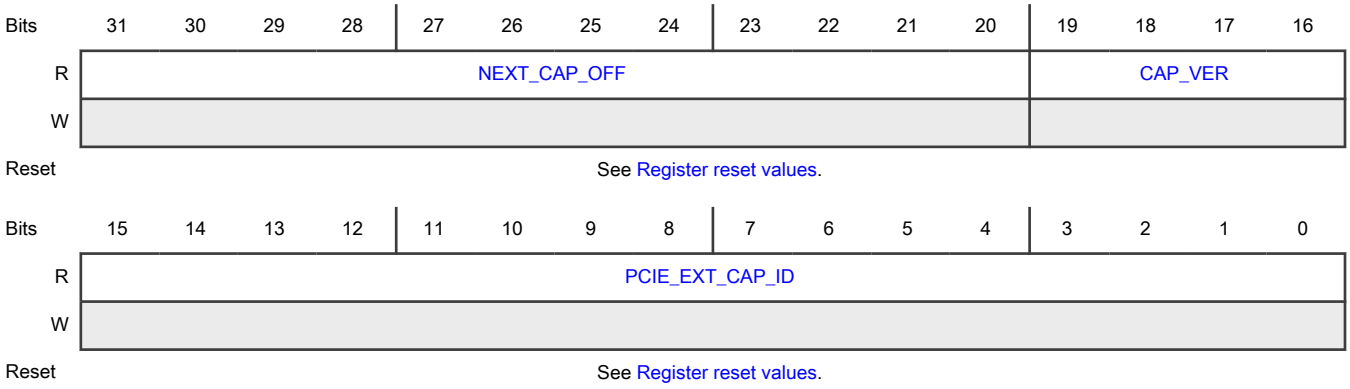
Offset

Register	Offset
PCIE_CFC_RTR_CAP_HDR	140h

Function

This is the PCIe config capability readiness time reporting capability header.

Diagram



Register reset values

Register	Reset value
PCIE_CFC_RTR_CAP_HDR	NETC_F0_PCI_HDR_TYPE0–NETC_F3_PCI_HDR_TYPE0: 0001_0022h NETC_F4_PCI_HDR_TYPE0: 1501_0022h

Fields

Field	Function
31-20 NEXT_CAP_OFF	Next capability offset This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of capabilities.
19-16 CAP_VER	Capability version Must be 1h for this version of the specification.
15-0 PCIE_EXT_CAP_ID	The Extended Capability ID for the Readiness Time Reporting Extended Capability is 0022h.

53.4.6.1.56 PCIe RTR readiness time reporting 1 register (PCIE_CFC_RTR_RTR1)

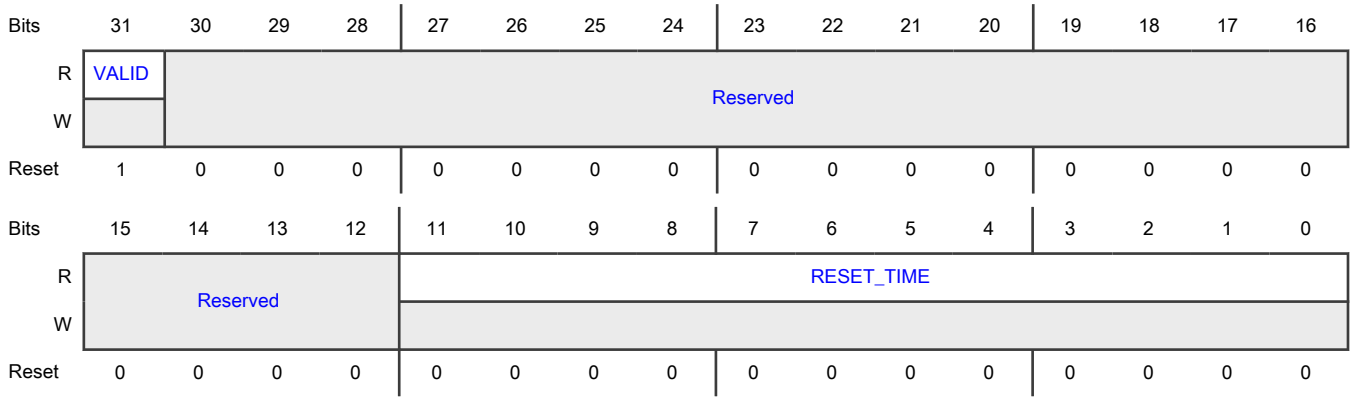
Offset

Register	Offset
PCIE_CFC_RTR_RTR1	144h

Function

This is the PCIe config capability Readiness Time Reporting 1 register.

Diagram



Fields

Field	Function
31 VALID	Valid If Set, indicates that all time values in this capability are valid. If Clear, indicates that the time values in this capability are not yet available. If this bit remains Clear and 1 minute has elapsed after all associated device driver(s) have started, software is permitted to assume that this bit will never be set.
30-12 —	Reserved
11-0 RESET_TIME	Reset Time The time the Function requires to become Configuration-Ready after the completion of Conventional Reset. This field is undefined when the Valid bit is Clear. This field must be less than or equal to the encoded value A1Eh.

53.4.6.1.57 PCIe RTR readiness time reporting 2 register (PCIE_CFC_RTR_RTR2)

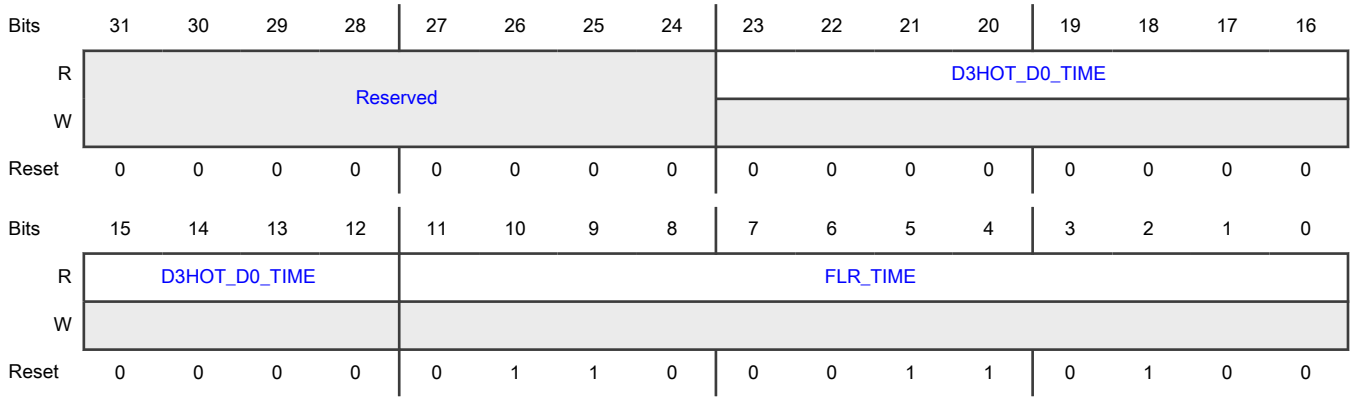
Offset

Register	Offset
PCIE_CFC_RTR_RTR2	148h

Function

This is the PCIe config capability Readiness Time Reporting 2 register.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-12 D3HOT_D0_TIME	D3 hot to D0 time $D3_{hot}$ to D0 Time is the time that the Function requires after it is directed from $D3_{hot}$ to D0 before it is Configuration-Ready and has returned to either $D0_{uninitialized}$ or $D0_{active}$ state (see the PCI Bus Power Management Interface Specification). This field is undefined when the PCIE_CFC_RTR_RTR1[VALID] bit is Clear. This field must be less than or equal to the encoded value 80Ah.
11-0 FLR_TIME	FLR Time The time that the Function requires to become Configuration-Ready after it was issued an FLR. This field is undefined when the PCIE_CFC_RTR_RTR1[VALID] bit is Clear. This field must be less than or equal to the encoded value A1Eh. **NOTE** The value is taken directly from IERB register NETCFLRCR. The value in this field is encoded, where bits 8-0 is the value, and bits 11-9 is the scale. The scale is hardwired as 32.768us.

53.4.6.1.58 PCIe SR-IOV capability header (PCIE_CFC_SRIOV_CAP_HDR)

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
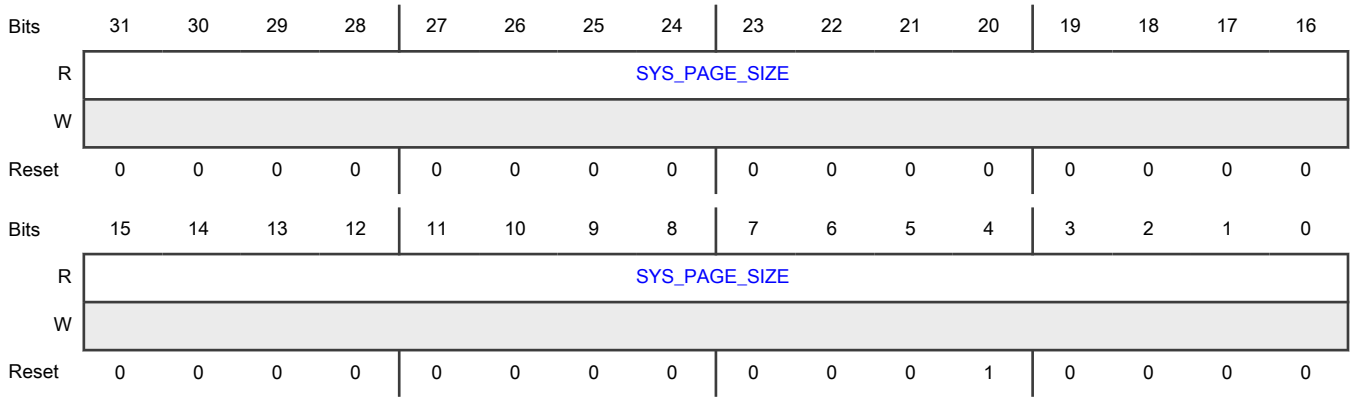
NETC_F0_PCI_HDR_TYPE0	—	PCIE_CFC_SRIOV_SYS_PAGE_SIZE
NETC_F1_PCI_HDR_TYPE0	—	PCIE_CFC_SRIOV_SYS_PAGE_SIZE
NETC_F2_PCI_HDR_TYPE0	—	PCIE_CFC_SRIOV_SYS_PAGE_SIZE
NETC_F3_PCI_HDR_TYPE0	—	PCIE_CFC_SRIOV_SYS_PAGE_SIZE
NETC_F4_PCI_HDR_TYPE0	PCIE_CFC_SRIOV_SYS_PAGE_SIZE	—

Diagram



Fields

Field	Function
31-0 SYS_PAGE_SIZE	System page size This field defines the page size the system will use to map the VFs' memory addresses. Software must set the value of the System Page Size to one of the page sizes set in the Supported Page Sizes. As with Supported Page Sizes, if bit *n* is set in System Page Size, the VFs associated with this PF are required to support a page size of 2^{n+12}. For example, if bit 1 is Set, the system is using an 8-KB page size. The results are undefined if System Page Size is zero. The results are undefined if more than one bit is set in System Page Size. The results are undefined if a bit is Set in System Page Size that is not Set in Supported Page Sizes. VF Enable must be zero when System Page Size is written. The results are undefined if System Page Size is written when VF Enable is Set. Default value is 10h (i.e., 64 KB).

53.4.6.1.71 PCIe SR-IOV VF base address register a (PCIE_CFC_VF_BAR0 - PCIE_CFC_VF_BAR5)

Offset

Register	Offset
PCIE_CFC_VF_BAR0	174h
PCIE_CFC_VF_BAR1	178h
PCIE_CFC_VF_BAR2	17Ch
PCIE_CFC_VF_BAR3	180h
PCIE_CFC_VF_BAR4	184h
PCIE_CFC_VF_BAR5	188h

Function

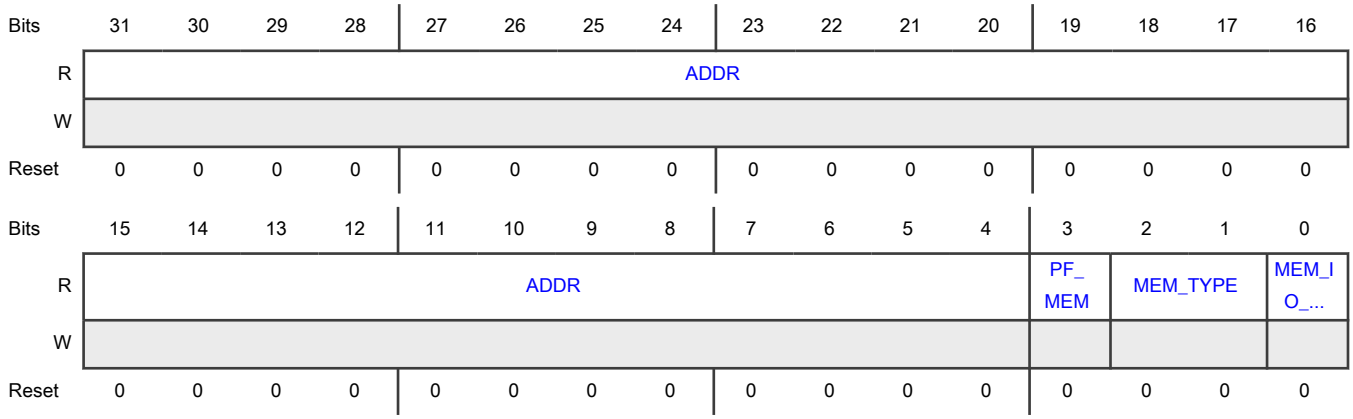
This is the PCIe config capability SR-IOV VF base address register.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
NETC_F0_PCI_HDR_TYPE0	—	PCIE_CFC_VF_BAR0–PCIE_CFC_VF_BAR5
NETC_F1_PCI_HDR_TYPE0	—	PCIE_CFC_VF_BAR0–PCIE_CFC_VF_BAR5
NETC_F2_PCI_HDR_TYPE0	—	PCIE_CFC_VF_BAR0–PCIE_CFC_VF_BAR5
NETC_F3_PCI_HDR_TYPE0	—	PCIE_CFC_VF_BAR0–PCIE_CFC_VF_BAR5
NETC_F4_PCI_HDR_TYPE0	PCIE_CFC_VF_BAR0–PCIE_CFC_VF_BAR5	—

Diagram



Fields

Field	Function
31-4 ADDR	Address space (low register for 64-bit BARs). Not supported, hardwired to 000000h.
3 PF_MEM	BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	BARs used. This register is hardwired to 0h.

53.4.6.1.72 PCIe SR-IOV VF migration state array offset register (PCIE_CFC_SRIOV_VF_MIG_STATE_ARR_OFF)

Offset

Register	Offset
PCIE_CFC_SRIOV_VF_MIG_STATE_ARR_OFF	18Ch

Function

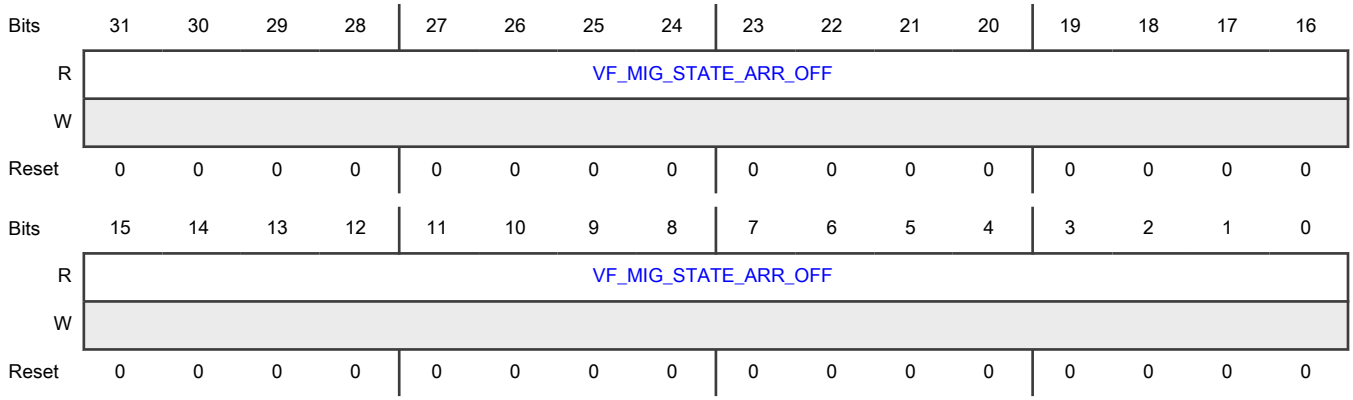
This is the PCIe config capability SR-IOV VF migration state array offset register.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
NETC_F0_PCI_HDR_TYPE0	—	PCIE_CFC_SRIOV_VF_MIG_STATE_ARR_OFF
NETC_F1_PCI_HDR_TYPE0	—	PCIE_CFC_SRIOV_VF_MIG_STATE_ARR_OFF
NETC_F2_PCI_HDR_TYPE0	—	PCIE_CFC_SRIOV_VF_MIG_STATE_ARR_OFF
NETC_F3_PCI_HDR_TYPE0	—	PCIE_CFC_SRIOV_VF_MIG_STATE_ARR_OFF
NETC_F4_PCI_HDR_TYPE0	PCIE_CFC_SRIOV_VF_MIG_STATE_ARR_OFF	—

Diagram



Fields

Field	Function
31-0 VF_MIG_STATE_ARR_OFF	VF migration state array offset VF migration not supported. Hardwired to all 0b's.

53.4.6.2 NETC PCI Express ECAM VF config register descriptions

This section describes the PCI Express Type0 config header and capabilities as they relate to the virtual functions of NETC.

53.4.6.2.1 VF_PCI_Config_Header_Type0 memory map

NETC_VF1_PCI_HDR_TYPE0 base address: 6010_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	PCI device ID and vendor ID register (PCI_CFH_DID_VID)	32	R	FFFF_FFFFh
4h	PCI command register (PCI_CFH_CMD)	16	RW	0000h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
6h	PCI status register (PCI_CFH_STAT)	16	R	0010h
8h	PCI revision ID and classcode register (PCI_CFH_REVID_CLASSCODE)	32	R	0200_0103h
Ch	PCI cache line size register (PCI_CFH_CL_SIZE)	8	R	00h
Dh	PCI latency timer register (PCI_CFH_LAT_TIMER)	8	R	00h
Eh	PCI header type register (PCI_CFH_HDR_TYPE)	8	R	00h
Fh	PCI BIST register (PCI_CFH_BIST)	8	R	00h
10h	PCI base address register 0 (PCI_CFH_BAR0)	32	R	0000_0000h
14h	PCI base address register 1 (PCI_CFH_BAR1)	32	R	0000_0000h
18h	PCI base address register 2 (PCI_CFH_BAR2)	32	R	0000_0000h
1Ch	PCI base address register 3 (PCI_CFH_BAR3)	32	R	0000_0000h
20h	PCI base address register 4 (PCI_CFH_BAR4)	32	R	0000_0000h
24h	PCI base address register 5 (PCI_CFH_BAR5)	32	R	0000_0000h
28h	PCI cardbus CIS register (PCI_CFH_CARDBUS_CIS)	32	R	0000_0000h
2Ch	PCI subsystem vendor ID register (PCI_CFH_SUBSYS_VID)	16	R	1957h
2Eh	PCI subsystem ID register (PCI_CFH_SUBSYS_ID)	16	R	EF00h
30h	PCI expansion ROM base address register (PCI_CFH_EXP_ROM_BA)	32	R	0000_0000h
34h	PCI capabilities pointer register (PCI_CFH_CAP_PTR)	8	R	40h
40h	PCI PCIe capabilities list register (PCI_CFC_PCIE_CAP_LIST)	16	R	8010h
42h	PCI PCIe capabilities register (PCI_CFC_PCIE_CAP)	16	R	0092h
44h	PCI PCIe device capabilities register (PCI_CFC_PCIE_DEV_CAP)	32	R	1000_0000h
48h	PCI PCIe device control register (PCI_CFC_PCIE_DEV_CTL)	16	RW	0000h
4Ah	PCI PCIe device status register (PCI_CFC_PCIE_DEV_STAT)	16	R	0000h
64h	PCI PCIe device capabilities 2 register (PCI_CFC_PCIE_DEV_CAP2)	32	R	0000_0000h
68h	PCI PCIe device control 2 register (PCI_CFC_PCIE_DEV_CTL2)	16	R	0000h
80h	PCI MSI-X capabilities list register (PCI_CFC_MSIX_CAP_LIST)	16	R	0011h
82h	PCI MSI-X message control register (PCI_CFC_MSIX_MSG_CTL)	16	RW	0000h
84h	PCI MSI-X table offset/BIR register (PCI_CFC_MSIX_TABLE_OFF_BIR)	32	R	0000_0003h
88h	PCI MSI-X PBA offset/BIR register (PCI_CFC_MSIX_PBA_OFF_BIR)	32	R	0000_0803h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
100h	PCIe AER extended capability header (PCIE_CFC_AER_EXT_CAP_HDR)	32	R	1301_0001h
104h	PCIe AER uncorrectable error status register (PCIE_CFC_AER_UCORR_ERR_STAT)	32	RW	0000_0000h
108h	PCIe AER uncorrectable error mask register (PCIE_CFC_AER_UCORR_ERR_MASK)	32	RW	0040_0000h
10Ch	PCIe AER uncorrectable error severity register (PCIE_CFC_AER_UCORR_ERR_SEV)	32	RW	0040_0000h
110h	PCIe AER correctable error status register (PCIE_CFC_AER_CORR_ERR_STAT)	32	RW	0000_0000h
114h	PCIe AER correctable error mask register (PCIE_CFC_AER_CORR_ERR_MASK)	32	RW	0000_4000h
118h	PCIe AER capabilities and control register (PCIE_CFC_AER_CAP_CTL)	32	R	0000_0000h
130h	PCIe ACS capability header (PCIE_CFC_ACS_CAP_HDR)	32	R	1401_000Dh
134h	PCIe ACS capability register (PCIE_CFC_ACS_CAP)	16	R	0000h
136h	PCIe ACS control register (PCIE_CFC_ACS_CTL)	16	R	0000h
140h	PCIe readiness time reporting capability header (PCIE_CFC_RTR_CAP_HDR)	32	R	0001_0022h
144h	PCIe RTR readiness time reporting 1 register (PCIE_CFC_RTR_RTR1)	32	R	8000_0000h
148h	PCIe RTR readiness time reporting 2 register (PCIE_CFC_RTR_RTR2)	32	R	0000_0634h

53.4.6.2.2 PCI device ID and vendor ID register (PCI_CFH_DID_VID)

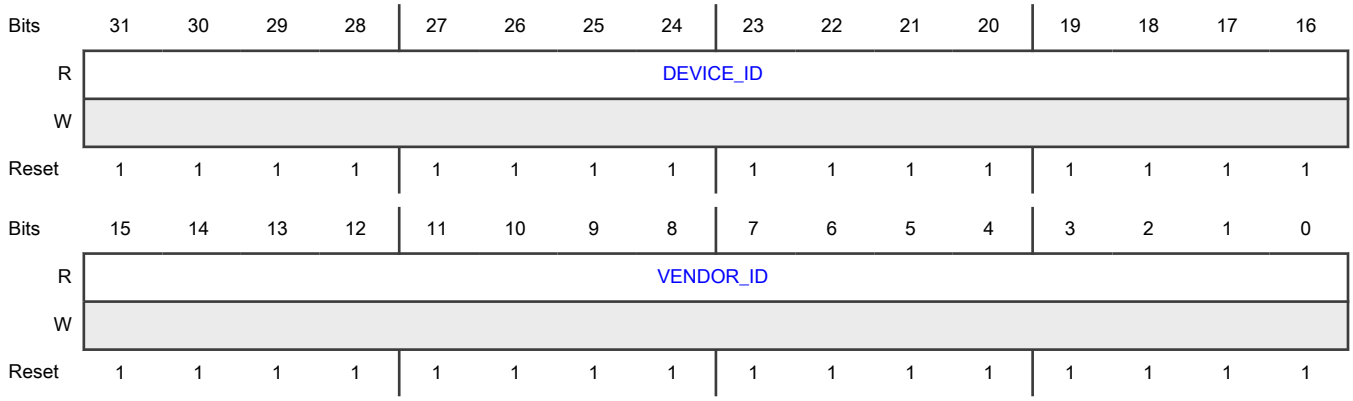
Offset

Register	Offset
PCI_CFH_DID_VID	0h

Function

This is the PCI config header device and vendor ID register.

Diagram



Fields

Field	Function
31-16 DEVICE_ID	Device ID This field in all VFs returns FFFFh when read. For SR-IOV the VF device ID is determined from the VF Device ID field in the SR-IOV capability register.
15-0 VENDOR_ID	Vendor ID Returns 0xFFFF for all VFs.

53.4.6.2.3 PCI command register (PCI_CFH_CMD)

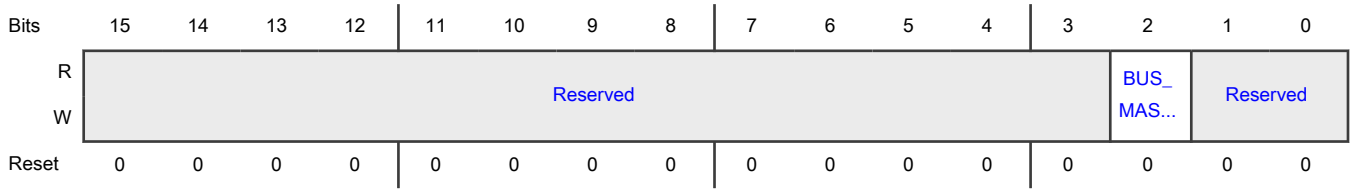
Offset

Register	Offset
PCI_CFH_CMD	4h

Function

This is the PCI config header command register.

Diagram



Fields

Field	Function
15-3 —	Reserved
2 BUS_MASTER_EN	Bus master enable Controls the ability of a PCI Express Endpoint to issue Memory and I/O Read/Write Requests. When this bit is Set, the PCI Express Function is allowed to issue Memory or I/O Requests. When this bit is Clear, the PCI Express Function is not allowed to issue any Memory or I/O Requests. Note that as MSI/MSI-X interrupt Messages are inband memory writes, setting the Bus Master Enable bit to 0b disables MSI/MSI-X interrupt Messages as well. Transactions for a VF that has its Bus Master Enable set must not be blocked by transactions for VFs that have their Bus Master Enable cleared.
1-0 —	Reserved

53.4.6.2.4 PCI status register (PCI_CFH_STAT)

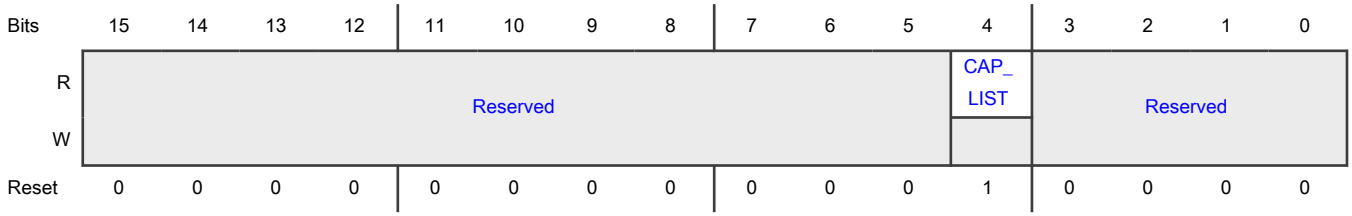
Offset

Register	Offset
PCI_CFH_STAT	6h

Function

This is the PCI config header status register.

Diagram



Fields

Field	Function
15-5 —	Reserved
4 CAP_LIST	Capabilities List Indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, this bit must be hardwired to 1b.
3-0 —	Reserved

53.4.6.2.5 PCI revision ID and classcode register (PCI_CFH_REVID_CLASSCODE)

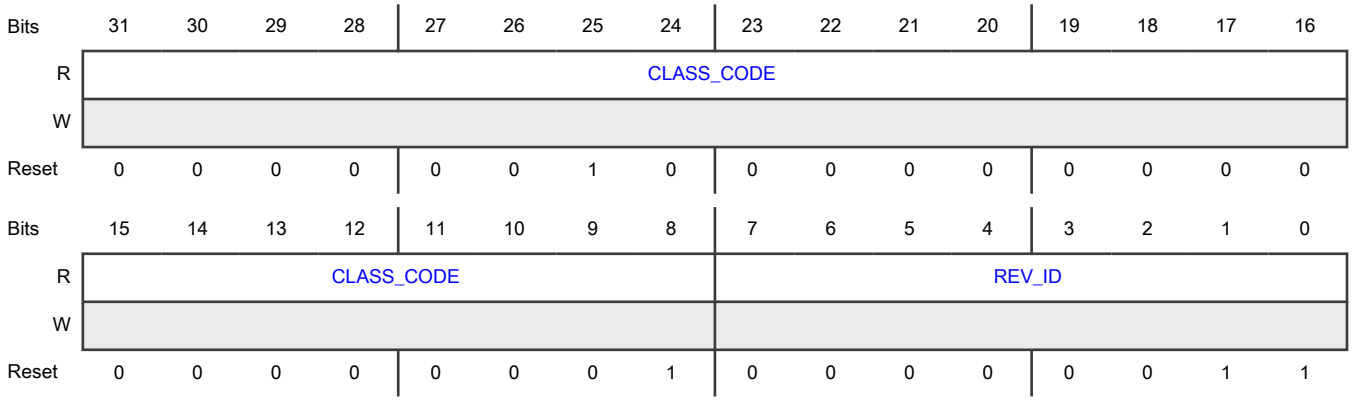
Offset

Register	Offset
PCI_CFH_REVID_CLASSCODE	8h

Function

This is the PCI config header revision ID and classcode register.

Diagram



Fields

Field	Function
31-8 CLASS_CODE	Class code Returns the same value as the PF.
7-0 REV_ID	Revision ID This register specifies a device specific revision identifier and is a vendor defined extension to the Device ID. This field will match IPBRR0[MAJOR] setting.

53.4.6.2.6 PCI cache line size register (PCI_CFH_CL_SIZE)

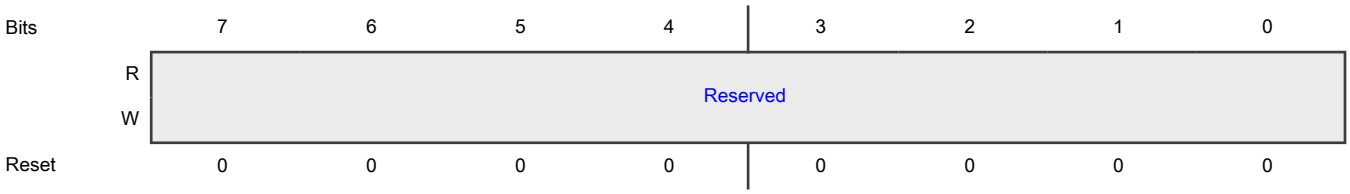
Offset

Register	Offset
PCI_CFH_CL_SIZE	Ch

Function

This is the PCI config header cache line size register.

Diagram



Fields

Field	Function
7-0 —	Cache line size For Virtual Functions, this field is reserved and hardwired to 0b.

53.4.6.2.7 PCI latency timer register (PCI_CFH_LAT_TIMER)

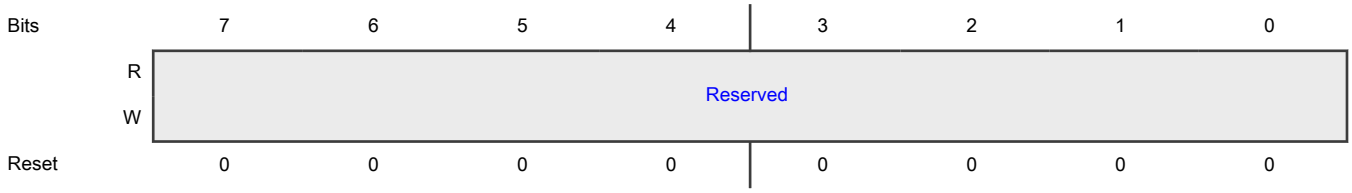
Offset

Register	Offset
PCI_CFH_LAT_TIMER	Dh

Function

This is the PCI config header latency timer register.

Diagram



Fields

Field	Function
7-0 —	Latency timer Does not apply to PCI Express. Hardwired to 00h.

53.4.6.2.8 PCI header type register (PCI_CFH_HDR_TYPE)

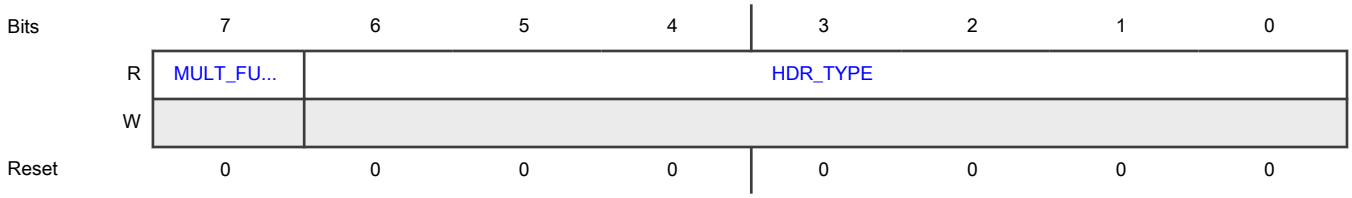
Offset

Register	Offset
PCI_CFH_HDR_TYPE	Eh

Function

This is the PCI config header type register.

Diagram



Fields

Field	Function
7 MULT_FUNC_DEV	Multi-function device For VFs this field is not applicable and is hardwired to 0b.
6-0 HDR_TYPE	Header type This field identifies the layout of the second part of the predefined header (beginning at byte 10h in Configuration Space). This register is hardwired to 00h (Type 0 header for both PFs and VFs).

53.4.6.2.9 PCI BIST register (PCI_CFH_BIST)

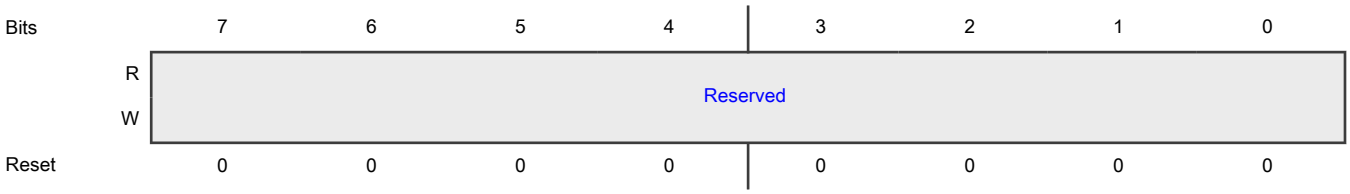
Offset

Register	Offset
PCI_CFH_BIST	Fh

Function

This is the PCI config header BIST register.

Diagram



Fields

Field	Function
7-0 —	Not supported. This register is hardwired to 00h.

53.4.6.2.10 PCI base address register 0 (PCI_CFH_BAR0)

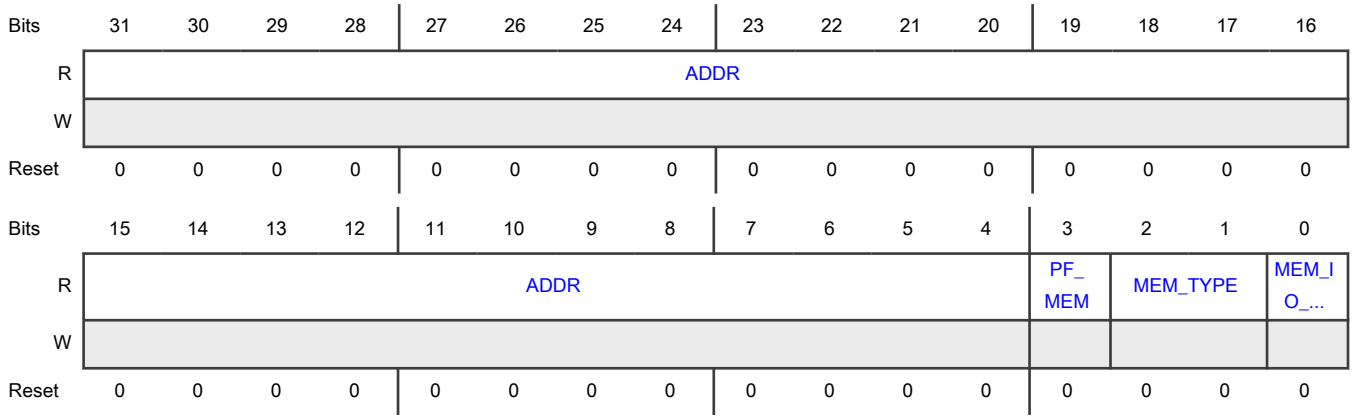
Offset

Register	Offset
PCI_CFH_BAR0	10h

Function

This is the PCI config header base address register 0.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.2.11 PCI base address register 1 (PCI_CFH_BAR1)

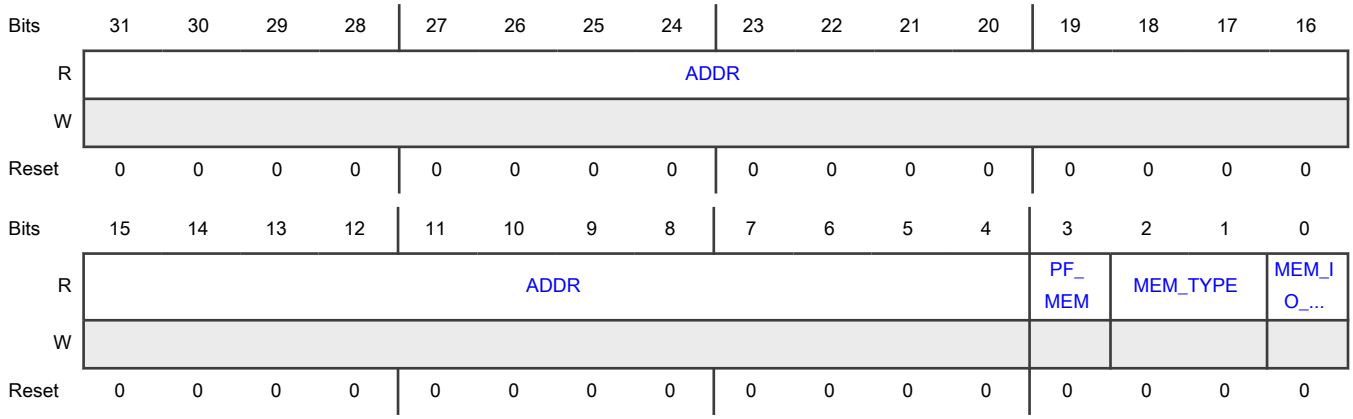
Offset

Register	Offset
PCI_CFH_BAR1	14h

Function

This is the PCI config header base address register 1.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.2.12 PCI base address register 2 (PCI_CFH_BAR2)

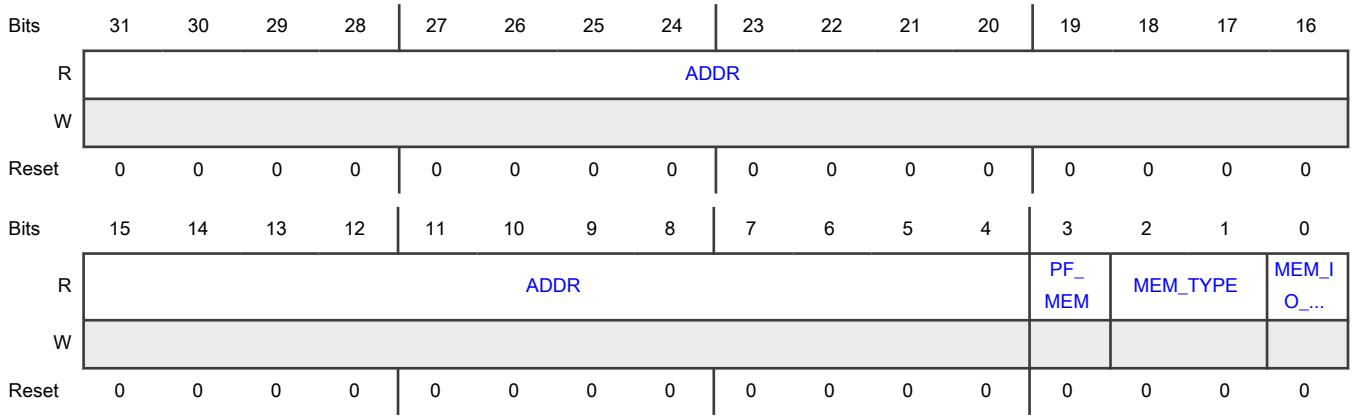
Offset

Register	Offset
PCI_CFH_BAR2	18h

Function

This is the PCI config header base address register 2.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.2.13 PCI base address register 3 (PCI_CFH_BAR3)

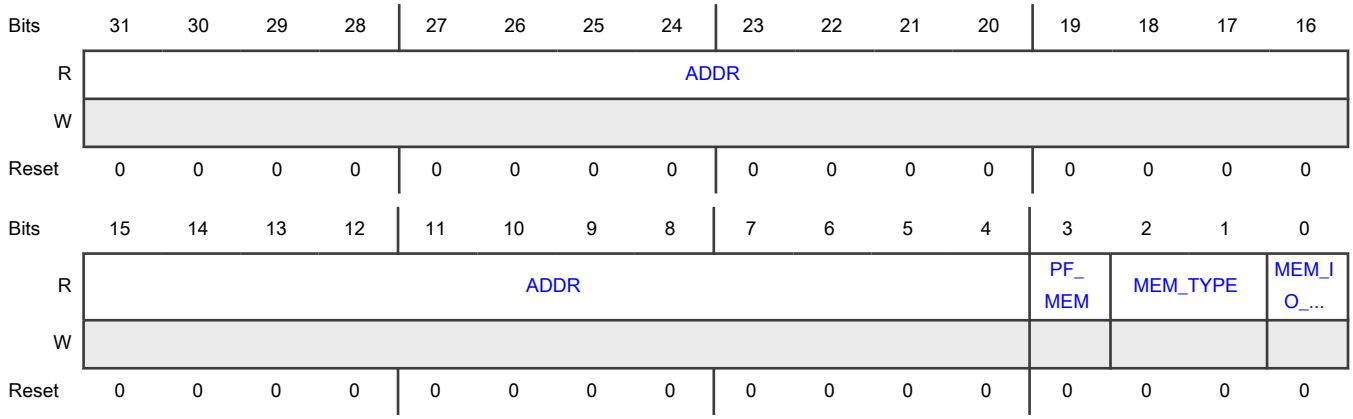
Offset

Register	Offset
PCI_CFH_BAR3	1Ch

Function

This is the PCI config header base address register 3.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.2.14 PCI base address register 4 (PCI_CFH_BAR4)

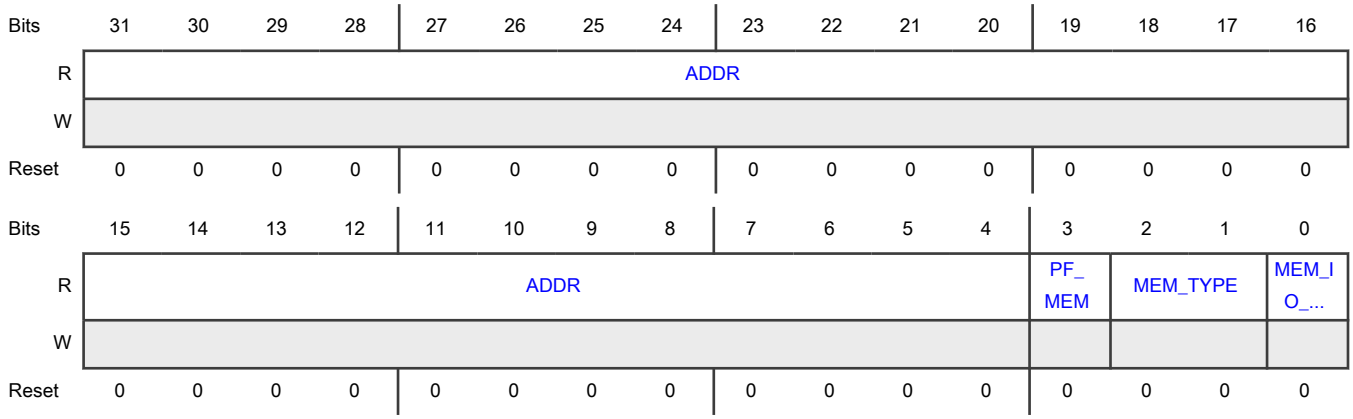
Offset

Register	Offset
PCI_CFH_BAR4	20h

Function

This is the PCI config header base address register 4.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.2.15 PCI base address register 5 (PCI_CFH_BAR5)

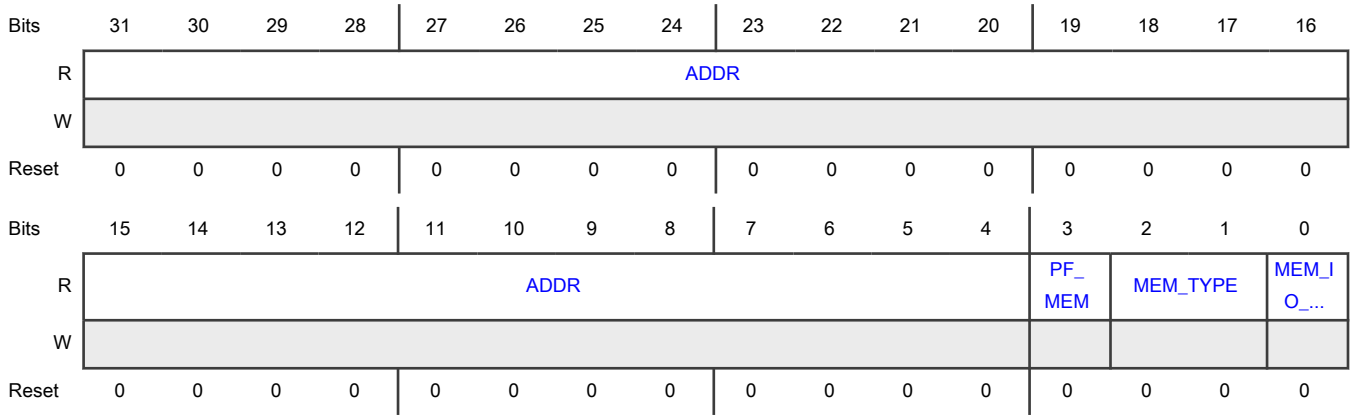
Offset

Register	Offset
PCI_CFH_BAR5	24h

Function

This is the PCI config header base address register 5.

Diagram



Fields

Field	Function
31-4 ADDR	EA BARs used. This register is hardwired to 000000h.
3 PF_MEM	EA BARs used. This register is hardwired to 0h.
2-1 MEM_TYPE	EA BARs used. This register is hardwired to 0h.
0 MEM_IO_IND	EA BARs used. This register is hardwired to 0h.

53.4.6.2.16 PCI cardbus CIS register (PCI_CFH_CARDBUS_CIS)

Offset

Register	Offset
PCI_CFH_CARDBUS_CIS	28h

Function

This is the PCI config header cardbus CSI register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CARDBUS_CIS_PTR															
W

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CARDBUS_CIS_PTR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 CARDBUS_CIS_PTR	Not applicable. This register is hardwired to 0000_0000h.

53.4.6.2.17 PCI subsystem vendor ID register (PCI_CFH_SUBSYS_VID)

Offset

Register	Offset
PCI_CFH_SUBSYS_VID	2Ch

Function

This is the PCI config header subsystem vendor ID register. The value read is taken from IERB register E*a*_CFH_SIDSVID.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SYBSYSTEM_VENDOR_ID															
W																
Reset	0	0	0	1	1	0	0	1	0	1	0	1	0	1	1	1

Fields

Field	Function
15-0 SYBSYSTEM_VENDOR_ID	This Read Only field identifies the manufacturer of the subsystem. The field in the PF and associated VFs must return the same value when read.

53.4.6.2.18 PCI subsystem ID register (PCI_CFH_SUBSYS_ID)

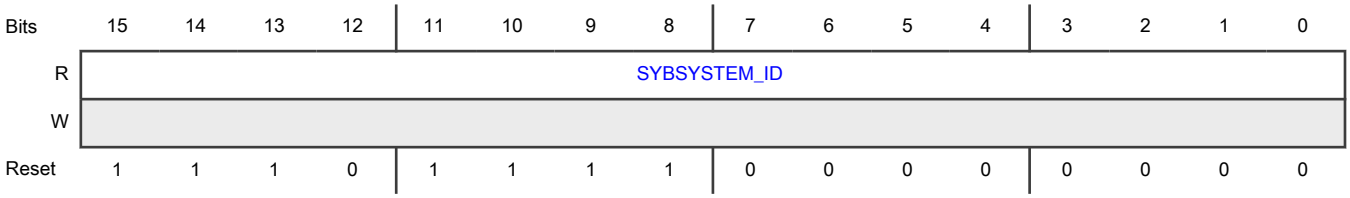
Offset

Register	Offset
PCI_CFH_SUBSYS_ID	2Eh

Function

This is the PCI config header subsystem ID register. The value read is taken from IERB register E*a*_CFC_VFDID.

Diagram



Fields

Field	Function
15-0 SYBSYSTEM_ID	This Read Only field identifies the particular subsystem. The Device may have a different value in the PF and the VF.

53.4.6.2.19 PCI expansion ROM base address register (PCI_CFH_EXP_ROM_BA)

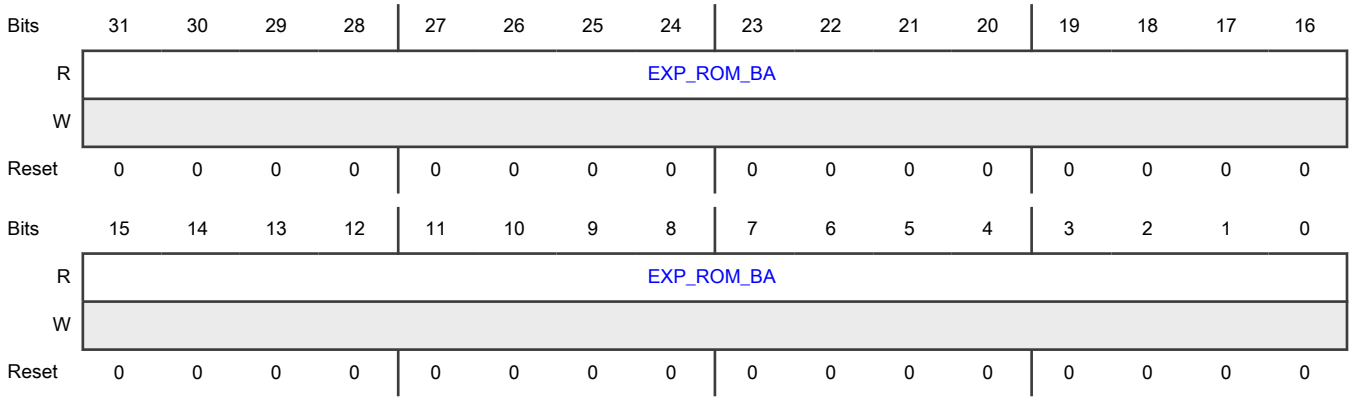
Offset

Register	Offset
PCI_CFH_EXP_ROM_BA	30h

Function

This is the PCI config header expansion ROM base address register.

Diagram



Fields

Field	Function
31-0 EXP_ROM_BA	Not applicable. This register is hardwired to 0000_0000h.

53.4.6.2.20 PCI capabilities pointer register (PCI_CFH_CAP_PTR)

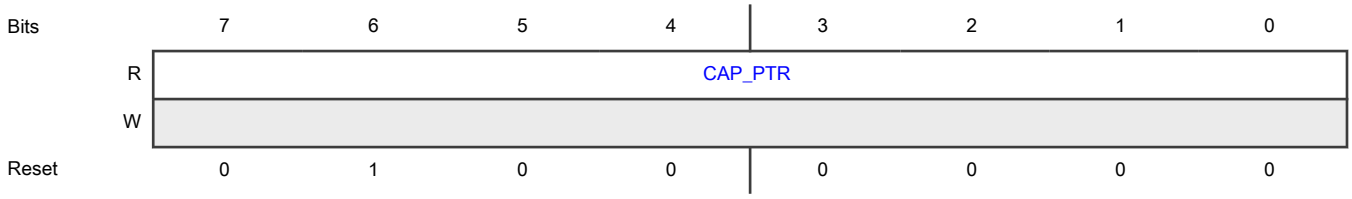
Offset

Register	Offset
PCI_CFH_CAP_PTR	34h

Function

This is the PCI config header capabilities pointer register.

Diagram



Fields

Field	Function
7-0 CAP_PTR	This register is used to point to a linked list of new capabilities implemented by this device. This register is only valid if the “Capabilities List” bit in the Status Register is set. If implemented, the bottom two bits are reserved and should be set to 00b. Software should mask these bits off before using this register as a pointer in Configuration Space to the first entry of a linked list of new capabilities. Hardwired to 40h.

53.4.6.2.21 PCI PCIe capabilities list register (PCI_CFC_PCIE_CAP_LIST)

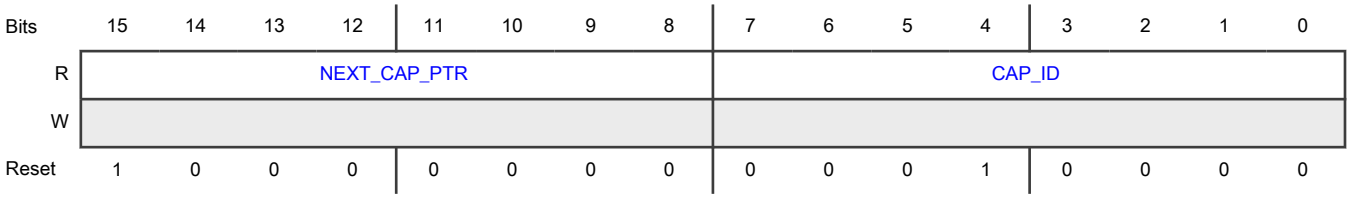
Offset

Register	Offset
PCI_CFC_PCIE_CAP_LIST	40h

Function

This is the PCI config capability PCIe capabilities list register.

Diagram



Fields

Field	Function
15-8 NEXT_CAP_PTR	This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of capabilities. Hardwired to 80h.
7-0 CAP_ID	Indicates the PCI Express Capability structure. Hardwired to 10h.

53.4.6.2.22 PCI PCIe capabilities register (PCI_CFC_PCIE_CAP)

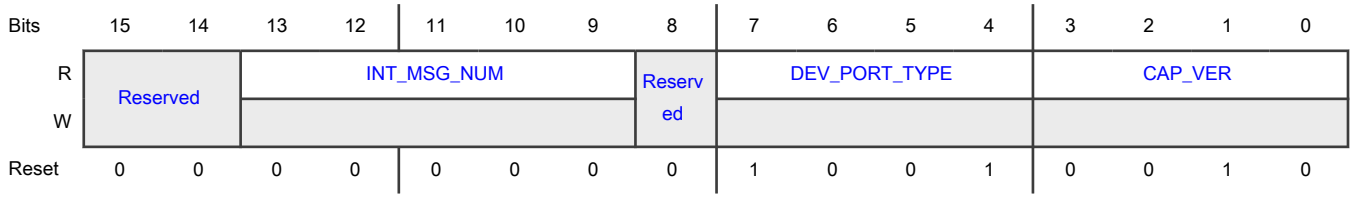
Offset

Register	Offset
PCI_CFC_PCIE_CAP	42h

Function

This is the PCI config capability PCIe capabilities register.

Diagram



Fields

Field	Function
15-14 —	Reserved
13-9 INT_MSG_NUM	Interrupt message number This field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this capability structure. For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant. If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined. Errors for ENETC are handled through the Event Collector. Hardwired to 00h.
8 —	Reserved
7-4 DEV_PORT_TYPE	Device/Port type Indicates the specific type of this PCI Express Function. Hardwired to 9h to indicate Root Complex Integrated Endpoint.
3-0 CAP_VER	Capability Version Indicates PCI-SIG defined PCI Express Capability structure version number. Hardwired to 2h.

53.4.6.2.23 PCI PCIe device capabilities register (PCI_CFC_PCIE_DEV_CAP)

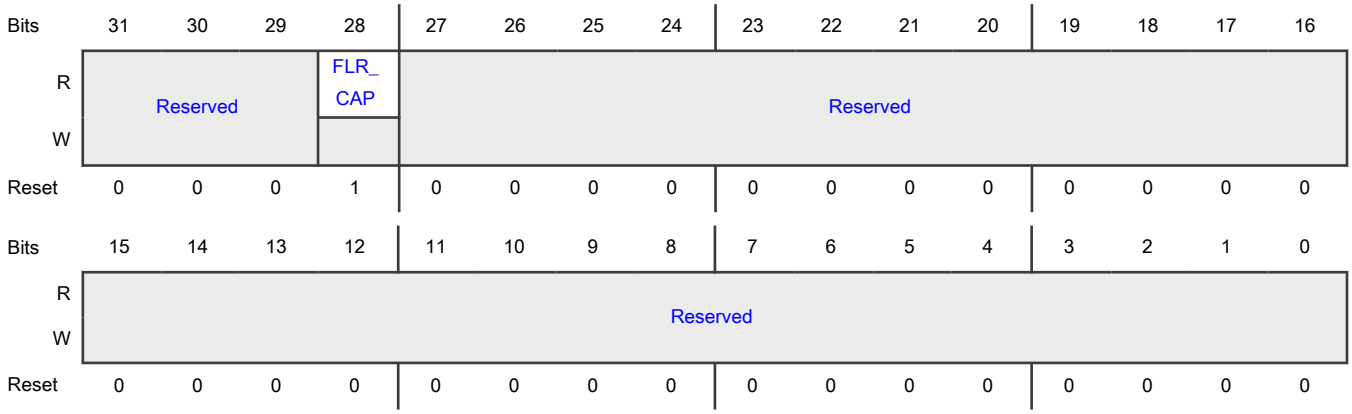
Offset

Register	Offset
PCI_CFC_PCIE_DEV_CAP	44h

Function

This is the PCI config capability PCIe device capabilities register.

Diagram



Fields

Field	Function
31-29 —	Reserved
28 FLR_CAP	Function level reset capability A value of 1b indicates the function supports the optional Function Level Reset (FLR) mechanism. Hardwired to 1b.
27-0 —	Reserved

53.4.6.2.24 PCI PCIe device control register (PCI_CFC_PCIE_DEV_CTL)

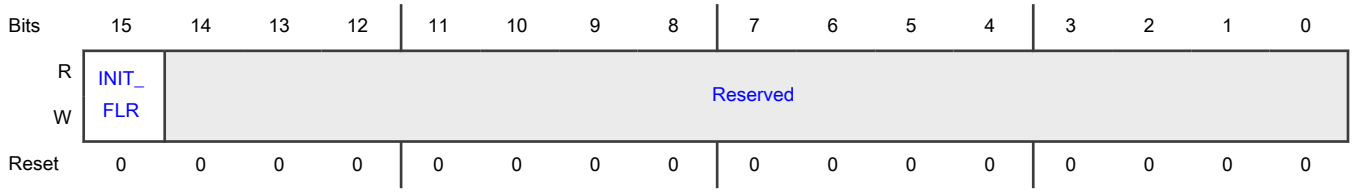
Offset

Register	Offset
PCI_CFC_PCIE_DEV_CTL	48h

Function

This is the PCI config capability PCIe device control register.

Diagram



Fields

Field	Function
15 INIT_FLR	Initiate function level reset A write of b1 initiates Function Level Reset (FLR). The bit will self-clear when the reset sequence is complete and function can be re-configured by software.
14-0 —	Reserved

53.4.6.2.25 PCI PCIe device status register (PCI_CFC_PCIE_DEV_STAT)

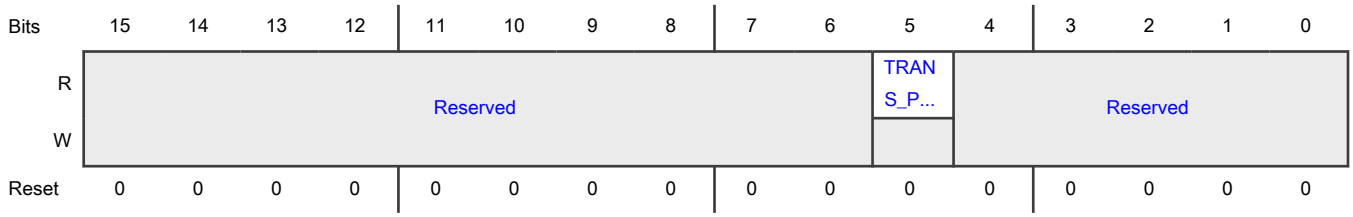
Offset

Register	Offset
PCI_CFC_PCIE_DEV_STAT	4Ah

Function

This is the PCI config capability PCIe device status register.

Diagram



Fields

Field	Function
15-6 —	Reserved
5	Transaction pending

Table continues on the next page...

Table continued from the previous page...

Field	Function
TRANS_PEND	If set indicates that the Function has outstanding transactions on its external master interface.
4-0 —	Reserved

53.4.6.2.26 PCI PCIe device capabilities 2 register (PCI_CFC_PCIE_DEV_CAP2)

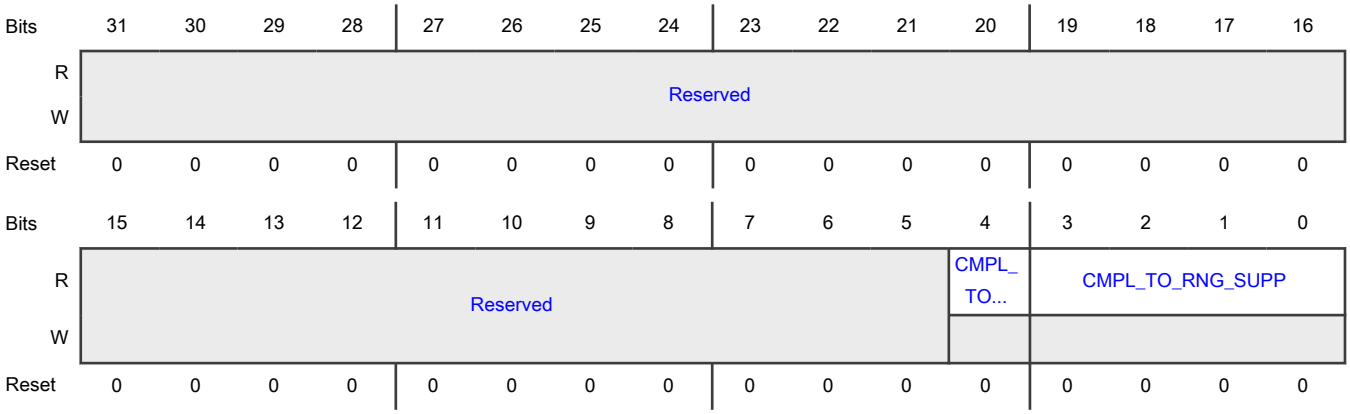
Offset

Register	Offset
PCI_CFC_PCIE_DEV_CAP2	64h

Function

This is the PCI config capability PCIe device capabilities 2 register.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 CMPL_TO_DIS_SUPP	Completion Timeout Disable Supported When set (b1) indicates support for the Completion Timeout Disable mechanism.
3-0	Completion Timeout Ranges Supported

Table continues on the next page...

Table continued from the previous page...

Field	Function
CMPL_TO_RNG_SUPP	Completion Timeout programming not supported, the Function assumes a timeout value in the range 50 µs to 50 ms.

53.4.6.2.27 PCI PCIe device control 2 register (PCI_CFC_PCIE_DEV_CTL2)

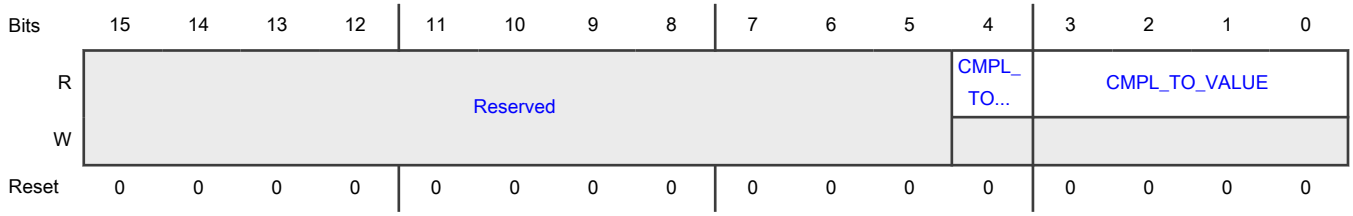
Offset

Register	Offset
PCI_CFC_PCIE_DEV_CTL2	68h

Function

This is the PCI config capability PCIe device control 2 register.

Diagram



Fields

Field	Function
15-5 —	Reserved
4 CMPL_TO_EN	Completion Timeout Enable Not supported. Hardwired to b0.
3-0 CMPL_TO_VALUE	Completion Timeout Value Completion Timeout programming not supported – the Function assumes a timeout value in the range 50 µs to 50 ms. Hardwired to b0000.

53.4.6.2.28 PCI MSI-X capabilities list register (PCI_CFC_MSIX_CAP_LIST)

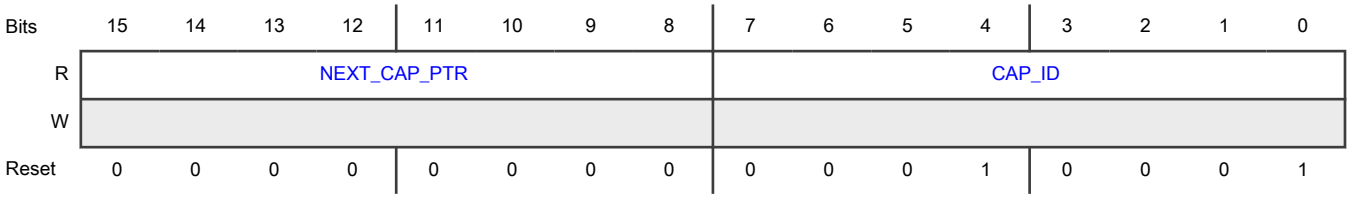
Offset

Register	Offset
PCI_CFC_MSIX_CAP_LIST	80h

Function

This is the PCI config capability MSI-X capabilities list register.

Diagram



Fields

Field	Function
15-8 NEXT_CAP_PTR	This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of capabilities. Hardwired to 00h.
7-0 CAP_ID	Indicates the MSI-X Capability structure. Hardwired to 11h.

53.4.6.2.29 PCI MSI-X message control register (PCI_CFC_MSIX_MSG_CTL)

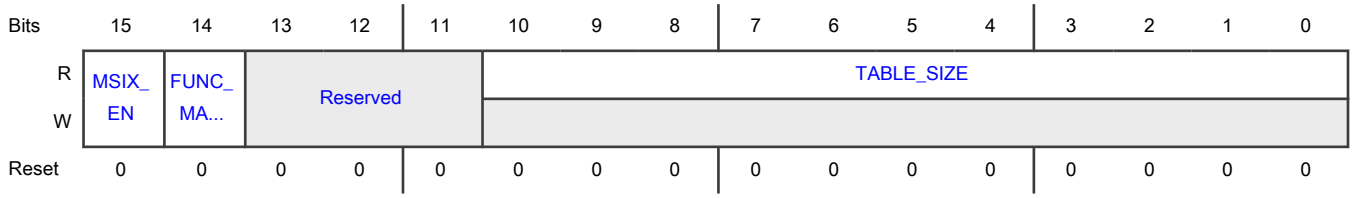
Offset

Register	Offset
PCI_CFC_MSIX_MSG_CTL	82h

Function

This is the PCI config capability MSI-X message control register.

Diagram



Fields

Field	Function
15 MSIX_EN	MSI-X enable If set, the function is permitted to use MSI-X to request service. System configuration software sets this bit to enable MSI-X. A device driver is prohibited from writing this bit to mask a function's service request. If 0, the function is prohibited from using MSI-X to request service. This bit's state after reset is 0 (MSI-X is disabled).
14 FUNC_MASK	Function mask If 1, all of the vectors associated with the function are masked, regardless of their per-vector Mask bit states. If 0, each vector's Mask bit determines whether the vector is masked or not. Setting or clearing the MSI-X Function Mask bit has no effect on the state of the per-vector Mask bits. This bit's state after reset is 0 (unmasked).
13-11 —	Reserved
10-0 TABLE_SIZE	Table size System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1. For example, a returned value of "00000000011" indicates a table size of 4. **NOTE** Table size is defined by ENETC register PSI*a*CFGR2[NUM_MSIX], mapped as VF*a*, and is immediately reflected here.

53.4.6.2.30 PCI MSI-X table offset/BIR register (PCI_CFC_MSIX_TABLE_OFF_BIR)

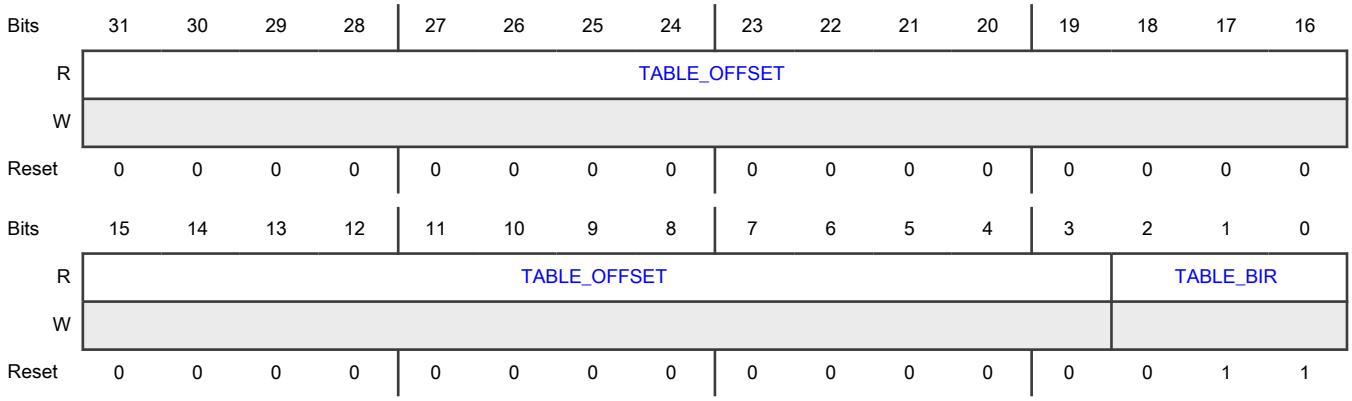
Offset

Register	Offset
PCI_CFC_MSIX_TABLE_OFF_BIR	84h

Function

This is the PCI config capability MSI-X table offset/BIR register.

Diagram



Fields

Field	Function
31-3 TABLE_OFFSET	Table Offset Used as an offset from the address contained by one of the function's Base Address registers to point to the base of the MSI-X Table. The lower 3 Table BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset.
2-0 TABLE_BIR	Table BIR Indicates which entry in the Enhanced Allocation capability with a matching BEI, is used to map the Function's MSI-X Table into Memory Space. For a 64-bit Base Address register, the Table BIR indicates the lower DWORD. Virtual functions hardwires this field to 011b (PE entry 3) for MSI-X table.

53.4.6.2.31 PCI MSI-X PBA offset/BIR register (PCI_CFC_MSIX_PBA_OFF_BIR)

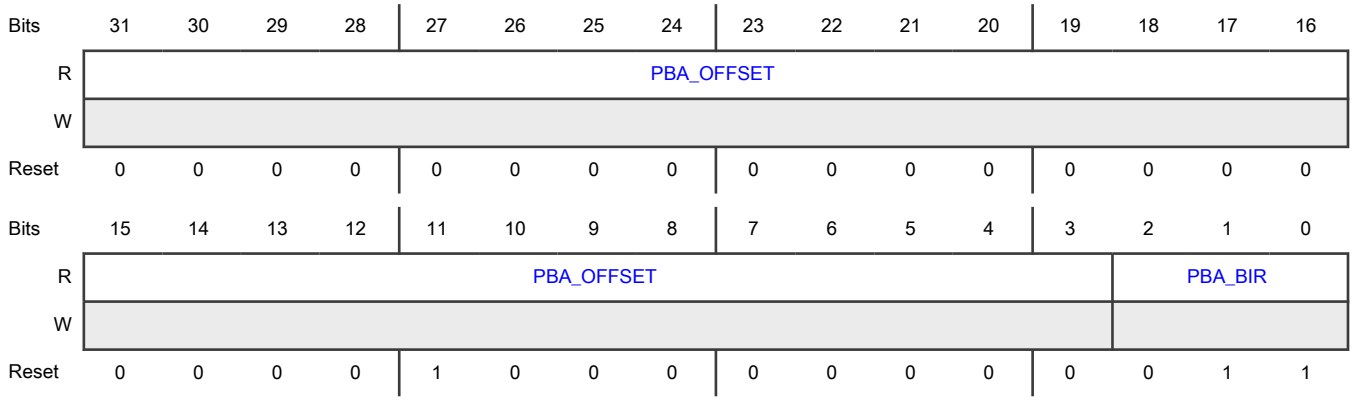
Offset

Register	Offset
PCI_CFC_MSIX_PBA_OFF_BIR	88h

Function

This is the PCI config capability MSI-X PBA offset/BIR register.

Diagram



Fields

Field	Function
31-3 PBA_OFFSET	PBA Offset Used as an offset from the address contained by one of the function's Base Address registers to point to the base of the MSI-X PBA. The lower 3 PBA BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset. The PBA structure directly follows the maximum possible MSI-X table size (2KB).
2-0 PBA_BIR	PBA BIR Indicates which entry in the Enhanced Allocation capability with a matching BEI, is used to map the Function's MSI-X PBA into Memory Space. For a 64-bit Base Address register, the PBA BIR indicates the lower DWORD. Virtual function hardwires this field to 011b (PE entry 3) for MSI-X PBA.

53.4.6.2.32 PCIe AER extended capability header (PCIE_CFC_AER_EXT_CAP_HDR)

Offset

Register	Offset
PCIE_CFC_AER_EXT_CAP_HDR	100h

Function

This is the PCIe config capability Advanced Error Reporting extended capability header.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEXT_CAP_OFF												CAP_VER

R	PCIE_EXT_CAP_ID															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-20 NEXT_CAP_OFF	Next capability offset This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of capabilities.
19-16 CAP_VER	Capability version Must be 1h for this version of the specification.
15-0 PCIE_EXT_CAP_ID	The Extended Capability ID for the AER Extended Capability is 0001h.

53.4.6.2.33 PCIe AER uncorrectable error status register (PCIE_CFC_AER_UCORR_ERR_STAT)

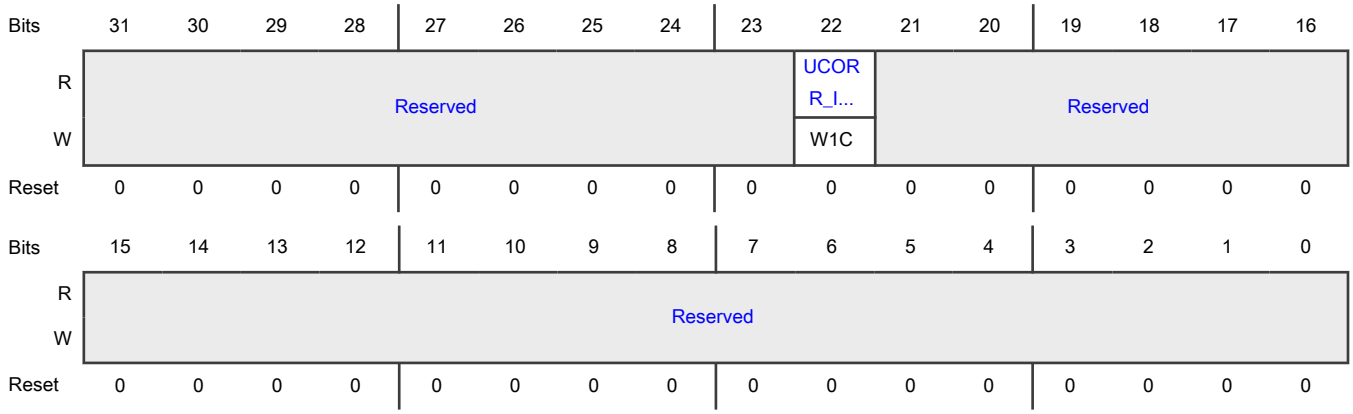
Offset

Register	Offset
PCIE_CFC_AER_UCORR_ERR_STAT	104h

Function

This is the PCIe config capability Advanced Error Reporting uncorrectable error status register. The Uncorrectable Error Status register indicates error detection status of individual errors on a PCI Express device Function. An individual error status bit that is set indicates that a particular error was detected; software may clear an error status by writing a 1b to the respective bit.

Diagram



Fields

Field	Function
31-23 —	Reserved
22 UCORR_INT_ERR	Uncorrectable internal error Set to indicate some uncorrectable internal error such as a multi-bit error in an internal memory has occurred. **NOTE** This bit is “sticky” and will be preserved across function level resets.
21-0 —	Reserved

53.4.6.2.34 PCIe AER uncorrectable error mask register (PCIE_CFC_AER_UCORR_ERR_MASK)

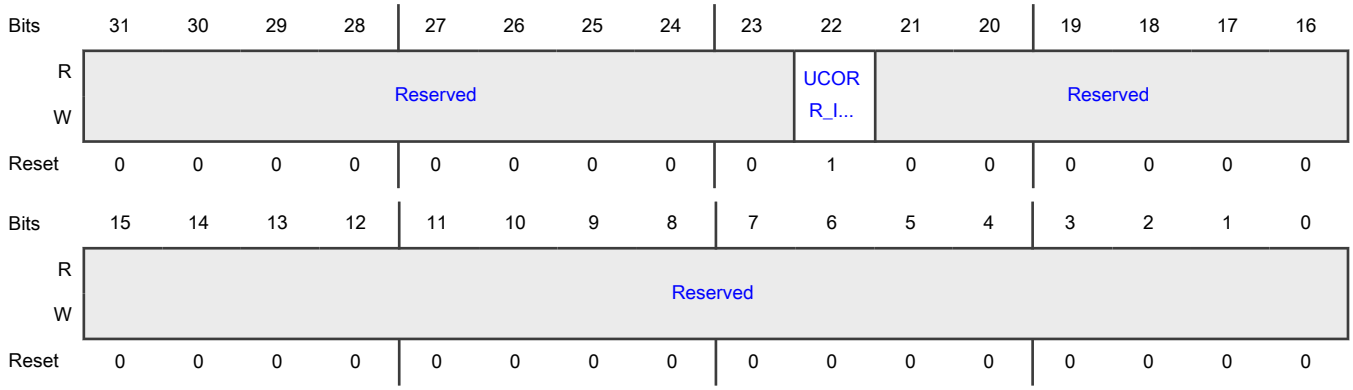
Offset

Register	Offset
PCIE_CFC_AER_UCORR_ERR_MASK	108h

Function

This is the PCIe config capability Advanced Error Reporting uncorrectable error mask register. The Uncorrectable Error Mask register controls reporting of individual errors by the device Function to the PCI Express Root Complex Event Collector via a PCI Express error Message. A masked error (respective bit set in the mask register) is not recorded or reported in the Header Log or First Error Pointer, and is not reported to the PCI Express Root Complex Event Collector by this Function. There is a mask bit per error bit of the Uncorrectable Error Status register.

Diagram



Fields

Field	Function
31-23 —	Reserved
22 UCORR_INT_ERR_MASK	Uncorrectable internal error mask 0 Not masked 1 Masked **NOTE** This bit is “sticky” and will be preserved across function level resets.
21-0 —	Reserved

53.4.6.2.35 PCIe AER uncorrectable error severity register (PCIE_CFC_AER_UCORR_ERR_SEV)

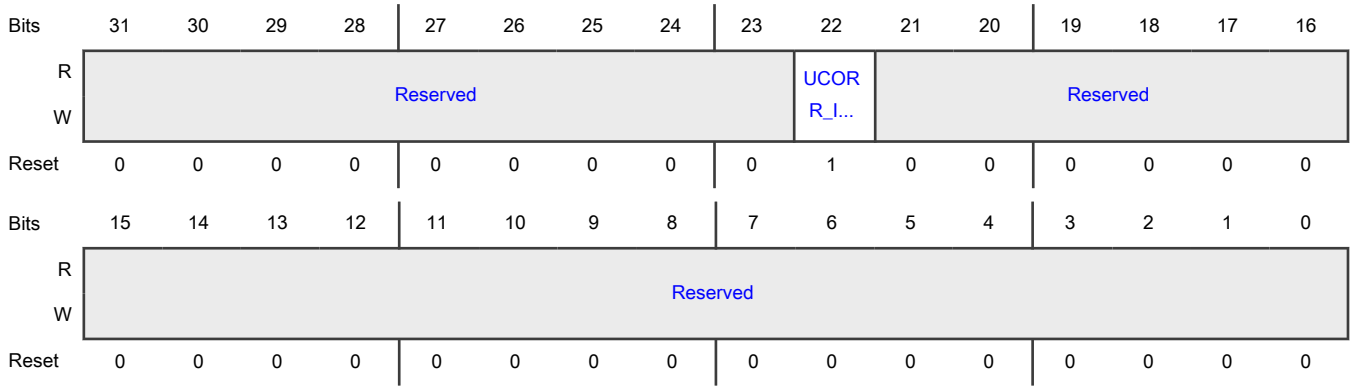
Offset

Register	Offset
PCIE_CFC_AER_UCORR_ERR_SEV	10Ch

Function

This is the PCIe config capability Advanced Error Reporting uncorrectable error severity register. The Uncorrectable Error Severity register controls whether an individual error is reported as a Non-fatal or Fatal error. An error is reported as fatal when the corresponding error bit in the severity register is Set. If the bit is Clear, the corresponding error is considered non-fatal.

Diagram



Fields

Field	Function
31-23 —	Reserved
22 UCORR_INT_SEV	Uncorrectable internal severity 0 Non-fatal 1 Fatal **NOTE** This bit is “sticky” and will be preserved across function level resets.
21-0 —	Reserved

53.4.6.2.36 PCIe AER correctable error status register (PCIE_CFC_AER_CORR_ERR_STAT)

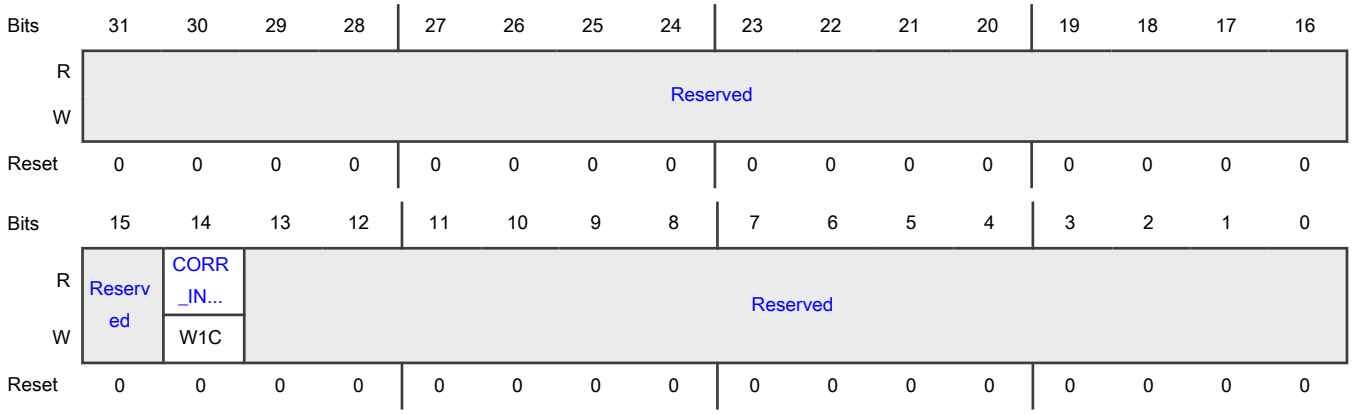
Offset

Register	Offset
PCIE_CFC_AER_CORR_ERR_STAT	110h

Function

This is the PCIe config capability Advanced Error Reporting correctable error status register. The Correctable Error Status register reports error status of individual correctable error sources on a PCI Express device Function. When an individual error status bit is Set, it indicates that a particular error occurred; software may clear an error status by writing a 1b to the respective bit.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 CORR_INT_ERR	Correctable internal error Set to indicate some correctable internal error has occurred such as a single bit error in an internal memory. **NOTE** This bit is “sticky” and will be preserved across function level resets.
13-0 —	Reserved

53.4.6.2.37 PCIe AER correctable error mask register (PCIE_CFC_AER_CORR_ERR_MASK)

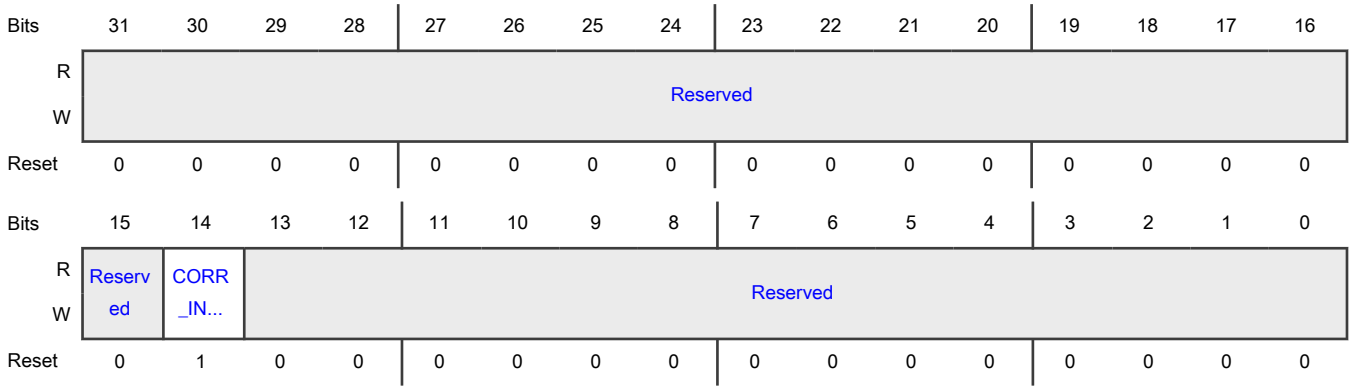
Offset

Register	Offset
PCIE_CFC_AER_CORR_ERR_MASK	114h

Function

This is the PCIe config capability Advanced Error Reporting correctable error mask register. The Correctable Error Mask register controls reporting of individual correctable errors by this Function to the PCI Express Root Complex via a PCI Express error Message. A masked error (respective bit set in the mask register) is not reported to the PCI Express Root Complex by this Function. There is a mask bit per error bit in the Correctable Error Status register.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 CORR_INT_MASK	Correctable internal error mask 0 Not masked 1 Masked **NOTE** This bit is “sticky” and will be preserved across function level resets.
13-0 —	Reserved

53.4.6.2.38 PCIe AER capabilities and control register (PCIE_CFC_AER_CAP_CTL)

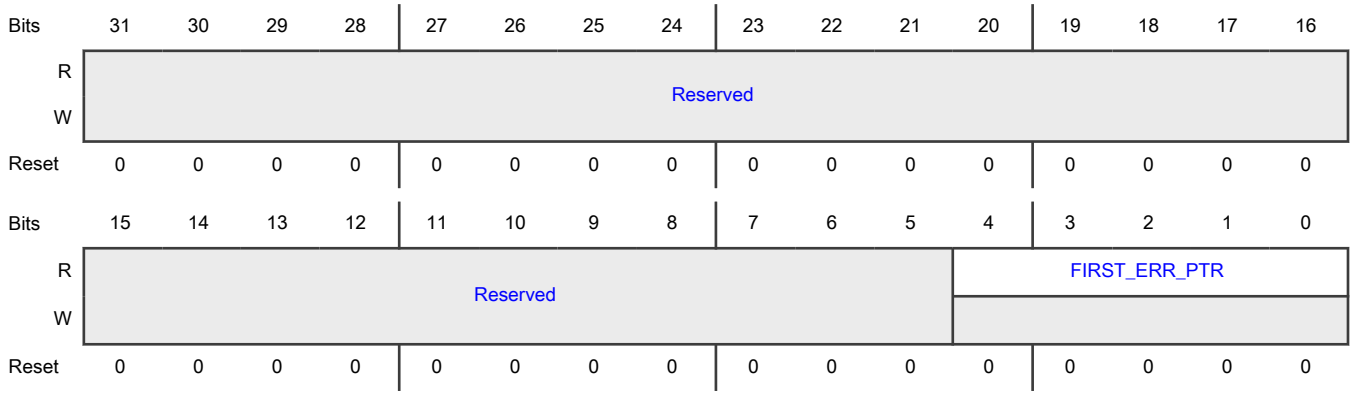
Offset

Register	Offset
PCIE_CFC_AER_CAP_CTL	118h

Function

This is the PCIe config capability Advanced Error Reporting capabilities and control register.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 FIRST_ERR_PTR	First error pointer The First Error Pointer is a field that identifies the bit position of the first error reported in the Uncorrectable Error Status register.

53.4.6.2.39 PCIe ACS capability header (PCIE_CFC_ACS_CAP_HDR)

Offset

Register	Offset
PCIE_CFC_ACS_CAP_HDR	130h

Function

This is the PCIe config capability Access Control Services (ACS) capability header.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	PCIE_EXT_CAP_ID															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

Fields

Field	Function
31-20 NEXT_CAP_OFF	Next capability offset This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of capabilities.
19-16 CAP_VER	Capability version Must be 1h for this version of the specification.
15-0 PCIE_EXT_CAP_ID	The Extended Capability ID for the ACS Extended Capability is 000Dh.

53.4.6.2.40 PCIe ACS capability register (PCIE_CFC_ACS_CAP)

Offset

Register	Offset
PCIE_CFC_ACS_CAP	134h

Function

This is the PCIe config capability Access Control Services (ACS) capability register.

Diagram

Fields

Field	Function
15-7 —	Reserved
6 ACS_DIR_TRANS_P2P	ACS direct translated P2P (T) Set to indicate that the Function supports direct translated peer-to-peer.
5-3 —	Reserved
2 ACS_P2P_REQ_REDIR	ACS P2P request redirect (R) Set to indicate that the Function supports peer-to-peer request redirection.
1 ACS_TRANS_BLOCK	ACS translation blocking (B) Set to indicate that the Function supports Translation Blocking.
0 —	Reserved

53.4.6.2.41 PCIe ACS control register (PCIE_CFC_ACS_CTL)

Offset

Register	Offset
PCIE_CFC_ACS_CTL	136h

Function

This is the PCIe config capability Access Control Services (ACS) control register.

Diagram

Fields

Field	Function
15-7 —	Reserved
6 ACS_DIR_TRANS_P2P_EN	ACS direct translated P2P enable (T) When set the Function determines how to direct peer-to-peer requests based on ATS Ignored if ACS Translation Blocking Enable is set. This bit is read-only if the functionality is not implemented.
5-3 —	Reserved
2 ACS_P2P_REQ_REDIR_EN	ACS P2P request redirect enable (R) When set the Function directs peer-to-peer requests to the SoC interconnect. This bit is read-only if the functionality is not implemented.
1 ACS_TRANS_BLOCK_EN	ACS translation blocking enable (B) When set the Function directs peer-to-peer requests to the SoC interconnect. This bit is read-only if the functionality is not implemented.
0 —	Reserved

53.4.6.2.42 PCIe readiness time reporting capability header (PCIE_CFC_RTR_CAP_HDR)

Offset

Register	Offset
PCIE_CFC_RTR_CAP_HDR	140h

Function

This is the PCIe config capability readiness time reporting capability header.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	PCIE_EXT_CAP_ID															
W																
Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1	0

Fields

Field	Function
31-20 NEXT_CAP_OFF	Next capability offset This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of capabilities.
19-16 CAP_VER	Capability version Must be 1h for this version of the specification.
15-0 PCIE_EXT_CAP_ID	The Extended Capability ID for the Readiness Time Reporting Extended Capability is 0022h.

53.4.6.2.43 PCIe RTR readiness time reporting 1 register (PCIE_CFC_RTR_RTR1)

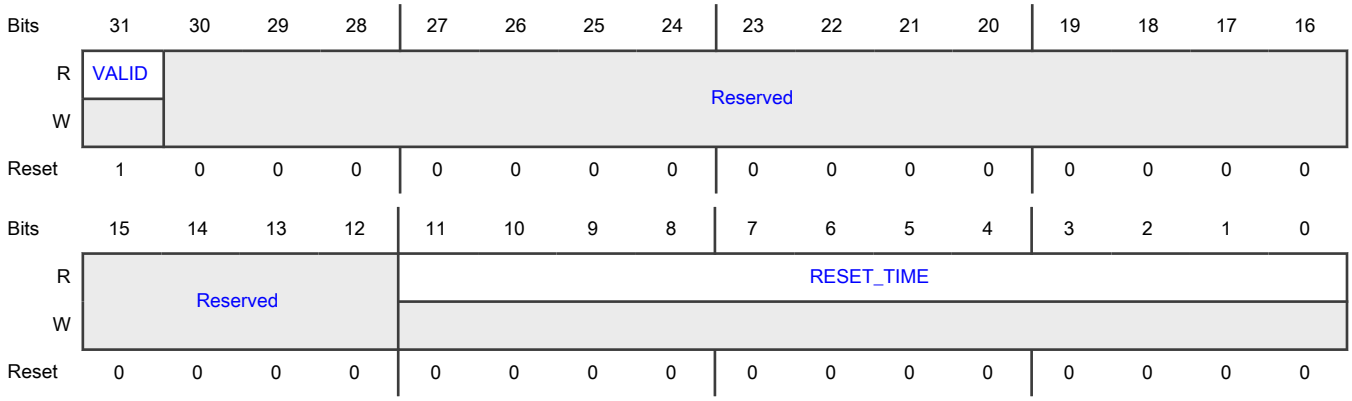
Offset

Register	Offset
PCIE_CFC_RTR_RTR1	144h

Function

This is the PCIe config capability Readiness Time Reporting 1 register.

Diagram



Fields

Field	Function
31 VALID	Valid If Set, indicates that all time values in this capability are valid. If Clear, indicates that the time values in this capability are not yet available. If this bit remains Clear and 1 minute has elapsed after all associated device driver(s) have started, software is permitted to assume that this bit will never be set.
30-12 —	Reserved
11-0 RESET_TIME	Reset Time The time the Function requires to become Configuration-Ready after the completion of Conventional Reset. This field is undefined when the Valid bit is Clear. This field must be less than or equal to the encoded value A1Eh.

53.4.6.2.44 PCIe RTR readiness time reporting 2 register (PCIE_CFC_RTR_RTR2)

Offset

Register	Offset
PCIE_CFC_RTR_RTR2	148h

Function

This is the PCIe config capability Readiness Time Reporting 2 register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								D3HOT_D0_TIME							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	D3HOT_D0_TIME				FLR_TIME											
W																
Reset	0	0	0	0	0	1	1	0	0	0	1	1	0	1	0	0

Fields

Field	Function
31-24 —	Reserved
23-12 D3HOT_D0_TIME	D3 hot to D0 time $D3_{hot}$ to D0 Time is the time that the Function requires after it is directed from $D3_{hot}$ to D0 before it is Configuration-Ready and has returned to either $D0_{uninitialized}$ or $D0_{active}$ state (see the PCI Bus Power Management Interface Specification). This field is undefined when the PCIE_CFC_RTR_RTR1[VALID] bit is Clear. This field must be less than or equal to the encoded value 80Ah.
11-0 FLR_TIME	FLR Time The time that the Function requires to become Configuration-Ready after it was issued an FLR. This field is undefined when the PCIE_CFC_RTR_RTR1[VALID] bit is Clear. This field must be less than or equal to the encoded value A1Eh. **NOTE** The value is taken directly from IERB register NETCFLRCR. The value in this field is encoded, where bits 8-0 is the value, and bits 11-9 is the scale. The scale is hardwired as 32.768us.

53.4.6.3 NETC Integrated Endpoint Register Block register descriptions

This section describes the Integrated Endpoint Register Block (IERB) registers. The IERB is a 64 KB size page containing registers that are used for pre-boot initialization, debug, and non-customer configuration.

The lower 32 KB of the IERB are reserved for architected registers required for IEPs. The upper 32 KB are used for NETC specific resources.

53.4.6.3.1 IERB memory map

NETC_IERB base address: 6080_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Capability register 0 (CAPR0)	32	R	0111_0651h
4h	Capability register 1 (CAPR1)	32	R	000E_000Eh

Register	Offset
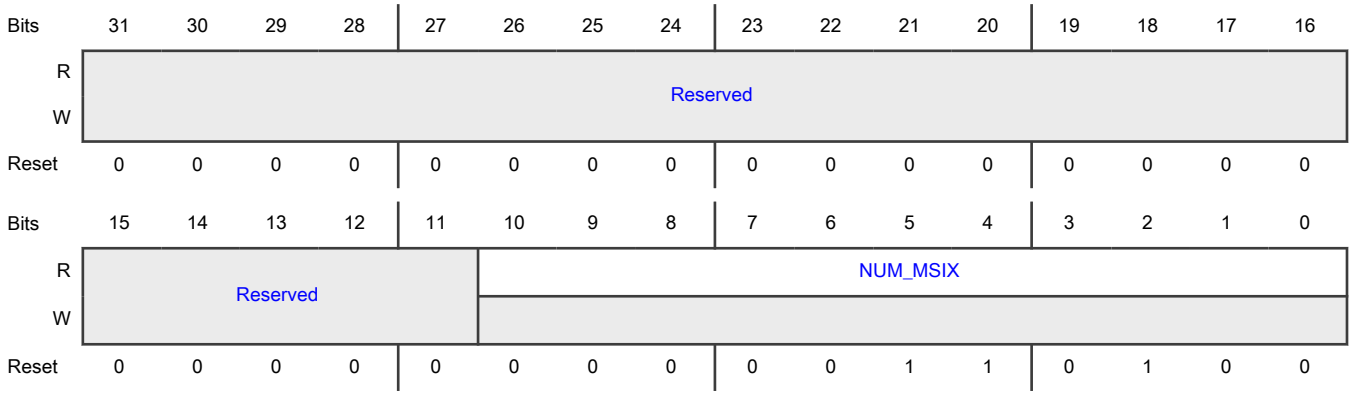
CAPR2	8h

Function

This is the capability register 2.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-0 NUM_MSIX	Number of MSI-X table entries available for allocation by NETC functions. Formula: NUM_MSIX+1 Range: 1..1024 **NOTE** If allocated entries to NETC functions exceed this value, error is indicated by NETCSR[ERROR]. One entry is always allocated to the EMDIO controller.

53.4.6.3.5 Capability register 3 (CAPR3)

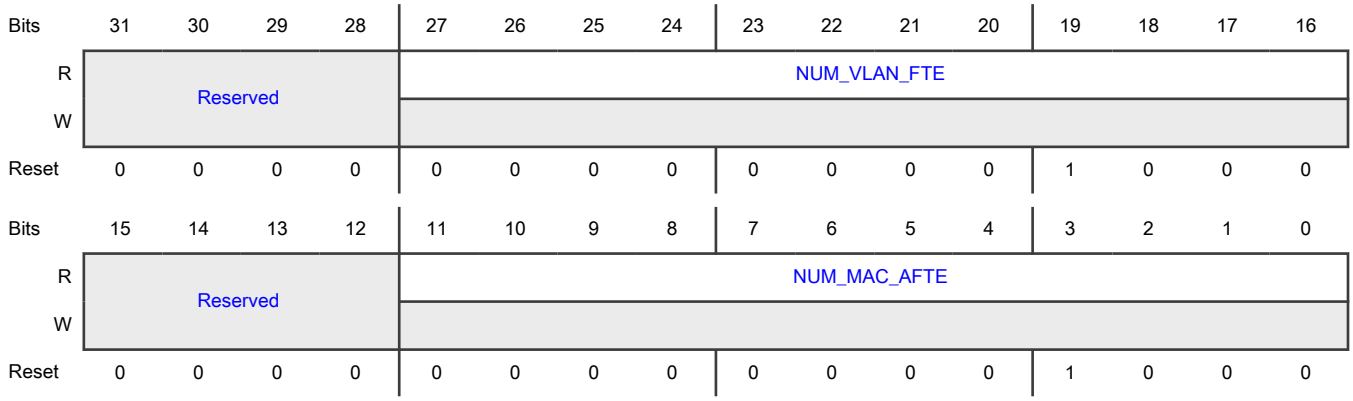
Offset

Register	Offset
CAPR3	Ch

Function

This is the capability register 3.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-16 NUM_VLAN_FTE	Total number of ENETC SI VLAN filter rules supported by NETC.
15-12 —	Reserved
11-0 NUM_MAC_AFTE	Total number of ENETC SI MAC address filter rules supported by NETC.

53.4.6.3.6 Common memory capability register (CMCAPR)

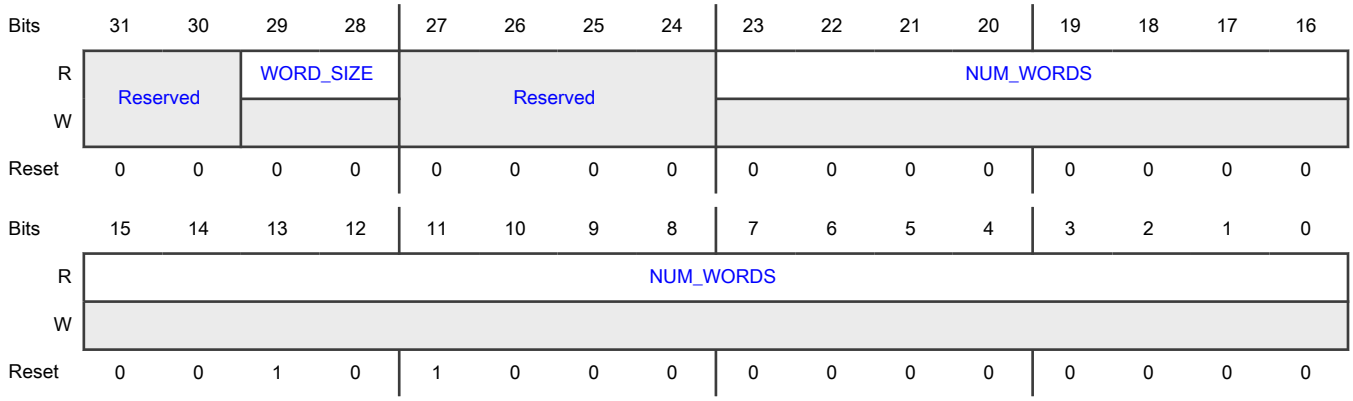
Offset

Register	Offset
CMCAPR	20h

Function

This is the common memory capability register.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-28 WORD_SIZE	Word size in bytes 0: 24B 1-3: reserved
27-24 —	Reserved
23-0 NUM_WORDS	Total amount of common memory in words available to NETC. This memory is partitioned between hash bucket table memory, each NETC function's index table memory with the remainder for buffering and hash tables.

53.4.6.3.7 Ingress port filter ternary memory capability register (IPFTMCAPR)

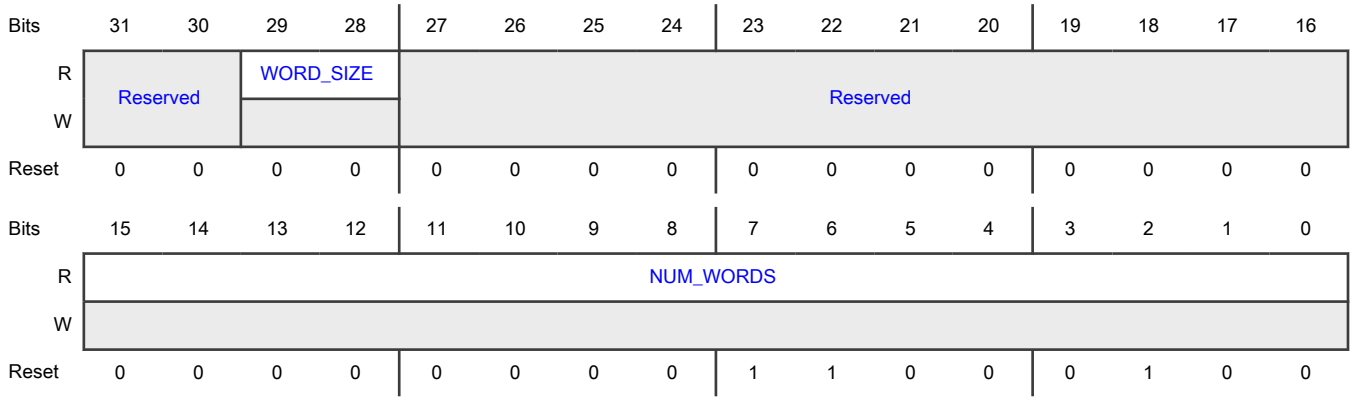
Offset

Register	Offset
IPFTMCAPR	30h

Function

This is the ingress port filter ternary memory capability register.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-28 WORD_SIZE	Word size in bits 0: 48 bits 1-3: reserved
27-16 —	Reserved
15-0 NUM_WORDS	Total amount of ternary memory in words available to NETC for ingress port filtering. This memory is partitioned between various NETC functions. **NOTE** If sum of allocated entries (S*a*IPFTMAR and E*a*IPFTMAR) exceed this value, error is indicated by NETCSR[ERROR].

53.4.6.3.8 Time gate scheduling memory capability register (TGSMCAPR)

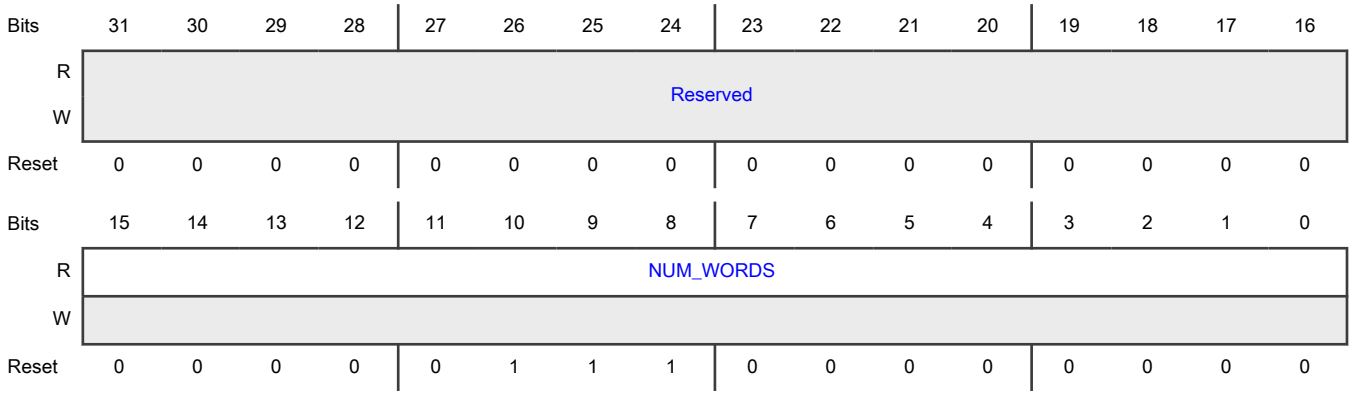
Offset

Register	Offset
TGSMCAPR	44h

Function

This is the time gate scheduling memory capability register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 NUM_WORDS	Total amount of Time Gate Scheduling memory in words available to NETC. **NOTE** This memory may be partitioned between switch and ENETC Instances. If sum of allocated entries (S*a*TGSTAR and E*a*TGSTAR) exceed this value, error is indicated by NETCSR[ERROR].

53.4.6.3.9 Shared memory depletion threshold register (SMDTR)

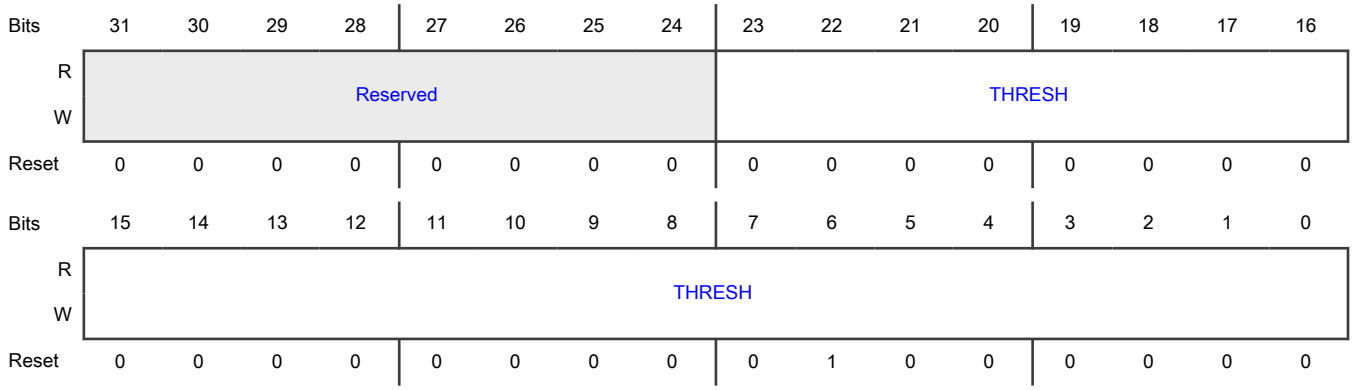
Offset

Register	Offset
SMDTR	80h

Function

This is the shared memory depletion threshold register.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 THRESH	Shared memory depletion threshold in Words. This sets the minimum amount of free memory that should be maintained in the datapath sub system, and when the amount of free memory falls below this threshold, a depletion indication is asserted, which may trigger "intelligent drop" of frames from the ingress queues in the ICM. Setting this field to 0 disables dropping of frames by Ingress Congestion Manager (ICM) due to internal shared memory depletion. It is recommended to set this field to 64 Words. **NOTE** This threshold is an added security in case of switch and ENETC common memory allocation results in amount of buffers used by all ENETCs being less than ERSMBAR[THRESH] value. There are error scenarios, such as Buffer loss or Free List corruption (see SMLCR for more info), where this condition may occur.

53.4.6.3.10 ENETC receive shared memory buffer allotment register (ERSMBAR)

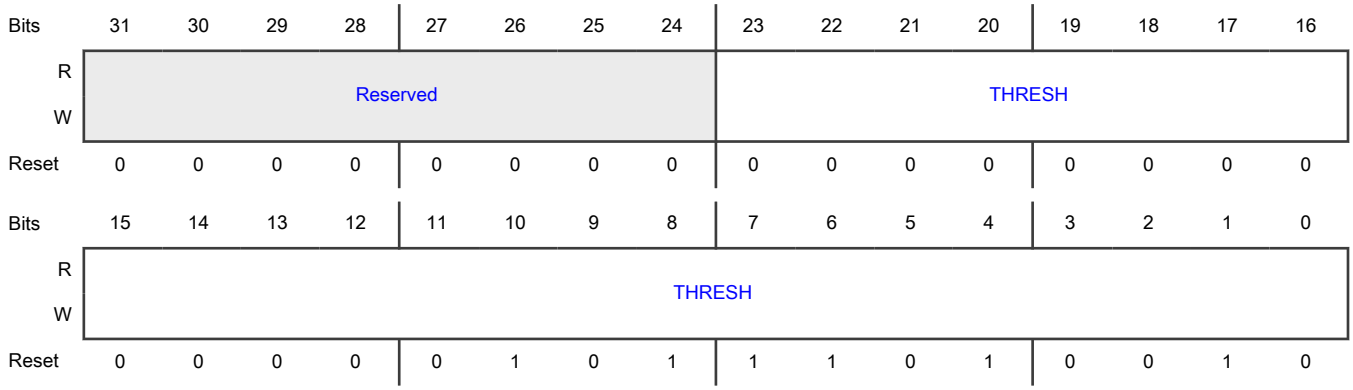
Offset

Register	Offset
ERSMBAR	84h

Function

This is the ENETC receive shared memory buffer allotment register.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 THRESH	Threshold in words for internal receive buffer memory used by all ENETC functions. If this threshold is exceeded, smart-drop from ICM queues may be triggered. The threshold should not be lower than the total number of ENETC instances multiplied by 2 times the maximum frame size.

53.4.6.3.11 HTA 0 HP configuration register (HTA0HPCR)

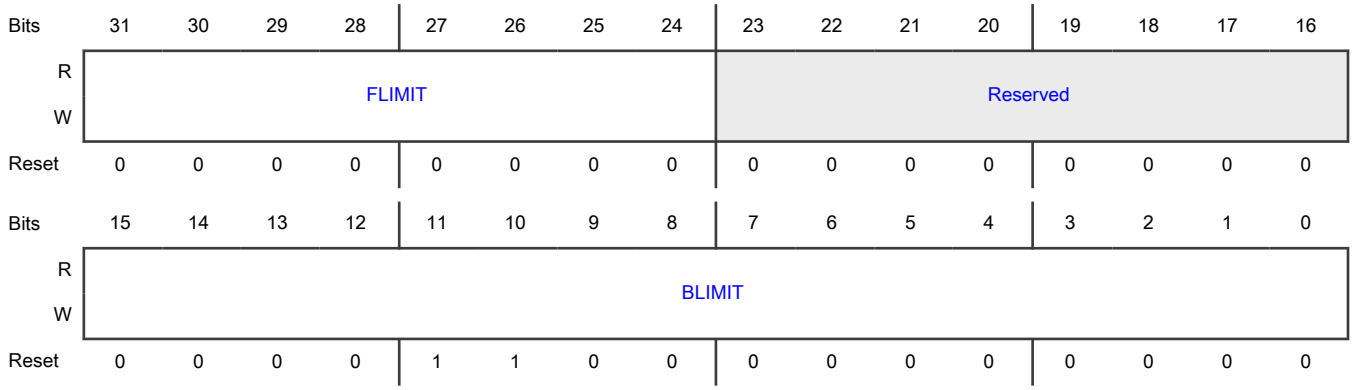
Offset

Register	Offset
HTA0HPCR	C0h

Function

This is the HTA high priority configuration register.

Diagram



Fields

Field	Function
31-24 FLIMIT	HTA global high priority frame limit. Sets the maximum amount of high priority frames that can be underway within HTA. 0x0 = no limit **NOTE** This limit is shared between ENETC instances using WBFS algorithm proportional to ENETC instance PSPEED.
23-16 —	Reserved
15-0 BLIMIT	HTA global high priority byte limit setting. Sets the maximum amount of high priority DMA work (in bytes) that can be underway within HTA. 0x0 = no limit **NOTE** This limit is shared between ENETC instances using WBFS algorithm proportional to ENETC instance PSPEED.

53.4.6.3.12 HTA 0 LP configuration register (HTA0LPCR)

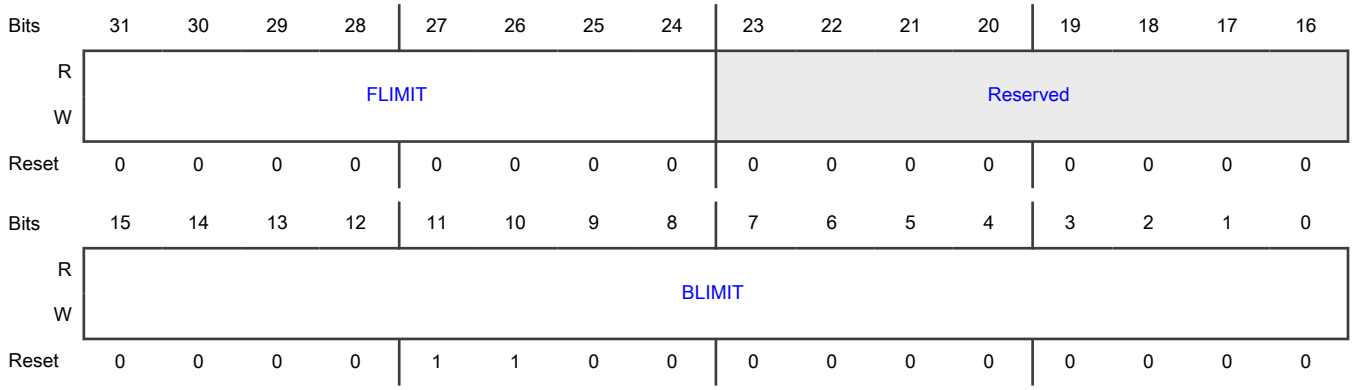
Offset

Register	Offset
HTA0LPCR	C4h

Function

This is the HTA low priority configuration register.

Diagram



Fields

Field	Function
31-24 FLIMIT	HTA global low priority Frame Limit. Sets the maximum amount of low priority frames that can be underway within HTA. 0x0 = no limit **NOTE** This is not per-port. WBFS is used to share this limit among ports.
23-16 —	Reserved
15-0 BLIMIT	HTA global low priority byte limit setting. Sets the maximum amount of low priority DMA work (in bytes) that can be underway within HTA. 0x0 = no limit **NOTE** This is not per-port. WBFS is used to share this limit among ports. Default: 2x1536B.

53.4.6.3.13 Hash bucket table memory allocation register (HBTMAR)

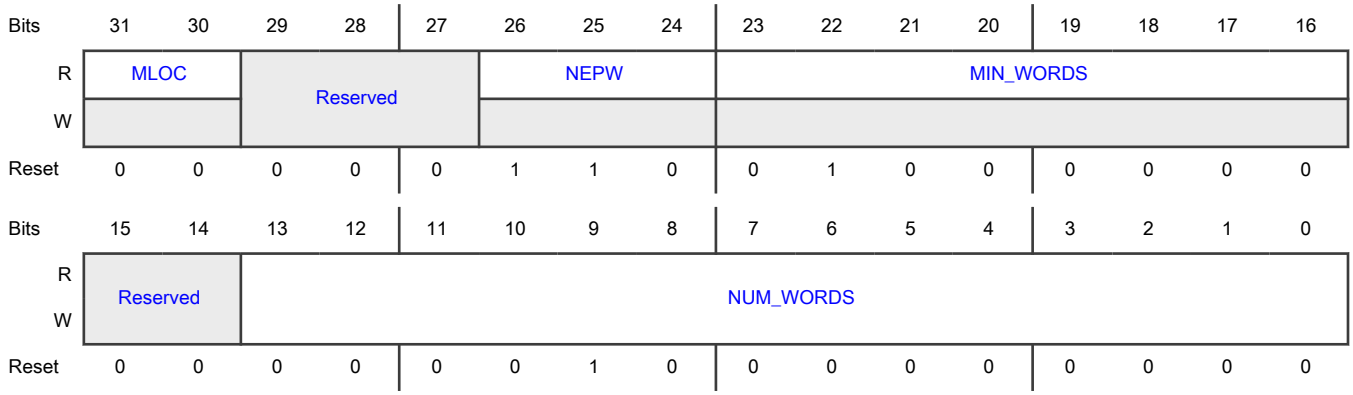
Offset

Register	Offset
HBTMAR	100h

Function

This is the hash bucket table memory allocation memory allocation register.

Diagram



Fields

Field	Function
31-30 MLOC	Indicates memory location of this table 0: Common memory 1-3: Reserved
29-27 —	Reserved
26-24 NEPW	Number of table entries per word.
23-16 MIN_WORDS	Minimum number of words required. NUM_WORDS should not be set to a value lower than MIN_WORDS.
15-14 —	Reserved
13-0 NUM_WORDS	Number of words allocated from Common Memory. **NOTE** This value is used to set the R/O global register HBTCAPR[NUM_ENTRIES] where NUM_ENTRIES = NUM_WORDS * NEPW. The allocated amount must be a power of 2 and greater than or equal to MIN_WORDS otherwise, a lower power of 2 is used and an error is indicated by NETCSR[ERROR].

53.4.6.3.14 Hash bucket table configuration register (HBTCR)

Offset

Register	Offset
HBTCR	104h

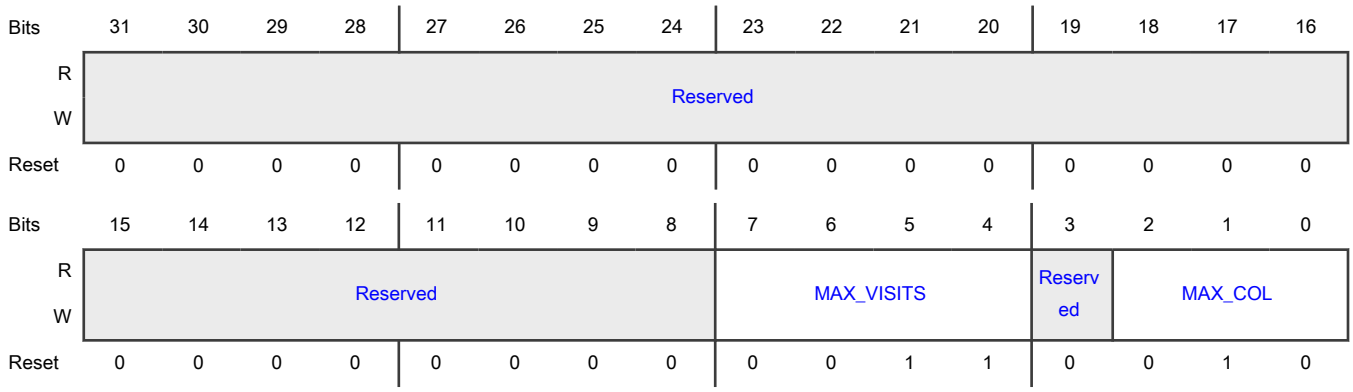
Function

This is the hash bucket table configuration register.

NOTE

The value of this register will be immediately reflected in the corresponding read-only global register HBTCAPR accessible to all switch and ENETC functions.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-4 MAX_VISITS	Specifies the maximum number of Hash Entries Visited during a Search Table Management Command. Range: 64..1K Formula: 64*(MAX_VISITS+1) MAX_VISITS=0..15 **NOTE** Value mirrored to Global HBTCAPR register which is in all Switch and ENETC Physical Functions.
3 —	Reserved
2-0 MAX_COL	Specifies the maximum EM/IM Hash collisions chain length allowed. Maximum is 3. Range: 1..3 Formula: MAX_COL+1 Don't allow entries to be added if it exceeds this value. **NOTE** Value mirrored to Global HBTCAPR register which is in all Switch and ENETC Physical Functions.

53.4.6.3.15 Guaranteed hash table entry memory capability register (GHTEMCAPR)

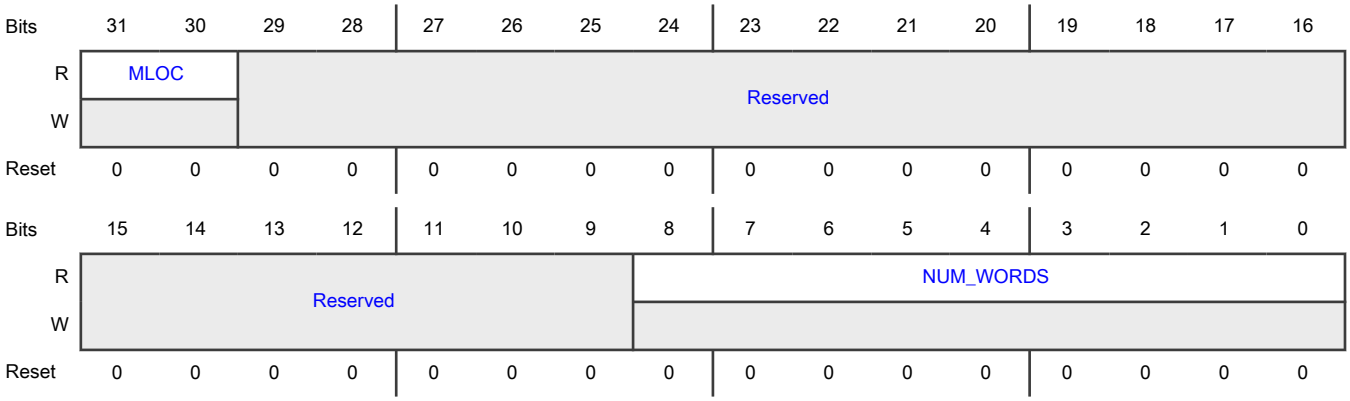
Offset

Register	Offset
GHTEMCAPR	108h

Function

This is the guaranteed hash table entry memory capability register.

Diagram



Fields

Field	Function
31-30 MLOC	Indicates memory location of this table 0: Common memory 1-3: Reserved
29-9 —	Reserved
8-0 NUM_WORDS	Total amount of words available to store the guaranteed hash table entries. When a hash table entry cannot be added because the hash bucket collision limit is exceeded, the entry can be added using a CAM (Context Addressable Memory) where the entry is stored in this table. Each guaranteed hash table entry occupies one word. **NOTE** This is only available for switch's FDB table and is reflected in value copied to switch's FDBHTCAPR[NUM_GMAC].

53.4.6.3.16 NETC FLR configuration register (NETCFLRCR)

Offset

Register	Offset
NETCFLRCR	170h

Function

Indicates the duration of the Function Level Reset (FLR) in steps of 32.768 microseconds.

The reset sequence includes the following three parts:

1. Quiesce (e.g.: processing of rings has stopped, pending frames flushed)
2. Reset of registers
3. Flush of table entries (e.g.: RFS/RSS). Hard coded to 4000 NETC cycles.

NOTE

The format of this register is identical to the PCIe Readiness Time Encoding format. Content is directly reflected in the PCIe Readiness Time Reporting Extended Capability. The maximum supported counter value is 2^{20} NETC cycles, and is calculated as NETCCLKCR[FREQ] x NETCFLRCR[VALUE] x 32.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31-12 —	Reserved
11-9 SCALE	Scale Scale used for VALUE, i.e. multiplier. Formula: $2^{5*SCALE}$ns where SCALE={0..5}

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Hard coded to 32.768 microseconds.
8-0 VALUE	Time duration value expressed in SCALE units.

53.4.6.3.17 NETC clock period fractional register (NETCCLKFR)

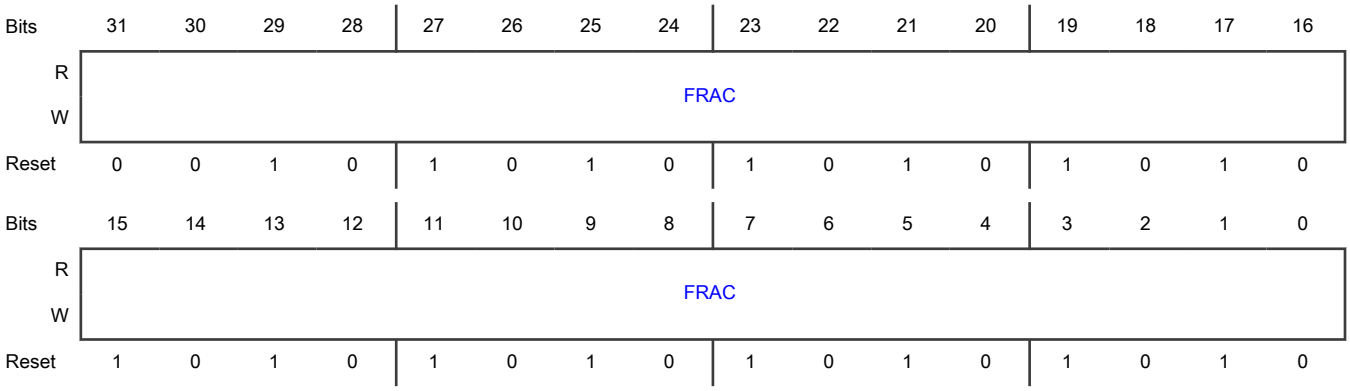
Offset

Register	Offset
NETCCLKFR	178h

Function

This is the NETC clock period fractional register.

Diagram



Fields

Field	Function
31-0 FRAC	NETC Clock Period's fractional nanosecond expressed as the number of fractional nanoseconds per NETC clock. Value is configured as the fractional portion of 1000/NETCCLKR[FREQ] * (2^{32}). Example: If Freq = 400 MHz, PERIOD=2 and FRAC=0x8000_0000. **NOTE** This value is writable in IERB (by pre-boot initialization), which is then copied to timer TMR_ADD during IERB lock.

53.4.6.3.18 NETC clock configuration register (NETCCLKCR)

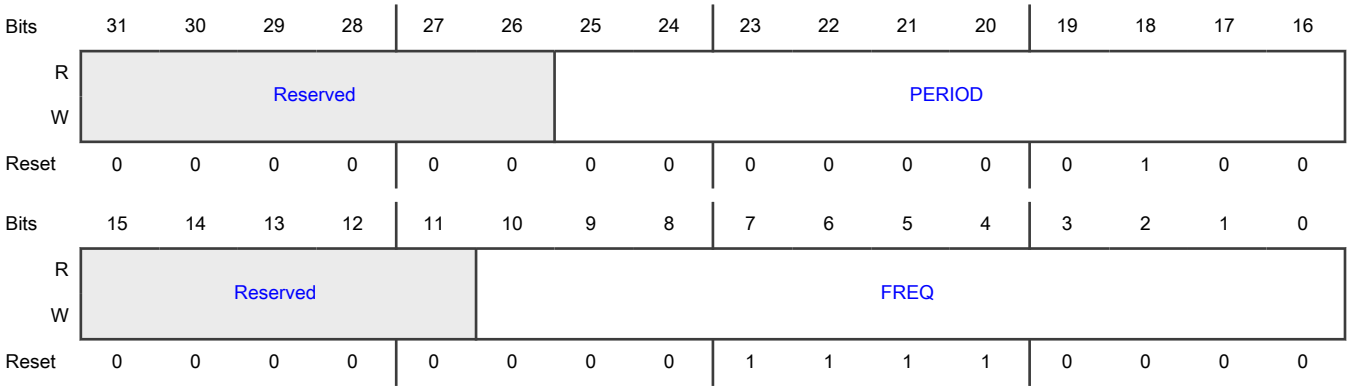
Offset

Register	Offset
NETCCLKCR	17Ch

Function

This is the NETC clock configuration register.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 PERIOD	Period NETC Clock Period expressed as the number of nanoseconds per NETC clock. Value is configured as the integer portion of 1000/FREQ. **NOTE** This value is writable in IERB (by pre-boot initialization), which is then copied to timer TMR_CTRL[PERIOD] during IERB lock.
15-11 —	Reserved
10-0 FREQ	Frequency This is the NETC clock frequency in MHz. **NOTE** Value is reflected in global register NETCCLKR.

53.4.6.3.19 System bus configuration register (SBCR)

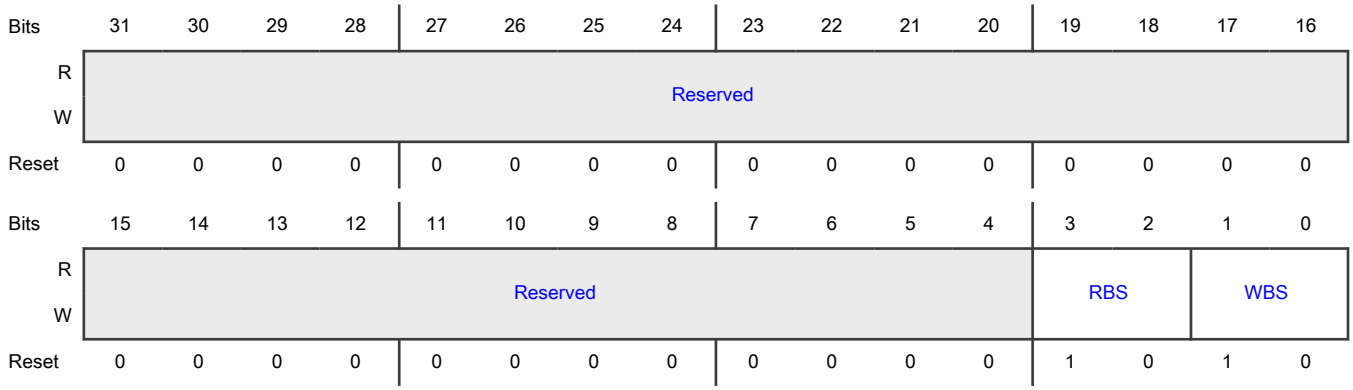
Offset

Register	Offset
SBCR	180h

Function

This is the system bus configuration register. It allows you to specify the address alignments at which system memory transactions issued by NETC are cracked into separate AXI transactions. For example, a setting of 64B will cause NETC to perform a large data transfer as a series of 64B AXI transactions, issued on natural 64B address alignments. If the large transfer does not start on a natural 64B aligned address, then the first 64B AXI transaction issued by NETC will not be 64B in size but will end at a 64B aligned addres such that the remaining 64B transactions in the large transfer are 64B address aligned.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-2 RBS	System Bus Maximum Read Burst Size. It indicates the maximum number of bytes to transfer in a read transaction. The size of the AXI bus is 64 bits. 0: 16B; ARLEN = 1 (2 data transfers) 1: 32B; ARLEN = 3 (4 data transfers) 2: 64B; ARLEN = 7 (8 data transfers) 3: 128B; ARLEN = 15 (16 data transfers)
1-0 WBS	System Bus Maximum Write Burst Size. It indicates the maximum number of bytes to transfer in a write transaction. The size of the AXI bus is 64 bits. 0: 16B; AWLEN = 1 (2 data transfers) 1: 32B; AWLEN = 3 (4 data transfers)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	2: 64B; AWLEN = 7 (8 data transfers) 3: 128B; AWLEN = 15 (16 data transfers) Note: The default setting of WBS=2 (64B) is recommended. WBS=3 may provide marginal performance benefit in configurations where system memory write latency is extremely high. Using WBS=3 (128B) setting requires that Receive Buffer Descriptor memory addresses be 128B address-aligned.

53.4.6.3.20 System bus outstanding transaction control register (SBOTCR)

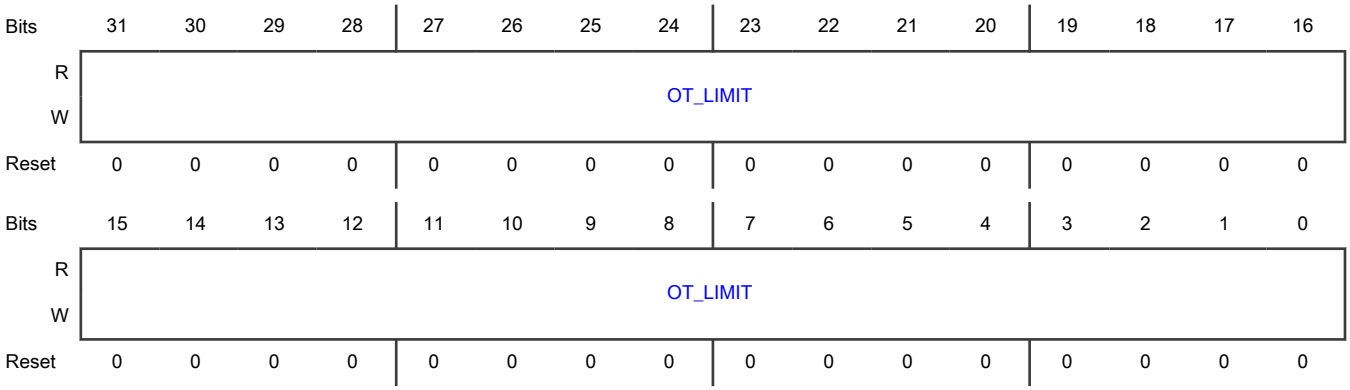
Offset

Register	Offset
SBOTCR	184h

Function

This is the system bus outstanding transaction control register.

Diagram



Fields

Field	Function
31-0 OT_LIMIT	This is a 32-bit read-write field, however only bits 23-16 and 7-0 have any effect on device behavior. Bits 31-24 and 15-8 are reserved for future use and should be written as 0x0. OT_LIMIT[7:0] encode a limit on outstanding non-critical NETC transactions, where "transaction" is defined as a read or write within a 32B address-aligned region. Setting this limit to a non-zero value N will cause NETC to initiate outstanding accesses to no more than N 32 byte address regions (one access per region). Valid range is 0-128, with a value of 0 meaning no limiting is applied. OT_LIMIT[23:16] encode a limit on all NETC transactions, relative to OT_LIMIT[7:0]. In other words, total outstanding NETC transactions (both critical and non-critical) are limited to OT_LIMIT[7:0] + OT_LIMIT[23:16] if OT_LIMIT[23:16] is non-zero.

Table continues on the next page...

Field	Function
	If OT_LIMIT[23:16] is 0 then no total transaction limit is applied and NETC will not throttle the issuing of critical transactions. Recommended setting for all applications is 0x0, however application characterization may determine that other client (CPU) access latency is improved by applying an upper limit on NETC DDR transactions.

53.4.6.3.21 Stream gating lag time for refresh register (SGLTTR)

Offset

Register	Offset
SGLTTR	190h

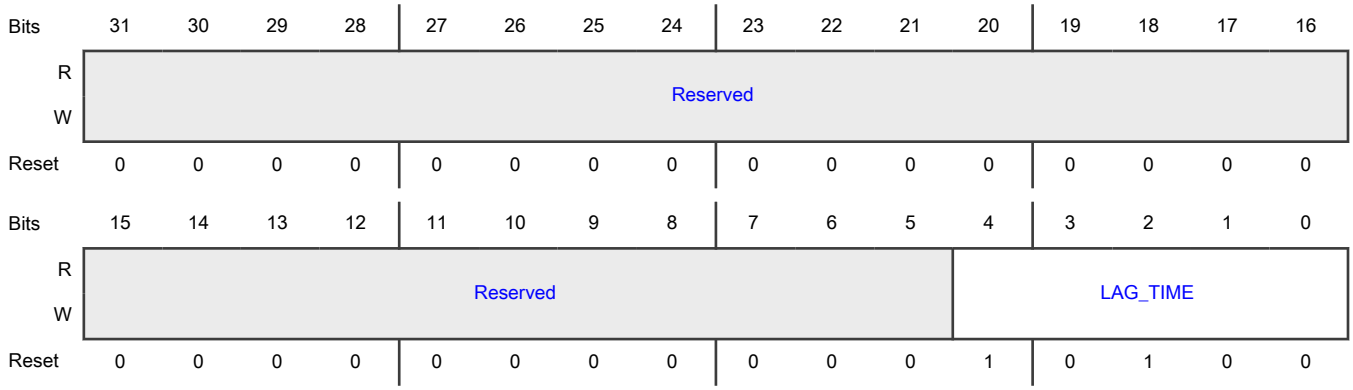
Function

SGLTTR register is used for stream gating to periodically update the last event time in each of the Stream Gating Instance table entries to ensure that the it doesn't go stale.

The last time value that is maintained in stream gating context is 30 bits (1 sec), hence it is valid for only one second in the past from current frame arrival time. Stream gating context is event triggered as such If there is no frame arrival for 1 second in the past the last time value will become stale. To ensure that the last event time value doesn't go stale, periodic updates are performed to advance the last event time to bring it closer to the current time but still keep in the past so that frame arrival time plus the propagation delay for the frame is still less than last event time.

SGLTTR value determines how far in the past the last time needs to be updated. Value programmed has to take into account the worst case propagation delay for the frame (i.e.. from the start of frame to when the end of frame is observed) as the last event time has to be less than the current frame arrival time. As such determining LAG_TIME setting in SGLTTR register depends on slowest line rate supported and worst case delay a frame can encounter. Default value is 65536ns. LAG_TIME specified must be less than or equal to 24 (i.e., Lag time is a nanosecond has to be less than or equal to 2^24)

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 LAG_TIME	Lag time is a nanosecond value = 2^{LAG_TIME} . Default LAG_TIME set to 0x14 means 2^{20} = 1.05 ms. To determine the lag time do the following. Calculate frame transfer delay for a maximum sized frame at the slowest line rate; Multiply by 2 to include worst case preemption delay; Then select LAG_TIME such that 2^{LAG_TIME} > determined total delay.

53.4.6.3.22 Root complex 0 binding configuration register (R0BCR)

Offset

Register	Offset
R0BCR	200h

Function

This is the root complex binding configuration register.

Diagram

5-4 MSI_WRDOMAIN	MSI-X write domain This is the domain attribute setting used when NETC generates MSI-X events. See System Interface Write Transaction Attribute Definitions table in Station interface buffer cache attribute register (SIBCAR) for valid settings.
3-0 MSI_WRCACHE	MSI-X write cache type This is the cache attribute setting used when NETC generates MSI-X events. See System Interface Write Transaction Attribute Definitions table in Station interface buffer cache attribute register (SIBCAR) for valid settings.

53.4.6.3.24 Root complex 0 MSI access management qualifier register (RC0MSIAMQR)

Offset

Register	Offset
RC0MSIAMQR	20Ch

Function

This is the root complex MSI access management qualifier register. It provides attributes for MSI-X memory write accesses for all functions of NETC.

NOTE

Changing the value in this register has immediate effect unless otherwise noted. Care should be taken when making changes to the values for an enabled and operational timer function to ensure that consistent behavior is maintained. It is strongly encouraged, but not required, that the function be disabled before making changes.

53.4.6.3.39 Link 0 binding configuration register (L0BCR)

Offset

Register	Offset
L0BCR	1010h

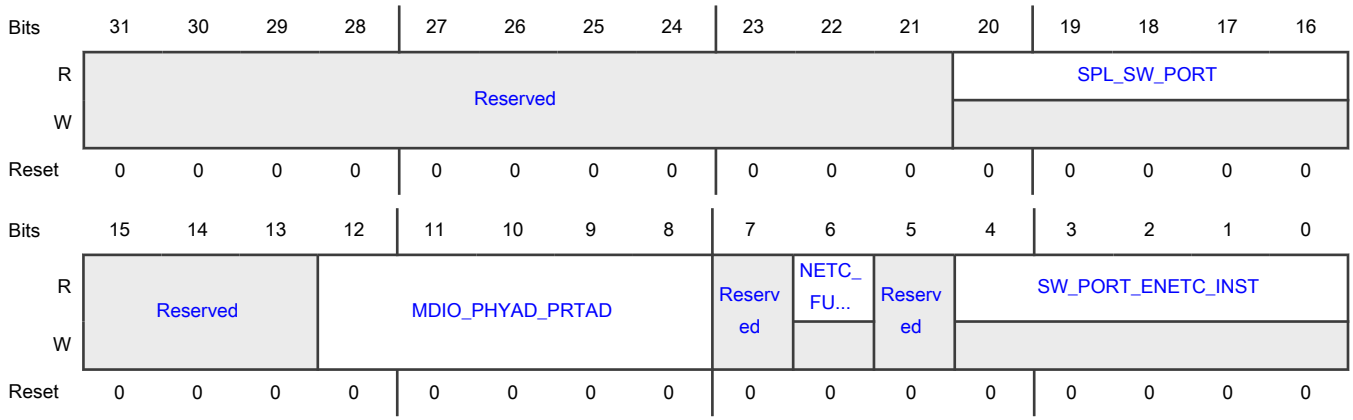
Function

Register configures the binding of link ends to NETC function. If this is a pseudo link, both link ends are bounded.

It is assumed that:

1. both ends of the pseudo link has the same LINK_TYPE
2. primary link end specifies its NETC function
3. if this is a pseudo link, then the other link end's NETC function is SWITCH
4. both ends of pseudo link's has the same ETM capabilities

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 SPL_SW_PORT	Secondary pseudo link end's switch port number. Valid if L*a*CAPR[LINK_TYPE]=Pseudo MAC. **NOTE** If more than one link refers to same SPL_SW_PORT, a link mapping error is flagged by NETCSR[ERROR] and the links detecting the misconfiguration are deemed unusable.
15-13 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
12-8 MDIO_PHYAD_PRTAD	This value indicate an MDIO PHY address. Depending on the link mode setting L*a*lOCAPR[REVMII], the value has the following meaning: 0 Indicates link external MDIO PHY's address for clause 22 and external MDIO port address for clause 45. 1 RevMII mode - Indicates link MDIO PHY's address when operating as a slave.
7 —	Reserved
6 NETC_FUNC	Primary link end's NETC Function Type. 0: Switch 1: ENETC **NOTE** NETCv3 does not currently support NETC_FUNC=Switch & LINK_TYPE=Pseudo MAC. If set, error is indicated by NETCSR[ERROR] and this link becomes unusable.
5 —	Reserved
4-0 SW_PORT_ENETC_INST	NETC_FUNC=ENETC: Primary link end's ENETC instance number mapped to this link end. NETC_FUNC=Switch: Primary link end's switch port number mapped to primary link end. **NOTE** If more than one link end refers to same ENETC_INST or SW_INST/SW_PORT, a link mapping error is flagged by NETCSR[ERROR] and the links detecting the misconfiguration are unusable.

53.4.6.3.40 Link a transmit byte credit comfort threshold register (L0TXBCCTR - L5TXBCCTR)

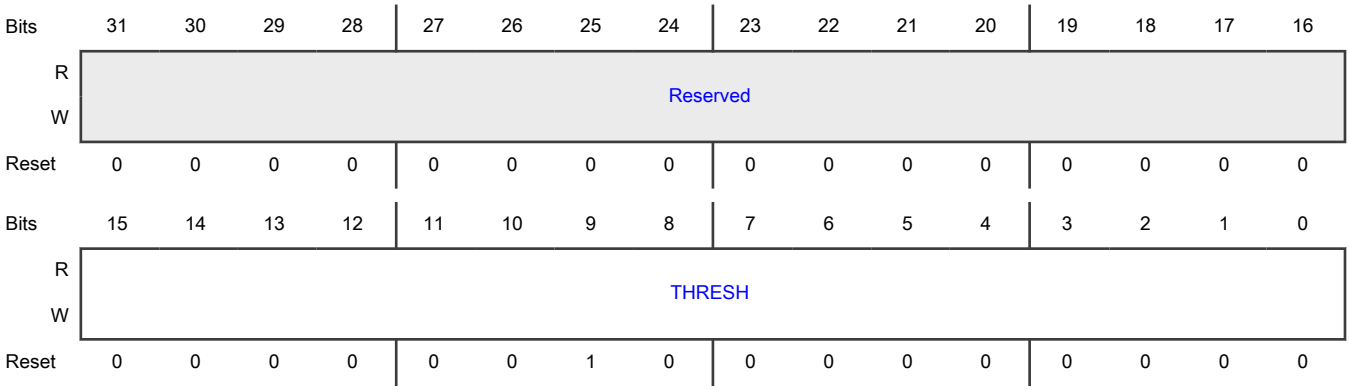
Offset

Register	Offset
L0TXBCCTR	1014h
L1TXBCCTR	1054h
L2TXBCCTR	1094h
L3TXBCCTR	10D4h
L4TXBCCTR	1114h
L5TXBCCTR	1154h

Function

This is the link transmit byte credit comfort threshold register. This register is used only if the link is bound to a switch port. This register is not used if the link is bound to an ENETC port.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 THRESH	Link's transmit byte credit comfort threshold from ETM towards port. Default value is 512B.

53.4.6.3.41 Link a end 0 MAC address register 0 (L0E0MAR0 - L5E0MAR0)

Offset

Register	Offset
L0E0MAR0	1020h
L1E0MAR0	1060h
L2E0MAR0	10A0h
L3E0MAR0	10E0h
L4E0MAR0	1120h
L5E0MAR0	1160h

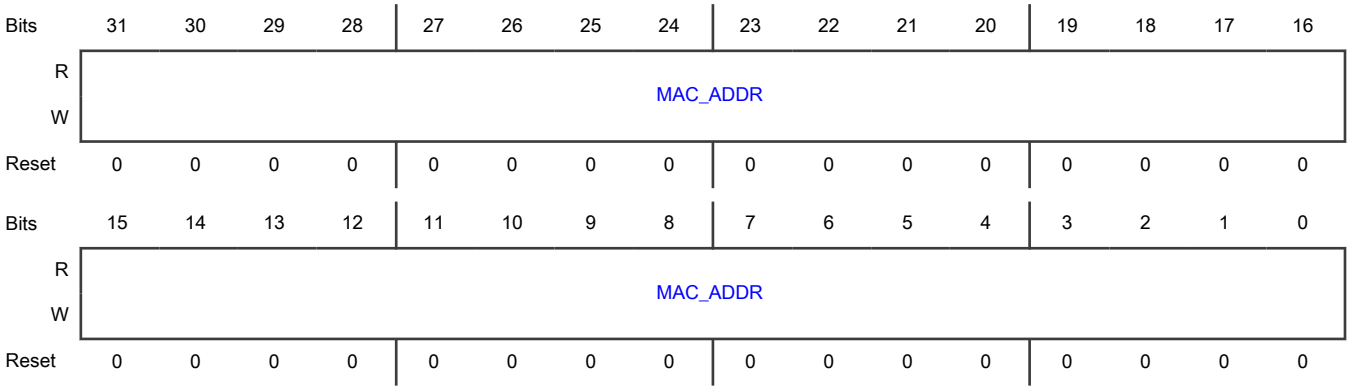
Function

This is the primary link end's MAC address register 0. It determines the initial value for port register PMAR0 in the ENETC or switch function as determined by the link binding.

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to port equivalent register during IERB lock. All updates after this must be done through the corresponding port register.

Diagram



Fields

Field	Function
31-0 MAC_ADDR	MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 4 most significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PMAR0 equals 14131211h.

53.4.6.3.42 Link a end 0 MAC address register 1 (L0E0MAR1 - L5E0MAR1)

Offset

Register	Offset
L0E0MAR1	1024h
L1E0MAR1	1064h
L2E0MAR1	10A4h
L3E0MAR1	10E4h
L4E0MAR1	1124h
L5E0MAR1	1164h

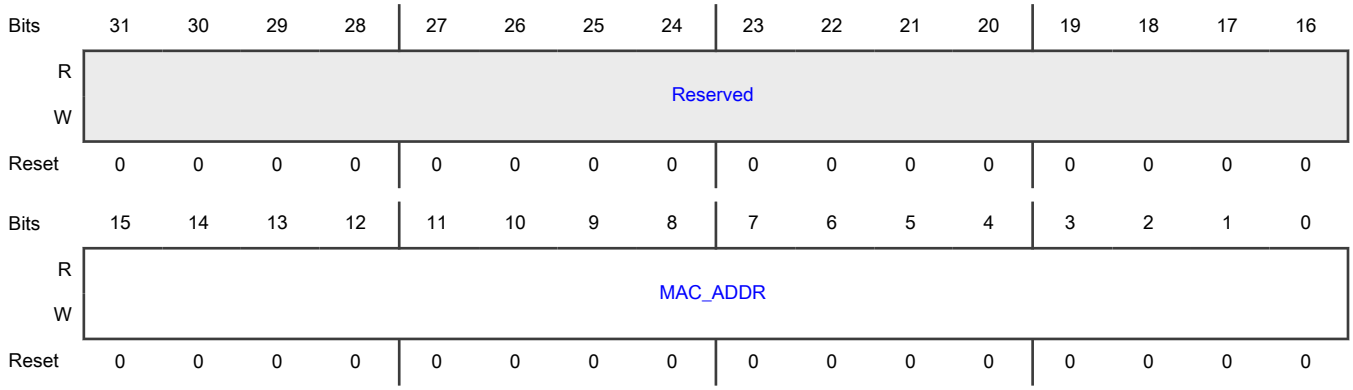
Function

This is the primary link end's MAC address register 1. It determines the initial value for port register PMAR1 in the ENETC or switch function as determined by the link binding.

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to port equivalent register during IERB lock. All updates after this must be done through the corresponding port register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 MAC_ADDR	MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 2 least significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PMAR1 equals xxxx1615h (where x should be set to 0)

53.4.6.3.43 Link 1 binding configuration register (L1BCR)

Offset

Register	Offset
L1BCR	1050h

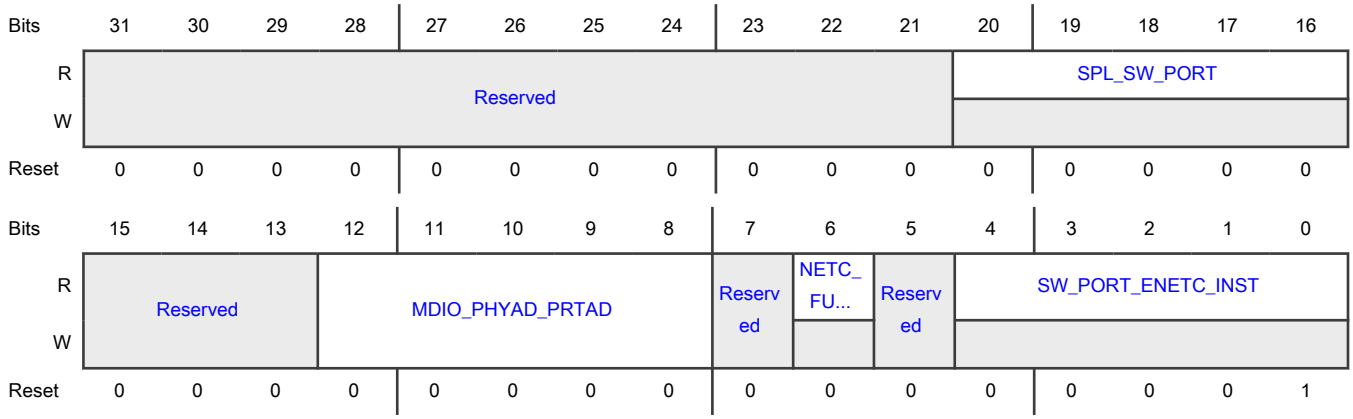
Function

Register configures the binding of link ends to NETC function. If this is a pseudo link, both link ends are bounded.

It is assumed that:

1. both ends of the pseudo link has the same LINK_TYPE
2. primary link end specifies its NETC function
3. if this is a pseudo link, then the other link end's NETC function is SWITCH
4. both ends of pseudo link's has the same ETM capabilities

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 SPL_SW_PORT	Secondary pseudo link end's switch port number. Valid if L*a*CAPR[LINK_TYPE]=Pseudo MAC. **NOTE** If more than one link refers to same SPL_SW_PORT, a link mapping error is flagged by NETCSR[ERROR] and the links detecting the misconfiguration are deemed unusable.
15-13 —	Reserved
12-8 MDIO_PHYAD_PRTAD	This value indicate an MDIO PHY address. Depending on the link mode setting L*a*lOCAPR[REVMII], the value has the following meaning: 0 Indicates link external MDIO PHY's address for clause 22 and external MDIO port address for clause 45. 1 RevMII mode - Indicates link MDIO PHY's address when operating as a slave.
7 —	Reserved
6 NETC_FUNC	Primary link end's NETC Function Type. 0: Switch 1: ENETC **NOTE** NETCv3 does not currently support NETC_FUNC=Switch & LINK_TYPE=Pseudo MAC. If set, error is indicated by NETCSR[ERROR] and this link becomes unusable.
5	Reserved

53.4.6.3.50 Link 5 binding configuration register (L5BCR)

Offset

Register	Offset
L5BCR	1150h

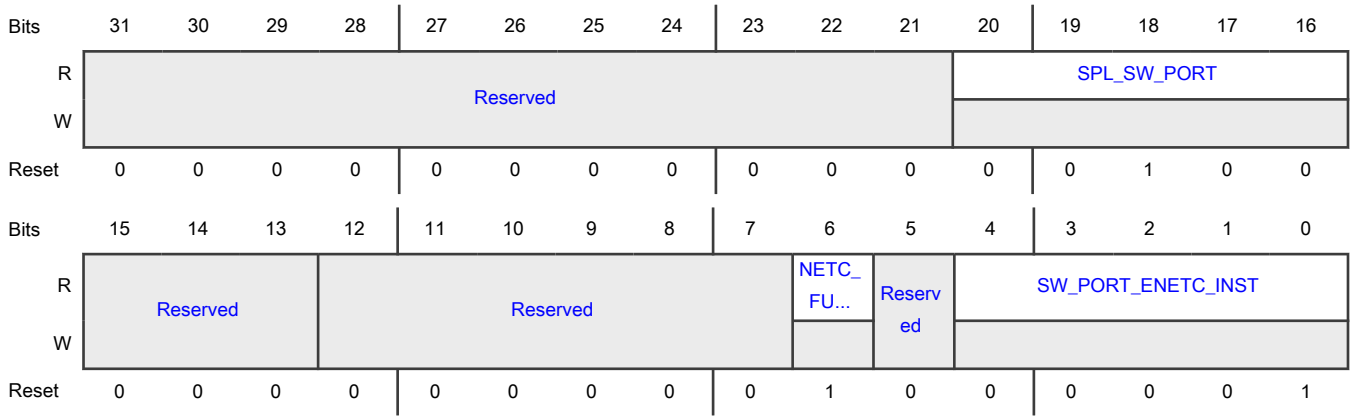
Function

Register configures the binding of link ends to NETC function. If this is a pseudo link, both link ends are bounded.

It is assumed that:

1. both ends of the pseudo link has the same LINK_TYPE
2. primary link end specifies its NETC function
3. if this is a pseudo link, then the other link end's NETC function is SWITCH
4. both ends of pseudo link's has the same ETM capabilities

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 SPL_SW_PORT	Secondary pseudo link end's switch port number. Valid if L*a*CAPR[LINK_TYPE]=Pseudo MAC. **NOTE** If more than one link refers to same SPL_SW_PORT, a link mapping error is flagged by NETCSR[ERROR] and the links detecting the misconfiguration are deemed unusable.
15-13 —	Reserved
12-7 —	Reserved
6 NETC_FUNC	Primary link end's NETC Function Type. 0: Switch 1: ENETC **NOTE** NETCv3 does not currently support NETC_FUNC=Switch & LINK_TYPE=Pseudo MAC. If set, error is indicated by NETCSR[ERROR] and this link becomes unusable.
5 —	Reserved
4-0 SW_PORT_ENETC_INST	NETC_FUNC=ENETC: Primary link end's ENETC instance number mapped to this link end. NETC_FUNC=Switch: Primary link end's switch port number mapped to primary link end. **NOTE** If more than one link end refers to same ENETC_INST or SW_INST/SW_PORT, a link mapping error is flagged by NETCSR[ERROR] and the links detecting the misconfiguration are unusable.

53.4.6.3.51 Link 5 end 1 MAC address register 0 (L5E1MAR0)

Offset

Register	Offset
L5E1MAR0	1168h

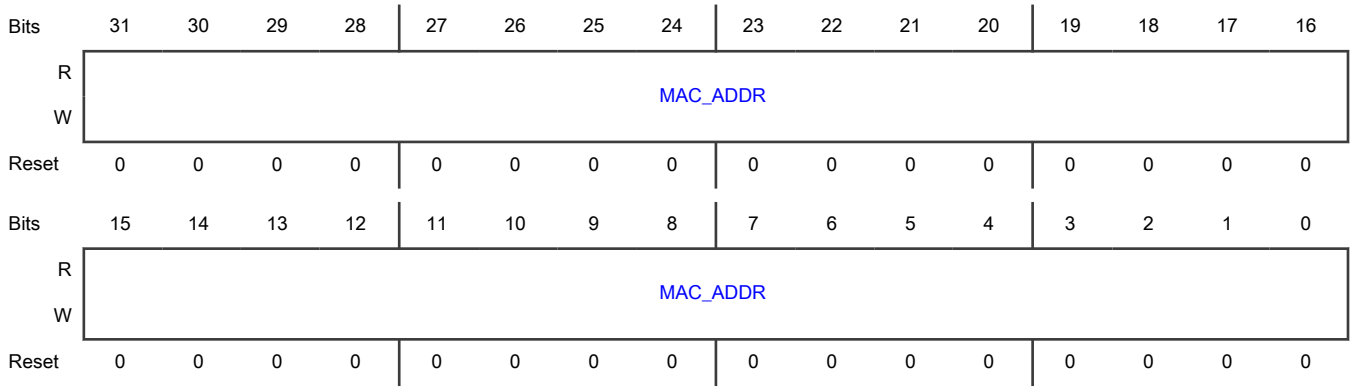
Function

This is the secondary link end's MAC address register 0. It determines the initial value for port register PMAR0 in a switch function as determined by the link binding.

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to port equivalent register during IERB lock. All updates after this must be done through the corresponding port register.

Diagram



Fields

Field	Function
31-0 MAC_ADDR	MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 4 most significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PMAR0 equals 14131211h.

53.4.6.3.52 Link 5 end 1 MAC address register 1 (L5E1MAR1)

Offset

Register	Offset
L5E1MAR1	116Ch

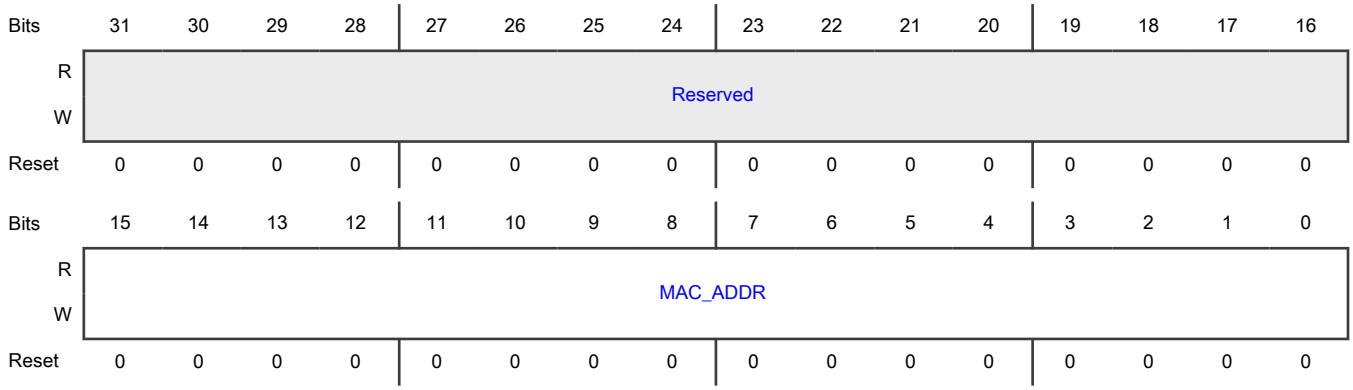
Function

This is the secondary link end's MAC address register 1. It determines the initial value for port register PMAR1 in a switch function as determined by the link binding.

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to port equivalent register during IERB lock. All updates after this must be done through the corresponding port register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 MAC_ADDR	MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 2 least significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PMAR1 equals xxxx1615h (where x should be set to 0)

53.4.6.3.53 Switch 0 binding configuration register (S0BCR)

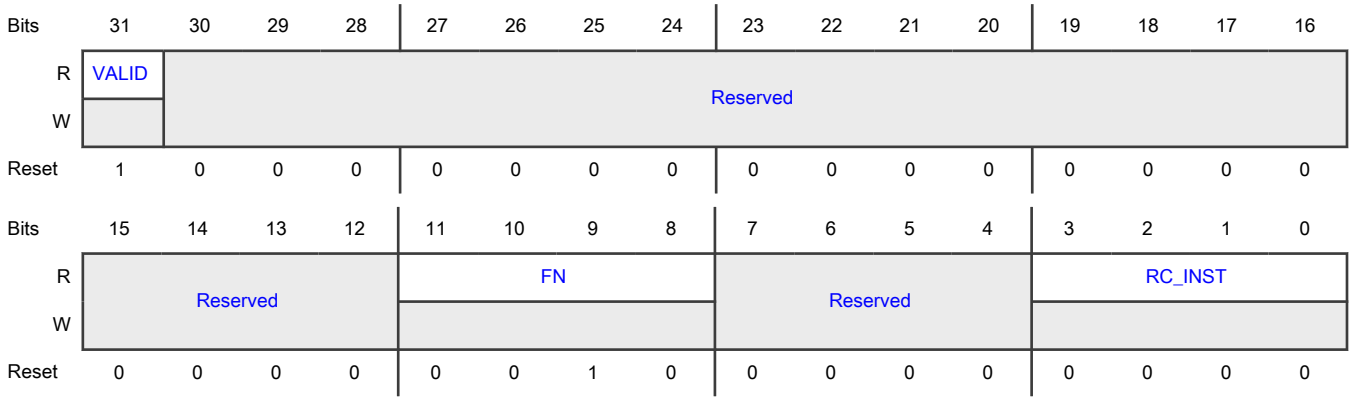
Offset

Register	Offset
S0BCR	2000h

Function

This is the switch binding configuration register.

Diagram



Fields

Field	Function
31 VALID	Set if switch instance is bounded to at least 1 link.
30-12 —	Reserved
11-8 FN	PCI device function number. **NOTE** For assignment of function number, see PCIe Function Number Assignment.
7-4 —	Reserved
3-0 RC_INST	Root complex instance number.

53.4.6.3.54 Switch 0 MSI-X configuration register (S0MCR)

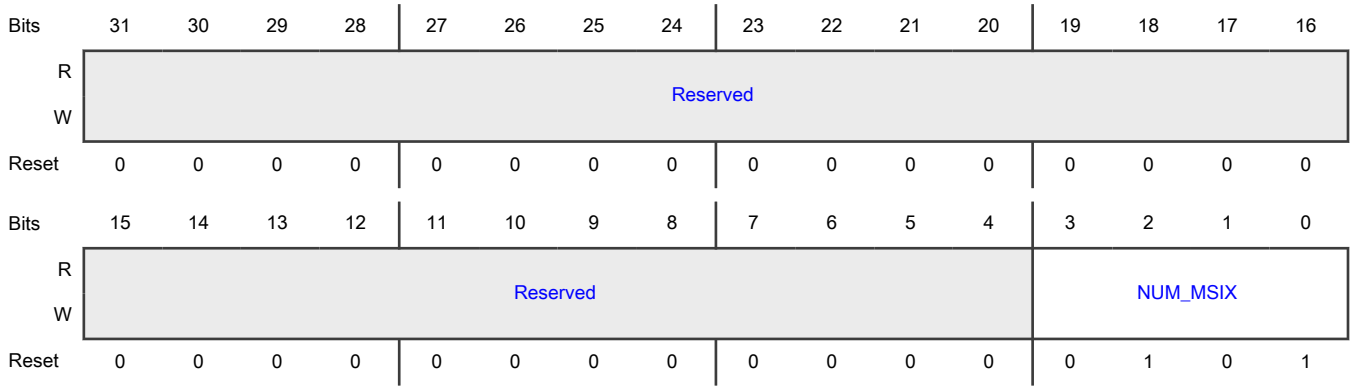
Offset

Register	Offset
S0MCR	2014h

Function

This is the switch MSI-X configuration register.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 NUM_MSIX	Number of MSI-X vectors supported for switch function. Formula: NUM_MSIX+1 Range: 1..16 **NOTE** Reset value of switch register SCAPR0[NUM_MSIX]. If total number of allocated MSI-X vectors exceed CAPR2[NUM_MSIX], error is indicated by NETCSR[ERROR].

53.4.6.3.55 Switch 0 config header device ID and vendor ID register (S0_CFH_DIDVID)

Offset

Register	Offset
S0_CFH_DIDVID	2020h

Function

This is the switch PCI Device and Vendor ID register.

NOTE

This register is continuously sampled, any changes will have immediate effect on reading the PCI function Type0 header.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

53.4.6.3.58 Switch 0 access management qualifier register (S0AMQR)

Offset

Register	Offset
S0AMQR	2040h

Function

This is the switch access management qualifier register. It provides attributes for each memory access transaction performed by the switch instance.

NOTE

Changing the value in this register has immediate effect unless otherwise noted. Care should be taken when making changes to the values for an enabled and operational switch function to ensure that consistent behavior is maintained. It is strongly encouraged, but not required, that the function be disabled before making changes.

31 BMT	Bypass memory translation The bit is an indication to the SMMU to by-pass memory translation whenever the PF is performing memory transactions, effectively handling the memory address as a true physical address. 0 Memory translation 1 Bypass memory translation
30-24 —	Reserved
23-20 AWQOS	Address Write QoS. AWQOS[3:1] signals are controlled by this register field's bits [3:1]. AWQOS[0] is controlled by the HTA block and is 0 for low priority DMA transactions and 1 for high priority DMA transactions. Only HTA Command threads are used for the switch and these threads are always low priority.

Table continues on the next page...

Table continued from the previous page...

Field	Function
19-16 ARQOS	Address Read QoS. ARQOS[3:1] signals are controlled by this register field's bits [3:1]. ARQOS[0] is controlled by the HTA block and is 0 for low priority DMA transactions and 1 for high priority DMA transactions. Only HTA Command threads are used for the switch and these threads are always low priority.
15-0 —	Reserved

53.4.6.3.59 Switch 0 boot loader parameter register b (S0BLPR0 - S0BLPR1)

Offset

Register	Offset
S0BLPR0	2048h
S0BLPR1	204Ch

Function

This register provides a mean for boot S/W (Pre-Boot Loader, boot ROM) to communicate parameters with running (device driver) software. Runtime software uses read-only global register FBLPR*a*.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31-0 PARAM_VAL	Boot loader parameter value.

53.4.6.3.60 Switch 0 shared memory buffer allotment register (S0SMBAR)

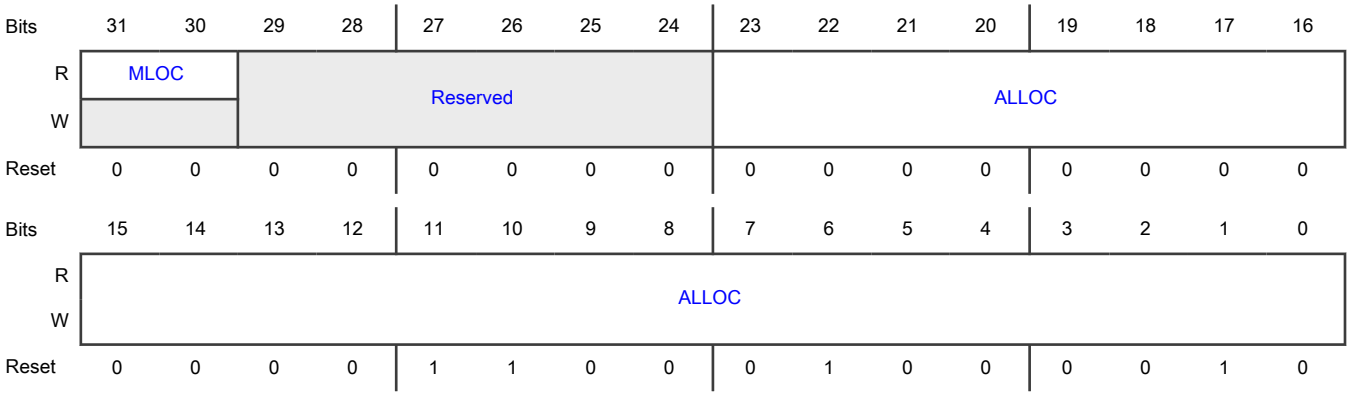
Offset

Register	Offset
S0SMBAR	2060h

Function

This is the switch shared memory buffer allotment register.

Diagram



Fields

Field	Function
31-30 MLOC	Indicates memory location 0: Common memory 1-3: Reserved
29-24 —	Reserved
23-0 ALLOC	Number of words allotted for the switch frame buffering memory. The amount of memory allotted should not be lower than the total number of switch ports multiplied by 2 times the maximum frame size that can be transmitted on the express MAC or the pseudo MAC plus 2 times the maximum frame size that can be transmitted on the preemptable MAC (the later applies only if preemption is enabled/used). **NOTE** Memory is managed via buffer pool mechanism.

53.4.6.3.61 Switch 0 hash table memory allotment register (S0HTMAR)

Offset

Register	Offset
S0HTMAR	2080h

Function

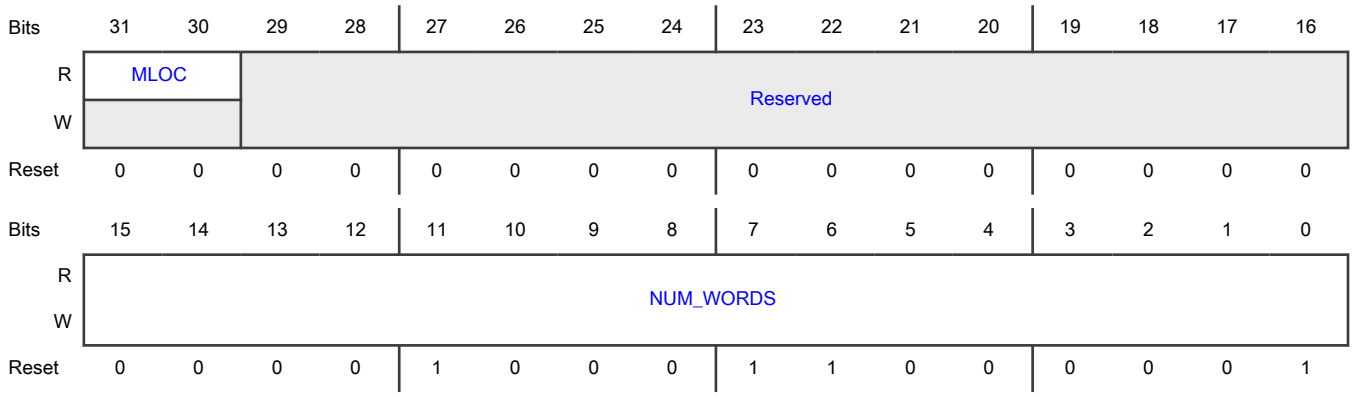
This is the switch hash table memory allotment register.

Maximum number of words allotted to the switch exact match hash tables from the common memory's shared region.

The hash tables are:

- Ingress Stream Identification table
- Ingress Stream Filter table
- VLAN Filter table
- FDB table
- L2 IPv4 Multicast Filter table

Diagram



Fields

Field	Function
31-30 MLOC	Indicates memory location of this table 0: Common memory 1-3: Reserved
29-16 —	Reserved
15-0 NUM_WORDS	Maximum number of words allotted to the switch exact match hash tables from the common memory's shared region.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Software driver is responsible to manage how the hash table memory is distributed amongst various hash tables. **NOTE** Reset value of switch HTMCAPR register. This value is writable in IERB (by pre-boot initialization), which is then copied to the switch function register during IERB lock.

53.4.6.3.62 Switch 0 index table memory allocation register (S0ITMAR)

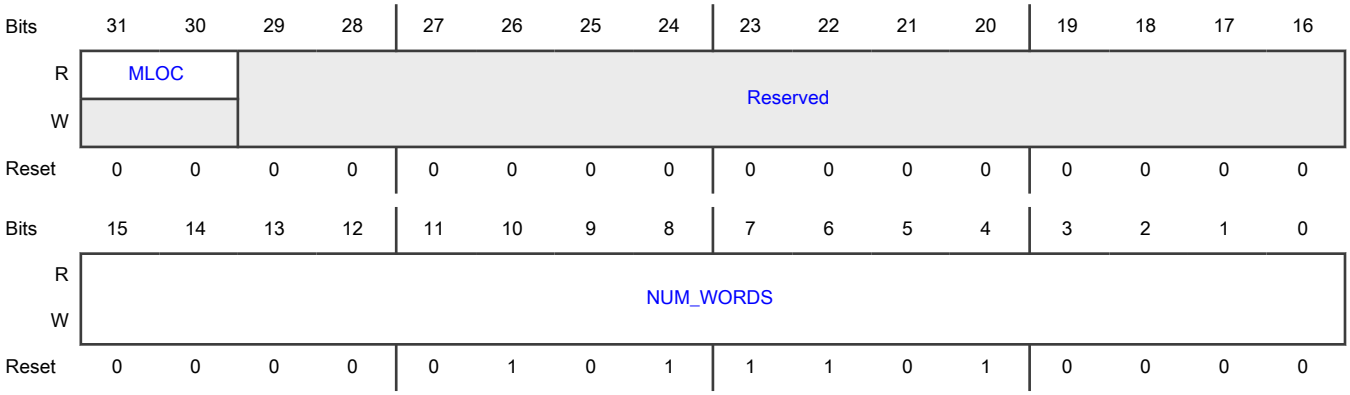
Offset

Register	Offset
S0ITMAR	2084h

Function

This is the switch index table memory allocation register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 NUM_WORDS	The number of words from index table memory assigned to this table. This value is writable in IERB (by pre-boot initialization), which is R/W in the switch version of this register. **NOTE** Each entry occupies 1 word.

53.4.6.3.67 Switch 0 ingress sequence generation index table memory allocation register (S0ISQGITMAR)

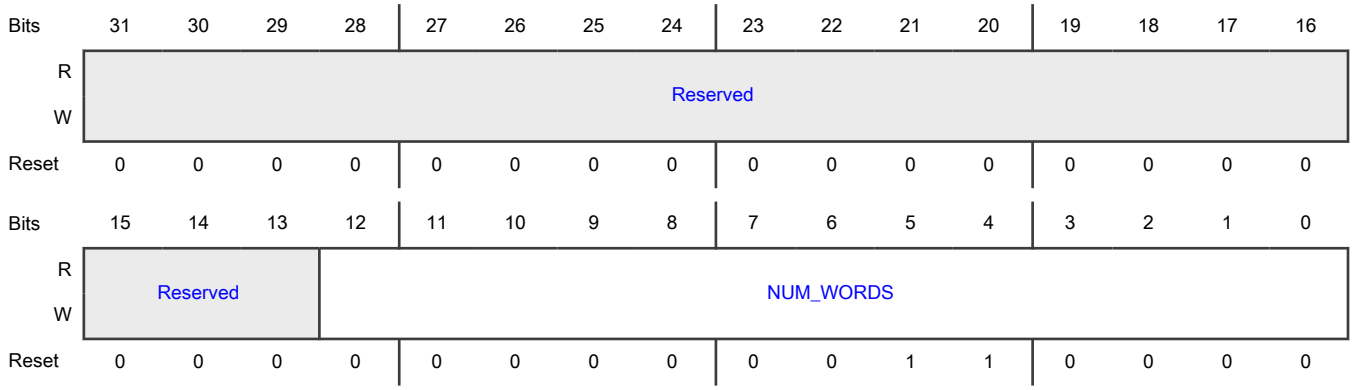
Offset

Register	Offset
S0ISQGITMAR	20ACh

Function

This is the switch ingress sequence generation index table memory allocation register.

Diagram



Fields

Field	Function
31-13 —	Reserved
12-0 NUM_WORDS	The number of words from index table memory assigned to this table. Number of entries assigned to the table is 8 * NUM_WORDS. This value is writable in IERB (by pre-boot initialization), which is R/W in the switch version of this register. **NOTE** There are 8 entries per word.

53.4.6.3.68 Switch 0 stream gate instance index table memory allocation register (S0SGIITMAR)

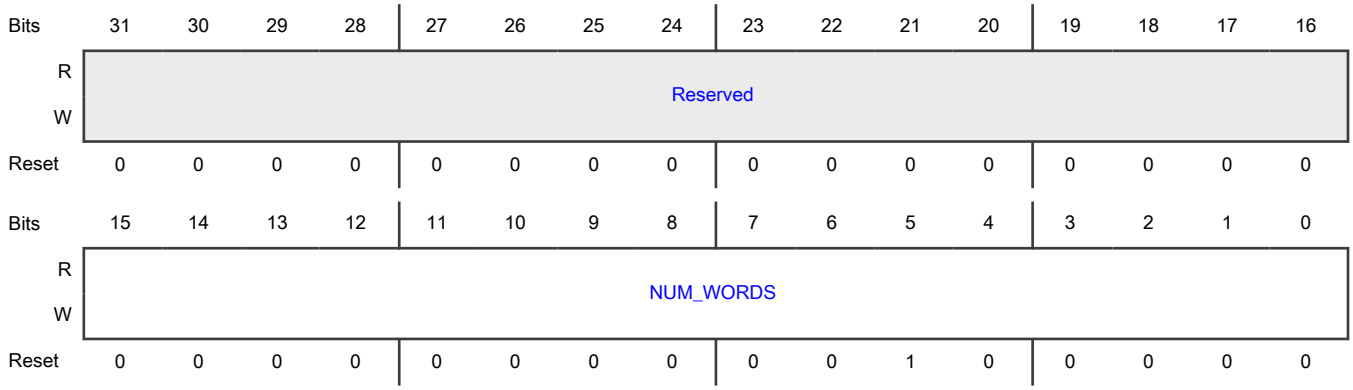
Offset

Register	Offset
S0SGIITMAR	20B4h

Function

This is the switch stream gate instance index table memory allocation register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 NUM_WORDS	The number of words from index table memory assigned to this table. This value is writable in IERB (by pre-boot initialization), which is R/W in the switch version of this register. **NOTE** Each entry occupies 1 word.

53.4.6.3.69 Switch 0 stream gate control list index table memory allocation register (S0SGCLITMAR)

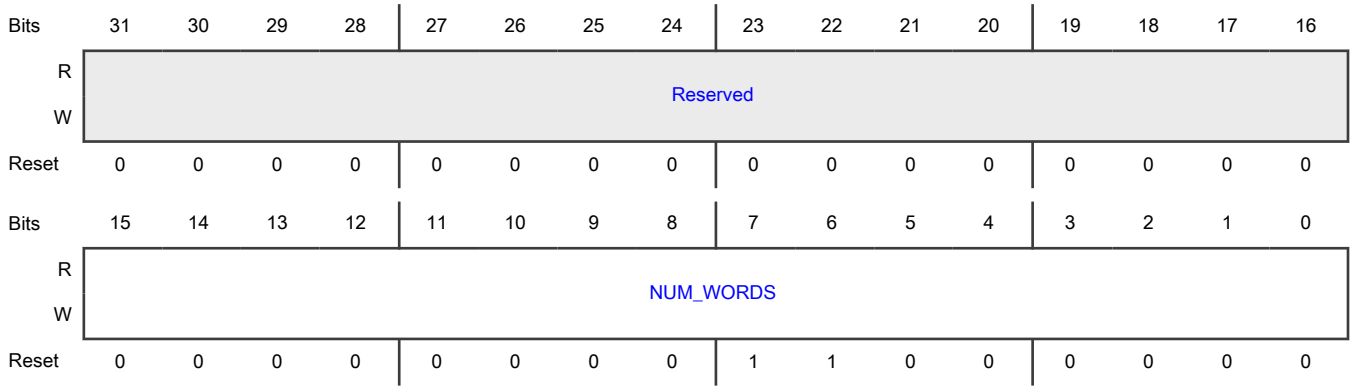
Offset

Register	Offset
S0SGCLITMAR	20B8h

Function

This is the switch stream gate control list index table memory allocation register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 NUM_WORDS	The number of words from index table memory assigned to this table. **NOTE** Each entry utilizes a variable number of words depending on the number of gates specified. Entry size in words is calculated as: 1 + ROUNDUP(NUM_GATES * 0.5).

53.4.6.3.70 Switch 0 frame modification index table memory allocation register (S0FMITMAR)

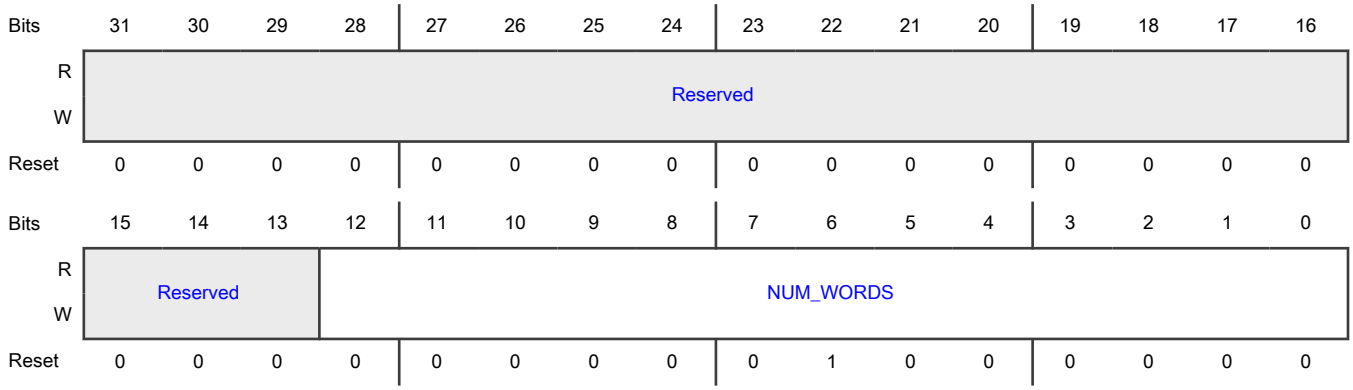
Offset

Register	Offset
S0FMITMAR	20BCh

Function

This is the switch frame modification index table memory allocation register.

Diagram



Fields

Field	Function
31-13 —	Reserved
12-0 NUM_WORDS	The number of words from index table memory assigned to this table. This value is writable in IERB (by pre-boot initialization), which is R/W in the switch version of this register. **NOTE** Each entry occupies 1 word.

53.4.6.3.71 Switch 0 frame modification data index table memory allocation register (S0FMDITMAR)

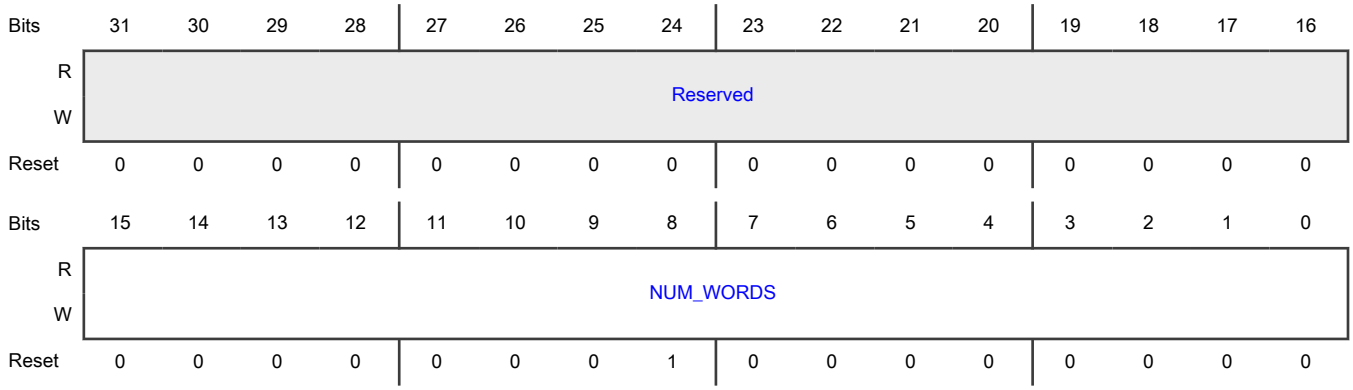
Offset

Register	Offset
S0FMDITMAR	20C0h

Function

This is the switch frame modification data index table memory allocation register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 NUM_WORDS	The number of words from index table memory assigned to this table. This value is writable in IERB (by pre-boot initialization), which is R/W in the switch version of this register. **NOTE** Each entry utilizes of a variable number of words depending on the data size requested by frame modification entry.

53.4.6.3.72 Switch 0 time gate scheduling table allocation register (S0TGSTAR)

Offset

Register	Offset
S0TGSTAR	20F0h

Function

This is the switch egress gate list table allocation register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved

R W	Reserved				NUM_WORDS											
Reset	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0

Fields

Field	Function
31-12 —	Reserved
11-0 NUM_WORDS	This field specifies the number of words in the Time Gate Scheduling internal memory (TGSMCAPR) allocated to support the switch Time Gate Scheduling table, which in turn contains the administrative gate control list and the operational gate control list of each switch port. The Time Gate Scheduling internal memory is shared between the switch and all the ENETC instances supporting time gate scheduling. The sum of all of the individual allocation (S0TGSTAR and E*a*TGSTARs) must not exceed the total size of the Time Gate Scheduling internal memory. The memory within this allocation is managed using a single free list of fixed equal size units (or words) of memory. Free memory units from the free list are available to be dynamically allocated to any gate control lists subject to the total memory available. Each gate control list is comprised of a sequence of gate operation entries where each entry occupies one word of memory. Note that a gate control list can contain a variable number of gate control operation entries. Hardware doesn't limit the number of gate operation entries (or memory) used by a specific switch port. **NOTE** Reset value of switch function's register TGSTCAPR.

53.4.6.3.73 Switch 0 time gate scheduling lookahead register (S0TGSLR)

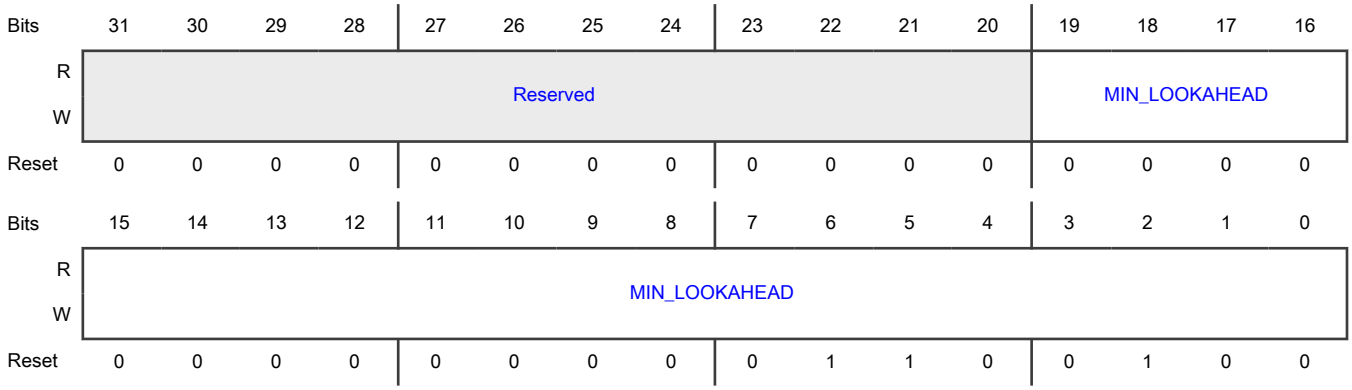
Offset

Register	Offset
S0TGSLR	20F4h

Function

This is the time gate scheduling lookahead register.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-0 MIN_LOOKAHEAD	Minimum lookahead This field specifies the amount of time to advance the IEEE 1588 time scale used by the time gate scheduler (at the frame scheduling timing point), to account for the time required to schedule and dequeue a frame. The time is specified in units of nanoseconds. The IEEE 1588 time scale used by the time gate scheduler, can also be advanced, on per port basis, by the time amount specified in PTGSATOR[ADV_TIME_OFFSET], to adjust for delay across the MAC plus if needed, delays outside of NETC (e.g. PHY delay). Both advanced times are cumulative, the IEEE 1588 time scale used by the time gate scheduler (at the frame scheduling timing point) on a given port, will be advanced by the amount of time resulting from adding the S0TGSLR[MIN_LOOKAHEAD] time to the PTGSATOR[ADV_TIME_OFFSET] time. Setting a too low value can cause a frame to miss its scheduled time-gated window or can cause a frame to overrun its scheduled time-gated window (not detected). Setting a too high value can lead to reduce link efficiency as opportunities to transmit a frame during a scheduled time-gated window can be lost. **NOTE** Value may need to be increased from the reset on value if NETC is running with a low clock frequency.

53.4.6.3.74 Switch 0 management port configuration register (S0MPCR)

Offset

Register	Offset
S0MPCR	2204h

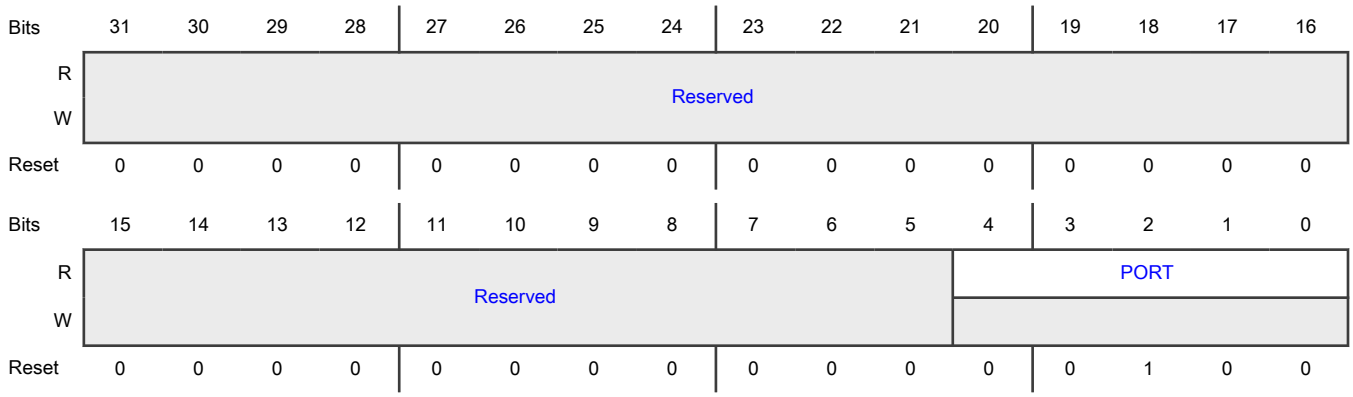
Function

This is the switch management port configuration register

NOTE

The value of this register will be immediately reflected in the corresponding read-only switch register of the same name (MPCR).

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 PORT	Specifies the destination port for frames identified as management. The value of this field will be immediately reflected in the corresponding read-only switch register MPCR.

53.4.6.3.75 Switch 0 VLAN Filter (hash) table default entry configuration registers 0 (S0VFHTDECR0)

Offset

Register	Offset
S0VFHTDECR0	2210h

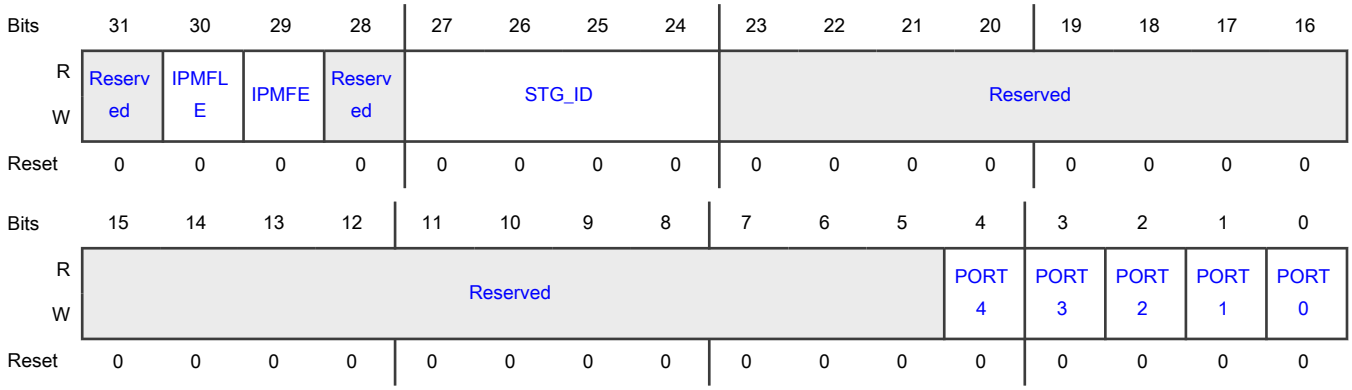
Function

This is the switch VLAN filter hash table default entry configuration registers 0.

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to switch register VFHTDECR0 during IERB lock. All updates after this must be done through the corresponding switch register.

Diagram



Fields

Field	Function
31 —	Reserved
30 IPMFLE	IP Multicast Flooding Enable If IP multicast filtering is performed (IPMFE = 1b, and the frame is identified as a multicast IP packet), and there was no match found, then the frame is forwarded according to this field. If IP multicast filtering is disabled (IPMFE = 0b), this field is ignored by hardware. 0b - IP Multicast Flooding disabled, the frame is discarded. 1b - IP Multicast Flooding enabled, the frame is flooded.
29 IPMFE	IP Multicast Filtering Enable Refer to the VLAN Filter table entry IPMFE field description, for more details 0b - No IP multicast filtering is performed. 1b - If the frame is identified as a multicast IP packet, then IP multicast filtering is performed. If the frame is not identified as an IP multicast packet, the IP multicast filtering is not performed.
28 —	Reserved
27-24 STG_ID	Spanning Tree Group Member ID Refer to the VLAN Filter table entry STG_ID field description, for more details
23-5 —	Reserved
4-0 PORTn	Port n. 0b - Port n is not a member of this VLAN. 1b - Port n is a member of this VLAN.

53.4.6.3.76 Switch 0 VLAN filter hash table default entry configuration registers 1 (S0VFHTDECR1)

Offset

Register	Offset
S0VFHTDECR1	2214h

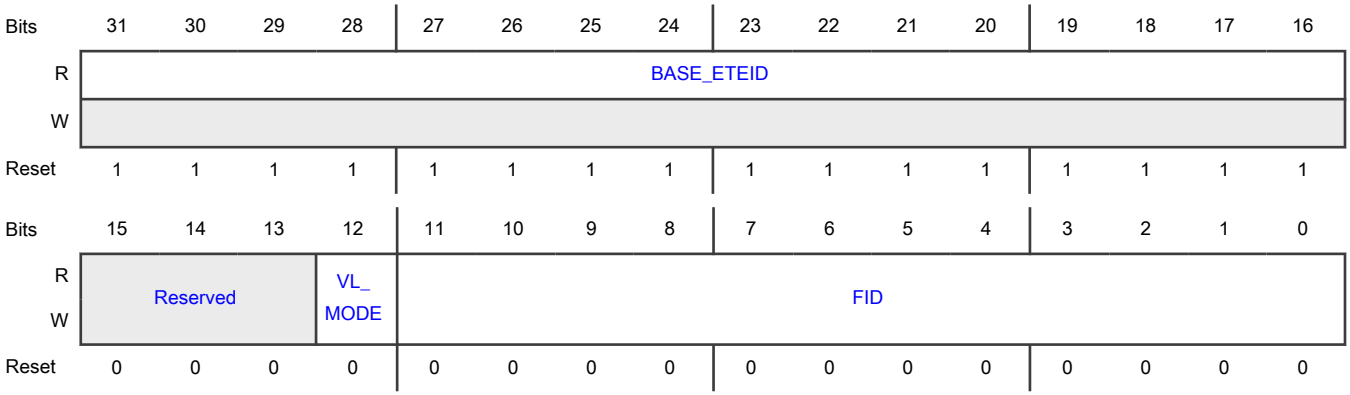
Function

This is the switch VLAN Filter (hash) table default entry configuration registers 1.

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to switch register VFHTDECR1 during IERB lock. All updates after this must be done through the corresponding switch register.

Diagram



Fields

Field	Function
31-16 BASE_ETEID	Base Egress Treatment Entry ID Refer to the VLAN Filter table entry BASE_ET_EID field description, for more details.
15-13 —	Reserved
12 VL_MODE	VLAN Learning Mode 0: Independent VLAN learning: FID is set to the VID assigned to the frame 1: Shared VLAN learning: Use the FID specified in this register **NOTE** Used to determine the FID when doing a lookup in the FDB table.
11-0	Filtering ID. Valid if VL_MODE = 1 (Shared).

Table continues on the next page...

Table continued from the previous page...

Field	Function
FID	The Filtering ID (FID) is a locally significant identifier (global to the switch), that is used as a key value when hardware performs a lookup into the FDB table and the L2 IPV4 Multicast Filter table. The FID is used to identify a set of VIDs, which in turn allows sharing of the same address (MAC, IP) between multiple VIDs during lookups into the FDB table and L2 IPV4 Multicast Filter table.

53.4.6.3.77 Switch 0 VLAN filter hash table default entry configuration registers 2 (S0VFHTDECR2)

Offset

Register	Offset
S0VFHTDECR2	2218h

Function

This is the switch VLAN Filter (hash) table default entry configuration registers 2.

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to switch register VFHTDECR2 during IERB lock. All updates after this must be done through the corresponding switch register.

Diagram

Field	Function
31-29 —	Reserved
28-27 MFO	MAC forwarding options: 0: Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1: No FDB lookup is performed, the frame is flooded 2: FDB lookup is performed, and if there is no match, the frame is flooded. 3: FDB lookup is performed, and if there is no match, the frame is discarded.
26-24 MLO	MAC learning options: 0: Reserved 1: Disable MAC learning. MAC learning function is not performed during the forwarding processing. 2: Hardware MAC learning is performed. 3: Software MAC learning secure. A MAC learning lookup is performed into the FDB table. If there is no match, no attempt is made to add a new entry, and the frame is redirect to the switch management port. If there is match, and the entry's port number does not match frame ingress port number, the frame is redirected to the switch management port if station move is allowed, otherwise the frame is discarded. 4: Software MAC learning unsecure. A MAC learning lookup is performed into the FDB table. If there is no match, no attempt is made to add a new entry, and a copy of the frame is sent to the switch management port. If there is match, and the entry's port number does not match frame ingress port number, the frame is copied to the switch management port if station move is allowed, otherwise the frame is discarded. 5: Disable MAC learning with SMAC validation. A MAC learning lookup is performed into the FDB table. If there is no match or there is a match but the ingress port is not a member of the FDB entry, the frame is discarded and counted against the bridge port discard count register (BPDCR) with discard reason BPDCRR0[MACLNFDR] set to 1.
23-5 —	Reserved
4-0 ES_PORTn	Egress Treatment Applicability Port. Valid if BASE_ETEID is not null. This field is used to set the Egress Treatment applicability port bitmap. If this field (port n) is set to 1, port n will have its bit set to 1 in the Egress Treatment applicability port bitmap.

53.4.6.3.87 ENETC a message cache attribute register (E0MCAR - E1MCAR)

Offset

Register	Offset
E0MCAR	3034h
E1MCAR	3134h

Function

This is the ENETC message cache attribute register. It is used to determine system interface attribute settings for PSI-VSI messaging reads and writes.

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to ENETC register SIMCAR during IERB lock. All updates after this must be done through the corresponding ENETC register.

53.4.6.3.89 ENETC a access management qualifier register (E0AMQR - E1AMQR)

Offset

Register	Offset
E0AMQR	3040h
E1AMQR	3140h

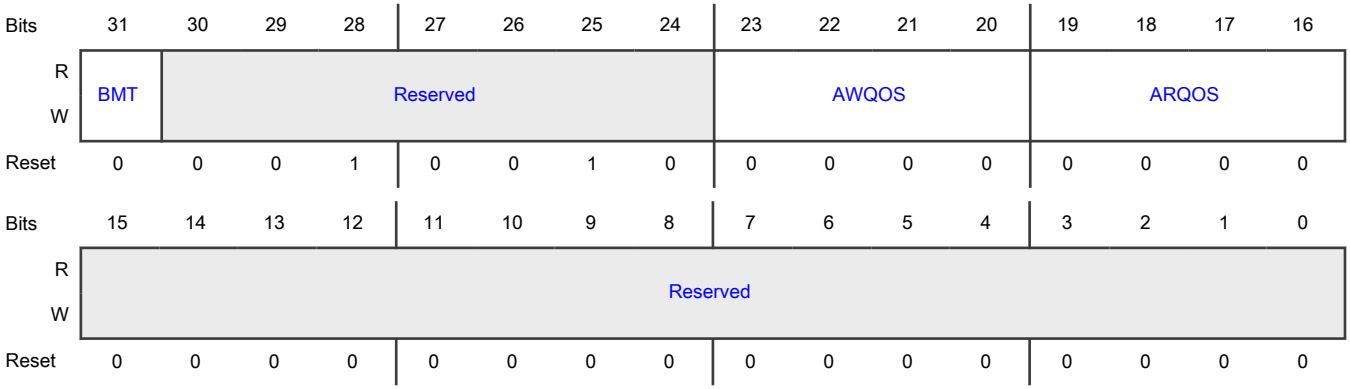
Function

This is the ENETC access management qualifier register. It provides attributes for each memory access transaction performed by the ENETC instance.

NOTE

Changing the value in this register has immediate effect unless otherwise noted. Care should be taken when making changes to the values for an enabled and operational ENETC function to ensure that consistent behavior is maintained. It is strongly encouraged, but not required, that the function be disabled before making changes.

Diagram



Fields

Field	Function
31 BMT	Bypass memory translation The bit is an indication to the SMMU to by-pass memory translation whenever the PF is performing memory transactions, effectively handling the memory address as a true physical address. 0 Memory translation 1 Bypass memory translation

31-24 —	Reserved
23-0	Receive buffer memory limit in words.

Table continues on the next page...

Table continued from the previous page...

Field	Function
LIMIT	This limit is used by the per-ENETC receive queues implemented for ingress congestion control. Ingress frames will be discarded if queue length exceeds this limit. Value of 0 means the number of memory words used within a port's priority tier is limited to 16k-1.

53.4.6.3.93 ENETC a transmit high priority tier byte credit register (E0TXHPTBCR - E1TXHPTBCR)

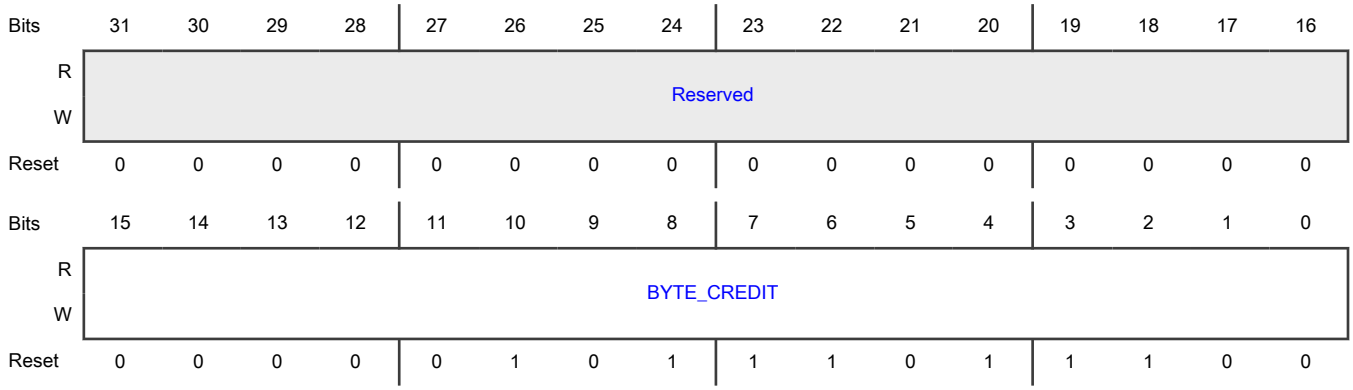
Offset

Register	Offset
E0TXHPTBCR	3070h
E1TXHPTBCR	3170h

Function

This is the ENETC transmit high priority tier byte credit register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 BYTE_CREDIT	This register field is used to configure the maximum number of high priority byte credits for the port-per-HTA Transmit priority (2 priorities) byte credit-based flow control mechanism. The port-per-HTA Transmit priority byte credit-based flow control mechanism is used to limit the amount of frame bytes in the ENETC transmit datapath that have been scheduled for transmission but not yet transferred to the MAC, for a given port. The byte credit count associated with the high priority tier is initialized to the value configured in this register field. The high priority tier is used for traffic directed to the express MAC or pseudo MAC. The byte credit

Table continues on the next page...

Table continued from the previous page...

Field	Function
	count is decremented when a high priority tier frame is scheduled by HTA transmit and incremented in chunks of 72 bytes, as the frame is being sent to the MAC. HTA is allowed to schedule a frame as long as the byte credit count is higher than 0. This will limit the number of frame bytes in the ENETC high priority transmit path to "E0TXHPTBCR[BYTE_CREDIT] + maximum frame size". It is recommended to set the maximum number of high priority byte credits to the larger value of the following two formulas: • Maximum link speed that can be configured in PCR[PSPEED] divided by 8 (unit in bytes), and then multiplied by EaTGSLR[MIN_LOOKAHEAD]; amount of byte credits required when time gate scheduling operation is enabled. For example, with PCR[PSPEED] set to 2 Gbit/s and EaTGSLR[MIN_LOOKAHEAD] set to 10 µs, the formula yields 2500 byte credits. • 700 + (maximum frame size divided by 2); amount of byte credits required when time gate scheduling operation is disabled; assuming a maximum frame size of 1536 bytes, the formula yields 1500 byte credits (is round up to the nearest 100). A value of zero in this register field disables the port-per-HTA Transmit priority byte credit-based flow control mechanism, for the high-priority tier.

53.4.6.3.94 ENETC a transmit low priority tier byte credit register (E0TXLPTBCR - E1TXLPTBCR)

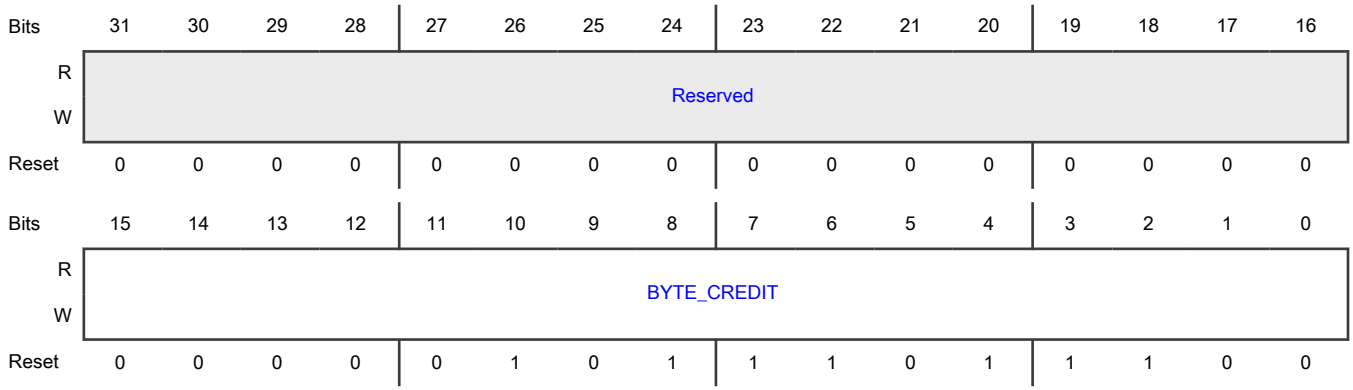
Offset

Register	Offset
E0TXLPTBCR	3074h
E1TXLPTBCR	3174h

Function

This is the ENETC transmit low priority tier byte credit register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 BYTE_CREDIT	This register field is used to configure the maximum number of low priority byte credits for the port-per-HTA Transmit priority (2 priorities) byte credit-based flow control mechanism. The port-per-HTA Transmit priority byte credit-based flow control mechanism is used to limit the amount of frame bytes in the ENETC transmit datapath that have been scheduled for transmission but not yet transferred to the MAC, for a given port. The byte credit count associated with the low priority tier is initialized to the value configured in this register field. The low priority tier only applies when IEEE 802.1Qbu frame preemption is enabled, and specifically used for traffic directed to the preemptable MAC. The byte credit count is decremented when a low priority tier frame is scheduled by HTA transmit and incremented in chunks of 72 bytes, as the frame is being sent to the MAC. HTA is allowed to schedule a frame as long as the byte credit count is higher than 0. This will limit the number of frame bytes in the ENETC low priority transmit path to "E0TXLPTBCR[BYTE_CREDIT] + maximum frame size". It is recommended to set the maximum number of low priority byte credits to the larger value of the following two formulas: • Maximum link speed that can be configured in PCR[PSPEED] divided by 8 (unit in bytes), and then multiplied by EaTGSLR[MIN_LOOKAHEAD]; amount of byte credits required when time gate scheduling operation is enabled. For example, with PCR[PSPEED] set to 2 Gbit/s and EaTGSLR[MIN_LOOKAHEAD] set to 10 µs, the formula yields 2500 byte credits. • 700 + (maximum frame size divided by 2); amount of byte credits required when time gate scheduling operation is disabled; assuming a maximum frame size of 1536 bytes, the formula yields 1500 byte credits (is round up to the nearest 100). A value of zero in this register field disables the port-per-HTA Transmit priority byte credit-based flow control mechanism, for the low-priority tier.

53.4.6.3.95 ENETC 0 hash table memory allotment register (E0HTMAR)

Offset

Register	Offset
E0HTMAR	3080h

Function

This is the ENETC hash table memory allotment register.

Number of words allotted to exact match hash tables from the common memory's shared region. Software driver is responsible to manage how the hash table memory is distributed amongst various hash tables. The hash tables are:

- Ingress Stream Identification table
- Ingress Stream Filter table

Diagram

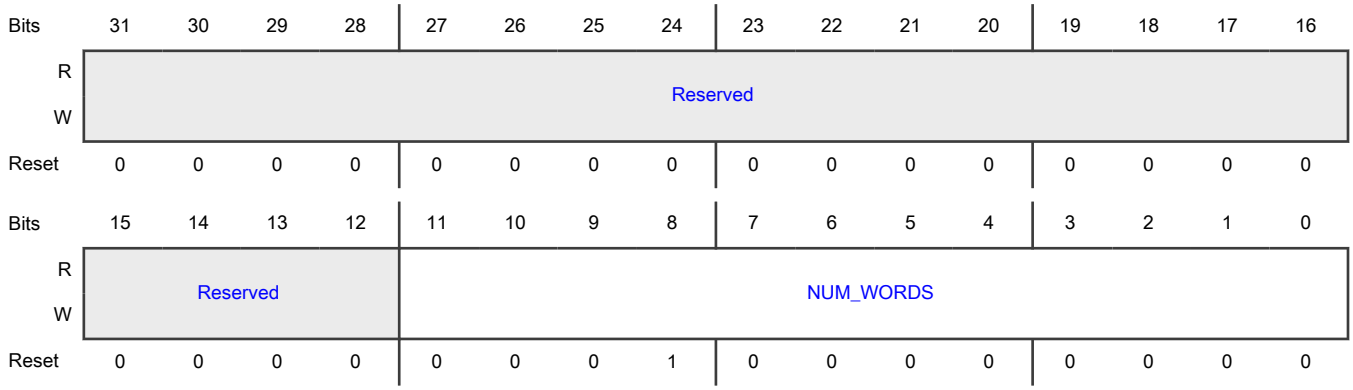
E1TGSTAR	31F0h

Function

This is the ENETC time gate scheduling table allocation register.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 NUM_WORDS	This field specifies the number of words in the Time Gate Scheduling internal memory (TGSMCAPR) allocated to support the ENETC instance a Time Gate Scheduling table, which in turn contains the administrative gate control list and the operational gate control list for the ENETC instance. The Time Gate Scheduling internal memory is shared between the switch and all of the ENETC instances supporting time gate scheduling. The sum of all of the individual allocation (S0TGSTAR and E*a*TGSTARs) must not exceed the total size of the Time Gate Scheduling internal memory. The memory withing this allocation is managed using a single free list of fixed equal size units (or words) of memory. Free memory units from the free list are available to be dynamically allocated to any gate control lists subject to the total memory available. Each gate control list is comprised of a sequence of gate operation entries where each entry occupies one word of memory. Note that a gate control list can contain a variable number of gate control operation entries. **NOTE** Reset value of ENETC register TGSTCAPR.

53.4.6.3.104 ENETC 0 time gate scheduling lookahead register (E0TGSLR)

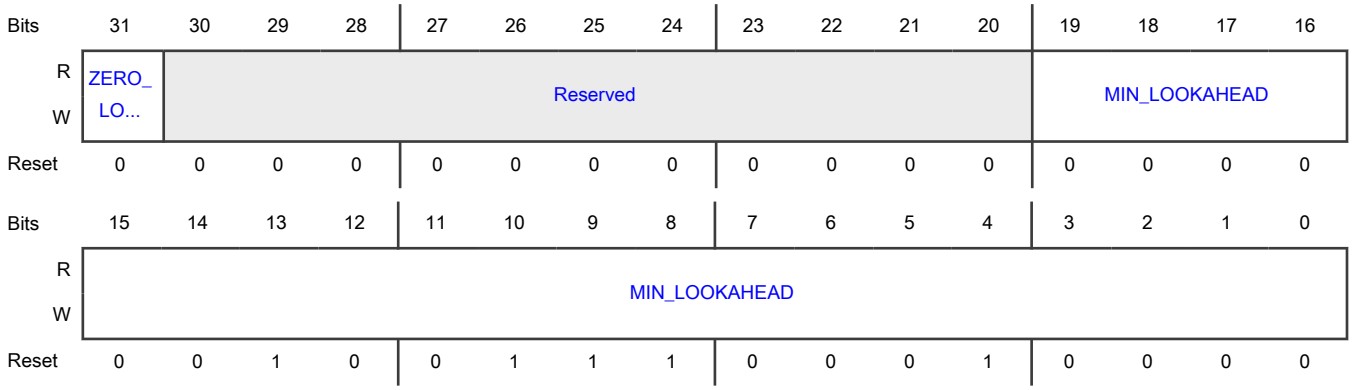
Offset

Register	Offset
E0TGSLR	30F4h

Function

This is the time gate scheduling lookahead register.

Diagram



Fields

Field	Function
31 ZERO_LOOKAHEAD	Zero Lookahead **NOTE** For ENETC bound to pseudo MAC, the default reset behaviour is to rate limit the port to the rate specified in PCR[PSPEED] without any DMA compensation delay. Only applicable if ENETC bound to pseudo MAC (L*a*CAPR[LINKTYPE=1). There is no equivalent field for the switch as there is no need to compensate for any DMA delay; power on reset value for the S0TGSLR[MIN_LOOKAHEAD] field is suitable to rate limit a switch port bound to pseudo MAC. 0b - Use MIN_LOOKAHEAD value 1b - If a gate control list is configured or when time specific departure is enabled on any traffic class (PTCaTSDR[TSDE] set to 1, where a corresponds to the traffic class number), use MIN_LOOKAHEAD value, otherwise use value of zero
30-20 —	Reserved
19-0 MIN_LOOKAHEAD	Minimum lookahead This field specifies the amount of time to advance the IEEE 1588 time scale used by the time-based scheduler (at the frame scheduling timing point), to account for the time required to schedule, dequeue and load (or DMA) frames from the host memory to NETC internal memory. The time is specified in units of nanoseconds. The IEEE 1588 time scale used by the time-based scheduler, can also be advanced, on per port basis, by the time amount specified in PTGSATOR[ADV_TIME_OFFSET], to adjust for delay across the MAC plus if needed, delays outside of NETC (e.g. PHY delay). Both advanced times are cumulative, the IEEE 1588 time scale used by the time-based scheduler (at the frame scheduling timing point) on a given port, will be advanced by the amount of time resulting from adding the EaTGSLR[MIN_LOOKAHEAD] time to the PTGSATOR[ADV_TIME_OFFSET] time. Setting a too low value in the case of time gate scheduling, can cause a frame to miss it's scheduled time-gated window (frame dropped with appropriate error reported in return BD) or can cause a frame to

3-0 NUM_VSI	Indicates the number of VSIs supported for this ENETC instance. **NOTE** VSI PCIe function numbers will be sequentially assigned. The VSI 0 function number can be determined from the PCIe SR-IOV capability registers. If allocated VSI instances exceed CAPR0[NUM_VSI], error is indicated by NETCSR[ERROR].

53.4.6.3.108 ENETC 1 MSI-X configuration register (E1MCR)

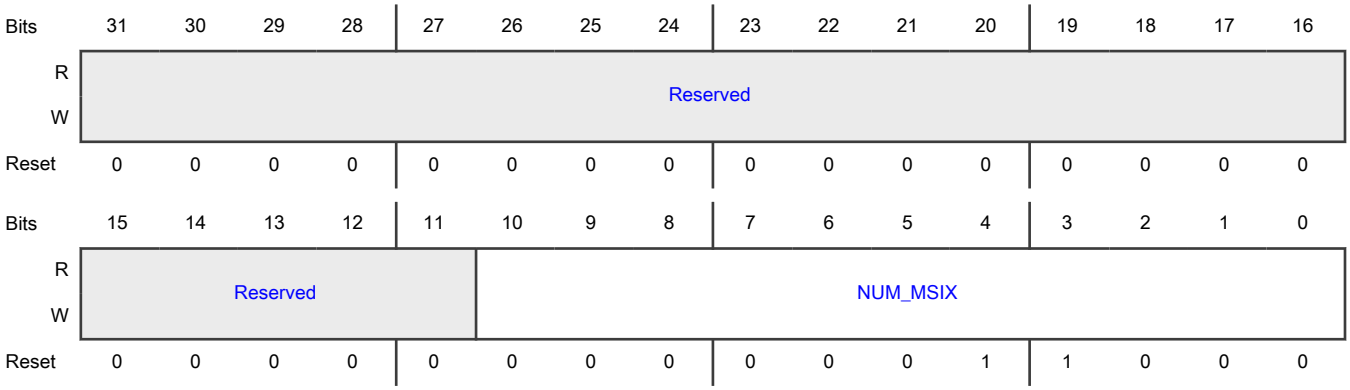
Offset

Register	Offset
E1MCR	3114h

Function

This is the ENETC MSI-X configuration register.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-0	Number of MSI-X vectors supported for ENETC function.

Table continues on the next page...

Table continued from the previous page...

Field	Function
NUM_MSIX	Formula: NUM_MSIX+1 Range: 1..1024 **NOTE** Reset value of ENETC register ECAPR1[NUM_MSIX]. If total number of allocated MSI-X vectors exceed CAPR2[NUM_MSIX], error is indicated by NETCSR[ERROR].

53.4.6.3.109 ENETC 1 config header device ID and vendor ID register (E1_CFH_DIDVID)

Offset

Register	Offset
E1_CFH_DIDVID	3120h

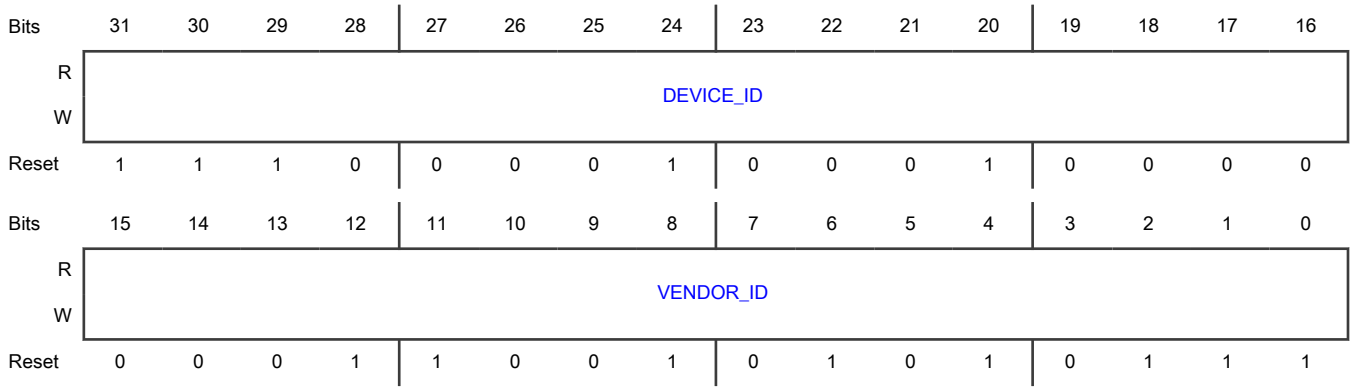
Function

This is the ENETC PCI Device and Vendor ID register.

NOTE

This register is continuously sampled, any changes will have immediate effect on reading the PCI function Type0 header.

Diagram



Fields

Field	Function
31-16 DEVICE_ID	Device ID This field identifies the device ID of the device shown in the PCIe Device ID Register (02h).
15-0	Vendor ID

Table continues on the next page...

Table continued from the previous page...

Field	Function
VENDOR_ID	This field identifies the manufacturer of the device as shown in the PCIe Vendor ID Register (00h). The default value will indicate Freescale (0x1957).

53.4.6.3.110 ENETC 1 config header subsystem ID and subsystem vendor ID register (E1_CFH_SIDSVID)

Offset

Register	Offset
E1_CFH_SIDSVID	3124h

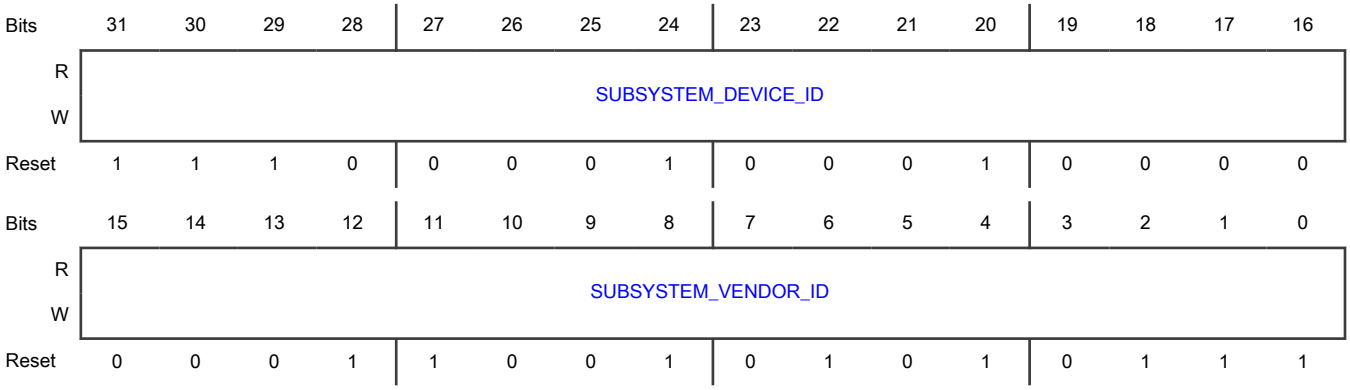
Function

This is the ENETC PCI Subsystem ID and Subsystem Vendor ID register.

NOTE

This register is continuously sampled, any changes will have immediate effect on reading the PCI function Type0 header.

Diagram



Fields

Field	Function
31-16 SUBSYSTEM_DEVICE_ID	Subsystem Device ID This field identifies the particular subsystem as shown in the PCIe Subsystem ID Register (2Eh).
15-0 SUBSYSTEM_VENDOR_ID	Subsystem Vendor ID This field identifies the manufacturer of the subsystem as shown in the PCIe Subsystem Vendor ID Register (2Ch). The default value is the same as E*a*_CFH_DIDVID[VENDOR_ID].

53.4.6.3.111 ENETC 1 hash table memory allotment register (E1HTMAR)

Offset

Register	Offset
E1HTMAR	3180h

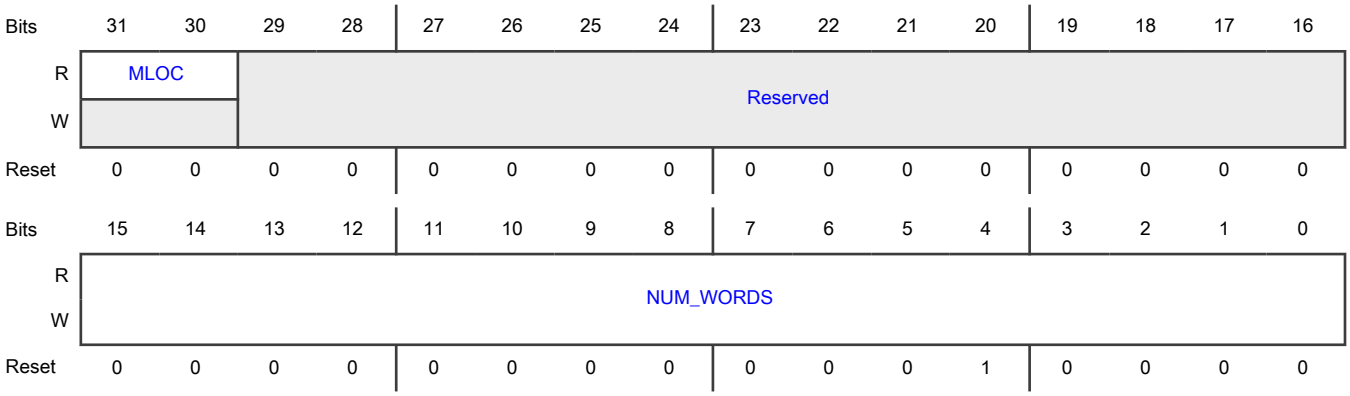
Function

This is the ENETC hash table memory allotment register.

Number of words allotted to exact match hash tables from the common memory's shared region. Software driver is responsible to manage how the hash table memory is distributed amongst various hash tables. The hash tables are:

- Ingress Stream Identification table
- Ingress Stream Filter table

Diagram



Fields

Field	Function
31-30 MLOC	Indicates memory location of this table 0: Common memory 1-3: Reserved
29-16 —	Reserved
15-0 NUM_WORDS	Number of words allotted to exact match hash table from the common memory's shared region. **NOTE** Reset value of ENETC's HTMCAPR register. This value is writable in IERB (by pre-boot initialization), which is then copied to the ENETC function register during IERB lock.

53.4.6.3.112 ENETC 1 index table memory allocation register (E1ITMAR)

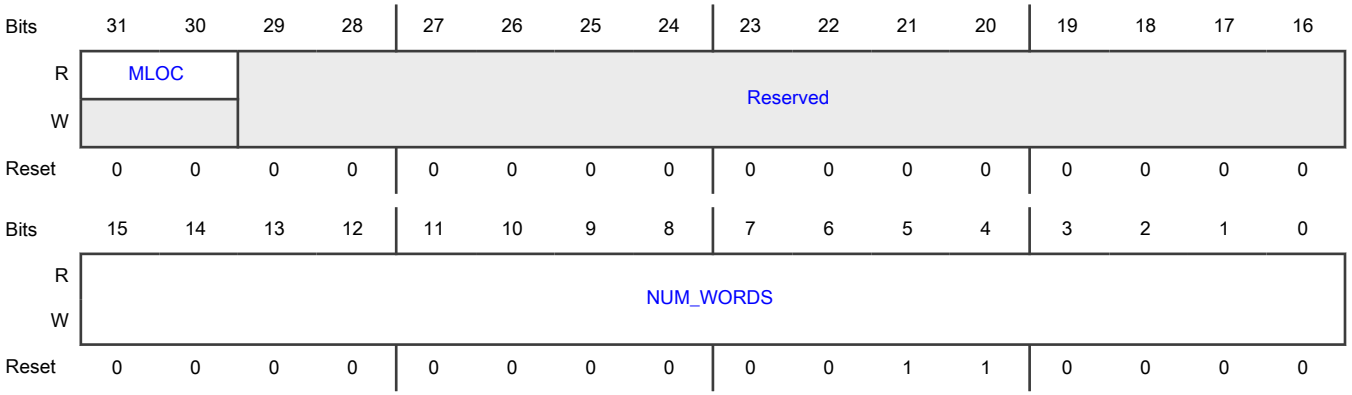
Offset

Register	Offset
E1ITMAR	3184h

Function

This is the ENETC index table memory allocation register.

Diagram



Fields

Field	Function
31-30 MLOC	Indicates memory location of this table 0: Common memory 1-3: Reserved
29-16 —	Reserved
15-0 NUM_WORDS	Number of WORDS allocated to ENETC's index table memory. **NOTE** Reset value of ENETC instance ITMCAPR register. Distribution of the table memory to various tables is done via various Index Table Memory Allocation Registers (xITMAR).

53.4.6.3.113 ENETC 1 rate policer index table memory allocation register (E1RPITMAR)

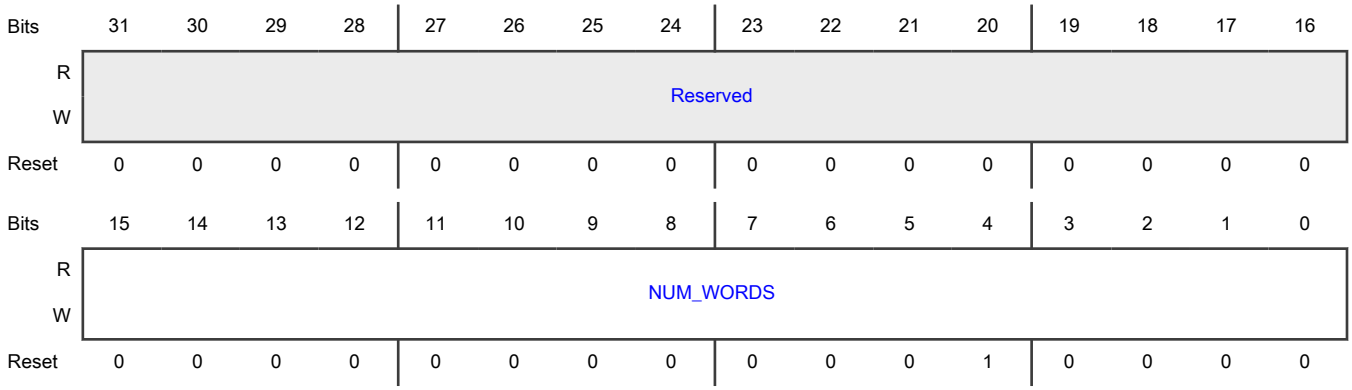
Offset

Register	Offset
E1RPITMAR	31A0h

Function

This is the ENETC rate policer index table memory allocation register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 NUM_WORDS	The number of words from index table memory assigned to this table. Number of entries assigned to the table is ROUNDDOWN(NUM_WORDS / 4). This value is writable in IERB (by pre-boot initialization), which is R/W in the ENETC version of this register. **NOTE** Each entry occupies 4 words.

53.4.6.3.114 ENETC 1 ingress stream counter index table memory allocation register (E1ISCITMAR)

Offset

Register	Offset
E1ISCITMAR	31A4h

Function

This is the ENETC ingress stream counter index table memory allocation register.

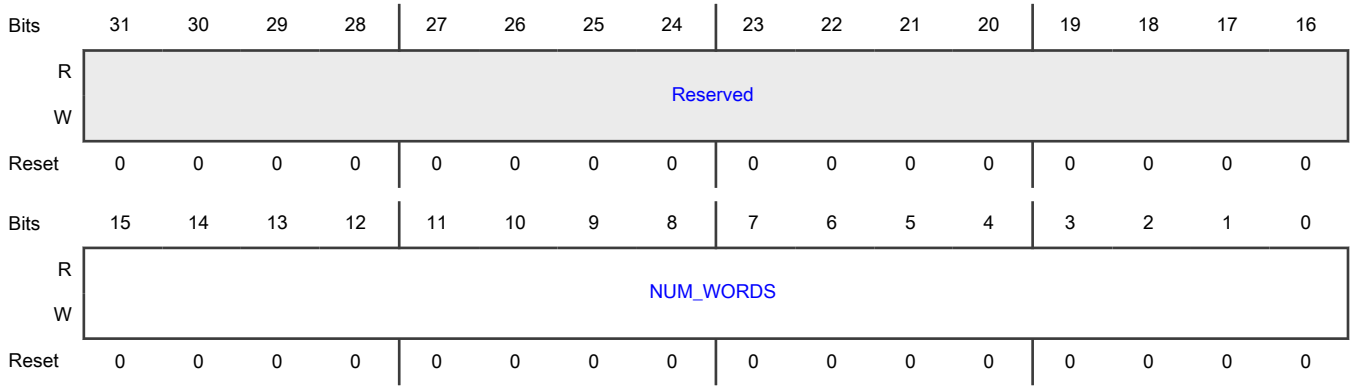
This is the ENETC stream gate instance index table memory allocation register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 NUM_WORDS	The number of words from index table memory assigned to this table. This value is writable in IERB (by pre-boot initialization), which is R/W in the ENETC version of this register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Each entry occupies 1 word.

53.4.6.3.117 ENETC 1 stream gate control list index table memory allocation register (E1SGCLITMAR)

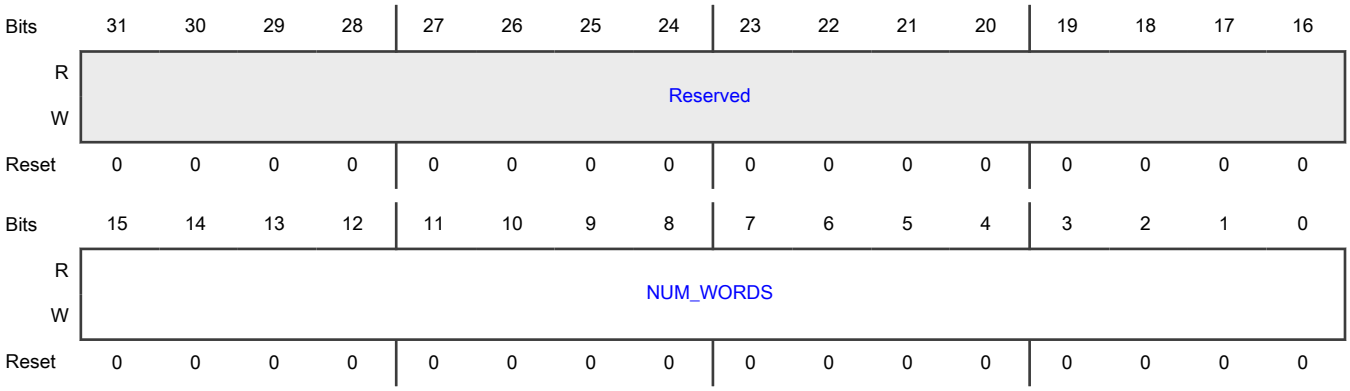
Offset

Register	Offset
E1SGCLITMAR	31B8h

Function

This is the ENETC stream gate control list index table memory allocation register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 NUM_WORDS	The number of words from index table memory assigned to this table. **NOTE** Each entry utilizes a variable number of words depending on the number of gates specified. Entry size in words is calculated as: 1 + ROUNDUP(NUM_GATES * 0.5).

53.4.6.3.118 ENETC 1 time gate scheduling lookahead register (E1TGSLR)

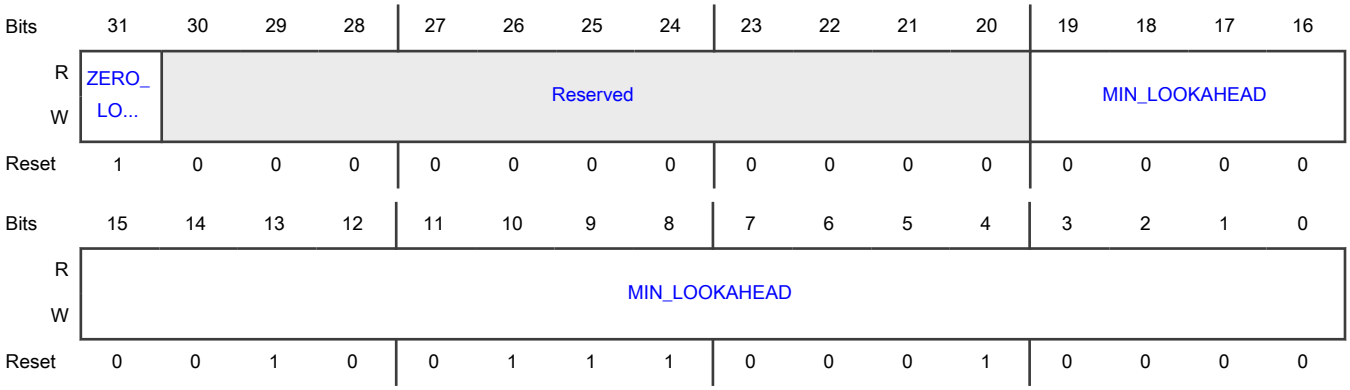
Offset

Register	Offset
E1TGSLR	31F4h

Function

This is the time gate scheduling lookahead register.

Diagram



Fields

Field	Function
31 ZERO_LOOKAHEAD	Zero Lookahead **NOTE** For ENETC bound to pseudo MAC, the default reset behaviour is to rate limit the port to the rate specified in PCR[PSPEED] without any DMA compensation delay. Only applicable if ENETC bound to pseudo MAC (L*a*CAPR[LINKTYPE=1). There is no equivalent field for the switch as there is no need to compensate for any DMA delay; power on reset value for the S0TGSLR[MIN_LOOKAHEAD] field is suitable to rate limit a switch port bound to pseudo MAC. 0b - Use MIN_LOOKAHEAD value 1b - If a gate control list is configured or when time specific departure is enabled on any traffic class (PTCaTSDR[TSDE] set to 1, where a corresponds to the traffic class number), use MIN_LOOKAHEAD value, otherwise use value of zero
30-20 —	Reserved
19-0	Minimum lookahead

Table continues on the next page...

Table continued from the previous page...

Field	Function
MIN_LOOKAHEAD	This field specifies the amount of time to advance the IEEE 1588 time scale used by the time-based scheduler (at the frame scheduling timing point), to account for the time required to schedule, dequeue and load (or DMA) frames from the host memory to NETC internal memory. The time is specified in units of nanoseconds. The IEEE 1588 time scale used by the time-based scheduler, can also be advanced, on per port basis, by the time amount specified in PTGSATOR[ADV_TIME_OFFSET], to adjust for delay across the MAC plus if needed, delays outside of NETC (e.g. PHY delay). Both advanced times are cumulative, the IEEE 1588 time scale used by the time-based scheduler (at the frame scheduling timing point) on a given port, will be advanced by the amount of time resulting from adding the EaTGSLR[MIN_LOOKAHEAD] time to the PTGSATOR[ADV_TIME_OFFSET] time. Setting a too low value in the case of time gate scheduling, can cause a frame to miss it's scheduled time-gated window (frame dropped with appropriate error reported in return BD) or can cause a frame to overrun its scheduled time-gated window (not detected). In the case of time specific departure, it can cause the frame to be transmitted later than the specified transmit time. Setting a too high value in the case of time gate scheduling, can cause a port to consume excessive transmit internal memory. It is recommended to set the minimum lookahead to 10,000 nanoseconds.

53.4.6.3.119 VSI 0 access management qualifier register (V0AMQR)

Offset

Register	Offset
V0AMQR	4000h

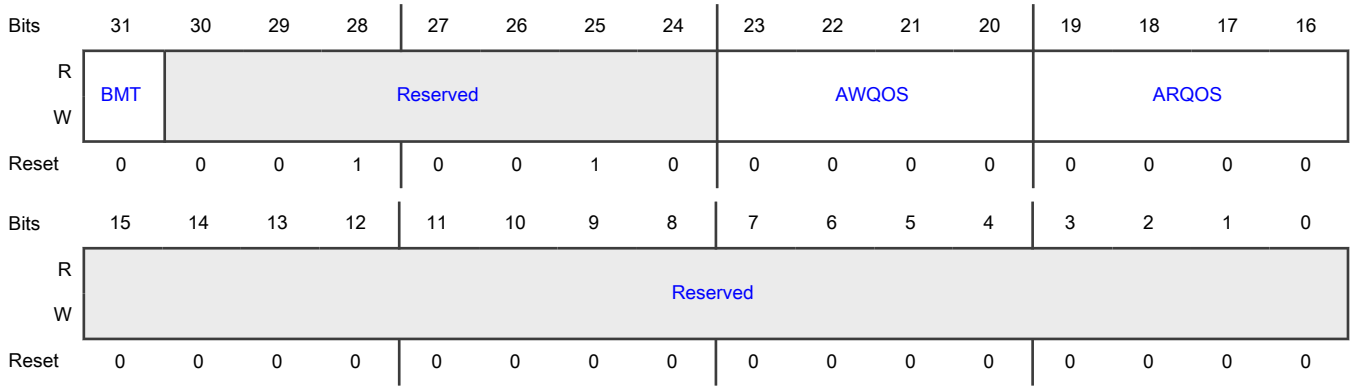
Function

This is the VSI access management qualifier register. It provides attributes for each memory access transaction performed by the VSI instance.

NOTE

Changing the value in this register has immediate effect unless otherwise noted. Care should be taken when making changes to the values for an enabled and operational virtual function to ensure that consistent behavior is maintained. It is strongly encouraged, but not required, that the virtual function be disabled before making changes.

Diagram



Fields

Field	Function
31 BMT	Bypass memory translation The bit is an indication to the SMMU to by-pass memory translation whenever the PF is performing memory transactions, effectively handling the memory address as a true physical address. 0 Memory translation 1 Bypass memory translation
30-24 —	Reserved
23-20 AWQOS	Address Write QoS. AWQOS[3:1] signals are controlled by this register field's bits [3:1]. AWQOS[0] is controlled by the HTA block and is 0 for low priority DMA transactions and 1 for high priority DMA transactions.
19-16 ARQOS	Address Read QoS. ARQOS[3:1] signals are controlled by this register field's bits [3:1]. ARQOS[0] is controlled by the HTA block and is 0 for low priority DMA transactions and 1 for high priority DMA transactions.
15-0 —	Reserved

53.4.6.3.120 VSI 0 boot loader parameter register b (V0BLPR0 - V0BLPR1)

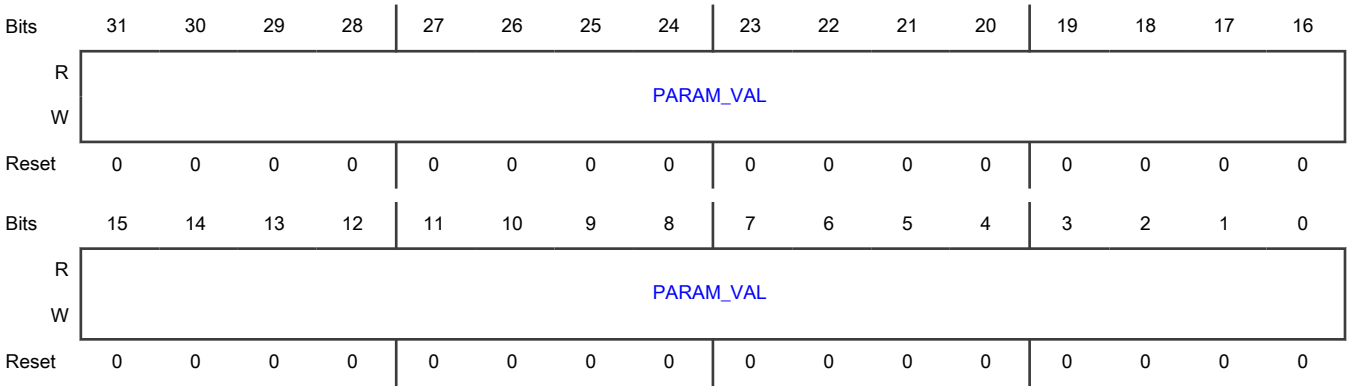
Offset

Register	Offset
V0BLPR0	4008h
V0BLPR1	400Ch

Function

This register provides a mean for boot S/W (Pre-Boot Loader, boot ROM) to communicate parameters with running (device driver) software. Runtime software uses read-only global register V*a*FBLPR*b*.

Diagram



Fields

Field	Function
31-0 PARAM_VAL	Boot loader parameter value.

53.4.6.3.121 VSI 0 primary MAC address register 0 (V0PMAR0)

Offset

Register	Offset
V0PMAR0	4010h

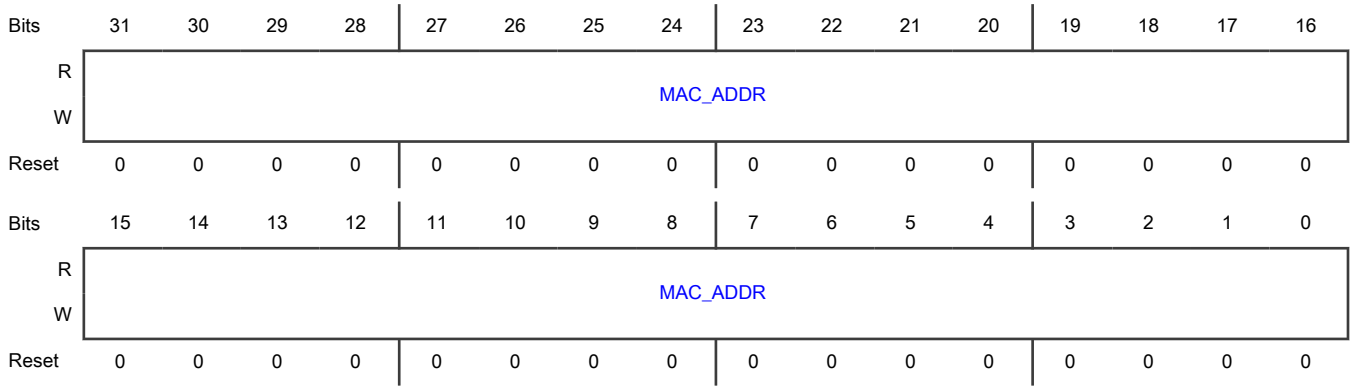
Function

This is the VSI instance primary MAC address register 0. It determines the initial value for ENETC register PSI*a*PMAR0, where a = 1, 2 .. n. .

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to ENETC register PSI*a*PMAR0 , where a = 1, 2 .. n, during IERB lock; V0PMAR0 is copied to PSI1PMAR0, V1PMAR0 is copied to PSI2PMAR0, and so on. All updates after this must be done through the corresponding register PSI*a*PMAR0.

Diagram



Fields

Field	Function
31-0 MAC_ADDR	MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset (register bit offset 0-7). This field contains the 4 most significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then V*a*PMAR0 equals 14131211h.

53.4.6.3.122 VSI 0 primary MAC address register 1 (V0PMAR1)

Offset

Register	Offset
V0PMAR1	4014h

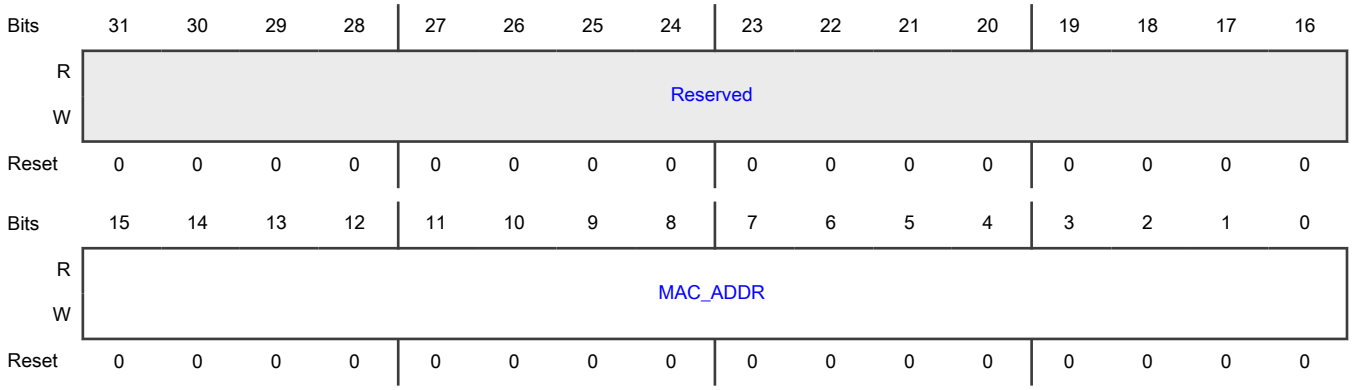
Function

This is the VSI instance primary MAC address register 1. It determines the initial value for register PSI*a*PMAR1, where a = 1, 2 .. n.

NOTE

This value is writable in IERB (by pre-boot initialization), which is then copied to ENETC register PSI*a*PMAR1 , where a = 1, 2 .. n, during IERB lock; V0PMAR1 is copied to PSI1PMAR1, V1PMAR1 is copied to PSI2PMAR1, and so on. All updates after this must be done through the corresponding register PSI*a*PMAR1.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 MAC_ADDR	MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 2 least significant bytes of the MAC address (least significant byte is stored in register bit offset 8-15). For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then V*a*PMAR1 equals xxxx1615h (where x should be set to 0)

53.4.6.4 NETC privileged register descriptions

This section describes the NETC privileged register page which is 64KB in size. It controls global reset and global error handling for NETC. Errors that affect only a function such as ENETC or switch have a similar set of registers in their respective address mapped region.

53.4.6.4.1 Privileged memory map

R W	Reserved														LOCK	SR
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	u[1]	0

1. Configured by SoC

Fields

Field	Function
31-2 —	Reserved
1 LOCK	Lock This bit can be read after reset to determine if the IERB registers are configurable. Registers are writable only when LOCK=0. If set to 1, while LOCK=0, all IERB configuration registers will be write inhibited. This also starts the initialization sequence of NETC, see NETCSR[STATE]. The lock is complete when NETCSR[STATE]=0. If written with 0, while LOCK=1, IERB configuration registers are unlocked and a warm reset is performed. The LOCK bit will return to 0 after warm reset sequence is done, hence software may poll this bit for completion. **NOTE** Warm reset is not to be used for interrupting NETC initialization sequence.
0 SR	Soft reset When set (0b1), resets all registers, and essential logic back to POR state. Register NETCFLRCR indicates the minimum amount of time for the reset sequence to complete. All functions are issued a request to quiesce during this time. This bit will self-clear and software may poll this bit to determine when soft reset sequence is complete.

53.4.6.4.3 NETC status register (NETCSR)

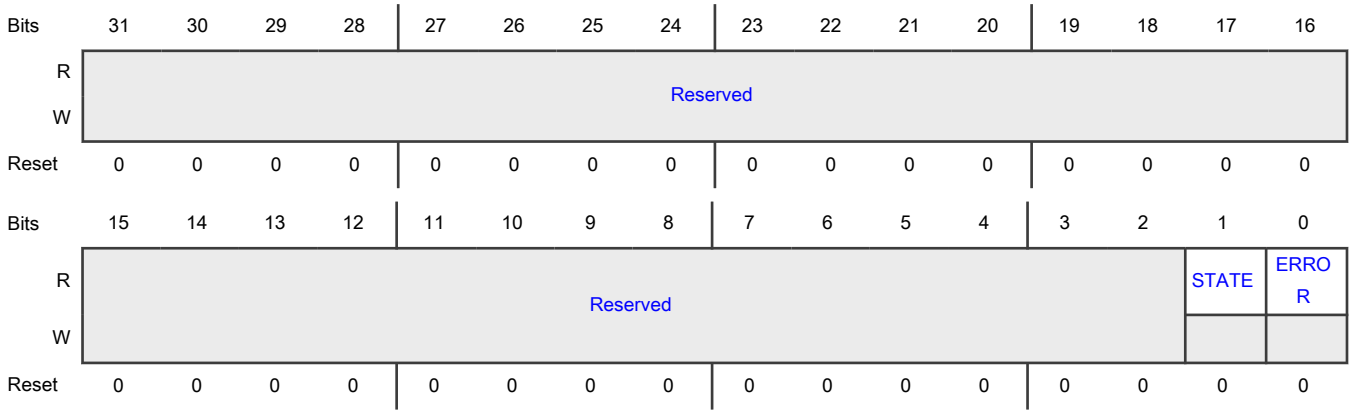
Offset

Register	Offset
NETCSR	104h

Function

This is the NETC status register.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 STATE	Indicates NETC's global operational state 0: NETC is ready for operation. 1: NETC has inhibited write access to IERB registers and is in the process of initializing NETC. The OSR register in NETC base functions include the state of this bit and may also include function specific initialization requirements. A function should wait to become operational until after the OSR[STATE] bit clears.
0 ERROR	Error 0: Configuration is valid. 1: The current IERB configuration setting is invalid due to error in binding or resource allocation. Operating NETC in current condition could lead to undefined behavior. The following IERB registers are checked for compliance: • IPFTMCAPR[NUM_WORDS] • TGSMCAPR[NUM_WORDS] • HBTMAR[NUM_WORDS] • L*a*BCR • E*a*BCR1[NUM_RX_BDR/NUM_TX_BDR] • E*a*BCR2[NUM_VSI] • T*a*MCR[NUM_MSIX], S*a*MCR[NUM_MSIX], E*a*MCR[NUM_MSIX] The following I/O configuration inputs are checked for compliance: • L*a*MCAPR[MII_PROT] • L*a*IOCAPR[IO_VAR]

53.4.6.4.4 Memory Error Injection Config Register (MEICR)

Offset

Register	Offset
MEICR	208h

Function

NETC is capable of injecting memory faults in all the locations where ECC is checked (on all memory read interfaces). One bit is flipped on the data bus for single bit errors, and two bits for multi-bit errors.

Software must arm the Safety Mechanism (SM), and the next transaction coming through this SM will trigger the fault, detection, and reporting. It is up to software to target a specific PCI function, or a specific engine (using engine disables) if a specific error detection and report is desired.

Only one fault injection can be configured at a time.

Diagram

53.4.6.4.5 Correctable memory error configuration register (CMECR)

Offset

Register	Offset
CMECR	E00h

Function

The correctable memory error configuration register can disable the event reporting to the Root Complex Event Collector. While correctable errors do not cause any harm, detecting many of these events could indicate a more severe issue. The threshold can be set to trigger the event.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 THRESHOLD	Threshold Determines how many single bit ECC errors must be detected before error status bit is set and correctable memory error is reported to PCIe Event Collector. 0 Disabled (no reporting) >0 Threshold value (1-255).

53.4.6.4.6 Correctable memory error status register (CMESR)

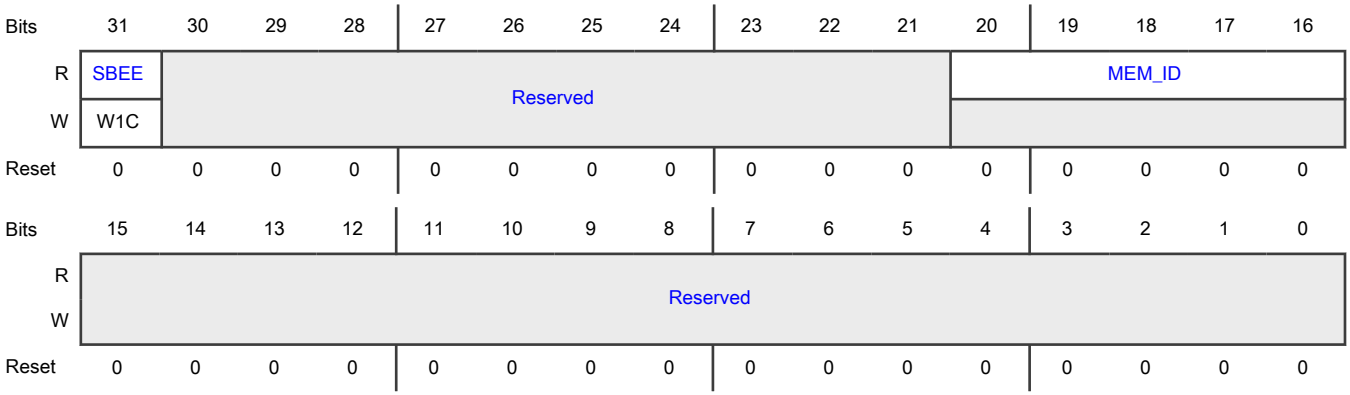
Offset

Register	Offset
CMESR	E04h

Function

This is the correctable memory error status register.

Diagram



Fields

Field	Function
31 SBEE	Single-bit ECC error When set, a threshold number of single-bit ECC error has occurred in the memory defined by MEM_ID. Write 1 to clear.
30-21 —	Reserved
20-16 MEM_ID	Memory ID See Table 392 for list of memory identifiers.
15-0 —	Reserved

53.4.6.4.7 Correctable memory error count register (CMECTR)

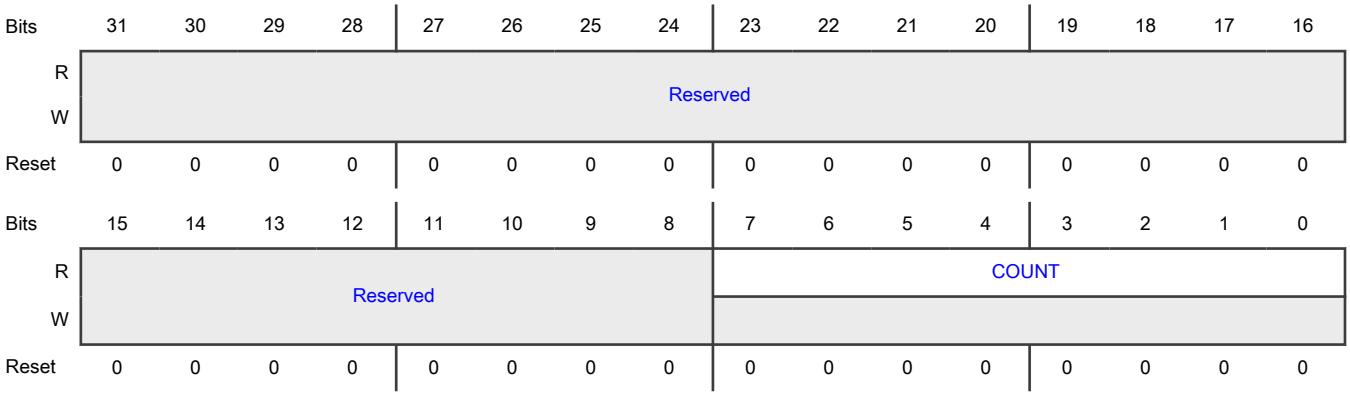
Offset

Register	Offset
CMECTR	E0Ch

Function

This is the correctable memory error count register which tracks how many events have been detected.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Count Indicates how many single-bit ECC error have been detected. After a read operation, the field's value clears to 0.

53.4.6.4.8 Uncorrectable non-fatal memory error configuration register (UNMECR)

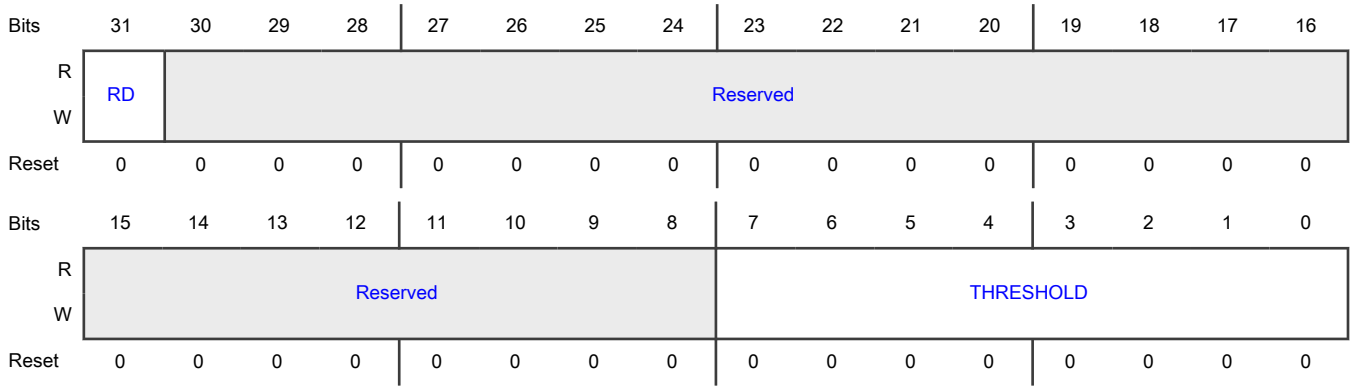
Offset

Register	Offset
UNMECR	E30h

Function

The uncorrectable non-fatal memory error configuration register can disable event reporting to all PCIe functions.

Diagram



Fields

Field	Function
31 RD	Report disable When reporting is enabled and UNMESR0[MBEE] is set, an uncorrectable error is reported to all PCIe functions' Advanced Error Reporting capability register, PCIE_CFC_AER_UCORR_ERR_STAT. 0 Enabled 1 Disabled
30-8 —	Reserved
7-0 THRESHOLD	Threshold Determines how many non-fatal memory errors must be detected before error status bit is set. 0 Disabled (no reporting) >0 Threshold value (1-255).

53.4.6.4.9 Uncorrectable non-fatal memory error status register 0 (UNMESR0)

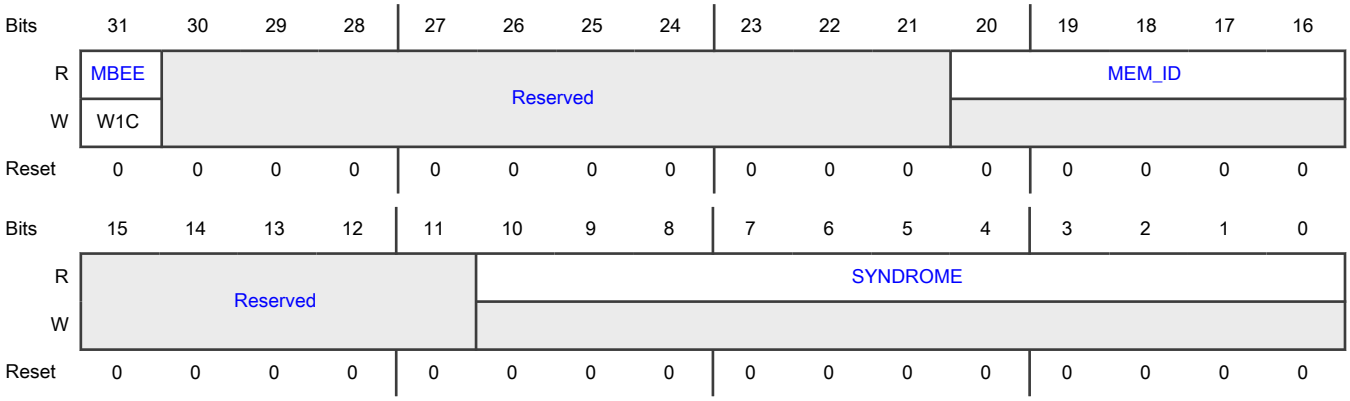
Offset

Register	Offset
UNMESR0	E34h

Function

This is the uncorrectable non-fatal memory error status register 0.

Diagram



Fields

Field	Function
31 MBEE	Multi-bit ECC error When set, a programmable threshold number of multi-bit ECC errors has occurred in internal memory as defined by MEM_ID. The reaction to the error may result in dropping the frame being processed or in stomping on the FCS of the frame if the error is detected while the transmission of the frame is in progress. Write 1 to clear.
30-21 —	Reserved
20-16 MEM_ID	Memory ID See Table 392 for list of memory identifiers.
15-11 —	Reserved
10-0 SYNDROME	Syndrome Identifies the first pertinent bit position (column) in memory that caused the error.

53.4.6.4.10 Uncorrectable non-fatal memory error status register 1 (UNMESR1)

Offset

Register	Offset
UNMESR1	E38h

Function

This is the uncorrectable non-fatal memory error status register 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	Reserved								COUNT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Count Indicates how many frames have been dropped due to internal memory error. After a read operation, the field's value clears to 0.

53.4.6.4.12 Uncorrectable fatal memory error configuration register (UFMECR)

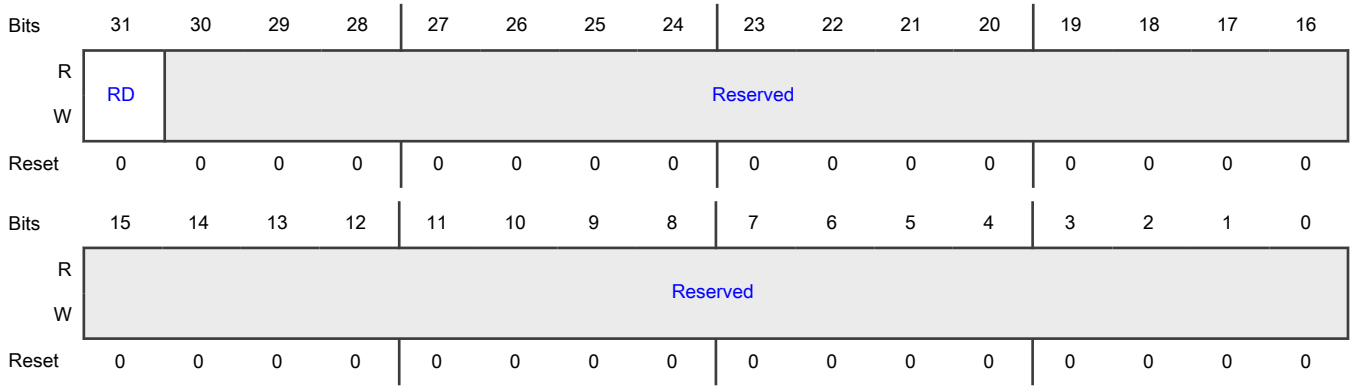
Offset

Register	Offset
UFMECR	E40h

Function

The uncorrectable fatal memory error configuration register can disable event reporting to all PCIe functions.

Diagram



Fields

Field	Function
31 RD	Report disable When reporting is enabled, and UFMESR0[MBEE] is set, an uncorrectable error is reported to all PCIe functions' Advanced Error Reporting capability register, PCIE_CFC_AER_UCORR_ERR_STAT. 0 Enabled 1 Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-0 —	Reserved

53.4.6.4.13 Uncorrectable fatal memory error status register 0 (UFMESR0)

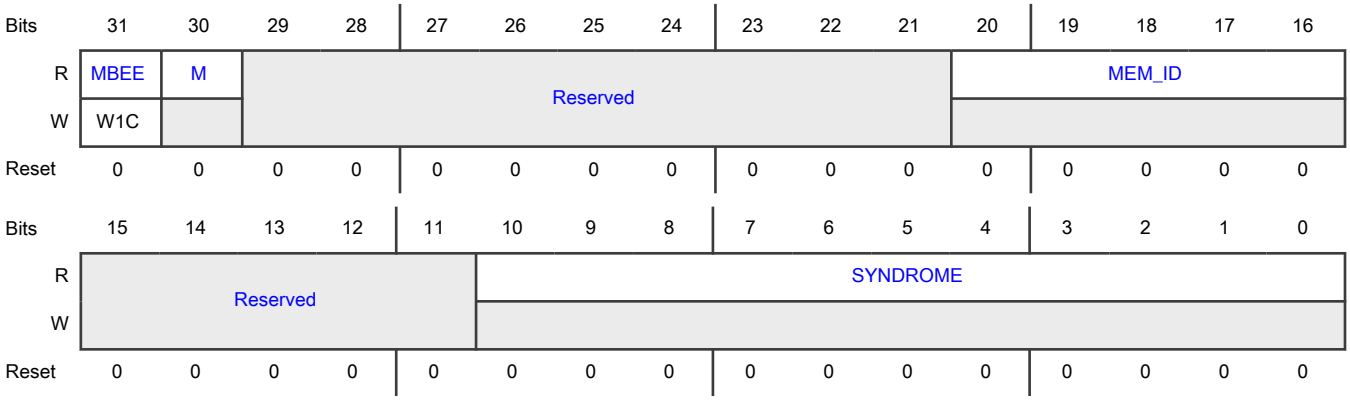
Offset

Register	Offset
UFMESR0	E44h

Function

This is the uncorrectable fatal memory error status register 0.

Diagram



Fields

Field	Function
31 MBEE	Multi-bit ECC error When set, a fatal multi-bit ECC error has occurred in the memory defined by MEM_ID. The function has entered a safe state: • PCIe bus master enable is cleared (0b0) for all functions • Station interface is disabled for all functions (SIMR[EN]=0b0) • Pseudo MAC ports are disabled (POR[TXDIS/RXDIS]=0b1) • Ethernet-MAC ports are disabled (PM*a*_COMMAND_CONFIG[RX_EN/TX_EN]=0b0) For recovery, S/W should reset NETC by issuing a Soft Reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Write 1 to clear.
30 M	Multiple Multiple multi-bit ECC error events detected. The last event is captured.
29-21 —	Reserved
20-16 MEM_ID	Memory ID See Table 392 for list of memory identifiers.
15-11 —	Reserved
10-0 SYNDROME	Syndrome Identifies the first pertinent bit position (column) in memory that caused the error.

53.4.6.4.14 Uncorrectable fatal memory error status register 1 (UFMESR1)

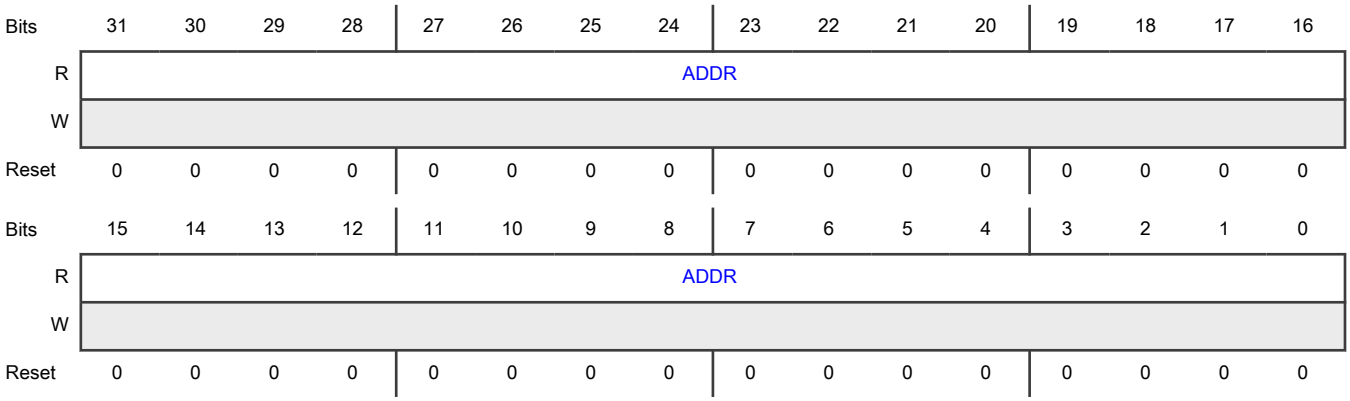
Offset

Register	Offset
UFMESR1	E48h

Function

This is the uncorrectable fatal memory error status register 1.

Diagram



Fields

Field	Function
31-0 ADDR	Address Address information (row) of last ECC event.

53.4.6.5 Switch base register descriptions

This section describes the switch specific base registers for one or more instances.

There may be differences in actual implemented registers or register fields as well as reset values between instances. The function's base address register value can be discovered from reading the PCIe Enhanced Allocation Base Address Register Equivalent Index 0 (EA BEI 0).

53.4.6.5.1 Switch memory map

SW0_BASE pcie ea bei 0 offset: 60A0_0000h

53.4.6.5.2 Switch capability register 0 (SCAPR0)

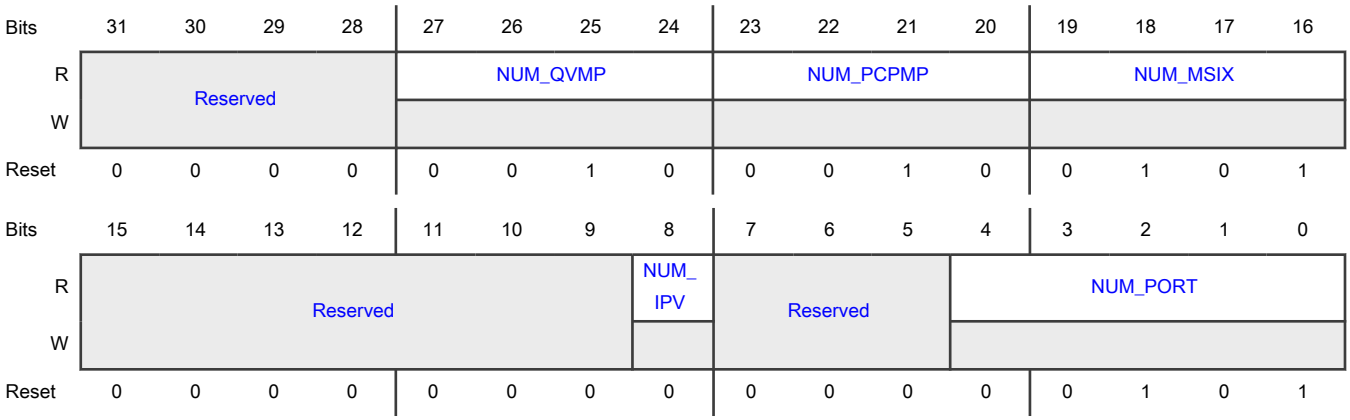
Offset

Register	Offset
SCAPR0	0h

Function

This is the switch capability register 0.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24	Number of QoS to VLAN PCP mapping profiles supported. Defines range of *a* in QOSVLANMPaR*a*R.

Table continues on the next page...

Table continued from the previous page...

Field	Function
NUM_QVMP	**NOTE** Value of 0 implies no Mapping Profiles supported.
23-20 NUM_PCPMP	Number of VLAN PCP to PCP mapping profiles supported. Define range of *a* in PCP2PCPMP*a*R; where *a* = {0..NUM_PCPMP-1}. **NOTE** Value of 0 implies no mapping profiles supported.
19-16 NUM_MSIX	Number of MSI-X vectors supported by switch function. Range: 1..16 Formula: NUM_MSIX+1 **NOTE** Value derived from IERB's S*a*MCR register.
15-9 —	Reserved
8 NUM_IPV	Number of IPVs supported 0: 8 IPV 1: Reserved
7-5 —	Reserved
4-0 NUM_PORT	Number of ports supported. **NOTE** Value derived from IERB's L*a*BCR registers. where a corresponds to the link number.

53.4.6.5.3 Switch capability register 1 (SCAPR1)

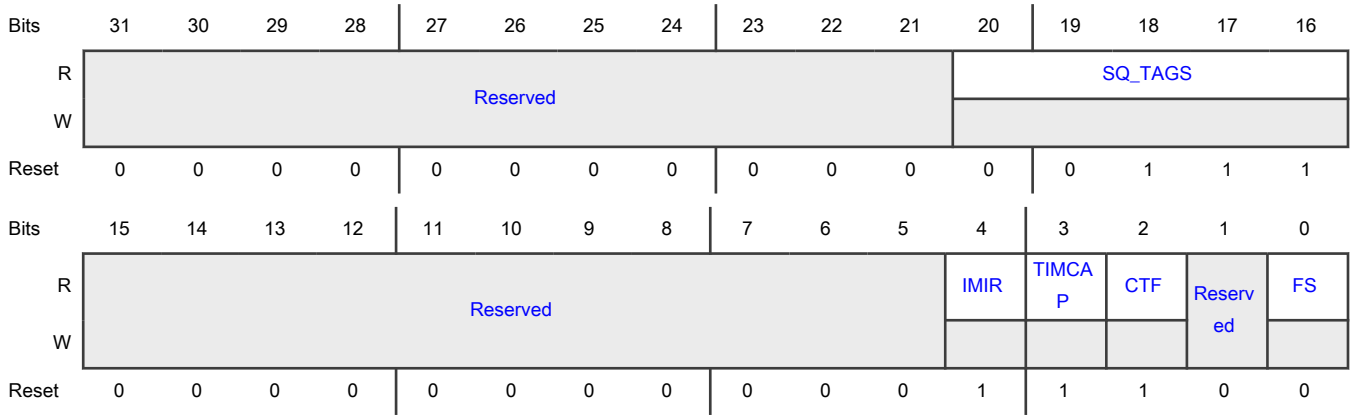
Offset

Register	Offset
SCAPR1	4h

Function

This is the switch capability register 1.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 SQ_TAGS	Indicates which FRER Sequence Tags are supported xxxx1: 802.1CB draft 2.0 R-TAG xxx1x: 802.1CB R-TAG xx1xx: HSR Tag All other values reserved.
15-5 —	Reserved
4 IMIR	Ingress mirroring functionality supported. 0: Not supported 1: Supported
3 TIMCAP	Time capture capability supported. 0: Not supported 1: Supported
2 CTF	Cut-through forwarding supported. 0: Not supported 1: Supported
1 —	Reserved
0	Functional safety capability supported.

Table continues on the next page...

Table continued from the previous page...

Field	Function
FS	If set, additional integrity error checks are performed; this includes, but not limited to, internal FCS and parity error checks. 0: Not supported 1: Supported

53.4.6.5.4 Buffer pool capability register (BPCAPR)

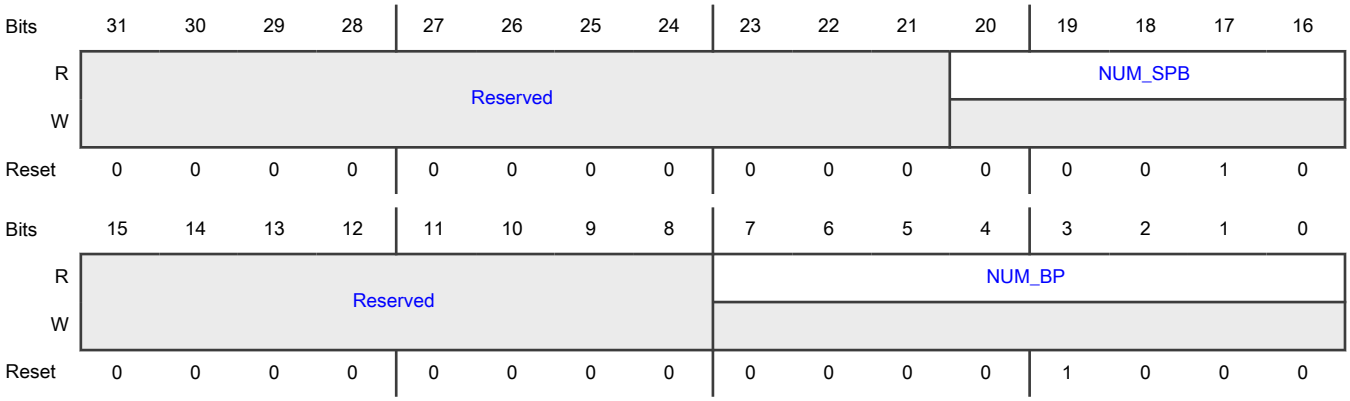
Offset

Register	Offset
BPCAPR	8h

Function

This is the buffer pool capability register

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 NUM_SPB	Number of shared buffer pools supported.
15-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 NUM_BP	Number of buffer pools supported.

53.4.6.5.5 Forwarding capability register (FCAPR)

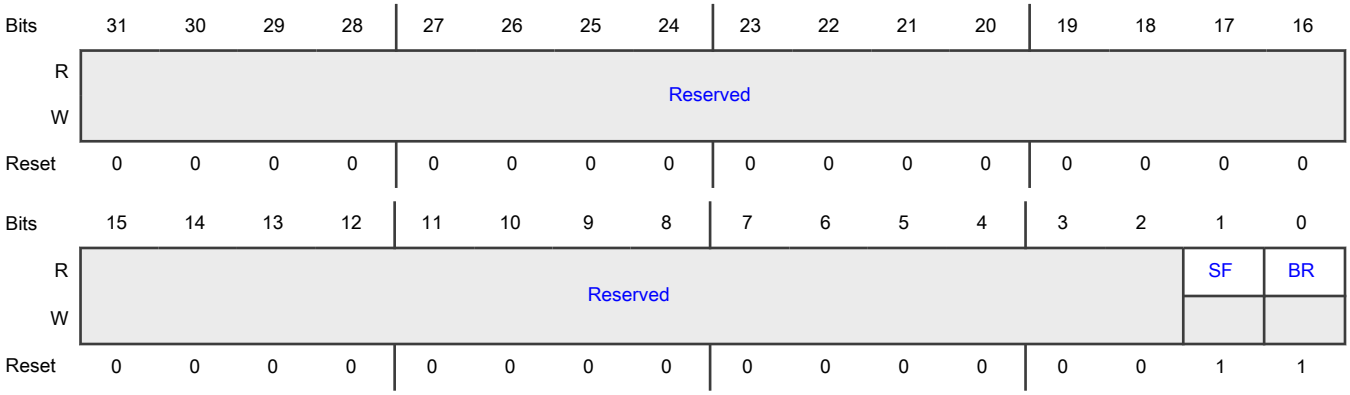
Offset

Register	Offset
FCAPR	18h

Function

This is the forwarding capability register.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 SF	Stream forwarding supported Stream forwarding provides the ability to identify a stream and forward it to a set of ports with ability to enable source port pruning. 0b - Not supported 1b - Supported
0	802.1Q bridge forwarding support.

Table continues on the next page...

Table continued from the previous page...

Field	Function
BR	See BRCAPR for more information. 0b - Not supported 1b - Supported

53.4.6.5.6 Shared memory buffer capability register (SMBCAPR)

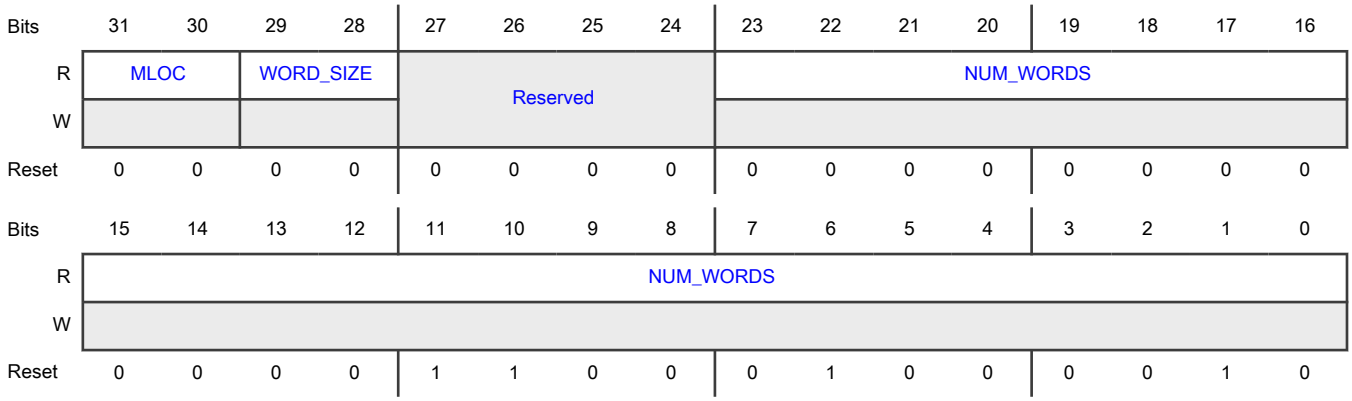
Offset

Register	Offset
SMBCAPR	40h

Function

This is the shared memory buffer capability register.

Diagram



Fields

Field	Function
31-30 MLOC	Indicates memory location 00b - Common memory 01b-11b - Reserved
29-28 WORD_SIZE	Word size in bytes. 00b - 24 bytes 01b-11b - Reserved
27-24	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
23-0 NUM_WORDS	Number of words available for the switch frame buffering. This value is writable in IERB register S*a*SMBAR (by pre-boot initialization), and is immediately reflected here. **NOTE** Memory is managed via buffer pool mechanism.

53.4.6.5.7 Shared memory buffer operational register 0 (SMBOR0)

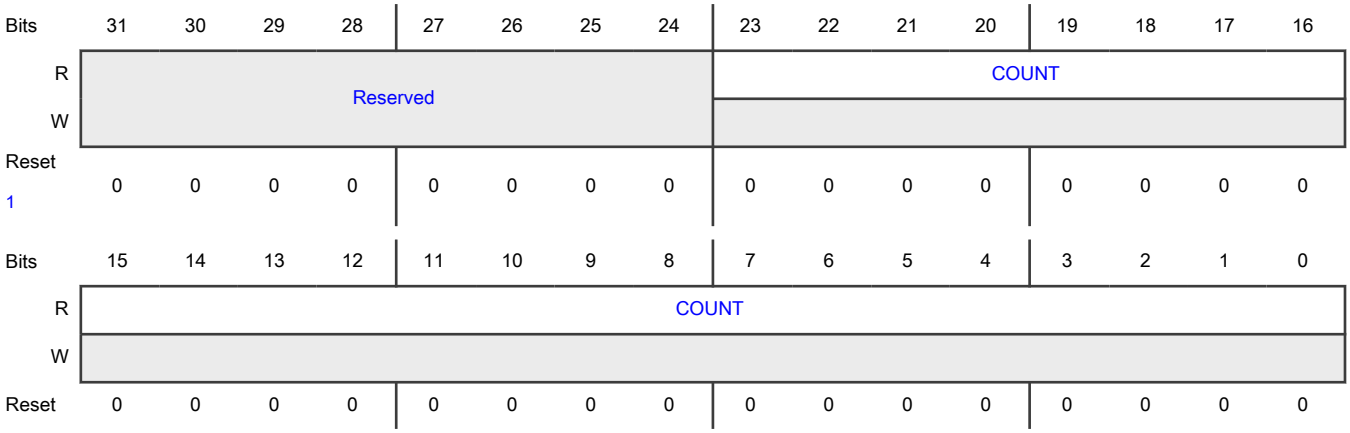
Offset

Register	Offset
SMBOR0	44h

Function

This is the shared memory buffer operational register 0.

Diagram



1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-24 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-0 COUNT	Number of words in use for frame buffering.

53.4.6.5.8 Shared memory buffer operational register 1 (SMBOR1)

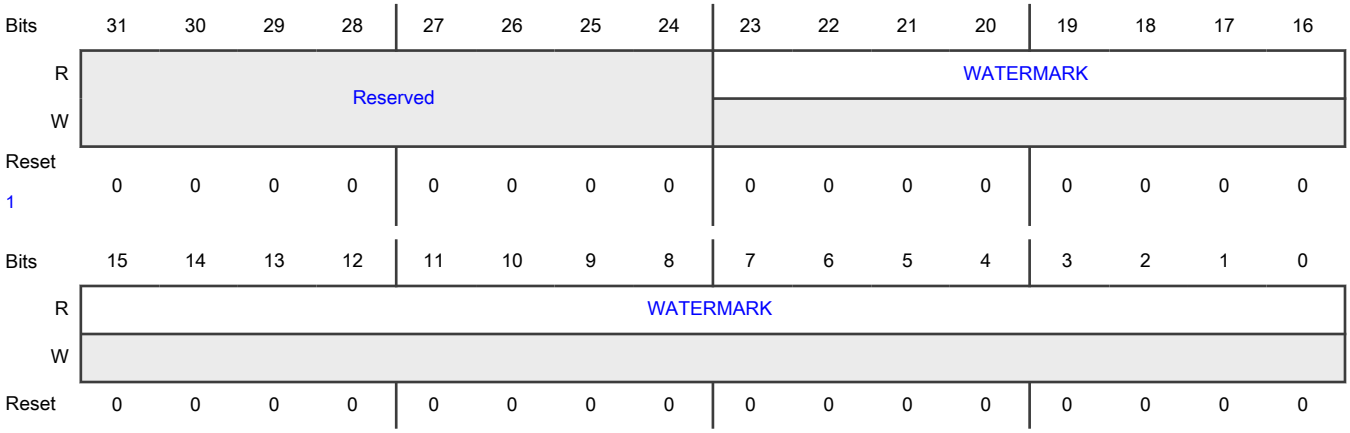
Offset

Register	Offset
SMBOR1	48h

Function

This is the shared memory buffer operational register 1.

Diagram



1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-24 —	Reserved
23-0 WATERMARK	High watermark of words in use for frame buffering since the last read. **NOTE** Value reset to SMBOR0[COUNT] after a read.

53.4.6.5.9 Command cache attribute register (CCAR)

Offset

Register	Offset
CCAR	80h

Function

This is the command cache attribute register. It is used to determine system attributes for reads and writes of command descriptor and data.

NOTE

The switch will sample the IERB value of this register when PCIe Memory Access bit is set (b1). All updates after this must be done through this register.

Diagram

31-5 —	Reserved
4-0 PORT	Switch Management Port Specifies the switch port number designated as a switch management port. Reset value is determined by it's equivalent IERB Register (S0MPCR)

53.4.6.5.11 Ingress mirror destination configuration register 0 (IMDCR0)

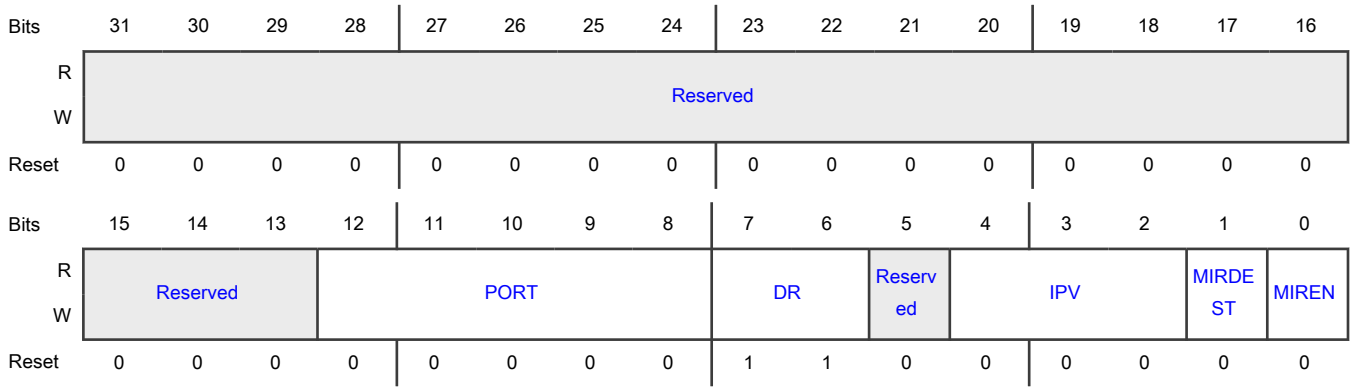
Offset

Register	Offset
IMDCR0	420h

Function

This is the ingress mirror destination configuration register 0.

Diagram



Fields

Field	Function
31-13 —	Reserved
12-8 PORT	Port where ingress mirrored frames are sent. Valid if MIRDEST=0.
7-6	Mirrored packet's DR (drop resilience).

Table continues on the next page...

Table continued from the previous page...

Field	Function
DR	
5 —	Reserved
4-2 IPV	Mirrored packet's IPV.
1 MIRDEST	Indicates the mirror destination 0b - Port as specified by PORT field 1b - Switch management port
0 MIREN	Mirror enable. 0b - Ingress mirroring disabled 1b - Ingress mirroring enabled

53.4.6.5.12 Ingress mirror destination configuration register 1 (IMDCR1)

Offset

Register	Offset
IMDCR1	424h

Function

This is the ingress mirror destination configuration register 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved								EFM_LEN_CHANGE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	EFMEID															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-23 —	Reserved
22-16 EFM_LEN_CHANGE	Egress Frame Modification Frame Length change in 2s complement notation. This field specifies the frame length change that represents the effective frame length change of the egress frame modification actions configured in the EFMEID field of this register. This frame length change value is used to adjust the frame length metadata, which in turn is passed to the egress scheduling and management functions to represent the actual length of the frame on the transmission link. Specifying explicitly the frame length change avoids having the hardware to read the egress frame modifications entry and compute the frame length change itself. Frame Length change is specified in unit of bytes using a 2's complement notation. Supported range: -10 bytes (removing one VLAN tag and one R-TAG/HSR) to +6 bytes (adding one VLAN tag and replacing a 4-byte 802.1CB draft 2.0 R-TAG with 6-byte 802.1CB R-TAG or HSR tag). Valid if EFMEID is not null (i.e: not 0xFFFF).
15-0 EFMEID	Egress Frame Modification Entry Id Only applicable if MIRDEST=0. Note that EFMEID[L2_ACT]=1b and EFMEID[PLD_ACT]=001b are not supported **NOTE** 0xFFF is a Null Frame Modification Entry.

53.4.6.5.13 Cut-through forwarding count register (CTFCR)

Offset

Register	Offset
CTFCR	440h

Function

This is the cut-through forwarding count register.

Diagram

Offset

Register	Offset
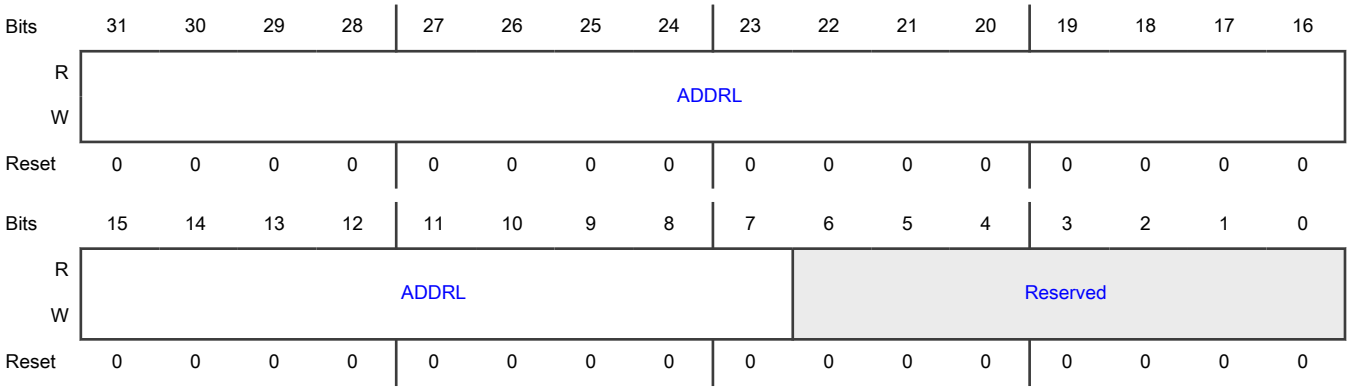
CBDR0BAR0	810h
CBDR1BAR0	840h

Function

This is the lower address register for the base memory address location of the command BD ring. The address must be 128 byte aligned.

Diagram



Fields

Field	Function
31-7 ADDRL	Lower address bits 31-7.
6-0 —	Reserved

53.4.6.5.17 Command BDR a base address register 1 (CBDR0BAR1 - CBDR1BAR1)

Offset

Register	Offset
CBDR0BAR1	814h
CBDR1BAR1	844h

Function

This is the upper address register for the base memory address location of the command BD ring.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	ADDRH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 ADDRH	Upper address bits 63-32.

53.4.6.5.18 Command BDR a producer index register (CBDR0PIR - CBDR1PIR)

Offset

Register	Offset
CBDR0PIR	818h
CBDR1PIR	848h

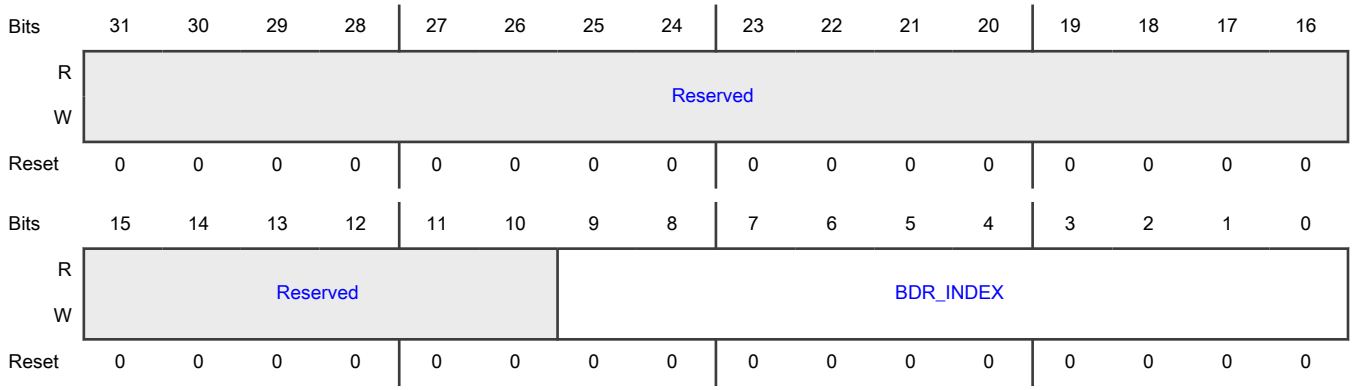
Function

This is the command BDR producer index register. When the BD ring is enabled the value of this register and the consumer index register, CBDR*a*CIR, determines switch's unprocessed BDs of the ring. This value also determines how many BD's are committed to the BDR by software. Software should initialize this register while the ring is disabled to reflect an empty state or a pre-loaded BDR state.

To add one or more buffer descriptors to an enabled command ring, software should first check to make sure the ring is not full by reading CBDR*a*CIR. Note that maximum number of BDs allowed on a ring is one less than the ring size. A memory barrier must be used to guarantee update of the BD(s) to memory before writing the producer index register.

There is no wrap bit to indicate full/empty. One entry is used to differentiate between full and empty. When producer index + 1 equals consumer index, the ring is considered full. When the producer/consumer indices match, the ring is always considered empty.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 BDR_INDEX	Command buffer descriptor ring producer index. Range of index depends on ring size CBDR*a*LENR[LENGTH].

53.4.6.5.19 Command BDR a consumer index register (CBDR0CIR - CBDR1CIR)

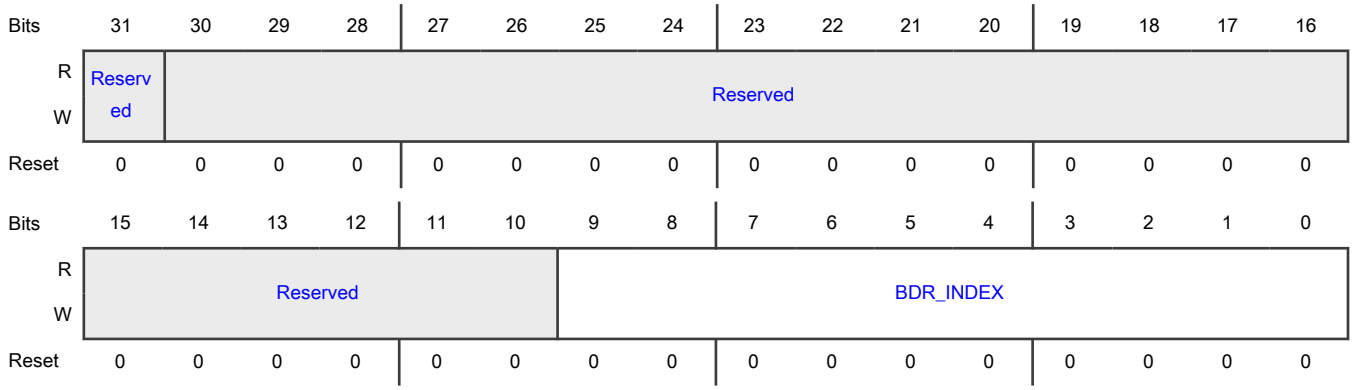
Offset

Register	Offset
CBDR0CIR	81Ch
CBDR1CIR	84Ch

Function

This is the command BDR consumer index register. It reflects the next BD to be processed by NETC and trails the CBDR*a*PIR index value. Software should only update/reset this value when the BD ring is re-initialized. Disabling the BD ring has no effect on this register. Software can calculate available entries in the ring by using the software producer index and this register value.

Diagram



Fields

Field	Function
31 —	Reserved
30-10 —	Reserved
9-0 BDR_INDEX	Command buffer descriptor ring consumer index. Range of index depends on ring size CBDR*s*LENR[LENGTH].

53.4.6.5.20 Command BDR a length register (CBDR0LENR - CBDR1LENR)

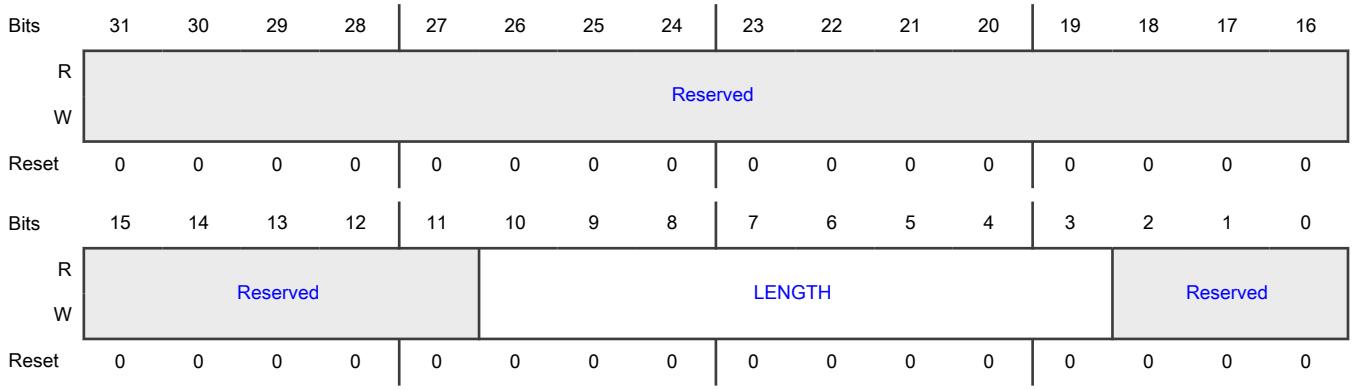
Offset

Register	Offset
CBDR0LENR	820h
CBDR1LENR	850h

Function

This is the command BDR length register. It determines the size of the transmit ring in sets of 8 BDs.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-3 LENGTH	BD ring length Size of ring in sets of 8 BDs. Maximum ring size is 1K.
2-0 —	Reserved

53.4.6.5.21 Command BDR a interrupt enable register (CBDR0IER - CBDR1IER)

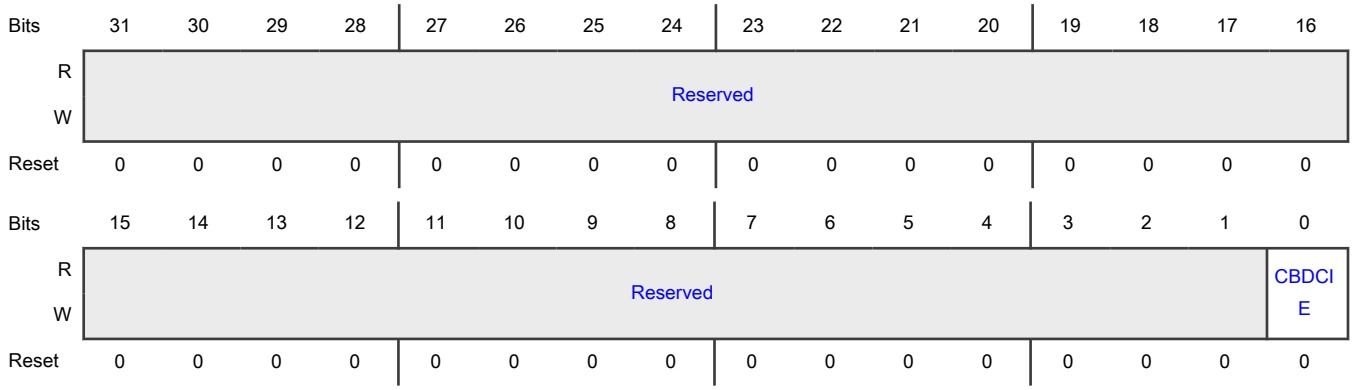
Offset

Register	Offset
CBDR0IER	8A0h
CBDR1IER	8B0h

Function

This is the interrupt enable register for the command BD ring. If the enable bit and the corresponding detect bit in CBDR*a*IDR is set, interrupt will be triggered for the ring.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CBDCIE	Command BD completion interrupt enable 0 Disabled 1 Enabled

53.4.6.5.22 Command BDR a interrupt detect register (CBDR0IDR - CBDR1IDR)

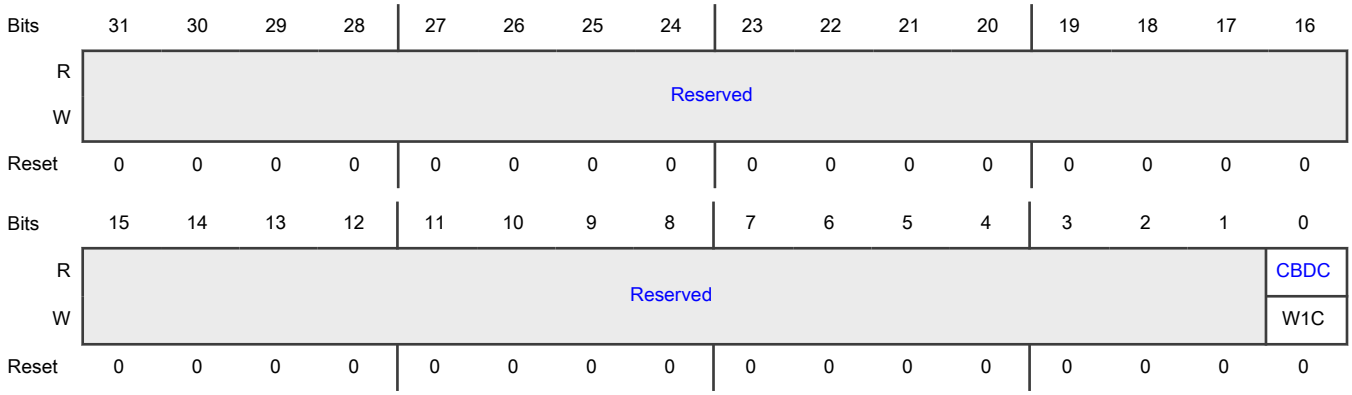
Offset

Register	Offset
CBDR0IDR	8A4h
CBDR1IDR	8B4h

Function

This is the interrupt detect register for the command buffer descriptor ring. Write 1 to clear.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CBDC	Command BD completed 0b - No BD with CI=1 completed 1b - Processed BD with CI=1

53.4.6.5.23 Command BDR a MSI-X vector register (CBDR0MSIVR - CBDR1MSIVR)

Offset

Register	Offset
CBDR0MSIVR	8A8h
CBDR1MSIVR	8B8h

Function

This is the command BDR MSI-X vector register.

Diagram

53.4.6.5.33 Bridge capability register (BRCAPR)

Offset

Register	Offset
BRCAPR	2000h

Function

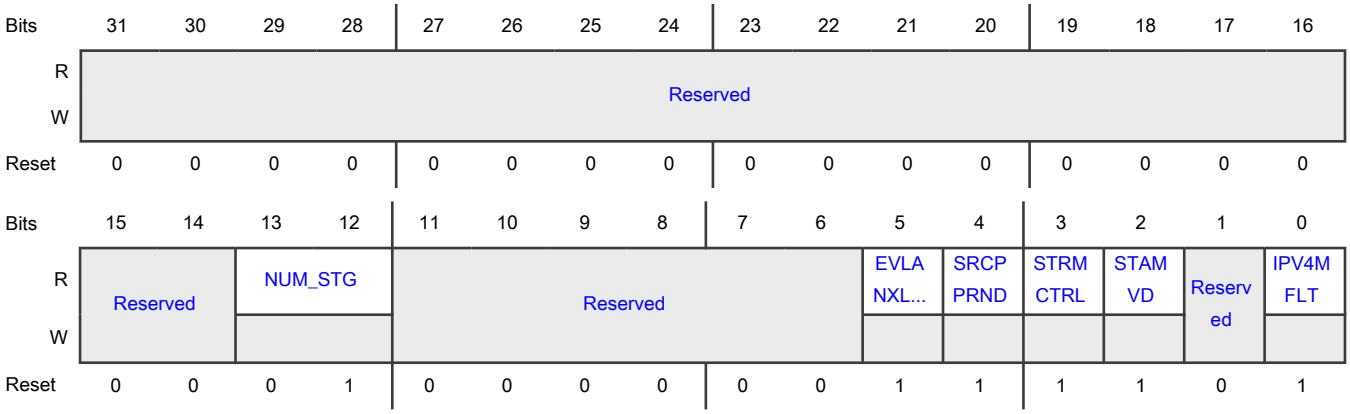
The following are basic bridge capabilities provided:

- **VLAN filtering:** Each VLAN belongs to a port membership set. Ingress VLAN filtering ensures that only frames belonging to the port member is allowed. Similarly, egress VLAN filtering ensures that we only forward frames to a port which is a member of the VLAN
- **MAC Learning** using FDB table; MAC learning options supported per VLAN are:
  1. Disable MAC learning
  2. Hardware MAC learning
  3. Software MAC learning secure; if SMAC is not found, or if an entry is found and the entry's port number does not match the frame ingress port number (and station move is allowed), redirect frame to switch management port.
  4. Software MAC learning unsecure; if an entry is not found, or if an entry is found and the entry's port number does not match the frame ingress port number (and station move is allowed), copy frame to switch management port.
  5. Disable MAC learning with SMAC validation. Ensure SMAC is in FDB otherwise discard frame.
- **MAC Forwarding** using FDB table. A MAC address may be a unicast, multicast or broadcast address. MAC forwarding options supported per VLAN if MAC DA is not found in FDB are:

1. Flood to all port members of the VLAN
2. Discard

- Other capabilities are specified in this CAPR.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-12 NUM_STG	Number of Spanning Tree Groups supported. 0: Not supported 1: Support 16 Spanning Tree Groups 2-3: Reserved The Spanning Tree Groups are defined in BPSTGSR.
11-6 —	Reserved
5 EVLANXLATE	Egress VLAN translation supported **NOTE** Accomplished using VLAN Filter table entry which can optionally specify an Egress Treatment table entry for each port membership in the VLAN. Each Egress Treatment table entry may specify a Frame Modification table entry which contains the egress VLAN translation action. 0b - Egress VLAN translation not supported 1b - Egress VLAN translation supported
4 SRCPPRND	Source port pruning disable supported

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When supported, it provides the capability to configure on a per port basis to transmit a frame on the same port it was received. Default bridge capability is to prevent a frame from being transmitted on same port. 0b - Source port pruning disable not supported 1b - Source port pruning disable supported
3 STRMCTRL	Storm Control supported. Storm control provides the ability to rate limit broadcast, multicast, unknown multicast, and unknown unicast traffic on a given port. 0b - Not supported 1b - Supported
2 STAMVD	Station Move Disable supported Provides the option to discard a frame when the MAC learning function finds an entry with the ingress port of the incoming frame not set in the FDB entry Destination Port Bitmap (station has moved). 0b - Not supported 1b - Supported
1 —	Reserved
0 IPV4MFLT	L2 IPv4 multicast filtering supported. 0b - Not supported 1b - Supported

53.4.6.5.34 VLAN filter hash table capability register (VFHTCAPR)

Offset

Register	Offset
VFHTCAPR	2008h

Function

This is the VLAN filter hash table capability register.

53.4.6.5.36 VLAN Filter (hash) table default entry configuration registers 0 (VFHTDECR0)

Offset

Register	Offset
VFHTDECR0	2010h

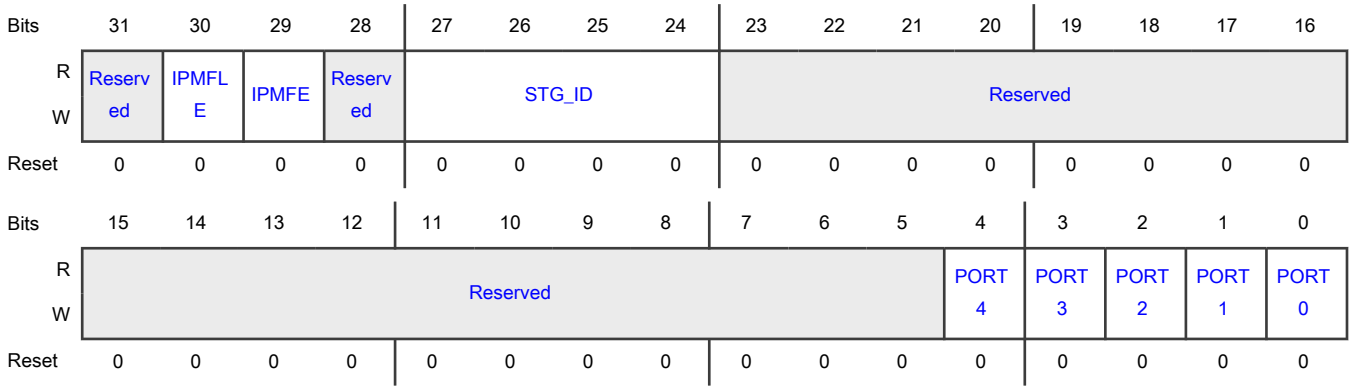
Function

This is the VLAN filter hash table default entry configuration registers 0, which determines the default entry when not found in VLAN filter lookup.

NOTE

The switch will sample the IERB value of this register (S0VFHTDECR0) when PCIe Memory Access bit is set (b1). All updates after this must be done through this register.

Diagram



Fields

Field	Function
31 —	Reserved
30 IPMFLE	IP Multicast Flooding Enable If IP multicast filtering is performed (IPMFE = 1b, and the frame is identified as a multicast IP packet), and there was no match found, then the frame is forwarded according to this field. If IP multicast filtering is disabled (IPMFE = 0b), this field is ignored by hardware. 0b - IP Multicast Flooding disabled, the frame is discarded. 1b - IP Multicast Flooding enabled, the frame is flooded.
29 IPMFE	IP Multicast Filtering Enable Refer to the VLAN Filter table entry IPMFE field description, for more details 0b - No IP multicast filtering is performed. 1b - If the frame is identified as a multicast IP packet, then IP multicast filtering is performed. If the frame is not identified as an IP multicast packet, the IP multicast filtering is not performed.
28 —	Reserved
27-24 STG_ID	Spanning Tree Group Member ID. Refer to the VLAN Filter table entry STG_ID field description, for more details
23-5 —	Reserved
4-0 PORTn	Port n This field specifies if port number n is a member of this VLAN. Port membership is used for source pruning in ingress VLAN filtering and destination pruning in egress VLAN filtering. This field is also used as a default

Table continues on the next page...

Table continued from the previous page...

Field	Function
	destination for a miss from an FDB table lookup (or for the case where the VLAN is configured to not perform an FDB lookup). 0b - Port is not a member of this VLAN. 1b - Port is a member of this VLAN.

53.4.6.5.37 VLAN filter hash table default entry configuration registers 1 (VFHTDECR1)

Offset

Register	Offset
VFHTDECR1	2014h

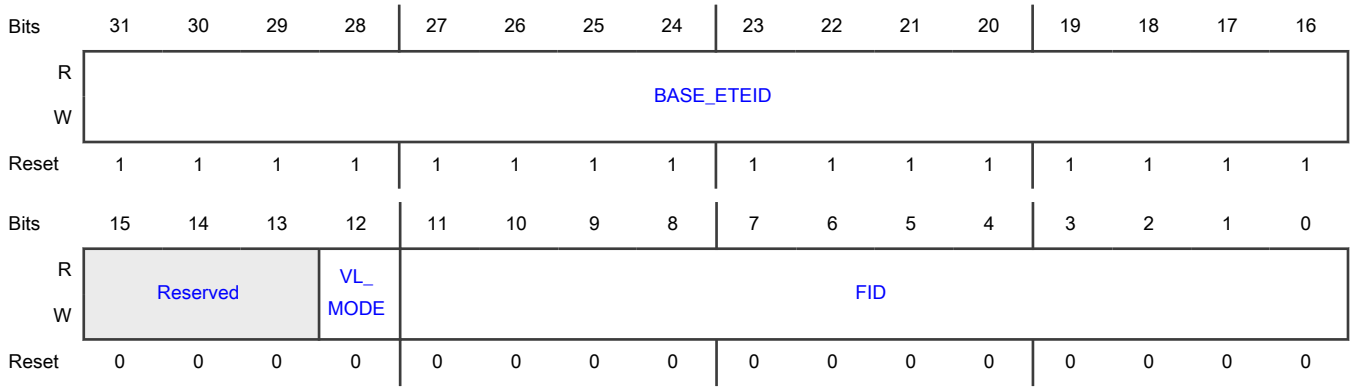
Function

This is the VLAN Filter (hash) table default entry configuration registers 1.

NOTE

The switch will sample the IERB value of this register (S0VFHTDECR1) when PCIe Memory Access bit is set (b1). All updates after this must be done through this register.

Diagram



Fields

Field	Function
31-16 BASE_ETEID	Base Egress Treatment Entry ID Refer to the VLAN Filter table entry BASE_ET_EID field description, for more details.
15-13 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 VL_MODE	VLAN Learning Mode 0: Independent VLAN learning: FID is set to the VID assigned to the frame 1: Shared VLAN learning: Use the FID specified in this register **NOTE** Used to determine the FID when doing a lookup in the FDB table.
11-0 FID	Filtering ID. Valid if VL_MODE = 1 (Shared). The Filtering ID (FID) is a locally significant identifier (global to the switch), that is used as a key value when hardware performs a lookup into the FDB table and the L2 IPV4 Multicast Filter table. The FID is used to identify a set of VIDs, which in turn allows sharing of the same address (MAC, IP) between multiple VIDs during lookups into the FDB table and L2 IPV4 Multicast Filter table.

53.4.6.5.38 VLAN filter hash table default entry configuration registers 2 (VFHTDECR2)

Offset

Register	Offset
VFHTDECR2	2018h

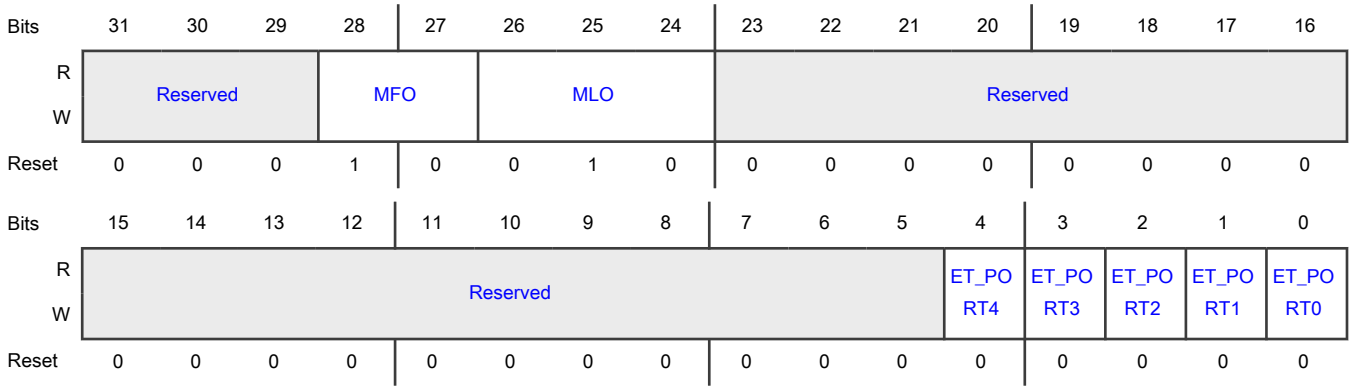
Function

This is the VLAN Filter (hash) table default entry configuration registers 2.

NOTE

The switch will sample the IERB value of this register (S0VFHTDECR2) when PCIe Memory Access bit is set (b1). All updates after this must be done through this register.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-27 MFO	MAC forwarding options: 0: Reserved 1: No FDB lookup is performed, the frame is flooded. 2: FDB lookup is performed, and if there is no match, the frame is flooded. 3: FDB lookup is performed, and if there is no match, the frame is discarded.
26-24 MLO	MAC learning options: 0: Reserved 1: Disable MAC learning. MAC learning function is not performed during the forwarding processing. 2: Hardware MAC learning is performed. 3: Software MAC learning secure. A MAC learning lookup is performed into the FDB table. If there is no match, no attempt is made to add a new entry, and the frame is redirect to the switch management port. If there is match, and the entry's port number does not match frame ingress port number, the frame is redirected to the switch management port if station move is allowed, otherwise the frame is discarded. 4: Software MAC learning unsecure. A MAC learning lookup is performed into the FDB table. If there is no match, no attempt is made to add a new entry, and a copy of the frame is sent to the switch management port. If there is match, and the entry's port number does not match frame ingress port number, the frame is copied to the switch management port if station move is allowed, otherwise the frame is discarded. 5: Disable MAC learning with SMAC validation. A MAC learning lookup is performed into the FDB table. If there is no match or there is a match but the ingress port is not a member of the FDB entry, the frame is discarded and counted against the bridge port discard count register (BPDCR) with discard reason BPDCRR0[MACLNFDR] set to 1. All other values reserved.
23-5 —	Reserved
4-0 ET_PORTn	Egress Treatment Applicability Port n. This field specifies if port number n has an entry in the Egress Treatment table for the Egress Treatment group (base index) specified in VFHTDECR1[BASE_ETEID]. This field is valid if VFHTDECR1[BASE_ETEID] is not null. 0b - Port has no entry in the Egress Treatment table 1b - Port has an entry in the Egress Treatment table

53.4.6.6.6 Port outer native VLAN register (PONVLANR)

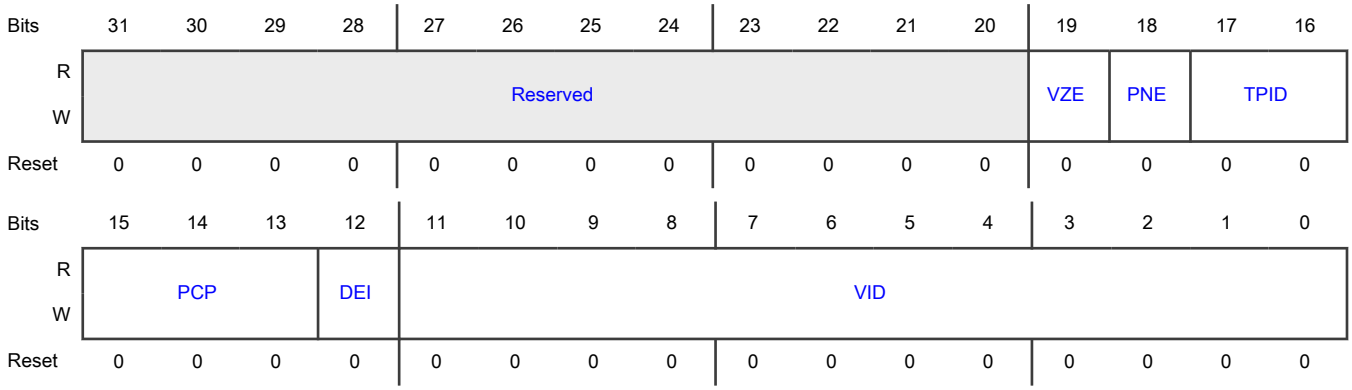
Offset

Register	Offset
PONVLANR	80h

Function

This is the outer native VLAN for the port. It is used for classification when untagged frames are received by the port.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 VZE	VID 0 Enable Enables and disables usage of the port outer native VLAN VID when the VID in the frame's outer VLAN tag is zero (priority tagged frame). 0b - Disabled 1b - Enabled
18 PNE	Port Native VLAN Enable Enables and disables usage of the port outer native VLAN (PCP, DEI and VID) when the outer VLAN tag is not present in the frame. 0b - Disabled 1b - Enabled
17-16 TPID	Identifies which known VLAN Ethertype is used 00b - Standard C-VLAN 0x8100 01b - Standard S-VLAN 0x88A8 10b - Custom VLAN as defined by CVLANR1[ETYPE] 11b - Custom VLAN as defined by CVLANR2[ETYPE]
15-13 PCP	Priority code point A 3-bit field which refers to the IEEE 802.1p class of service and maps to the frame priority level.
12 DEI	Drop eligible indicator May be used separately or in conjunction with PCP to indicate frames eligible to be dropped in the presence of congestion.

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-0 VID	VLAN identifier The VLAN identifier is a 12-bit field specifying the VLAN to which the frame belongs.

53.4.6.6.7 Port inner native VLAN register (PINVLANR)

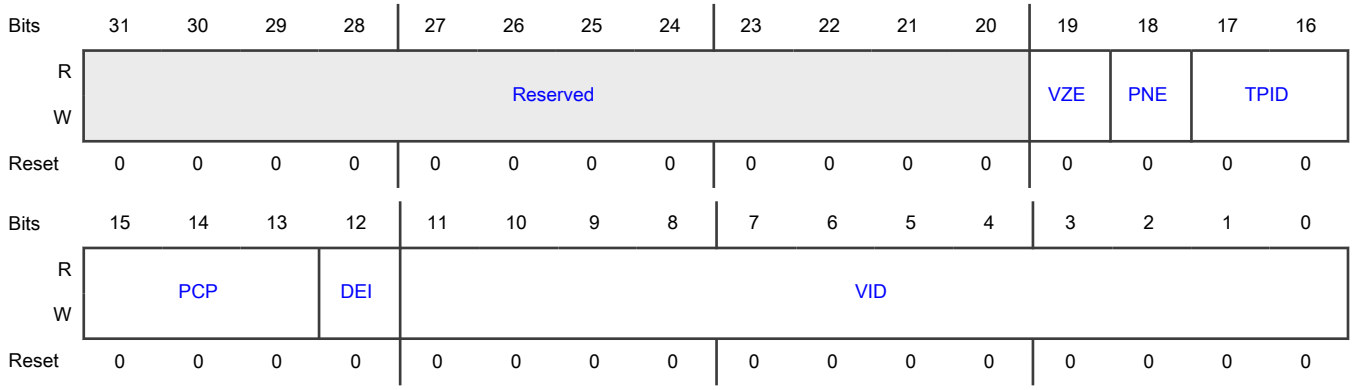
Offset

Register	Offset
PINVLANR	84h

Function

This is the inner native VLAN for the port. It is used for classification when untagged frames are received by the port.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 VZE	VID 0 Enable Enables and disables usage of the port inner native VLAN VID when the VID in the frame's inner VLAN tag is zero (priority tagged frame). 0b - Disabled 1b - Enabled
18	Port Native VLAN Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
PNE	Enables and disables usage of the port inner native VLAN (PCP, DEI and VID) when the inner VLAN tag is not present in the frame. 0b - Disabled 1b - Enabled
17-16 TPID	Identifies which known VLAN Ethertype is used 00b - Standard C-VLAN 0x8100 01b - Standard S-VLAN 0x88A8 10b - Custom VLAN as defined by CVLANR1[ETYPE] 11b - Custom VLAN as defined by CVLANR2[ETYPE]
15-13 PCP	Priority code point A 3-bit field which refers to the IEEE 802.1p class of service and maps to the frame priority level.
12 DEI	Drop eligible indicator May be used separately or in conjunction with PCP to indicate frames eligible to be dropped in the presence of congestion.
11-0 VID	VLAN identifier The VLAN identifier is a 12-bit field specifying the VLAN to which the frame belongs.

53.4.6.6.8 Port VLAN classification control register (PVCLCTR)

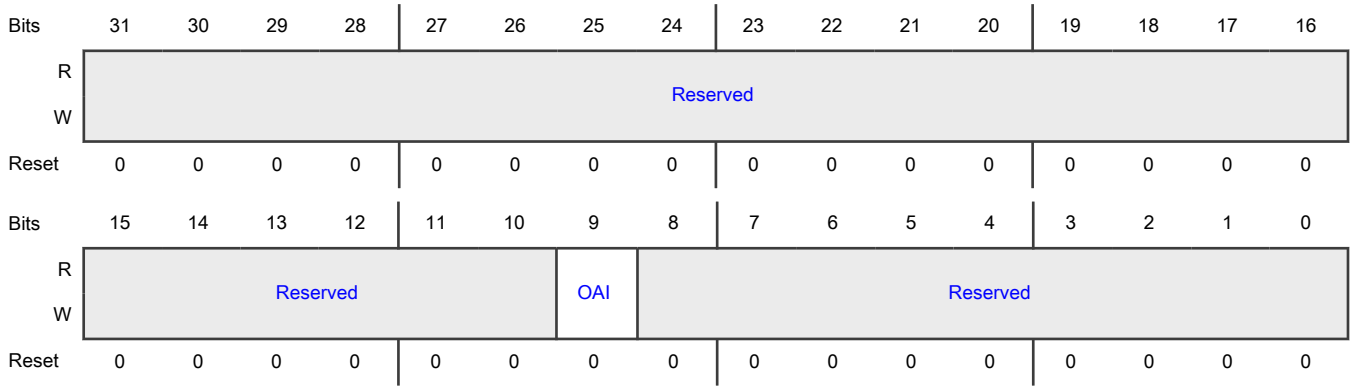
Offset

Register	Offset
PVCLCTR	88h

Function

This register controls the VLAN classification.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 OAI	Outer as Inner 0b - Indicates that the Inner is not valid if only one tag is found 1b - Indicates that the outer should be used as the Inner if only one tag is found
8-0 —	Reserved

53.4.6.6.9 Parser checksum configuration register (PARCSCR)

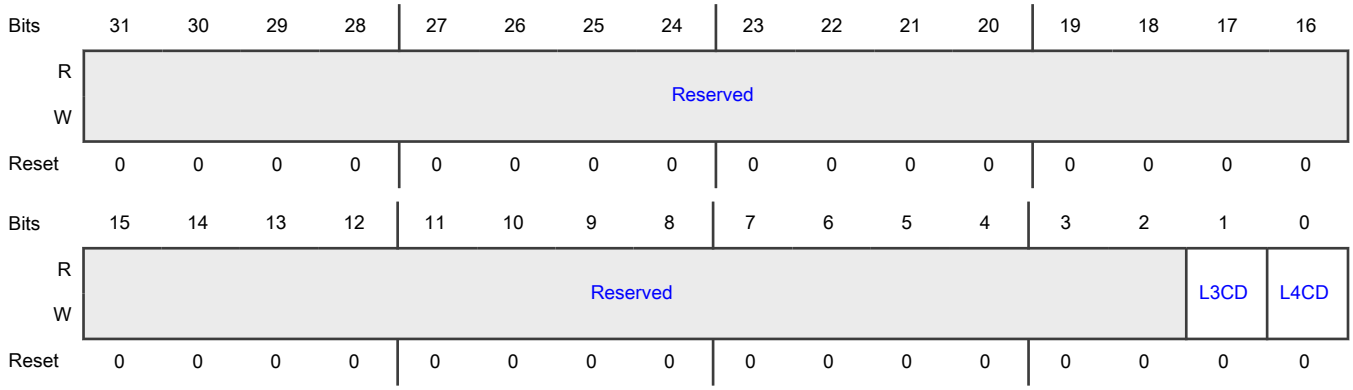
Offset

Register	Offset
PARCSCR	9Ch

Function

This is the parser checksum configuration register.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 L3CD	Layer 3 IPv4 Header checksum validation Disable. 0b - Enabled 1b - Disabled
0 L4CD	Layer 4 TCP and UDP checksum validation Disable. 0b - Enabled 1b - Disabled

53.4.6.6.10 Parser custom Ethertype a configuration register (PARCE0CR - PARCE3CR)

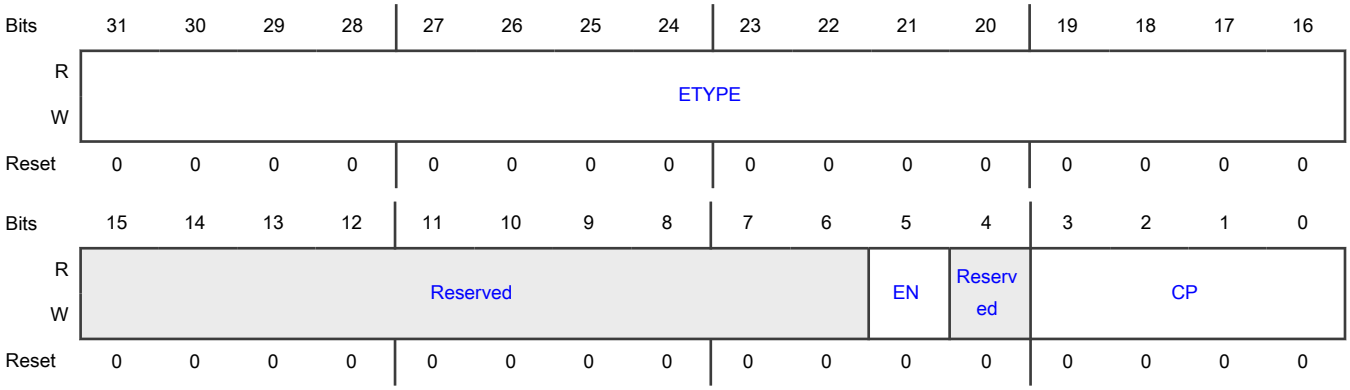
Offset

Register	Offset
PARCE0CR	A0h
PARCE1CR	A4h
PARCE2CR	A8h
PARCE3CR	ACh

Function

The HTA parser custom Ethertype register.

Diagram



Fields

Field	Function
31-16 ETYPE	ETYPE Upon detecting this ether type the associated code point will be mapped to the parse summary as a Non IP code point. All HTA parsing will stop
15-6 —	- Reserved
5 EN	Enable Enables the detection and mapping. 0b - Disabled 1b - Enabled
4 —	- Reserved
3-0 CP	Code Point This value is mapped to the parse summary as a Non IP code point with the parse summary "L2 Only" field set to the value stored in this field. Only a value of 0 (Unknown) is currently supported.

53.4.6.6.11 Port pause ON threshold register (PPAUONTR)

Offset

Register	Offset
PPAUONTR	108h

Function

This is the pause ON threshold register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	THRESH															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 —	Reserved
23-0 THRESH	Monitors the amount of data accumulated in the receive buffer and if this amount goes below the Pause OFF threshold (expressed in words) it then enters the "Pause OFF" state if Pause is enabled. Pause ON threshold has to be greater value than Pause OFF threshold. Setting this register to 0 or setting PPAUONTR to 0 disables pause generation.

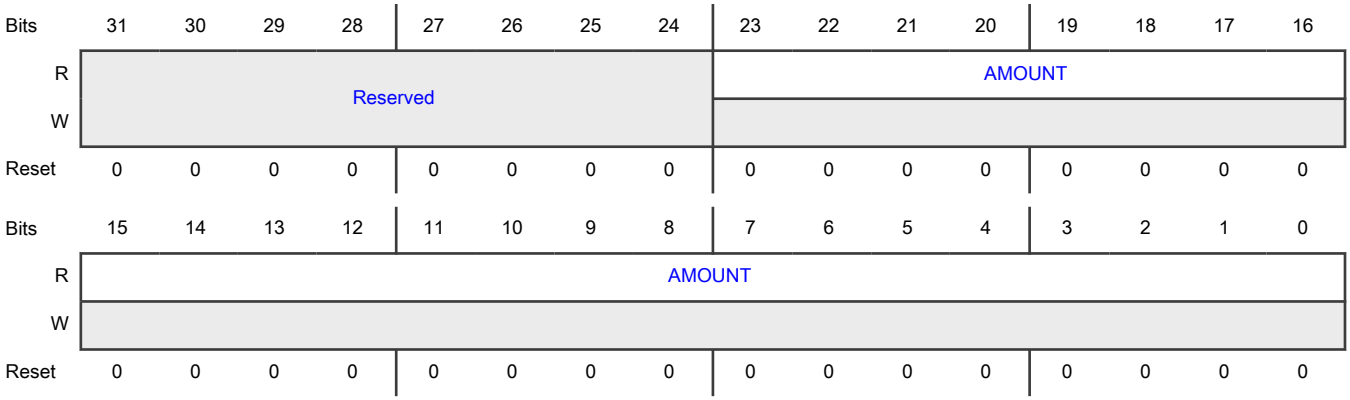
53.4.6.6.13 Port receive memory buffer entitlement register (PRXMBER)

Offset

Register	Offset
PRXMBER	120h

Function
This is the port receive memory buffer entitlement register.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 AMOUNT	Receive memory buffer entitlement in words This receive Memory Buffer Entitlement is used in determining smart drop for ingress congestion control. If a smart drop is to be performed, due receive memory buffer depletion, the receive queue that exceeds

Table continues on the next page...

Table continued from the previous page...

Field	Function
	entitlement amount the most will be selected for discard. Default value of 0 for this register results in fair share of the receive buffer memory across all ENETC instances. This value is writable in IERB (by pre-boot initialization), and is immediately reflected here. This value is R/W in the IERB space, and R/O by the ENETC function.

53.4.6.6.14 Port receive memory buffer limit register (PRXMBLR)

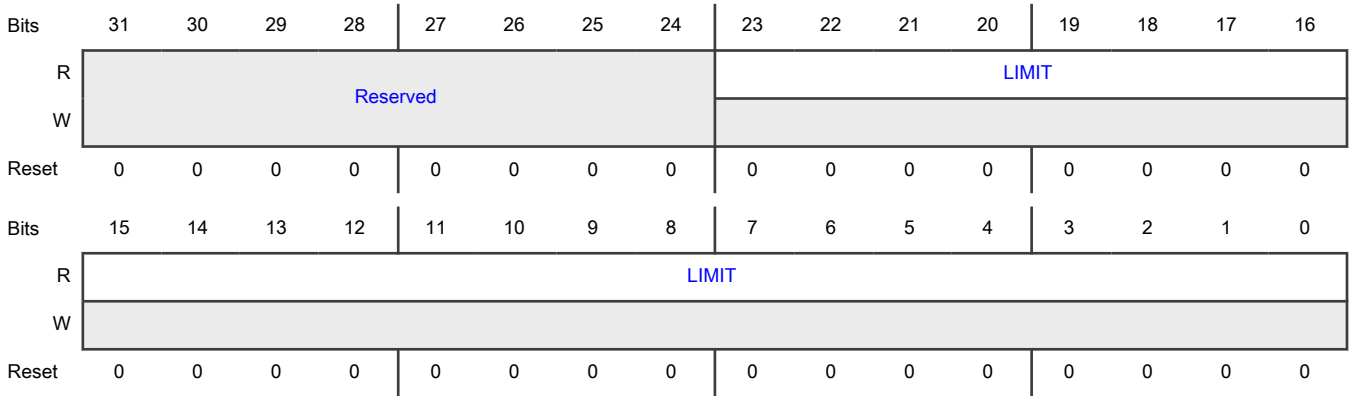
Offset

Register	Offset
PRXMBLR	124h

Function

This is the port receive memory buffer limit register.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 LIMIT	Receive buffer memory limit in words. This limit is used by the per-ENETC receive queues implemented for ingress congestion control. Ingress frames will be discarded if queue length exceeds this limit. Value of 0 means the number of memory words used within a port's priority tier is limited to 16k-1. This value is writable in IERB (by pre-boot initialization), and is immediately reflected here. This value is R/W in the IERB space, and R/O by the ENETC function.

53.4.6.6.15 Port receive buffer count register (PRXBCR)

Offset

Register	Offset
PRXBCR	128h

Function
This is the port receive buffer count register.

Diagram

R	COUNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 —	Reserved
23-0 COUNT	Current receive buffer usage count in words for this port.

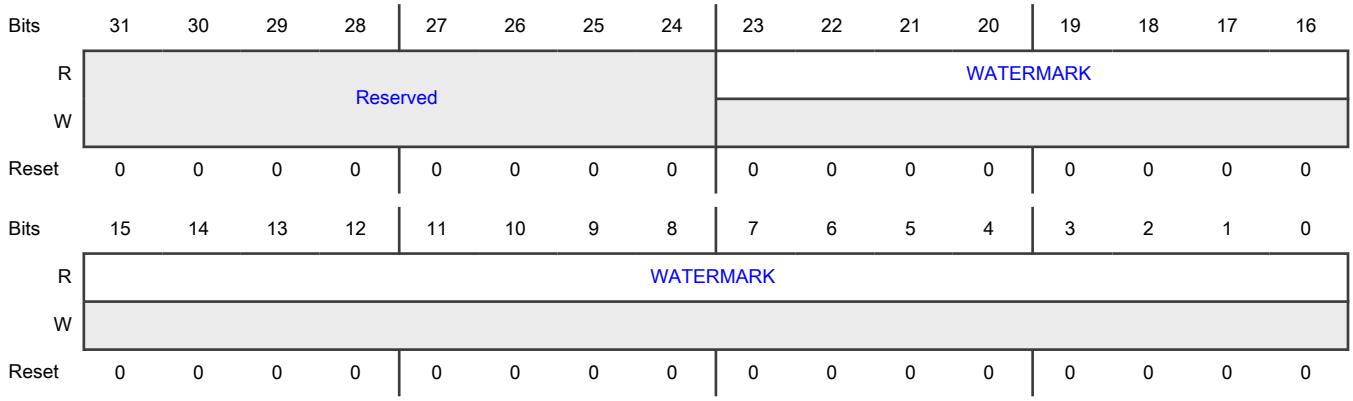
53.4.6.6.16 Port receive buffer count high watermark register (PRXBCHWMR)

Offset

Register	Offset
PRXBCHWMR	12Ch

Function
This is the port receive buffer count high watermark register.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 WATERMARK	High watermark in words for receive buffer usage since the last read of this register. After a read, this register is set equal to PRXBCR.

53.4.6.6.17 Port ingress congestion DR0 discard count register (PICDR0DCR)

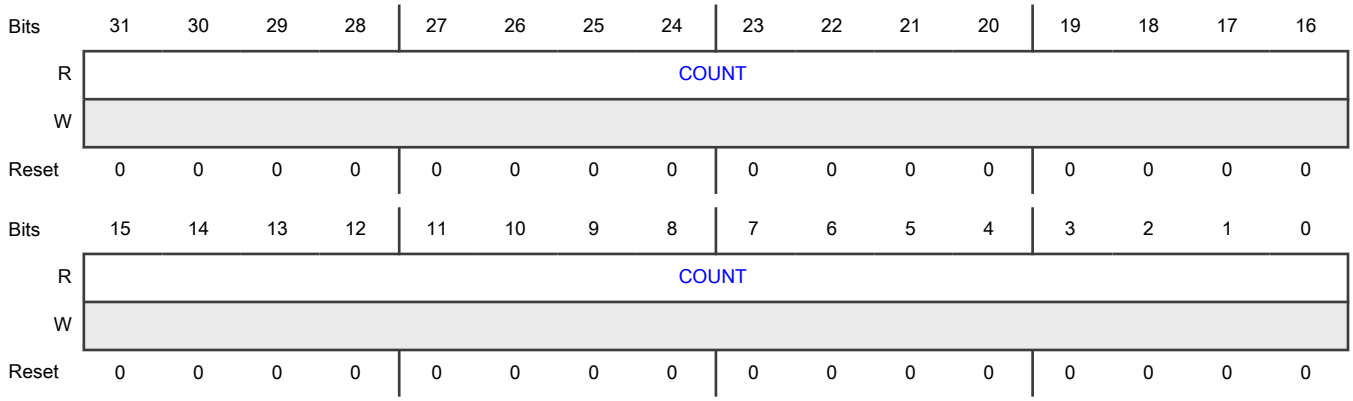
Offset

Register	Offset
PICDR0DCR	140h

Function

This is the port ingress congestion DR0 discard count register.

Diagram



Fields

Field	Function
31-0 COUNT	Number of frames discarded by Ingress Congestion Manager, for this port, and for each discard resilience (DR) value. A separate register is provided for each DR value. Reading this register provides the count of all frames discarded at this DR level, since the last reset of this count, without resetting the count. Resetting the count after the read can be done by reading the associated PICDR*a*DCRR register instead of this one. The discard count is incremented by the occurrence of the following events: • Port receive buffer limit exceeded • Internal memory congestion

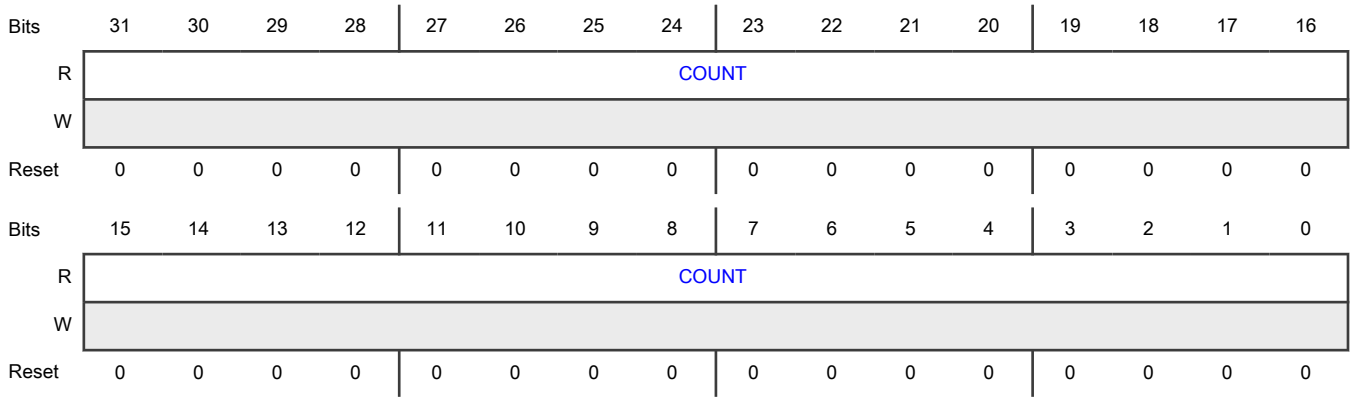
53.4.6.6.18 Port ingress congestion DRa discard count read-reset register (PICDR0DCRRR - PICDR3DCRRR)

Offset

Register	Offset
PICDR0DCRRR	148h
PICDR1DCRRR	158h
PICDR2DCRRR	168h
PICDR3DCRRR	178h

Function
This is the port ingress congestion DR discard count read-reset register.

Diagram



Fields

Field	Function
31-0 COUNT	Reading this register provides the count of all frames discarded at this DR level, since the last reset of this count, and also resets the count after the read. Other than the count reset, this register works the same as PICDR*a*DCR. After a read operation, the field's value clears to 0.

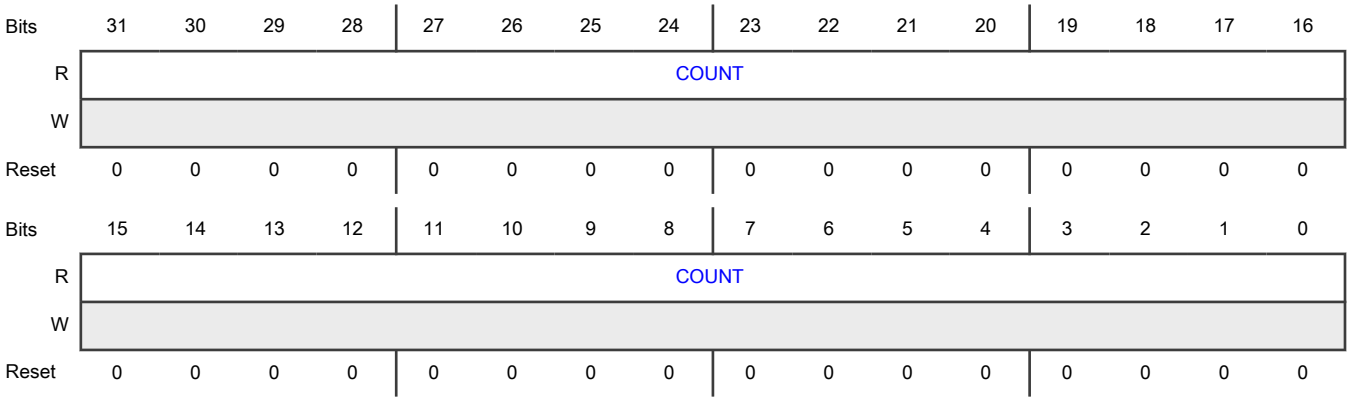
53.4.6.6.19 Port ingress congestion DR1 discard count register (PICDR1DCR)

Offset

Register	Offset
PICDR1DCR	150h

Function
This is the port ingress congestion DR1 discard count register.

Diagram



Fields

Field	Function
31-0 COUNT	Number of frames discarded by Ingress Congestion Manager, for this port, and for each discard resilience (DR) value. A separate register is provided for each DR value. Reading this register provides the count of all frames discarded at this DR level, since the last reset of this count, without resetting the count. Resetting the count after the read can be done by reading the associated PICDR*a*DCRR register instead of this one. The discard count is incremented by the occurrence of the following events: • Port receive buffer limit exceeded • Internal memory congestion

53.4.6.6.20 Port ingress congestion DR2 discard count register (PICDR2DCR)

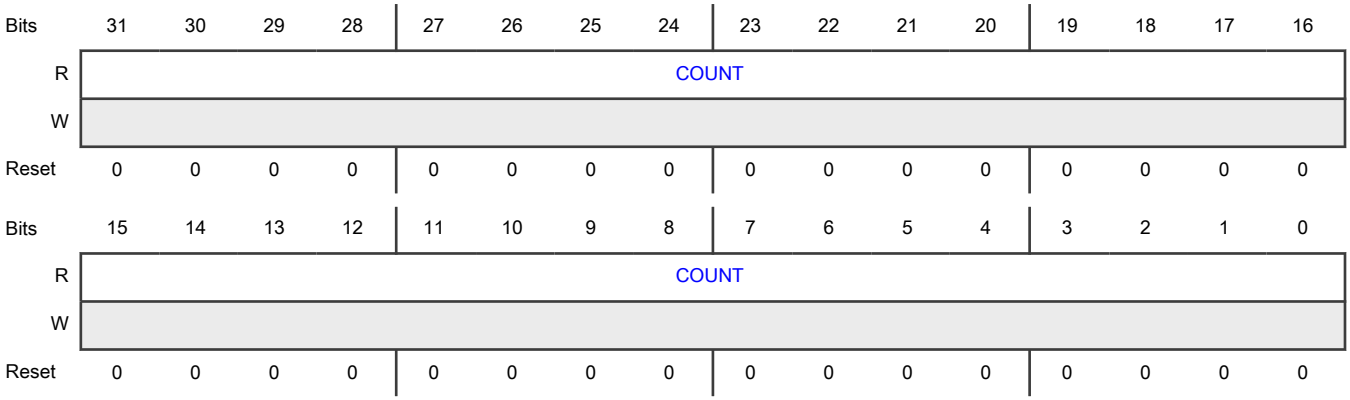
Offset

Register	Offset
PICDR2DCR	160h

Function

This is the port ingress congestion DR2 discard count register.

Diagram



Fields

Field	Function
31-0 COUNT	Number of frames discarded by Ingress Congestion Manager, for this port, and for each discard resilience (DR) value. A separate register is provided for each DR value. Reading this register provides the count of all frames discarded at this DR level, since the last reset of this count, without resetting the count. Resetting the count after the read can be done by reading the associated PICDR*a*DCRR register instead of this one. The discard count is incremented by the occurrence of the following events: • Port receive buffer limit exceeded • Internal memory congestion

53.4.6.6.21 Port ingress congestion DR3 discard count register (PICDR3DCR)

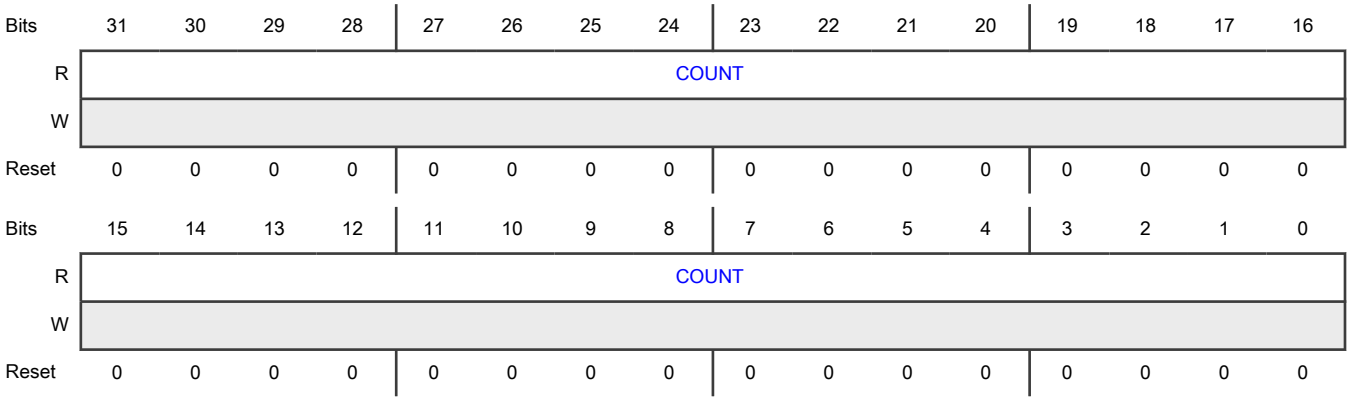
Offset

Register	Offset
PICDR3DCR	170h

Function

This is the port ingress congestion DR3 discard count register.

Diagram



Fields

Field	Function

53.4.6.6.32 Port unicast frames dropped VLAN filtering register (PUFDVFR)

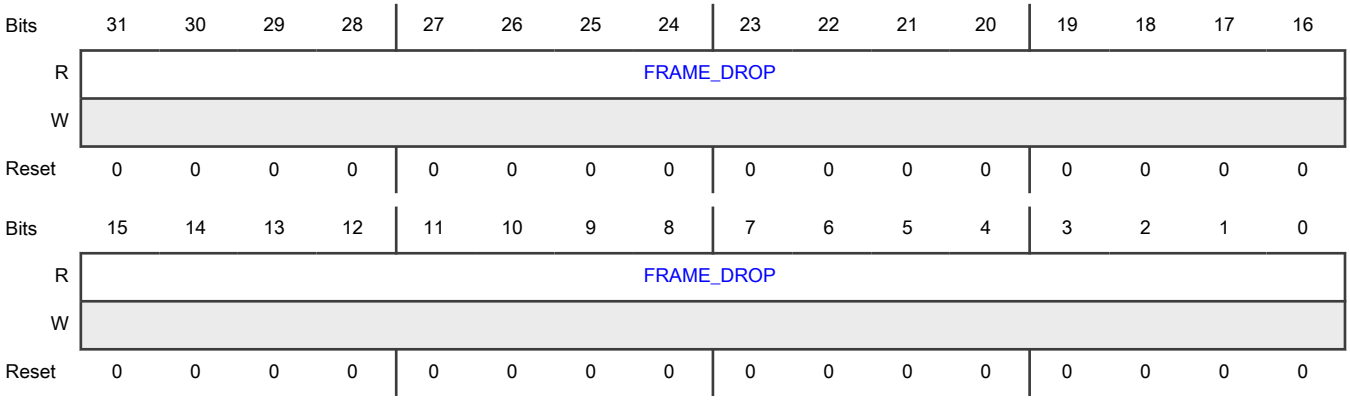
Offset

Register	Offset
PUFDVFR	2D0h

Function

This is the classification frame dropped due to VLAN filtering counter. Counter is incremented when a unicast frame is dropped due to VLAN filtering (i.e. frames that had a match for MAC filtering but didn't pass VLAN filtering).

Diagram



Fields

Field	Function
31-0 FRAME_DROP	VLAN filter unicast frame drop counter bits 31-0. Incremented for each dropped unicast frame by the L2 filtering function, as no SI qualifies for reception of the frame due to VLAN filtering.

53.4.6.6.33 Port multicast frames dropped VLAN filtering register (PMFDVFR)

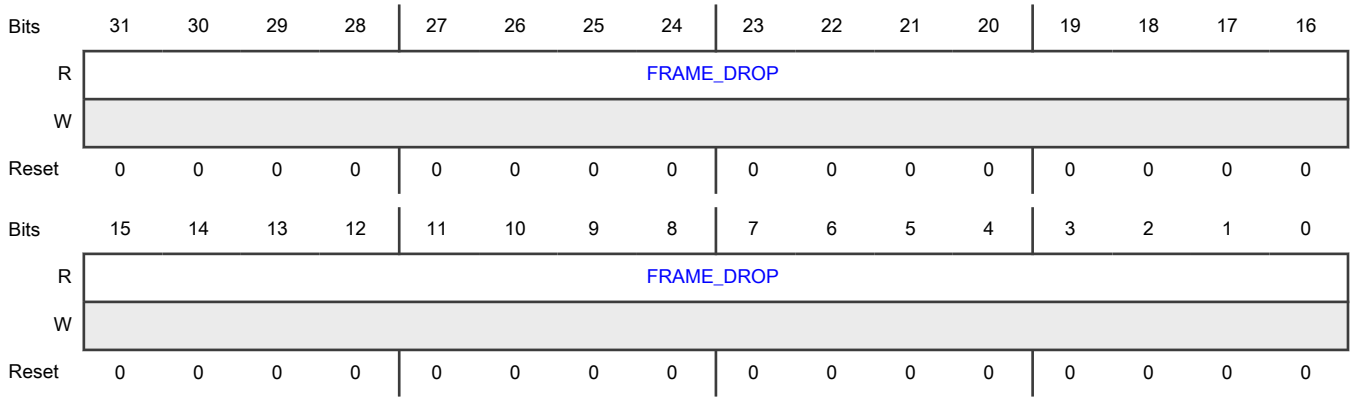
Offset

Register	Offset
PMFDVFR	2D4h

Function

This is the classification frame dropped due to VLAN filtering counter. Counter is incremented when a multicast frame is dropped due to VLAN filtering (i.e. frames that had a match for MAC filtering but didn't pass VLAN filtering).

Diagram



Fields

Field	Function
31-0 FRAME_DROP	VLAN filter multicast frame drop counter bits 31-0. Incremented for each dropped multicast frame by the L2 filtering function, as no SI qualifies for reception of the frame due to VLAN filtering.

53.4.6.6.34 Port broadcast frames dropped VLAN filtering register (PBFDVFR)

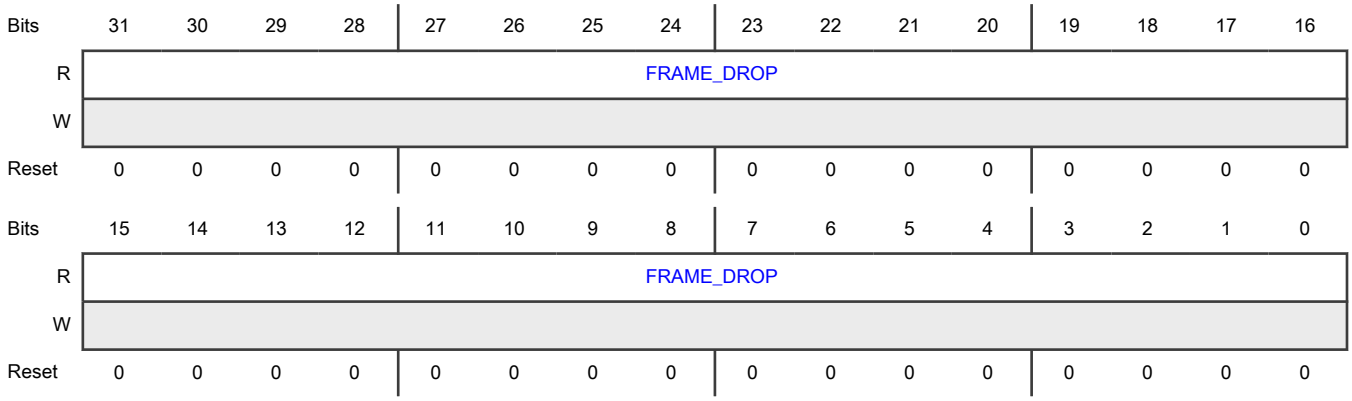
Offset

Register	Offset
PBFDVFR	2D8h

Function

This is the classification frame dropped due to VLAN filtering counter. Counter is incremented when a broadcast frame is dropped due to VLAN filtering (i.e. frames that had a match for MAC filtering but didn't pass VLAN filtering).

Diagram



Fields

Field	Function
31-0 FRAME_DROP	VLAN filter broadcast frame drop counter bits 31-0. Incremented for each dropped broadcast frame by the L2 filtering function, as no SI qualifies for reception of the frame due to VLAN filtering.

53.4.6.6.35 Port low power mode register (PLPMR)

Offset

Register	Offset
PLPMR	340h

Function

This is the low power mode register which provides the capability to enable the Wake-on-LAN feature. Enabling low power mode conveys to ENETC that low-power mode is about to be entered, and forces ENETC to progress to a quiesce state.

NOTE

Each module instance supports a different number of registers.

53.4.6.6.38 Transmit priority to traffic class mapping register 0 (PRIO2TCMR0)

Offset

Register	Offset
PRIO2TCMR0	380h

Function

This register describes the transmit BD ring's priority to traffic class mapping for priority 0 to 7. Each priority should be mapped to a different TC (more than one priority shouldn't be mapped to the same TC). To support multiple transmit BD rings assigned to the same TC, the transmit BD rings should be assigned the same priority value.

Fields

Field	Function
31-1 —	Reserved
0 SM	Switch Management **NOTE** Capability flag is set to 1 if the ENETC's port is connected to switch port via pseudo link and the switch has configured his management port to be this port. That is, if PCAPR[LINK_TYPE]=pseudo link and switch's Management Port Configuration Register MPCR[PORT] is the remote end of the ENETC's port. 0b - ENETC instance has no switch management capability 1b - ENETC instance has switch management capability

53.4.6.6.41 Switch management host reason a receive BD ring mapping register (SMHR1BDRMR - SMHR15BDRMR)

Offset

For a = 1 to 15:

Register	Offset
SMHRaBDRMR	87Ch + (a × 4h)

Function

This register applies to ENETC whose port is bound to a pseudo link (PCAPR[LINK_TYPE]=1) with the remote port being designated as a switch management port.

If the frame metadata field Host Reason is set to non-zero (i.e. not a regular forwarded frame), the BD ring is selected by mapping the Host Reason to a receive BD ring using this mapping register.

NOTE

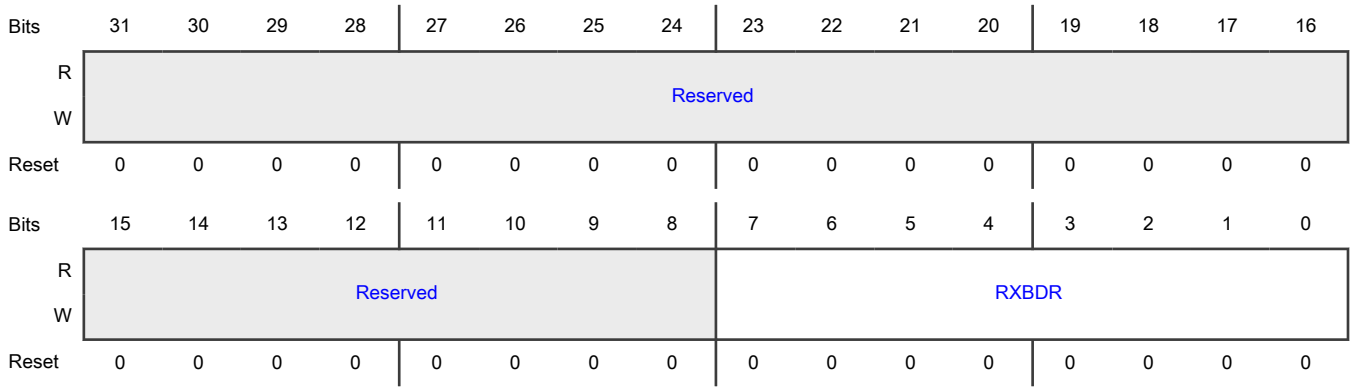
Valid if SMCAPR[SM]=1.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_BASE	—	SMHR1BDRMR–SMHR15BDRMR
ENETC1_BASE	SMHR1BDRMR–SMHR15BDRMR	—

Diagram



Fields

Field	Function

R	PRIM_MAC_ADDR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PRIM_MAC_ADDR	Primary MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset (register bit offset 0-7). This field contains the 4 most significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PSI*a*PMAR0 equals 14131211h.

53.4.6.6.43 Port station interface 0 primary MAC address register 1 (PSI0PMAR1)

Offset

Register	Offset
PSI0PMAR1	2004h

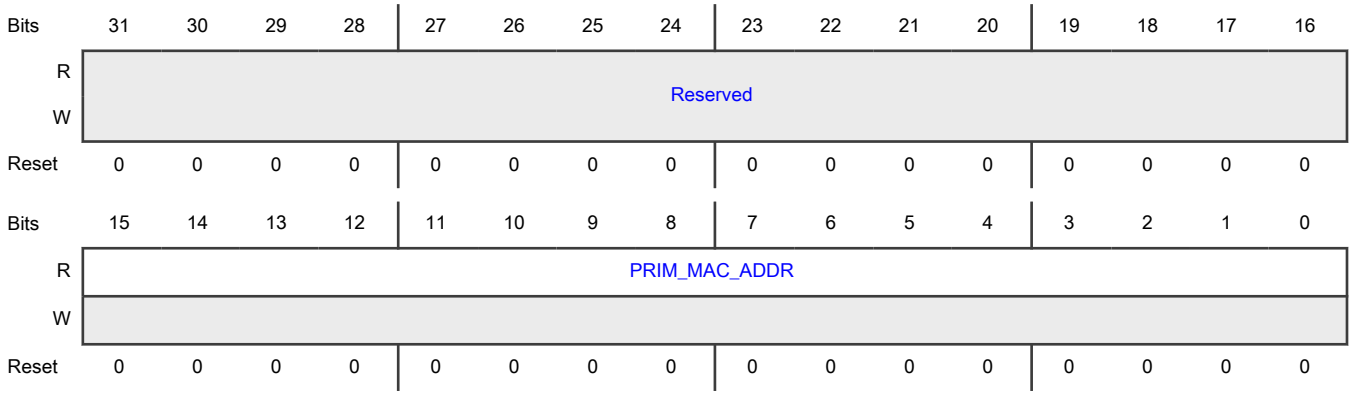
Function

This is the SI's primary MAC address register 1.

NOTE

This value is taken directly from the port PMAR1 register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PRIM_MAC_ADDR	Primary MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 2 least significant bytes of the MAC address (least significant byte is stored in register bit offset 8-15). For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PSI*a*PMAR1 equals xxxx1615h (where x should be set to 0).

53.4.6.6.44 Port station interface a VLAN register (PSI0VLANR - PSI1VLANR)

Offset

Register	Offset
PSI0VLANR	2008h
PSI1VLANR	2088h

Function

This is the SI-based VLAN. It is used for SI-based VLAN insertion (VLAN tag to be inserted) and SI-based VLAN removal (VLAN tag to be matched for removal)

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

17-16 TPID	Tag protocol identifier 00b - Standard C-VLAN 0x8100 01b - Standard S-VLAN 0x88A8 10b - Custom VLAN as defined by CVLANR1[ETYPE]. Note that CVLANR1[V] is not checked for SI-based VLAN insertion; TPID value specified in CVLANR1[ETYPE] will be used to construct the VLAN header regardless of the value specified in CVLANR1[V].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Custom VLAN as defined by CVLANR2[ETYPE]. Note that CVLANR2[V] is not checked for SI-based VLAN insertion; TPID value specified in CVLANR2[ETYPE] will be used to construct the VLAN header regardless of the value specified in CVLANR2[V].
15-13 PCP	Priority code point A 3-bit field which refers to the IEEE 802.1p class of service and maps to the frame priority level.
12 DEI	Drop eligible indicator May be used separately or in conjunction with PCP to indicate frames eligible to be dropped in the presence of congestion.
11-0 VID	VLAN identifier The VLAN identifier is a 12-bit field specifying the VLAN to which the frame belongs.

53.4.6.6.45 Port station interface 0 configuration register 0 (PSI0CFGR0)

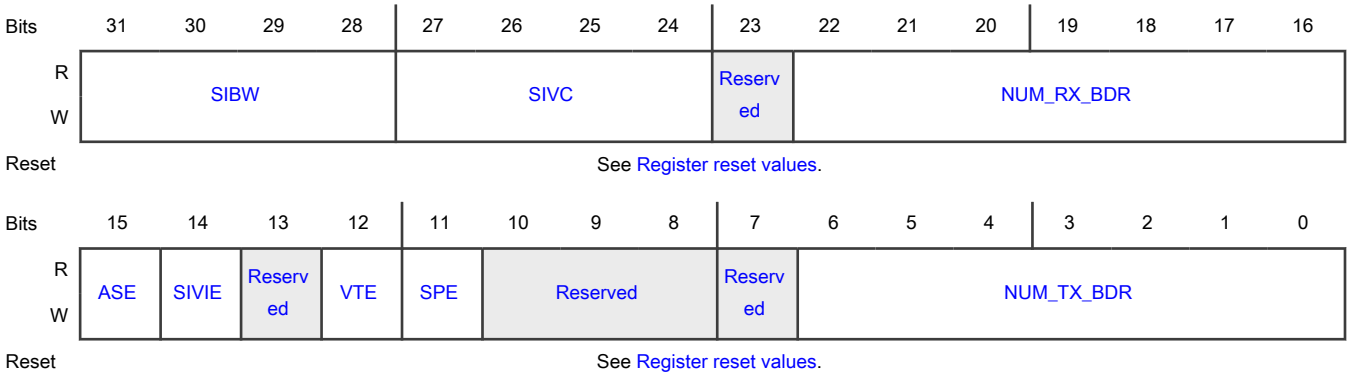
Offset

Register	Offset
PSI0CFGR0	2010h

Function

The station interface configuration register determines the features and capabilities of an SI.

Diagram



Register reset values

Register	Reset value
PSI0CFGR0	ENETC0_BASE: 0004_0004h ENETC1_BASE: 000A_000Ah

Fields

Field	Function
31-28 SIBW	Station interface traffic class bandwidth weight Frames are selected for transmission between station interfaces based on a per traffic class basis using the Weighted Fair Bandwidth Sharing algorithm. This value specifies a relative weight and is defined as credits per byte. A higher number indicates less bandwidth. For example, to balance the bandwidth for traffic class 7 between SI 0/1 to allow SI 0 twice the bandwidth, set the weight to 2 and 4 respectively. Note that a setting of 0x0 (reset default) will give an SI absolute priority over any SIs with a non-zero SIBW setting. If multiple SIs are configured with SIBW=0x0 then they each receive equal share of the traffic class bandwidth. 0: Highest bandwidth 1: Next highest bandwidth ... 14: Next lowest bandwidth 15: Lowest bandwidth
27-24 SIVC	Station interface VLAN control Determines which VLAN Ethertypes can be inserted by the SI driver (e.g. VF) either in the frame data or through the Tx BD. It also determines which VLAN Ethertypes are acceptable for VLAN removal (as seen by SI). Bit: 24 Standard C-VLAN 0x8100 25 Standard S-VLAN 0x88A8 26 Custom VLAN as defined by CVLANR1[ETYPE] 27 Custom VLAN as defined by CVLANR2[ETYPE]
23 —	Reserved
22-16 NUM_RX_BDR	Number of receive buffer descriptor rings assigned to the SI Range: 0..64 The following rules apply when modifying this field: • By default all rings are assigned to SI 0 (PSI) • Total number of assigned rings must not exceed the number of available rings defined by the port, ECAPR2[NUM_RX_BDR] • Assignment of rings to SIs should be done in increasing order, i.e. SI *n+1* cannot start ring management until SI *n* has been assigned rings • Reconfiguring number of assigned rings to SI *n* requires complete ring management reconfiguration for SI *n+1* and above
15	Anti-spoofing enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ASE	When anti-spoofing is enabled, source MAC address used by SI is compared against the primary MAC address. If it is different, the frame is not transmitted and an error is reported in the status field of the BD. 0: Disabled 1: Enabled
14 SIVIE	SI-based VLAN Insertion Enable This field controls whether insertion of the SI-based VLAN into frames sent by this SI is enabled. 0b - SI-based VLAN insertion disabled 1b - SI-based VLAN insertion enabled
13 —	Reserved
12 VTE	VLAN Tag Extract This field controls whether SI-based VLAN tag is removed from the frame before delivery to the SI. This tag must be the first tag, immediately following the SMAC address to be recognized and removed. After extraction, the resulting frame is presented to the SI for processing. 0b - SI-based VLAN removal disabled 1b - SI-based VLAN removal enabled
11 SPE	Source Pruning Enable 0b - Disabled 1b - Enabled
10-8 —	Reserved
7 —	Reserved
6-0 NUM_TX_BDR	Number of transmit buffer descriptor rings assigned to the SI Range: 0..64 The following rules apply when modifying this field: • By default all rings are assigned to SI 0 (PSI) • Total number of assigned rings must not exceed the number of available rings defined by the port, ECAPR2[NUM_TX_BDR] • Assignment of rings to SIs should be done in increasing order, i.e. SI *n+1* cannot start ring management until SI *n* has been assigned rings • Reconfiguring number of assigned rings to SI *n* requires complete ring management reconfiguration for SI *n+1* and above

53.4.6.6.46 Port station interface 0 configuration register 2 (PSI0CFGR2)

Offset

Register	Offset
PSI0CFGR2	2018h

Function

The station interface configuration register 2 determines the number of MSI-X table entries (vectors) allocated to a station interface.

The total number of vectors available to the ENETC instance is determined by ECAPR1[NUM_MSIX]. All vectors are initially assigned to the PSI, less 1 vector per VSI.

Diagram

PSI0MMHFR1	ENETC0_BASE,ENETC1_BASE: 0000_0000h
PSI1MMHFR1	0000_0000h

Fields

Field	Function
31-0 MAC_HASH_FLT_HIGH	Upper 32-bits (63-32) of multicast MAC hash filter table indexed by unicast MAC address hash.

53.4.6.6.53 Port station interface a VLAN hash filter register 0 (PSI0VHFR0 - PSI1VHFR0)

Offset

Register	Offset
PSI0VHFR0	2060h
PSI1VHFR0	20E0h

Function

This is the station interface VLAN hash filter table register 0.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_BASE	PSI0VHFR0	PSI1VHFR0
ENETC1_BASE	PSI0VHFR0–PSI1VHFR0	—

PSI1VHFR1	0000_0000h

Fields

Field	Function
31-0 VLAN_HASH_FLT_HIGH	Upper 32-bits (63-32) of VLAN hash filter table indexed by VLAN hash.

53.4.6.6.55 Port station interface 1 primary MAC address register 0 (PSI1PMAR0)

Offset

Register	Offset
PSI1PMAR0	2080h

Function

This is the SI's primary MAC address register.

NOTE

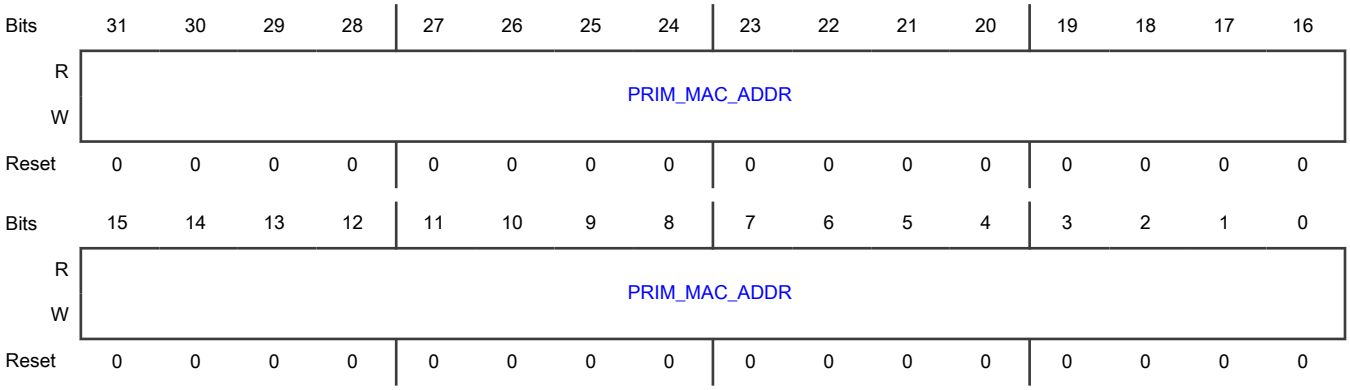
This value is taken directly from the port PMAR0 register.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_BASE	—	PSI1PMAR0
ENETC1_BASE	PSI1PMAR0	—

Diagram



Fields

Field	Function
31-0 PRIM_MAC_ADDR	Primary MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset (register bit offset 0-7). This field contains the 4 most significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PSI*a*PMAR0 equals 14131211h.

53.4.6.6.56 Port station interface 1 primary MAC address register 1 (PSI1PMAR1)

Offset

Register	Offset
PSI1PMAR1	2084h

Function

This is the SI's primary MAC address register 1.

NOTE

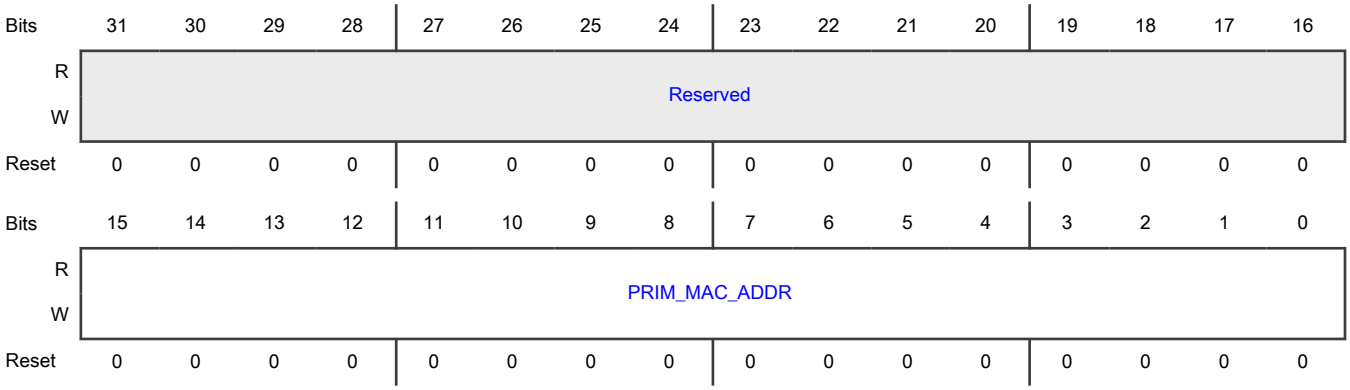
This value is taken directly from the port PMAR1 register.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_BASE	—	PSI1PMAR1
ENETC1_BASE	PSI1PMAR1	—

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PRIM_MAC_ADDR	Primary MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 2 least significant bytes of the MAC address (least significant byte is stored in register bit offset 8-15). For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PSI*a*PMAR1 equals xxxx1615h (where x should be set to 0).

53.4.6.6.57 Port station interface 1 configuration register 0 (PSI1CFGR0)

Offset

Register	Offset
PSI1CFGR0	2090h

Function

The station interface configuration register determines the features and capabilities of an SI.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_BASE	—	PSI1CFGR0
ENETC1_BASE	PSI1CFGR0	—

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 SIBW	Station interface traffic class bandwidth weight Frames are selected for transmission between station interfaces based on a per traffic class basis using the Weighted Fair Bandwidth Sharing algorithm. This value specifies a relative weight and is defined as credits per byte. A higher number indicates less bandwidth. For example, to balance the bandwidth for traffic class 7 between SI 0/1 to allow SI 0 twice the bandwidth, set the weight to 2 and 4 respectively. Note that a setting of 0x0 (reset default) will give an SI absolute priority over any SIs with a non-zero SIBW setting. If multiple SIs are configured with SIBW=0x0 then they each receive equal share of the traffic class bandwidth. 0: Highest bandwidth 1: Next highest bandwidth ... 14: Next lowest bandwidth 15: Lowest bandwidth
27-24 SIVC	Station interface VLAN control

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Determines which VLAN Ethertypes can be inserted by the SI driver (e.g. VF) either in the frame data or through the Tx BD. It also determines which VLAN Ethertypes are acceptable for VLAN removal (as seen by SI). Bit: 24 Standard C-VLAN 0x8100 25 Standard S-VLAN 0x88A8 26 Custom VLAN as defined by CVLANR1[ETYPE] 27 Custom VLAN as defined by CVLANR2[ETYPE]
23 —	Reserved
22-16 NUM_RX_BDR	Number of receive buffer descriptor rings assigned to the SI Range: 0..64 The following rules apply when modifying this field: • By default all rings are assigned to SI 0 (PSI) • Total number of assigned rings must not exceed the number of available rings defined by the port, ECAPR2[NUM_RX_BDR] • Assignment of rings to SIs should be done in increasing order, i.e. SI *n+1* cannot start ring management until SI *n* has been assigned rings • Reconfiguring number of assigned rings to SI *n* requires complete ring management reconfiguration for SI *n+1* and above
15 ASE	Anti-spoofing enable When anti-spoofing is enabled, source MAC address used by SI is compared against the primary MAC address. If it is different, the frame is not transmitted and an error is reported in the status field of the BD. 0: Disabled 1: Enabled
14 SIVIE	SI-based VLAN Insertion Enable This field controls whether insertion of the SI-based VLAN into frames sent by this SI is enabled. 0b - SI-based VLAN insertion disabled 1b - SI-based VLAN insertion enabled
13 —	Reserved
12 VTE	VLAN Tag Extract

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field controls whether SI-based VLAN tag is removed from the frame before delivery to the SI. This tag must be the first tag, immediately following the SMAC address to be recognized and removed. After extraction, the resulting frame is presented to the SI for processing. 0b - SI-based VLAN removal disabled 1b - SI-based VLAN removal enabled
11 SPE	Source Pruning Enable 0b - Disabled 1b - Enabled
10-8 —	Reserved
7 —	Reserved
6-0 NUM_TX_BDR	Number of transmit buffer descriptor rings assigned to the SI Range: 0..64 The following rules apply when modifying this field: • By default all rings are assigned to SI 0 (PSI) • Total number of assigned rings must not exceed the number of available rings defined by the port, ECAPR2[NUM_TX_BDR] • Assignment of rings to SIs should be done in increasing order, i.e. SI *n+1* cannot start ring management until SI *n* has been assigned rings • Reconfiguring number of assigned rings to SI *n* requires complete ring management reconfiguration for SI *n+1* and above

53.4.6.6.58 Port station interface 1 configuration register 1 (PSI1CFGR1)

Offset

Register	Offset
PSI1CFGR1	2094h

Function

The station interface PRIO to TC mapping register maps the VSI traffic class a to set transmit traffic class.

The mapping is done from the PRIO2TCMR0 value to a traffic class, allowing the PSI to restrict (VSI) use.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

53.4.6.6.59 Port station interface 1 configuration register 2 (PSI1CFGR2)

Offset

Register	Offset
PSI1CFGR2	2098h

Function

The station interface configuration register 2 determines the number of MSI-X table entries (vectors) allocated to a station interface.

The total number of vectors available to the ENETC instance is determined by ECAPR1[NUM_MSIX]. All vectors are initially assigned to the PSI, less 1 vector per VSI.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_BASE	—	PSI1CFGR2

Fields

Field	Function
31-8 —	Reserved
7-0 NUM_VLAN_FTE	Number of VLAN filter table entries assigned to the SI. Number of assigned entries to all SIs must not exceed the total number of available SI VLAN filter rules per port as defined by PSIVLANFCAPR[NUM_VLAN_FTE]. This field should be initialized once at start-up, before SI capability discovery starts. Modifying the setting during run-time may lead to undefined behavior.

53.4.6.7 Switch and ENETC common base register descriptions

This section describes the switch and ENETC common registers for one or more instances.

There may be differences in actual implemented registers or register fields as well as reset values between instances. The function's base address register value can be discovered from reading the PCIe Enhanced Allocation Base Address Register Equivalent Index 0 (EA BEI 0).

53.4.6.7.1 Switch_ENETC_Common memory map

Instance	Address space	PCIe EA BEI 0 offset
ENETC0_COMMON	PCI_F3_BAR_0	60B1_0000h

53.4.6.7.4 Operational state register (OSR)

Offset

Register	Offset
OSR	1010h

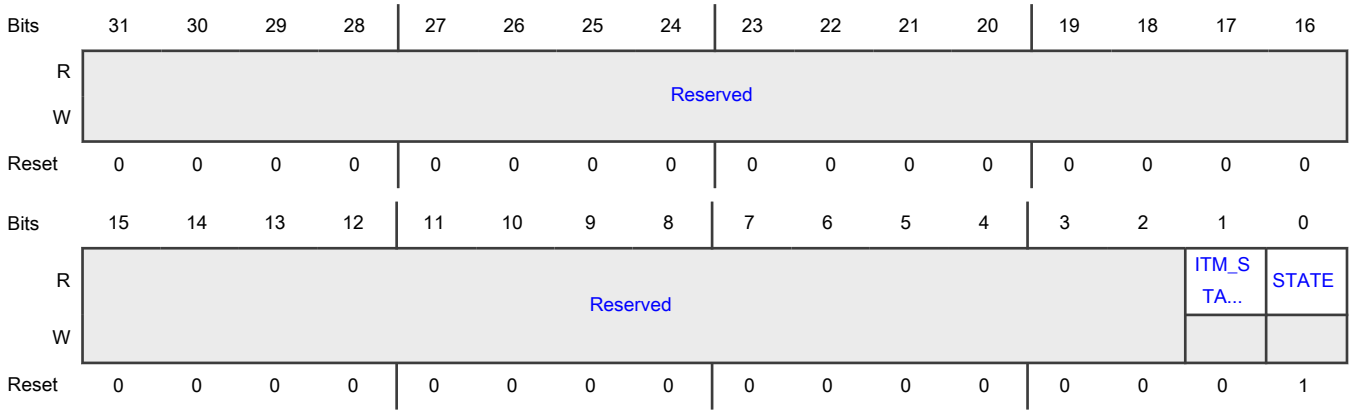
Function

This is the operational state register.

NOTE

Register is not affected by reset. A write to this read-only register will return an error.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 ITM_STATE	Indicates the index table memory (common memory) operational state. 0: Index table memory properly configured 1: Index table memory is overly-provisioned. That is, the sum of all the index tables' *ITMAR[NUM_WORDS] is greater than ITMCAPR[NUM_WORDS]. **CAUTION** If ITM_STATE is set, then all index table commands are rejected until this state is cleared. A write to a *ITMAR register will re-evaluate this state.
0 STATE	Indicates the function's operational state 0: Function is operationally ready. 1: Function is in the process of initializing memory. **CAUTION** Software must not write any device registers until state indicates it is operational.

53.4.6.7.5 Correctable memory error configuration register (CMECR)

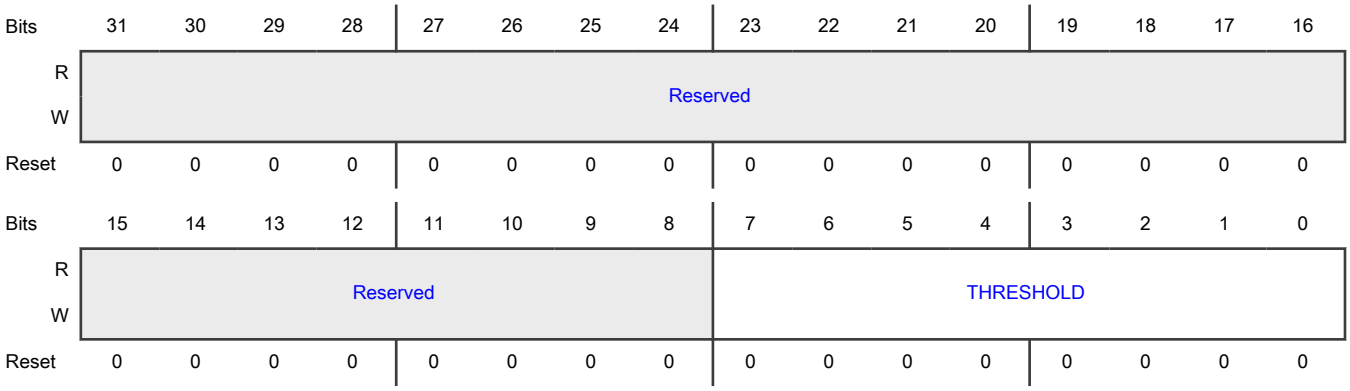
Offset

Register	Offset
CMECR	1040h

Function

The correctable memory error configuration register can disable the event reporting to the Root Complex Event Collector. While correctable errors do not cause any harm, detecting many of these events could indicate a more severe issue. The threshold can be set to trigger the event.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 THRESHOLD	Threshold Determines how many single bit ECC errors must be detected before error status bit is set and correctable memory error is reported to PCIe Event Collector. 0: Disabled (no reporting) >0: Threshold value (1-255)

53.4.6.7.6 Correctable memory error status register (CMESR)

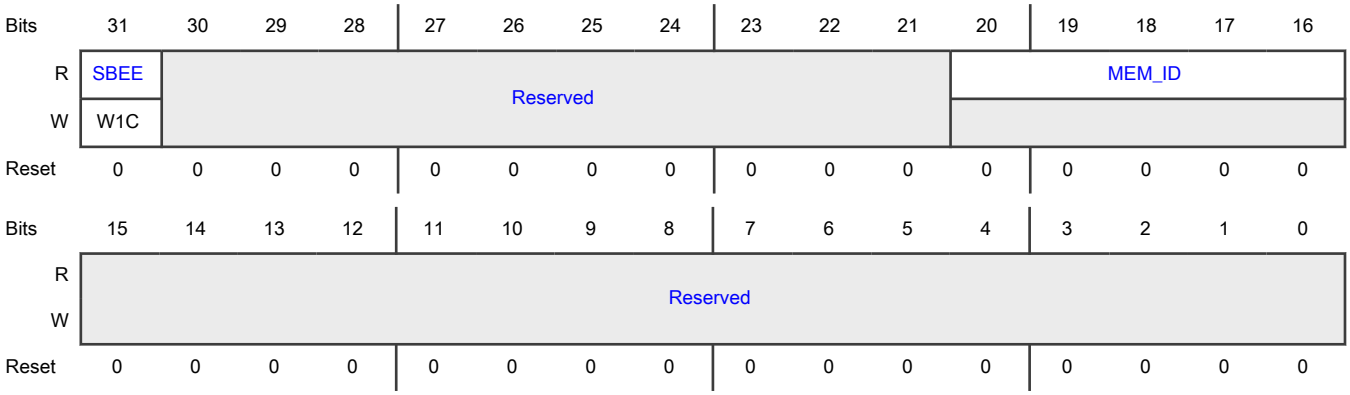
Offset

Register	Offset
CMESR	1044h

Function

This is the correctable memory error status register.

Diagram



Fields

Field	Function
31 SBEE	Single-bit ECC error When set, a threshold number of single-bit ECC error has occurred in the memory defined by MEM_ID. Write 1 to clear.
30-21 —	Reserved
20-16 MEM_ID	Memory ID See Table 392 for list of memory identifiers.
15-0 —	Reserved

53.4.6.7.7 Correctable memory error count register (CMECTR)

Offset

Register	Offset
CMECTR	104Ch

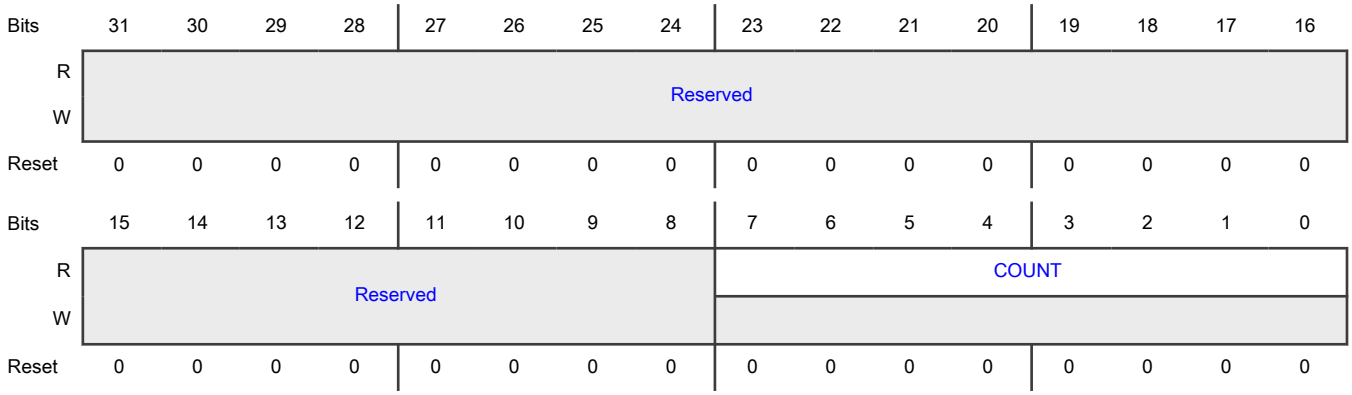
Function

This is the correctable memory error count register which tracks how many events have been detected.

NOTE

A write to this read-only register will return an error.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Count Indicates how many single-bit ECC error have been detected. After a read operation, the field's value clears to 0.

53.4.6.7.8 Uncorrectable non-fatal MAC error configuration register (UNMACECR)

Offset

Register	Offset
UNMACECR	1060h

Function

The uncorrectable non-fatal MAC error configuration register can disable the event reporting to the Root Complex Event Collector.

NOTE

A write to this read-only register will return an error.

Diagram

53.4.6.7.23 Internal MDIO MSI-X vector register (IMDIOMSIVR)

Offset

Register	Offset
IMDIOMSIVR	10E4h

Function

This is the internal Ethernet MAC MDIO MSI-X vector control register. Number of vectors supported for the switch is defined in SCAPR0[NUM_MSIX]. Number of vectors supported for ENETC is defined in ECAPR1[NUM_MSIX].

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

R	TIMESTAMP															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TIMESTAMP	Timestamp value in ns relative to SFD of the received frame. If received from pseudo MAC, timestamp value is relative to when the frame descriptor is transferred across the pseudo link. When the timestamp is captured, the TCRPSR[RX_CNT] register is incremented by 1 and the TCRPSR[RX_PORT] register is updated with the Rx port number of the trigger frame. Only the first frame (TCRPSR[RX_CNT] = 0) captures the Rx timestamp. Content is valid if TCRPSR[RX_CNT] is non-zero.

53.4.6.7.31 Time capture MSI-X vector register (TCMSIVR)

TGSTCAPR	ENETC0_COMMON,ENETC1_COMMON: 0220_0100h SW0_COMMON: 0220_0500h

Fields

Field	Function
31-26 —	Reserved
25-24 MAX_GCL_LEN	Maximum Gate Control List Length Indicates the maximum number of entries that can be specified in a gate control list even thought the total number of words available for storing the entries in the Time Gate Scheduling table (TGSTCAPR[NUM_WORDS]) wouldn't be exceeded. 00b - 64 01b - 128 10b - 256 11b - Reserved
23-20 ACCESS_METH	Access Method Indicates which configuration access methods are supported 1xxxb - Reserved x1xxb - Search xx1xb - EntryId xxx1b - Index
19-16 —	Reserved
15-0 NUM_WORDS	Number of Words Indicates the number of words available to this Time Gate Scheduling table. This corresponds to the total number of words available in the Time Gate Scheduling table, for storing the administrative gate control list and the operational gate control list of each table entry. This value is writable in IERB register S*a*TGSTAR/E*a*TGSTAR (by pre-boot initialization), and is immediately reflected here. **NOTE** Entry size is variable depending on the number of gates allocated for a given entry. Entry size in words is: NUM_GATES * 1.

53.4.6.7.75 Time gate scheduling table memory operation register (TGSTMOR)

53.4.6.7.79 Hash table memory capability register (HTMCAPR)

Offset

Register	Offset
HTMCAPR	1900h

Function

This is the hash table memory capability register. Maximum number of words allotted to exact match hash tables from the common memory's shared region.

Software driver is responsible to manage how the hash table memory is distributed amongst various hash tables. Following hash table's entries are 1 word in size:

- Ingress Stream Identification table

- Ingress Stream Filter table
- VLAN Filter table
- FDB table
- L2 IPv4 Multicast Filter table

NOTE

A write to this read-only register will return an error.

Fields

Field	Function
31 EN	Operational state of this key construction register: 0: Disabled: Exact Match Lookup must not utilize this key construction. 1: Enabled: Exact Match Lookup can utilize this key construction. **NOTE** Hardware sets this to 1 if Key Construction requested/specified in ISIDKCaCR0 and ISIDKCaPFbCR does not exceed ISIDCAPR[MAX_KSIZE]; otherwise it is set to 0. Hardware uses ISIDKCaCR0 as a trigger register to evaluate EN. As such any payload extraction for key construction must be configured first using ISIDKCaPFbCR before configuring ISIDKCaCR0.
30-16 —	Reserved
15-0 NUM_ENTRIES	Indicates the number of Ingress Stream Identification, i.e., table 30 entries added using this key. **NOTE** Software driver must ensure that this value is 0 in order to modify ISIDKC*a*CR0.

53.4.6.7.84 Ingress stream identification key construction a configuration register 0 (ISIDKC0CR0 - ISIDKC3CR0)

Offset

Register	Offset
ISIDKC0CR0	1924h
ISIDKC1CR0	1944h
ISIDKC2CR0	1964h
ISIDKC3CR0	1984h

Function

The function supports (ISIDCAPR[NUM_KC]+1)/2 pairs of key construction registers. For a switch function, PISIDCR[KCPAIR] specifies the key construction pair used when constructing ISID key.

NOTE

This register format is applicable when PCR[HDR_FMT]=0. Hardware uses ISIDKCaCR0 as a trigger register to evaluate ISIDKCaOR[EN]. As such any payload extraction for key construction has to be configured first using ISIDKCaPFbCR before configuring ISIDKCaCR0.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_COMMON	ISIDKC0CR0–ISIDKC1CR0	ISIDKC2CR0–ISIDKC3CR0

Fields

Field	Function
31-11 —	Reserved
10 ETP	EtherType Present. Specifies whether the EtherType after any VLAN or redundancy sequence (R-TAG, HSR tag) headers is present in the key. 0b - Not present 1b - Present
9 SQTP	Sequence Tag (code point) Present. Specifies whether a sequence tag code point is present in the key. The 1-byte sequence tag code points are defined as follows: 0: No R-TAG/HSR tag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1: 802.1CB draft 2.0 R-TAG 2: R-TAG 3: HSR Tag 4-255: Reserved 0b - Not present 1b - Present
8 IPCPP	Inner PCP Present. Specifies whether the inner PCP is present in the key. If IPCPP is set 1 or IVIDP is set 1, or both are set 1, a 2-byte value must be entered in the frame key field of the Ingress Stream Identification table entry with the following definition: • Bit 15 **V** - VLAN tag present in the frame (0 = not present, 1 = present). • Bit 14:12 **PCP** – PCP value to be matched if IPCPP is set to 1 (must be set to 0 if IPCPP=0). • Bit 11:0 **VID** – VID value to be matched if IVIDP is set to 1 (must be set to 0 if IVIDP=0). Most significant byte of the 2-byte 'V[15], PCP[14:12] and VID [11:0]' would be stored at the lowest byte offset. Least significant byte (that is VID[7:0]) would be stored at the next byte offset. Required settings for the following matches: • **Outer PCP only** - IPCPP set to 1 and IVIDP set to 0, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, set to '1, 0, VID value to match'. • **Outer VLAN ID and PCP** - IPCPP and IVIDP set to 1, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, set to '1, PCP value to match, VID value to match'. • **Outer VLAN not present** - IPCPP or IVIDP (or both) set to 1, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, all set to 0. The inner VLAN tag is considered present in the frame if VLAN classification has deemed the inner VLAN tag valid and the VLAN tag was not taken from the port VLAN configuration register. 0b - Not present 1b - Present
7 IVIDP	Inner VID Present. Specifies whether the inner VLAN ID is present in the key. If IVIDP is set 1 or IPCPP is set 1, or both are set 1, a 2-byte value must be entered in the frame key field of the Ingress Stream Identification table entry with the following definition: • Bit 15 **V** - VLAN tag present in the frame (0 = not present, 1 = present) • Bit 14:12 **PCP** – PCP value to be matched if IPCPP is set to 1 (must be set to 0 if IPCPP=0) • Bit 11:0 **VID** – VID value to be matched if IVIDP is set to 1 (must be set to 0 if IVIDP=0) Most significant byte of the 2-byte 'V[15], PCP[14:12] and VID [11:0]' would be stored at the lowest byte offset. Least significant byte (that is VID[7:0]) would be stored at the next byte offset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Required settings for the following matches: • **Inner VLAN ID only** - IVIDP set to 1 and IPCPP set to 0, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, set to '1, 0, VID value to match'. • **Inner VLAN ID and PCP** - IVIDP and IPCPP set to 1, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, set to '1, PCP value to match, VID value to match'. • **Inner VLAN not present**- IVIDP or IPCPP (or both) set to 1, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, all set to 0. The inner VLAN tag is considered present in the frame if VLAN classification has deemed the inner VLAN tag valid and the VLAN tag was not taken from the port VLAN configuration register. 0b - Not present 1b - Present
6 OPCPP	Outer PCP Present Specifies whether the outer PCP is present in the key. If OPCPP is set 1 or OVIDP is set 1, or both are set 1, a 2-byte value must be entered in the frame key field of the Ingress Stream Identification table entry with the following definition: • Bit 15 **V** - VLAN tag present in the frame (0 = not present, 1 = present) • Bit 14:12 **PCP** – PCP value to be matched if OPCPP is set to 1 (must be set to 0 if OPCPP=0) • Bit 11:0 **VID** – VID value to be matched if OVIDP is set to 1 (must be set to 0 if OVIDP=0) Most significant byte of the 2-byte 'V[15], PCP[14:12] and VID [11:0]' would be stored at the lowest byte offset. Least significant byte (i.e. VID[7:0]) would be stored at the next byte offset. Required settings for the following matches: • Outer PCP only - OPCPP set to 1 and OVIDP set to 0, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, set to '1, 0, VID value to match'. • Outer VLAN ID and PCP - OPCPP and OVIDP set to 1, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, set to '1, PCP value to match, VID value to match'. • Outer VLAN not present - OPCPP or OVIDP (or both) set to 1, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, all set to 0. The outer VLAN tag is considered present in the frame if VLAN classification has deemed the outer VLAN tag valid and the VLAN tag was not taken from the port VLAN configuration register. 0b - Outer VLAN header's PCP field not present in the key 1b - Outer VLAN header's PCP field present in the key
5 OVIDP	Outer VID Present Specifies whether the outer VLAN ID is present in the key. If OVIDP is set 1 or OPCPP is set 1, or both are set 1, a 2-byte value must be entered in the frame key field of the Ingress Stream Identification table entry with the following definition:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Bit 15 **V** - VLAN tag present in the frame (0 = not present, 1 = present) • Bit 14:12 **PCP** – PCP value to be matched if OPCPP is set to 1 (must be set to 0 if OPCPP=0) • Bit 11:0 **VID** – VID value to be matched if OVIDP is set to 1 (must be set to 0 if OVIDP=0) Most significant byte of the 2-byte 'V[15], PCP[14:12] and VID [11:0]' would be stored at the lowest byte offset. Least significant byte (i.e. VID[7:0]) would be stored at the next byte offset. Required settings for the following matches: • **Outer VLAN ID only** - OVIDP set to 1 and OPCPP set to 0, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, set to '1, 0, VID value to match'. • **Outer VLAN ID and PCP** - OVIDP and OPCPP set to 1, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, set to '1, PCP value to match, VID value to match'. • **Outer VLAN not present** - OVIDP or OPCPP (or both) set to 1, and 'V, PCP and VID' fields of the frame key entered in the Ingress Stream Identification entry, all set to 0. The outer VLAN tag is considered present in the frame if VLAN classification has deemed the outer VLAN tag valid and the VLAN tag was not taken from the port VLAN configuration register. 0b - Not present 1b - Present
4 SMACP	Source MAC (address) Present. Specifies whether the source MAC address is present in the key. 0b - Not present 1b - Present
3 DMACP	Destination MAC (address) Present Specifies whether the destination MAC address is present in the key. 0b - Not present 1b - Present
2 SPMP	Switch Port Masquerading (flag) Present Specifies whether the SPM flag is present in the key. SPM flag is defined as follows: 0: Frame originated from a switch port 1: Frame originated from management port (host) masquerading as switch port 0b - Not present 1b - Present
1 PORTP	Source Port Present Specifies whether the source port is present in the key. 0b - Not present 1b - Present

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 VALID	Valid Specifies whether, the key construction is valid. **NOTE** The precedence value of these entries are greater than ingress port filter table's entry IPF_CE[PR] value of 2. 0b - The entire key construction rule is not valid including any configuration payload key fields defined. 1b - The key construction rule is valid.

53.4.6.7.85 Ingress stream identification key construction a payload field b configuration register (ISIDKC0PF0CR - ISIDKC3PF3CR)

Offset

For a = 0 to 3; b = 0 to 3:

Register	Offset
ISIDKCaPFbCR	1930h + (a × 20h) + (b × 4h)

Function

Defines one of the 4 Ingress Stream Identification payload fields. Register is valid if its PFP field is set to 1.

If one payload field is to be specified, it has to be specified in ISIDKCaPF0CR with PFP set to 1 with payload size and offset specified and remaining payload registers have their PFP field set to 0.

If two payload fields are to be specified then the PFP of ISIDKCaPF0CR, ISIDKCaPF1CR must be set to 1 with payload size and offset specified and remaining payload field registers have their PFP field set to 0. Similar steps must be followed for specifying additional payload fields. (Note that if ISIDKCaPF0CR[PFP] =1,ISIDKCaPF1CR[PFP] =1,ISIDKCaPF2CR[PFP] =0 and if ISIDKCaPF3CR[PFP] =1, then payload size and offset specified in ISIDKCaPF0CR and ISIDKCaPF1CR will be used for key construction and ISIDKCaPF2CR, ISIDKCaPF3CR will not be considered for key construction).

NOTE

Hardware uses ISIDKCaCR0 as a trigger register to evaluate ISIDKCaOR[EN]. As such any payload extraction for key construction has to be configured first using ISIDKCaPFbCR before configuring ISIDKCaCR0.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_COMMON	ISIDKC0PF0CR–ISIDKC1PF3CR	ISIDKC2PF0CR–ISIDKC3PF3CR
ENETC1_COMMON	ISIDKC0PF0CR–ISIDKC1PF3CR	ISIDKC2PF0CR–ISIDKC3PF3CR

Register	Reset value
ISIDKC0PF0CR–ISIDKC1PF3CR	ENETC0_COMMON–SW0_COMMON: 0000_0000h
ISIDKC2PF0CR–ISIDKC3PF3CR	0000_0000h

Fields

Field	Function
31-23 —	Reserved
22-20 LBMASK	Payload Last Byte Mask: Number of least significant bits from the last payload key byte to mask.
19 —	Reserved
18-16 FBMASK	Payload First Byte Mask: Number of most significant bits of first payload key byte to mask.
15 —	Reserved
14-8	Payload Byte Offset where field extraction begins.

Table continues on the next page...

Table continued from the previous page...

Field	Function
BYTE_OFFSET	Payload offset byte 0 for the first payload field (ISIDKCaPF0CR) starts immediately after the payload Ethertype. Payload Ethertype starts immediately after source MAC address or VLAN tag(s)/RTAG/HSR (if any). Payload byte offset for subsequent payload fields (ISIDKCaPF1CR .. ISIDKCaPFbCR) starts immediately after the last byte of the previous payload field. Hardware will not be construct the Ingress Stream Identification table lookup key if the payload key field is not within the frame or if it is not within 116 bytes of the payload; where payload starts after the payload Ethertype which in turn is after source MAC address or VLAN, tag(s)/R-TAG/HSR (if any). Since the key cannot be constructed, the Ingres Stream Identification table lookup using this key construction rule will be by-passed.
7-5 —	Reserved
4-1 NUM_BYTES	The NUM_BYTES field is used to specify the size of the payload key field, as follows: Size of the payload key field = NUM_BYTES + 1; range is 1 to 16 bytes
0 PFP	Payload field Present 0: This payload field register is not used for constructing a key. 1: NUM_BYTES+1 consecutive bytes starting at BYTE_OFFSET are included in the Key.

53.4.6.7.86 Ingress stream filter hash table capability register (ISFHTCAPR)

11-9 —	Reserved
8 TIMER_CS	Timer Clock Selection: On receive, this field determines which of the two Rx timestamps (synchronized or free running) is reported to the host. On transmit, this field determines which of the two clock sources (synchronized clock or free running clock) is used for sampling the Tx timestamp on the pseudo MAC. For the Ethernet MAC, the PMa_COMMAND_CONFIG[TS_MODE] register determines which of the two clock sources (synchronized clock or free running clock) is used for sampling the Tx timestamp. 0 Synchronized timestamp (receive) and synchronized source clock (transmit, pseudo MAC only) with unit of nanoseconds 1 Free running timestamp (receive) and free running source clock (transmit, pseudo MAC only) with unit of NETC clock ticks
7-5 —	Reserved
4 L2DOSE	L2 Ethernet DoS Protection Enable 0 L2 IP DoS protection is disabled. 1 L2 IP DoS protection is enabled. Refer to DOSL2CR, for more details. Valid if HDR_FMT=0.
3-1 —	Reserved
0 HDR_FMT	Indicates the frame format received/transmitted on the port 0 Ethernet frame format 1 Reserved

53.4.6.8.6 Port MAC address register 0 (PMAR0)

Offset

Register	Offset
PMAR0	20h

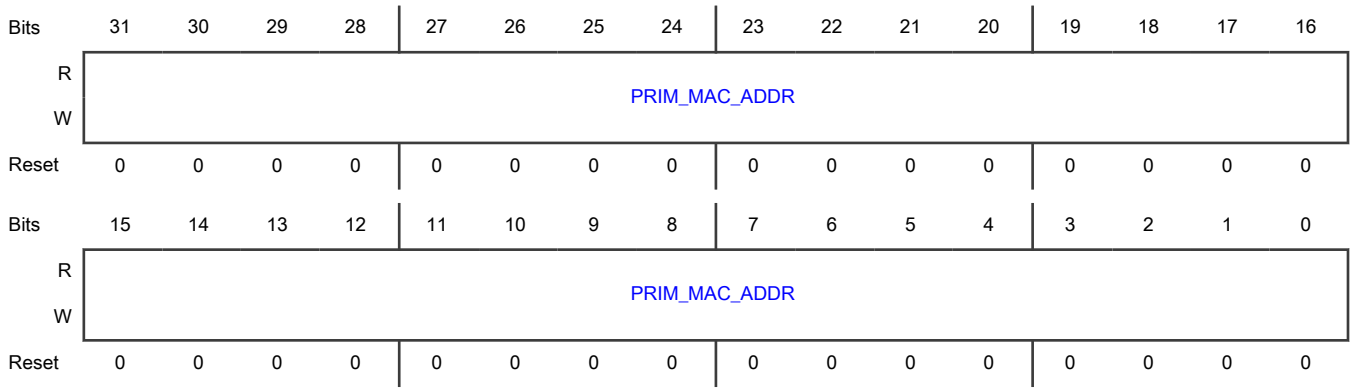
Function

This is the port MAC address register 0.

NOTE

The port will sample the IERB L*a*E*b*MAR0 value when PCIe Memory Access bit is set (0b1). All updates after this must be done through this register.

Diagram



Fields

Field	Function
31-0 PRIM_MAC_ADDR	Primary MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset (register bit offset 0-7). This field contains the 4 most significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then P*a*MAR0 equals 14131211h.

53.4.6.8.7 Port MAC address register 1 (PMAR1)

Offset

Register	Offset
PMAR1	24h

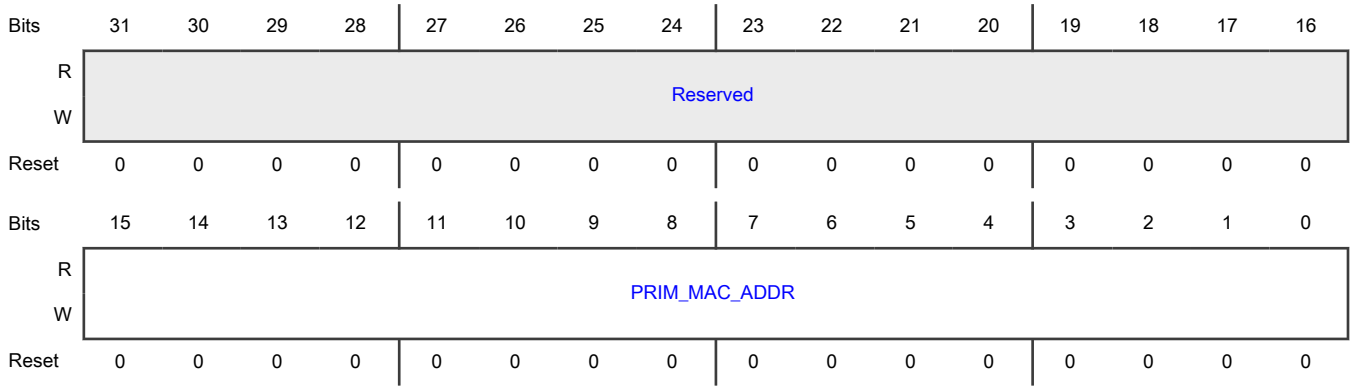
Function

This is the port MAC address register 1.

NOTE

The port will sample the IERB L*a*E*b*MAR1 value when PCIe Memory Access bit is set (0b1). All updates after this must be done through this register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PRIM_MAC_ADDR	Primary MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 2 least significant bytes of the MAC address (least significant byte is stored in register bit offset 8-15). For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then P*a*MAR1 equals xxxx1615h (where x should be set to 0).

53.4.6.8.8 Port TPID acceptance register (PTAR)

Offset

Register	Offset
PTAR	50h

Function

This register controls the VLAN classification.

Diagram

53.4.6.8.11 Port parser configuration register (PPCR)

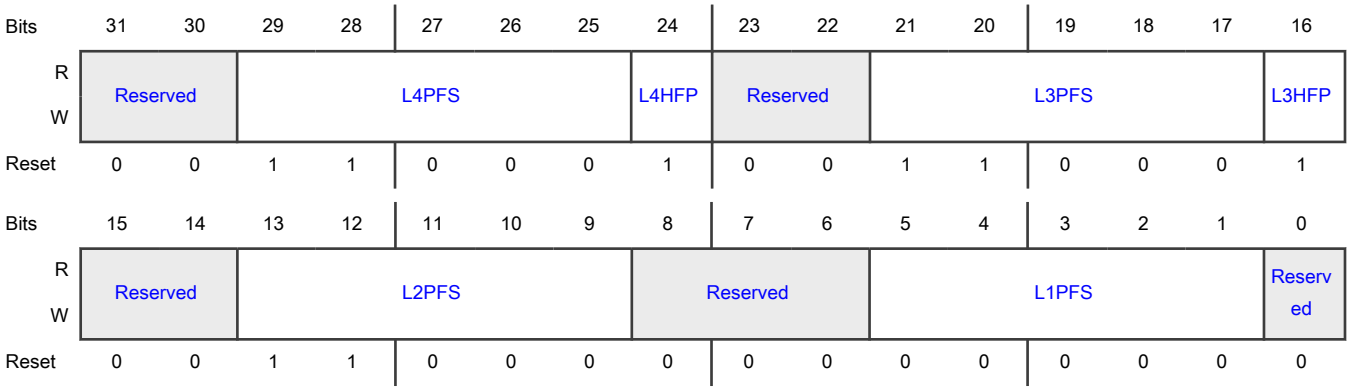
Offset

Register	Offset
PPCR	80h

Function

This register indicates how much the parser needs to look into the frame for the given port. Purpose is to minimize the number of bytes required to be received before keyed lookup operation. This improve packet processing latency for cut-through forwarding.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-25 L4PFS	L4 payload fields size in bytes This is the largest L4 Payload size used by any table lookup key by this port. Payload size range is from 0..24 Bytes, starting immediately after the Destination Port. **NOTE** This field is valid if L4HFP=1.
24 L4HFP	L4 Header fields present **NOTE** Valid if PCR[HDR_FMT]=0. 0b - No L4 header present. Indicates to the parser of not parsing the L4 header. Parsing in this case would go as far as the L3 header if configured to parse it (L3HFP=1) regardless of whether or not there is an L4 header in the frame. This option should not be used if there are any table lookup entries that contain L4 key fields that could be matched against a frame. 1b - Parse L4 header if present in the frame
23-22 —	Reserved
21-17 L3PFS	L3 payload fields size in bytes This is the largest L3 Payload size used by any table lookup key by this port.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Payload size range is from 0..24 Bytes, starting immediately after the Destination IP Address, when parsing is ending at this layer. **NOTE** Valid if L3HFP=1.
16 L3HFP	L3 header fields present **NOTE** Valid if PCR[HDR_FMT]=0. 0b - No L3 header present. Indicates to the parser of not parsing the L3 header. Parsing in this case would go as far as the L2 header regardless of whether or not there is an L3 header in the frame. This option should not be used if there are any table lookup entries that contain L3/L4 key fields that could be matched against a frame. 1b - Parse L3 header if present in the frame.
15-14 —	Reserved
13-9 L2PFS	L2 payload fields size in bytes This is the largest L2 payload size used by any table lookup key by this port. Payload size range is from 0..24 Bytes, starting after the payload EtherType. The payload EtherType starts immediately after the SMAC or VLANs/R-TAG/HSR tag if any, when parsing is ending at this layer. **NOTE** Valid if PCR[HDR_FMT]=0.
8-6 —	Reserved
5-1 L1PFS	Unused
0 —	Reserved

53.4.6.8.12 Port ingress port filter configuration register (PIPFCR)

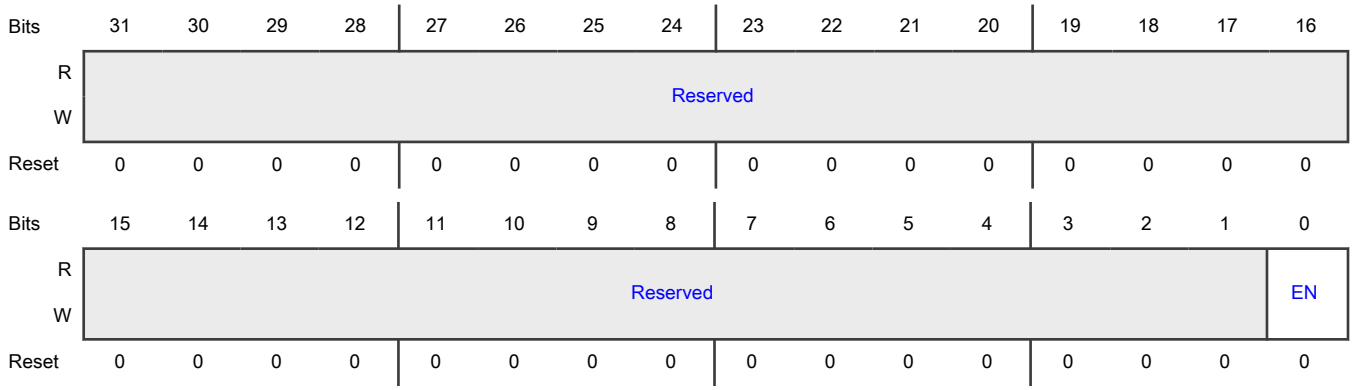
Offset

Register	Offset
PIPFCR	84h

Function

This is the port ingress port filter configuration register

Diagram



Fields

Field	Function

0 EN	0 Ingress Port Filter table lookup is disabled for this port 1 Ingress Port Filter table lookup is enabled for this port

53.4.6.8.13 Port stream gate configuration register (PSGCR)

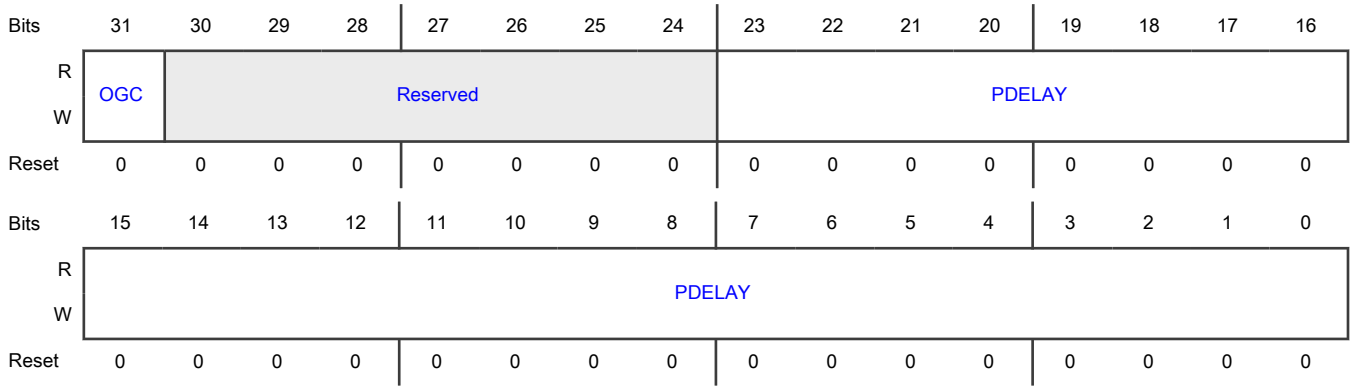
Offset

Register	Offset
PSGCR	A0h

Function

This is the port stream gate configuration register.

Diagram



Fields

Field	Function
31 OGC	Stream Gate Open Gate Check mode 0 Gate open check passes if the Start of Frame (SFD) is within the open gate interval 1 Gate open check passes if the entire frame is within the open gate interval. That is from SFD to End of Frame.
30-24 —	Reserved
23-0 PDELAY	Link propagation delay in nanoseconds. The frame reception timestamp(s) are adjusted by subtracting the link propagation delay from the Start of Frame receive timestamp and from the End of Frame receive timestamp (in the case where OGC is set to 1).

53.4.6.8.14 Port operational register (POR)

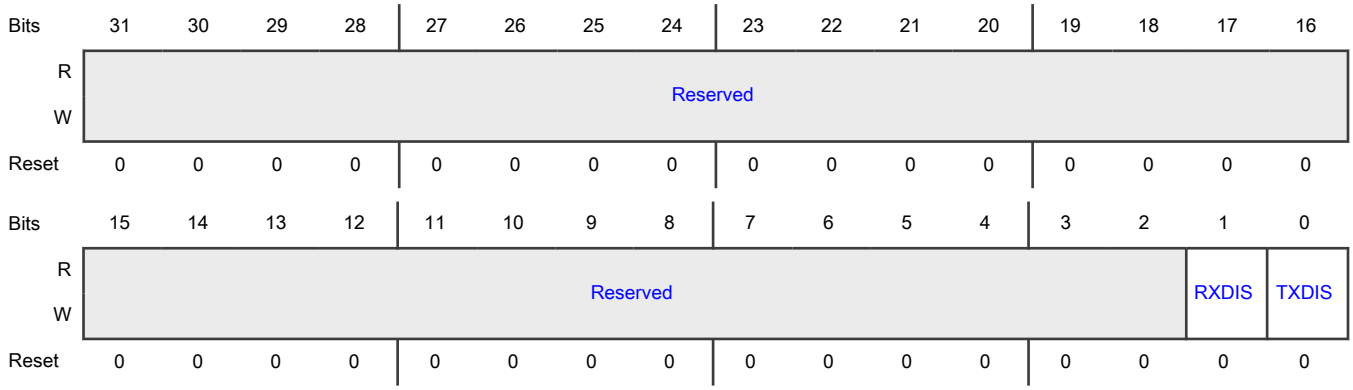
Offset

Register	Offset
POR	100h

Function

This is the port operational register

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RXDIS	Rx Disable. The frame discards are counted against the port's Rx discard count register (PRXDCR) along with the setting of the Receive Disable Discard Reason (RXDISDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). 0b - Rx path is enabled. 1b - Rx path is disabled. Any partially Rx reassembled frame, is discarded. While the Rx path is disabled, any new frame received from the MAC is discarded.
0 TXDIS	Tx Disable. While disabled, the following behaviors take place: • Any frame to be enqueued internally onto any switch Egress Traffic Management (ETM) class queue, is discarded. The frame discard is counted against the port's Tx discard count register (PTXDCR) along with the setting of the "Transmit Disable prior to Enqueue to ETM Discard Reason" (TXDISEDR) flag to 1 in the port's Tx discard count reason register 0 (PTXDCRR0). • Buffer descriptors from the ENETC transmit BD rings are no longer loaded from the host memory to internal memory. • The transmit scheduling mechanisms (e.g. time gate scheduling) will continue to function but with no frames available to be scheduled. Once enabled, the transmit scheduling mechanisms will resume normal operation without requiring any additional intervention. 0b - Tx path is enabled 1b - Tx path is disabled. Any frame queued internally on the port for transmission is flushed. Direct enqueued host originated switch management frames, area also discarded. The frame discards are counted against the port's Tx discard count register (PTXDCR) along with the setting of the "Transmit Disable Discard Reason" (TXDISDR) to 1 in the port's Tx discard count reason register 0 (PTXDCRR0).

53.4.6.8.15 Port status register (PSR)

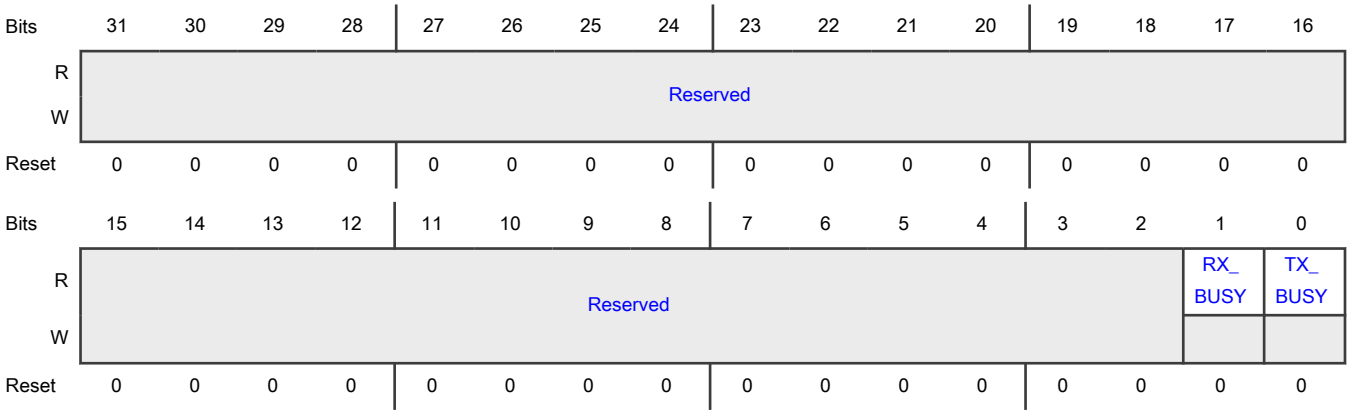
Offset

Register	Offset
PSR	104h

Function

This is the port status register.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RX_BUSY	Receive busy. Ingress (or receive) datapath processing pipeline is busy processing received frames from this port. 0b - Idle 1b - Busy
0 TX_BUSY	Transmit busy. Egress (or transmit) datapath processing pipeline is busy processing frames that are to be transmitted out of this port. 0b - Idle 1b - Busy

53.4.6.8.16 Port receive SDU overhead register (PRXSDUOR)

Offset

Register	Offset
PRXSDUOR	108h

Function

Overhead (number of bytes) to be added to the actual length of each frame based on the following selected SDU type:

0: PPDU (Physical Layer PDU) overhead: PPDU_BCO + MACSEC_BCO

1: MPDU (MAC PDU) overhead: MACSEC_BCO

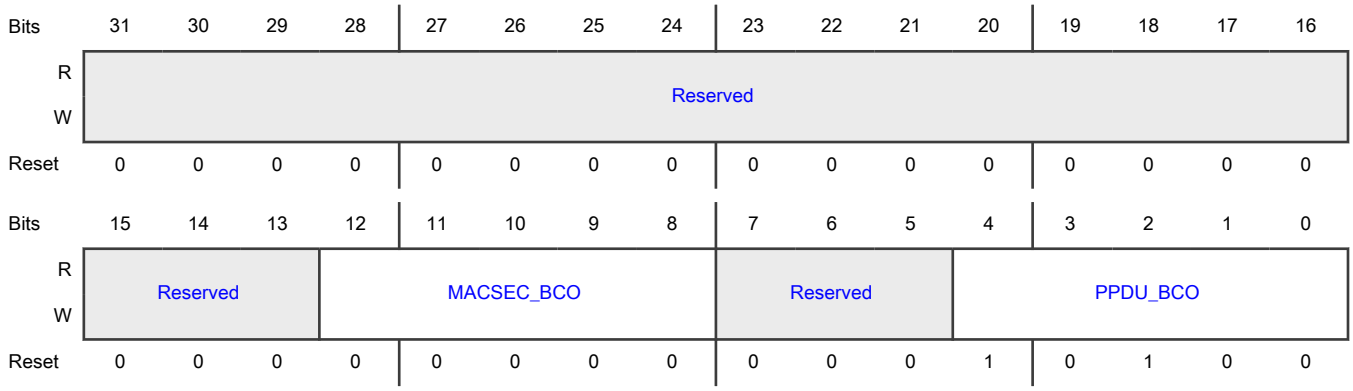
2: MSDU (MAC SDU) overhead: minus 16B (12B MAC Header + 4B FCS)

All other setting reserved.

This register is used by:

- Rate policing function
- Stream filtering function
- Stream gating function

Diagram



Fields

Field	Function
31-13 —	Reserved
12-8 MACSEC_BCO	MACSec byte count overhead Number of bytes of overhead due to MACSec encapsulation.
7-5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
4-0 PPDU_BCO	PPDU Byte count overhead PPDU Byte count overhead which includes IPG, SFD and Preamble. **NOTE** Default is 20 which is IPG(12) + SFD(1) + Preamble(7).

53.4.6.8.17 Port transmit SDU overhead register (PTXSDUOR)

Offset

Register	Offset
PTXSDUOR	10Ch

Function

Overhead (number of bytes) to be added to the actual length of each frame based on the selected SDU type

0: PPDU (Physical Layer PDU): PPDU_BCO + MACSEC_BCO

1: MPDU (MAC PDU): MACSEC_BCO

2: MSDU (MAC SDU): minus 16B (12B MAC Header + 4B FCS)

This register is used by:

- Per traffic class maximum frame length check where the SDU type is specified by PTC*a*TMSDUR.
- Time Gate Scheduling (TGS) where PPDU length is used to ensure that entire frame can be transmitted on the wire while the gate is open.
- Credit Base Shaping (CBS) where PPDU length is used to calculate the amount of bandwidth usage on the link

PTGSCR	ENETC0_PORT: 0000_0000h ENETC1_PORT: 8000_0000h SW0_PORT0–SW0_PORT3: 0000_0000h SW0_PORT4: 8000_0000h

Fields

Field	Function
31 TGE	Time Gating Enable Enables and disables the time gating function on the port. When disabling and then re-enabling, the disable time must be greater than the advance offset time configured in S*a*TGSLR/E*a*TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]. Software must also wait until PTGAGLSR[TG] is de asserted before re-enabling. 0b - Time gating disabled. The state of each gate is determined by the setting in PDGSR[DGS_TCn], where n is the traffic class number. If this field is set to 0 (disabling time gate scheduling), the operational gate control list and administrative gate control list (if present), will be removed. 1b - Time gating enabled. The initial state of each gate is determined by the setting in PDGSR[DGS_TCn], where n is the traffic class number. This field must be set to 1 (enabling time gate scheduling) before any administrative gate control list can be configured.
30-0 —	Reserved

53.4.6.8.22 Port time gate scheduling advance time offset register (PTGSATOR)

Offset

Register	Offset
PTGSATOR	120h

Function

This is the port time gate scheduling advance time offset register.

NOTE

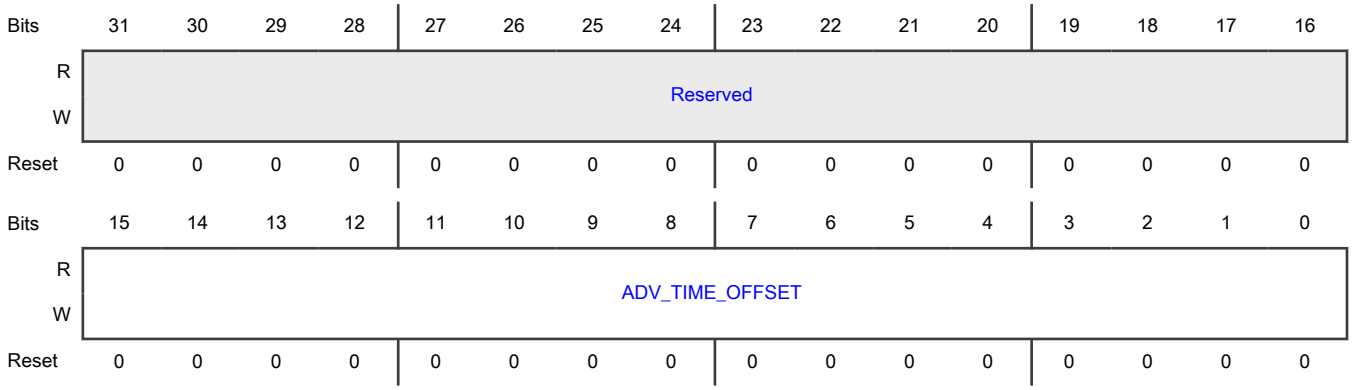
The function will sample the value in this register when PCIe Memory Access bit is set (0b1).

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_PORT	PTGSATOR	—
ENETC1_PORT	PTGSATOR	—
SW0_PORT0	—	PTGSATOR
SW0_PORT1	—	PTGSATOR
SW0_PORT2	—	PTGSATOR
SW0_PORT3	—	PTGSATOR
SW0_PORT4	—	PTGSATOR

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 ADV_TIME_OFFSET	Advance time offset This field specifies the amount of time to advance the IEEE 1588 time scale used by the time-based scheduler, to adjust for the latency encountered across the MAC plus if needed, delays outside of NETC (e.g. PHY delay). The time is specified in units of nanoseconds. The time value specified in this register advances both, the IEEE 1588 time scale used at the frame scheduling timing point (entry point of the time-based scheduler) and the IEEE 1588 time scale used at the point where frames are transferred to the MAC, which is implemented by a timestamp-based shaper (exit point of the time-based scheduler). Note that the IEEE 1588 time scale used by the time-based scheduler at the frame scheduling timing point, is also advanced, by the amount of time specified in S0TGSLR[MIN_LOOKAHEAD] for the switch and in E*a*TGSLR[MIN_LOOKAHEAD] for ENETC, to adjust for the time required to schedule, dequeue and for ENETC to load (or DMA) frames from the host memory to NETC internal memory. Advanced times specified respectively in S0TGSLR/E*a*TGSLR[MIN_LOOKAHEAD] and in PTGSATOR[ADV_TIME_OFFSET] are cumulative, at the frame scheduling timing point; i.e. the IEEE 1588 time scale used by the frame scheduling timing point (entry point of the time-based scheduler) on a given port. That is, the time reference at the frame scheduling point will be advanced by the amount of time resulting from adding the S0TGSLR/E*a*TGSLR[MIN_LOOKAHEAD] time to the PTGSATOR[ADV_TIME_OFFSET] time.

53.4.6.8.23 Port time gate scheduling hold advance register (PTGSHAR)

Offset

Register	Offset
PTGSHAR	124h

Function

This is the port time gate scheduling hold advance register

NOTE

SW0_PORT3	PTGSHAR	—
SW0_PORT4	—	PTGSHAR

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HOLDADVANCE															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15-0 HOLDADVANCE	This field indicates the amount of time prior to the Set-And-Hold-MAC time slot for asserting the Hold. The time is expressed in units of nanoseconds. This time interval corresponds to the transmission of the worst case (longest) fragment length that cannot be preempted plus associated physical layer overheads. For preemption, IEEE defines a minimum final fragment size of 64 bytes and allows the minimum non-final fragment size to be 64, 128, 192, or 256 bytes. For example, with a non-final fragment size of 64 bytes, a fragment that is 123 or fewer bytes in length cannot be preempted, because the non-final fragment would

Table continues on the next page...

Table continued from the previous page...

Field	Function
	be less than 64 bytes (60 bytes + 4 bytes for mCRC). The minimum non-final fragment size is configured in MAC_MERGE_MMCSR[RAFS]. Thus in the case, where MAC_MERGE_MMCSR[RAFS] is set to 64 bytes, meaning that the worst case (longest) fragment length that cannot be preempted is 123 bytes, the time for asserting the hold, would be set to 163 bytes transmission time prior to start the Set-And-Hold-MAC time slot; 20 bytes (IFG, preamble, SFD) + 123 bytes (non-preemptable fragment) + 20 bytes (IFG, preamble, SFD). The value reported in this field is 163 + 64 * MAC_MERGE_MMCSR[RAFS] byte time at PCR[PSPEED]. Note that this value doesn't account for any latency encountered in the MAC and MAC merge sublayer. Software needs to read PTGSATOR[ADV_TIME_OFFSET] and PTGSHCR[HOLD_SKEW]) to determine the latency adjustment across the MAC and MAC Merge layer.

53.4.6.8.24 Port time gate scheduling release advance register (PTGSRAR)

Offset

Register	Offset
PTGSRAR	128h

Function

This is the port time gate scheduling release advance register

Fields

Field	Function
31-20 —	Reserved
19-0 HOLD_SKEW	Hold-Skew in nanoseconds. This field specifies the amount of time to advance the IEEE 1588 time scale used in the transmit processing pipeline at the point where Hold/Release signal is asserted to the MAC merge sublayer. The time is specified in units of nanoseconds. This field is used to account for Hold/Release delay from the MAC client to the MAC merge sublayer plus if needed, frame delays outside of NETC (e.g. PHY delay). Note that if this field accounts for frame delays outside NETC, these delays must also be accounted in the same manner (same value) in PTGSATOR[ADV_TIME_OFFSET].

53.4.6.8.26 Port frame preemption configuration register (PFPCR)

Offset

Register	Offset
PFPCR	134h

Function

The port frame preemption configuration register enables the feature associated with the traffic class.

Fields

Field	Function
31-16 —	Reserved
15 SMREDR	Shared Memory Resource Exhaustion Discard Reason. Occurs if Ethernet Tx I/F (or Tx MAC client) cannot allocate a memory resource when modifying the frame. Cleared when written to 1.
14 SQRDDR	Egress Stream Sequence Recovery Duplicate Discard Reason Occurs if packet's sequence_number is a duplicate applies for either Match or Vector Recovery Algorithm). Cleared when written to 1.
13 SQRRDR	Egress Stream Sequence Recovery Rogue Discard Reason Occurs if a packet is discarded by the vector recovery algorithm because its sequence number has fallen outside of the recovery history window. Cleared when written to 1.
12 —	Reserved
11 SQRTNSQDR	Egress Stream Sequence Recovery Take No Sequence Discard Reason Occurs if the sequence recovery function discards a frame because it is tagless and ESQA_TGT_EID[SQR_TNSQ]=0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	A frame is considered tagless if it has no sequence tag, or if ESQA_TGT_EID[SQ_TAG] is not 0 and the tag type in the frame does not match the tag type specified in ESQA_TGT_EID[SQ_TAG]. Cleared when written to 1.
10 INVEQDR	Invalid Enqueue Port or Queue Discard Reason. Occurs if an enqueue is attempted to an invalid switch port or ETM class queue. Cleared when written to 1.
9 ITEDR	Invalid Table Entry Discard Reason. Occurs if • Table entry reference is not valid (i.e: was not allocated) • Table entry ID is outside of its table allocation range Cleared when written to 1.
8 QCONGDR	Queue Congestion Discard Reason Occurs if a frame is dropped because it couldn't be enqueued to an Egress Traffic Management (ETM) class queue. Cleared when written to 1. **NOTE** Each ETM class *a* set of queue also has a discard related counts.
7 MSDUEDR	Egress Maximum Service Data Unit Exceeded Discard Reason Occurs if store-and-forward frame is greater than the port Traffic Class's configured Maximum SDU size. Refer to PTC*a*TMSDUR. Cleared when written to 1.
6 TXDISEDR	Transmit Disable prior to Enqueue to ETM Discard Reason due to Port being in a Transmit disabled state (POR[TXDIS]=1). Cleared when written to 1.
5 FMMDR	Frame Modification Misconfiguration Discard Reason Software Misconfiguration due to: • Invalid frame header modification (i.e: delete a VLAN which is not present, ...) • Action to delete more payload bytes than amount of payload available in the frame. • Frame size plus modifications is greater than 16383 bytes. Cleared when written to 1.
4 TGSFTLDR	Time Gate Scheduling Frame Too Large Discard Reason Time Gate scheduling is enabled, and the frame was discarded because one of the following conditions was encountered:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The frame was too large to transmit during any gate-open interval. • There were no gate-open intervals for that traffic class in the entire operational gate control list; its gate was closed in every entry of the operational gate control list. Cleared when written to 1.
3 —	Reserved
2 PEDR	Parity Error Discard Reason Frame is discarded due to a parity error. Cleared when written to 1.
1 ECCEDR	ECC Error Discard Reason Frame is discarded due to unrecoverable ECC error detected while reading a table entry or frame from common memory. Cleared when written to 1.
0 TXDISDR	Transmit disable discard reason due to port being in transmit disabled state (POR[TXDIS]=1). This includes all frames flushed from Egress Traffic Management (ETM) class queues. Cleared when written to 1.

53.4.6.8.33 Port Tx discard count reason register 1 (PTXDCRR1)

53.4.6.8.35 Port traffic class a transmit maximum SDU register (PTC0TMSDUR - PTC7TMSDUR)

Offset

For a = 0 to 7:

Register	Offset
PTCaTMSDUR	208h + (a × 20h)

Function

This the port traffic class transmit service data unit register. It sets the maximum Service Data Unit (SDU, aka MTU) which determines the largest frame which can be sent, in the associated traffic class, on this port. Frames that exceed the limit are discarded. This limit must not exceed 0x07D0 (2000 bytes). Default is 1536 bytes.

Diagram

R W	MAXSDU															
Reset	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-25 —	Reserved
24 SF_MAXSDU_DIS	When cleared, the Tx Max SDU check is performed for Store and Forward frames. If the frame is greater than MAXSDU, it is discarded and counted in PTXDCR with discard reason of MSDUEDR. **NOTE** For Cut-Through frames, MAXSDU check is always performed.
23-18 —	Reserved
17-16 SDU_TYPE	Specifies the type of PDU/SDU (Protocol/Service Data Unit) whose length is being validated as seen on the link. 0: PPDU (Physical Layer PDU): Preamble, IFG, SFD along with MPDU. Not supported if cut-through frames are expected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1: MPDU: (MAC PDU): MAC Header, MSDU and FCS 2: MSDU (MAC SDU); MPDU minus 12B MAC Header and 4B FCS. Not supported if cut-through frames are expected. All other setting reserved. **NOTE** Overhead values are specified by register PTXSDUOR.
15-0 MAXSDU	Transmit Maximum SDU size in bytes (i.e: Max Frame size). When the frame is dequeued and the SDU size exceeds this value, the frame is discard and counted against Port Tx Discard Count Register (PTXDCR). **NOTE** For cut-through frames, this value is used as the presumptive maximum frame size.

53.4.6.8.36 Port transmit traffic class a credit based shaper register 0 (PTC0CBSR0 - PTC7CBSR0)

Offset

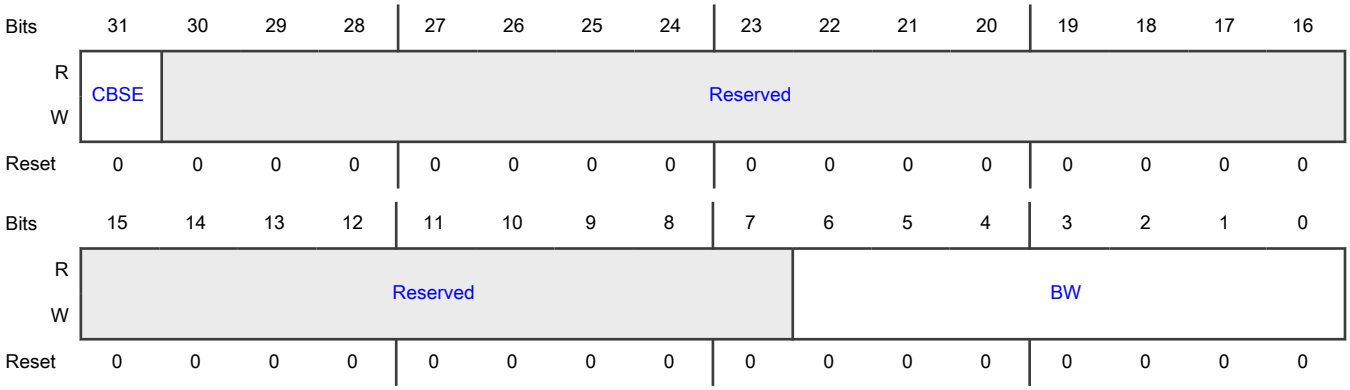
For a = 0 to 7:

Register	Offset
PTCaCBSR0	210h + (a × 20h)

Function

The port transmit traffic class credit based shaper register 0 is used to enable the credit-based shaper with the specification of the maximum bandwidth available to the traffic class.

Diagram



Fields

Field	Function
31 CBSE	Credit Based Shaper Enable Enables and disables the credit based shaper. 0b - Disabled 1b - Enabled
30-7 —	Reserved
6-0 BW	Bandwidth Bandwidth allocation is described in percentage units of the port transmit rate and ranging from 0-100 for the credit-based shaper. The sum of all traffic class credit-based shaper's bandwidth allocation cannot exceed 100. If there is an operational gate control list that is active, the bandwidth specified in this field only applies when the gate for the credit-based shaper traffic class, is open.

53.4.6.8.37 Port traffic class a credit based shaper register 1 (PTC0CBSR1 - PTC7CBSR1)

Offset

For a = 0 to 7:

Register	Offset
PTCaCBSR1	214h + (a × 20h)

Function

The port traffic class credit based shaper register 1 is used to specify the hiCredit parameter of the credit-based shaper.

Diagram

R W	HI_CREDIT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 HI_CREDIT	hicredit (in credit units) The maximum allowed accumulation of credits when conflicting transfers occur. This value represents the bursting capability of a class and should be set based on the traffic class number. Number of credits per bit is calculated as follows (NETC ClockFrequency / portTransmitRate) * 100 For example: • One AVB class (credit-based shaper enabled); highest priority traffic class • Bandwidth allocated to AVB class (idleSlope) is 70% of the port transmit rate • Port transmit rate: 1 Gbit/s • Maximum sized Ethernet frame: 2000 bytes hiCredit (bits) = maxSizedFrame * (idleSlope/portTxRate) hiCredit (bits) = 16 000 * 0.7 hiCredit (bits) = 11 200 hiCredit (credits) = 11 200 * (400*10^6*100) / 1*10^9 hiCredit (credits) = 448 000

53.4.6.8.38 Port time gate scheduling traffic class 1 status register (PTGSTC1SR)

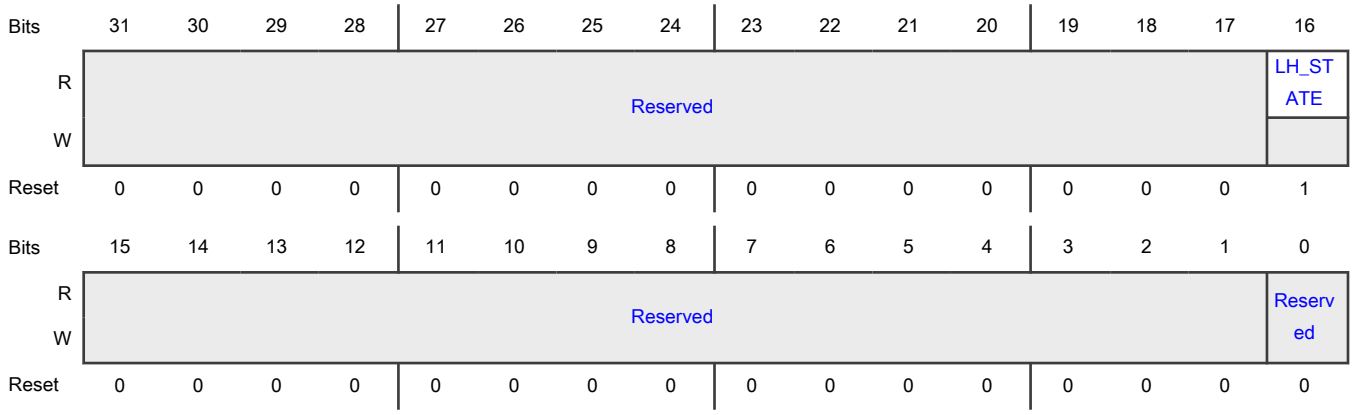
Diagram



Fields

Field	Function
31-30 —	Reserved
29 SRCPRND	Source Port Pruning Disable Disables and enables source port pruning. Source port pruning prevents a frame from being transmitted on the same port it was received from. 0b - Enabled 1b - Disabled
28 STAMVD	Station Move Disallow

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies whether a MAC station move is allowed. A MAC station move is an event detected by the MAC learning function where the source MAC address of a received frame is in the FDB table, but the port from which the frame was received is not set in its FDB entry Destination Port Bitmap. 0b - Allowed 1b - Disallowed. A received frame for which a MAC station move is detected, will be discarded.
27 BCASTE	Broadcast Storm Control Enable Enables and disables storm control for broadcast frames. The storm control rate policer used to limit broadcast frames is configured in BPSCR0. 0b - Disabled 1b - Enabled
26 MCASTE	Multicast Storm Control Enable Enables and disables storm control for multicast frames. The storm control rate policer used to limit multicast frames is configured in BPSCR1. 0b - Disabled 1b - Enabled
25 UMCASTE	Unknown Multicast Storm Control Enable Enables and disables storm control for unknown multicast frames. The storm control rate policer used to limit unknown multicast frames is configured in BPSCR1. 0b - Disabled 1b - Enabled
24 UUCASTE	Unknown Unicast Storm Control Enable Enables and disables storm control for unknown unicast frames. The storm control rate policer used to limit unknown unicast frames is configured in BPSCR0 0b - Disabled 1b - Enabled
23-16 —	Reserved
15-0 DYN_LIMIT	Dynamic Limit Specifies for a given port, the maximum number of dynamic entries in the FDB table. A value of 0 implies no limit except for maximum FDB dynamic entries allowed specified by FDBHTMCR[DYN_LIMIT]. Dynamic entries can be added by the hardware MAC learning function or by FDB table management command. In the case where the hardware MAC learning function cannot add a dynamic FDB entry due to this limit having been reached, the frame continues to be forwarded and BPMLFSR[BPMLLRFR] failure reason is set.

53.4.6.8.57 Bridge port default VLAN register (BPDVR)

Offset

R W	PCP			DEI	VID											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-27	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
26-25 TXTAGA	Transmit Bridge Port VLAN Tag Action This field applies only for a VLAN aware bridge, where the frame outer VLAN tag's VID is equal to the port default VID (VID field in this register). Note that the frame outer VLAN tag, is after any ingress frame modification actions (e.g. adding a port default "internal" VLAN header) have been logically applied, it is not necessarily the VLAN tag from the received frame. 0 No egress VLAN modification performed 1 Delete outer VLAN tag 2 Replace outer VLAN tag's VID with 0; frame to be transmitted as a priority tag frame. 3 Reserved **NOTE** Only applies if there is no Egress Treatment entry configured or if the frame modification entry ID configured in the Egress Treatment table entry is set to null.
24 RXVAM	Receive VLAN Aware Mode All frames to be forwarded using the 802.1Q bridge forwarding function must be a member of a VLAN, either assigned from the frame VLAN header or through the port default configuration. The VID assignment is dependent on the value entering in this field: 0 VLAN Aware: If the frame is untagged, an internal VLAN header is added to the frame using the VID, DEI, PCP and TPID from this register. If the frame has a VLAN header with VID=0 (priority tag), that VLAN header is internally modified to replace its VID with the VID from this register. This internal VLAN header is carried along with the frame in the form of ingress frame modification metadata actions (to be used later on to modify the actual frame when egressing out a port). However the VID from this internal VLAN header is used immediately for the subsequent VLAN operations. If any ingress frame modification actions have already been specified, one must ensure that the resulting ingress frame modification operation outputs the frame with a VLAN header. The VID from this resulting VLAN header is used for the subsequent VLAN operations. If the resulting ingress frame modification operation outputs an untagged frame, the frame is discarded. If the frame is tagged and no ingress frame modification actions have been specified, the assigned VID is taken from the frame's outer VLAN header. 1 VLAN Unaware: The VID from this register is assigned to the frame regardless of whether the frame is tagged or untagged, and this VID is used for subsequent VLAN operations.
23-20 RXTAGA	Receive Bridge Port Tag Acceptance Criteria xxx0 Discard untagged xxx1 Accept untagged xx0x Discard priority tagged xx1x Accept priority tagged x0xx Discard single tagged x1xx Accept single tagged 0xxx Discard double tagged

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1xxx Accept double tagged Frames discarded are counted against the bridge port discard count register (BPDCR) along with the setting of the Discard due to Bridge Port Acceptance Criteria Discard Reason (BPACDR) flag to 1 in the Bridge port discard count reason register 0 (BPDCRR0).
19-17 —	Reserved
16 TPID	Specifies the TPID value to be used to construct the internal VLAN header. 0 Standard C-VLAN 0x8100 1 Standard S-VLAN 0x88A8
15-13 PCP	Priority code point This field specifies the 3-bit PCP to be used to construct the internal VLAN header.
12 DEI	Drop eligible indicator This field specifies the 1-bit DEI to be used to construct the internal VLAN header.
11-0 VID	VLAN identifier Specifies the VID value to be used to construct or modify the internal VLAN header.

53.4.6.8.58 Bridge port spanning tree group state register (BPSTGSR)

Offset

Field	Function
	• Storm control Rate Policer Entry ID specified is outside the Rate Policer table size. • Storm control Rate Policer Entry ID is not found in the Rate Policer table (entry has not been added to the table) Reason cleared when written to 1.
11 UFMMDR	Untagged Frame Modification Misconfiguration Discard Reason Frame was discarded due to bridge port configured as VLAN aware with a non-null Ingress Frame Modification Entry ID (IFM_EID) resulting in the frame containing no VLAN headers, or with an outer priority tag (VID=0). Reason cleared when written to 1.
10 IPMFDR	IP Multicast Filter Discard Reason Frame was discarded due to a miss in L2 IPV4 Multicast Filter table. Reason cleared when written to 1.
9 NODESTDR	No Destination Discard Reason L2 forwarding decision resulted in discarding the frame since it resulted in no destination. Following are the possible causes: • Forwarding entry (FDB or L2 IPV4 Multicast Filter) has a destination with null bitmap • Source port pruning where destination bitmap containing only the incoming port. • Spanning tree group output port state not set to 2 (forwarding), resulting in a null destination port bit map. Reason cleared when written to 1.
8 MACFDDDR	MAC Forwarding Default Discard Reason Occurs if MFO = 3 (FDB lookup is performed, and if there is no match, the frame is discarded), MFO is settable by BPCR and VLAN Filter Table Entry. Reason cleared when written to 1.
7 STAMVDDR	Station Move Disallowed Discard Reason Occurs if STAMVD=1 and Source MAC found in FDB with port not matching received port. STAMVD is settable by BPCR and Ingress Stream table entry. The Station Move Disallowed Discard reason has a highest precedence level than the Ingress STG State Discard reason. If both discard reasons are encountered for a given frame, the Station Move Disallowed Discard reason will be reported. Reason cleared when written to 1.
6-4 —	Reserved
3	MAC Learn Not Found Discard Reason

Table continues on the next page...

Table continued from the previous page...

Field	Function
MACLNFDR	Occurs if VFHTDECR2[MLO] or VLAN Filter Table Entry's MLO = 5 (Disable MAC learning with SMAC validation). Reason cleared when written to 1.
2 BPVFLTDR	VLAN Filter (Port VLAN Membership) Discard Reason Occurs when VID (after ingress frame modification if applicable) received is not a member of this port. Reason cleared when written to 1.
1 ISTGSDR	Ingress STG State Discard Reason Occurs if port's STG State is Disabled or Learning. Reason cleared when written to 1.
0 BPACDR	Discard due to Bridge Port Acceptance Criteria Discard Reason Frame was discarded because it failed the Bridge Port Tag Acceptance Criteria. See BPDVR[RXTAGA]. Reason cleared when written to 1.

53.4.6.8.64 Bridge port discard count reason register 1 (BPDCRR1)

Offset

Register	Offset
BPDCRR1	58Ch

Function

This is the bridge port discard count reason register 1.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_PORT	—	BPDCRR1
ENETC1_PORT	—	BPDCRR1
SW0_PORT0	BPDCRR1	—
SW0_PORT1	BPDCRR1	—
SW0_PORT2	BPDCRR1	—

Fields

Field	Function
31-28 TT	Table type which caused the discard. 0 None 1 VLAN Filter table 2 FDB table 3 L2 IPV4 Multicast Filter table - Any Source Multicast (ASM) 4 L2 IPV4 Multicast Filter table - Source Specific Multicast (SSM) 5 Rate Policer table due to storm control 6-15 Reserved Reason cleared when written to 1.
27 —	Reserved
26-0 ENTRYID	Entry ID who last incremented Discard Count. Field represents the entry ID when the frames is discarded for any of the following reasons: BPVFLTDR, STAMVDDR, STRMCTRLDR, MISCDR. Reason cleared when written to 1.

53.4.6.8.65 Bridge port MAC learning failure status register (BPMLFSR)

Offset

Register	Offset
BPMLFSR	590h

Function

This is the bridge port MAC learning failure status register. A MAC learning failure is not reported if the frame is discarded on ingress.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_PORT	—	BPMLFSR
ENETC1_PORT	—	BPMLFSR
SW0_PORT0	BPMLFSR	—

Fields

Field	Function
31 MG	Magic Packet detection enable. 0 Normal operation or magic packet mode has exited with reception of a valid magic packet 1 All received frames are searched for the magic packet pattern.
30 TS_MODE	Transmit timestamp mode 0 Use synchronized ns time

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1 Use free running time
29 —	Reserved
28 RX_FLUSH	Ingress flush enable 0 Rx flush is not enabled 1 Rx flush is enabled. The MAC will immediately stop receiving line data and will flush the Rx pipeline out through the Rx FIFO with Rx error flag set. The MAC will stop receiving new packets until this bit is cleared. **NOTE** This operation does not require active Rx interface clocks.
27 —	Reserved
26 SWR	Software Reset. Self clearing bit. 1 Resets all statistic counters as well as the transmit and receive FIFOs. It should be issued after all traffic has been stopped as a result of clearing the rx/tx enable bits.
25 —	Reserved
24 —	Reserved
23 TX_LOWP_ENA	Transmit Low Power Idle Enable. Transmit low power idle is not supported in RMII mode or on MAC 1. When preemption is enabled, ensure that MAC 1 is idle (see PM1_IEVENT[TX_EMPTY]) before enabling the LPI on MAC 0. 0b - (default), the MAC operates in normal mode. 1b - The MAC completes the transmission of the current Frame and generates Low Power Idle Sequences to the line. It is advised to inspect IEVENT[TX_EMPTY] is set before enabling the LPI.
22 TX_FLUSH	Tx flush Egress Flush Enable. If set to 0b1, the MAC reads out the Tx FIFO and drops the data (data is not sent out on the line). If a frame is being transmitted when Tx flush is set to 1, the frame is aborted with an invalid FCS.
21-20 —	Reserved
19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
18 HD_FCEN	Half Duplex Flow Control Enable 0 Half duplex flow control is disabled 1 Half duplex flow control is enabled
17 —	Reserved
16 —	Reserved
15 TXP	Enable padding of frames in transmit direction (1, default). 0 - The MAC will not extend frames from the application to a minimum of 64 octets, allowing transmit of short frames (violating the Ethernet minimum size requirement). 1 - For any frames from the application which are less than 64 octets, the MAC will pad with 0s as needed to extend to 60 octets and append 4 octets of FCS. If the application is configured for user-generated or preserved CRC, the MAC will append the required padding bytes after the original FCS.
14 TS_PNT	Timestamp Point 0 Timestamp is captured based on SFD detect at boundary of MAC merge layer and pins/protocol gaskets. 1 Timestamp is captured based on PHY SFD detect pulse on Rx and Tx for 2-step timestamping. For 1-step timestamping, timestamp is captured at MAC merge layer pin/protocol gasket boundary regardless of this setting.
13 CNT_FRM_EN	Control frame reception enable 0 All control frames which are not PAUSE (opcode 0x0001) are discarded. 1 All control frames which are not PAUSE are forwarded to the user application.
12-11 LPBK_MODE	Loopback mode 0 MAC merge loopback using external Tx clock. The MAC Tx data post merge is looped back. If preemption is enabled on the port, both EMAC and PMAC should be in loopback mode. The external Tx clock for the selected interface must be running in this mode. 1: Reserved 2 MAC merge loopback using internal Tx clock. The MAC Tx data post merge is looped back. If preemption is enabled on the port, both EMAC and PMAC should be in loopback mode. The external Tx clock for the selected interface may be inactive in this mode. The target throughput per interface is as follows: XGMII - 10 Gbps SGMII - 2.5 Gbps GMII - 1 Gbps RGMII - 1 Gbps / 100 Mbps / 10 Mbps MII - 100 Mbps / 10 Mbps

Table continues on the next page...

Table continued from the previous page...

Field	Function
	RMII - 100 Mbps / 10 Mbps **NOTE** The target throughput rates will not be exactly matched for all device operating frequencies. For target rates of 1G/100M/10M, and given the operating frequency, f, the actual loopback throughput can be computed as follows: Actual = (Target * int($16*10^9$/f) * f) / $16*10^9$ For target rates of 2.5G/10G, and given the operating frequency, f, the actual loopback throughput can be computed as follows: Actual = (Target * int($16*10^9$/f * f * 3.2) / ($16*10^9$ * 3.1875) 3 Reserved
10 LOOP_ENA	Loopback enable 0 Configured for normal (non-loopback) operation. 1 Configured for internal loopback mode. Interface Tx clock must be running for internal loopback mode
9 TX_ADDR_INS	Transmit source MAC address insertion 0 MAC transmits the source MAC address unmodified from user application. 1 MAC overwrites the source MAC address with the MAC programmed address (PM*a*_MAC_ADDR_0/1).
8 PAUSE_IGN	Ignore PAUSE frame quanta 0 MAC stops transmit process for the duration specified in the PAUSE frame quanta of a received valid PAUSE frame. 1 MAC ignores received PAUSE frames.
7 PAUSE_FWD	Terminate/forward received PAUSE frames 0 MAC terminates received valid PAUSE frames. 1 MAC forwards received valid PAUSE frames to the user application.
6-2 —	Reserved
1 RX_EN	MAC receive path enable 0 MAC receive path is disabled 1 MAC receive path is enabled.
0	MAC transmit path enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TX_EN	0 MAC transmit path is disabled 1 MAC transmit path is enabled.

53.4.6.9.3 Port MAC a MAC Address Register 0 (PM0_MAC_ADDR_0 - PM1_MAC_ADDR_0)

Offset

Register	Offset
PM0_MAC_ADDR_0	Ch
PM1_MAC_ADDR_0	40Ch

Function

This is the port's MAC address register 0 which is used for transmit PAUSE frame generation and receive magic packet detection.

NOTE

This value is taken directly from the port PMAR0 register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	MAC_ADDR_0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MAC_ADDR_0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 MAC_ADDR_0	MAC address 0 This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset (register bit offset 0-7). This field contains the 4 most significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PM*a*_MAC_ADDR_0 equals 14131211h.

53.4.6.9.4 Port MAC a MAC Address Register 1 (PM0_MAC_ADDR_1 - PM1_MAC_ADDR_1)

Offset

Register	Offset
PM0_MAC_ADDR_1	10h
PM1_MAC_ADDR_1	410h

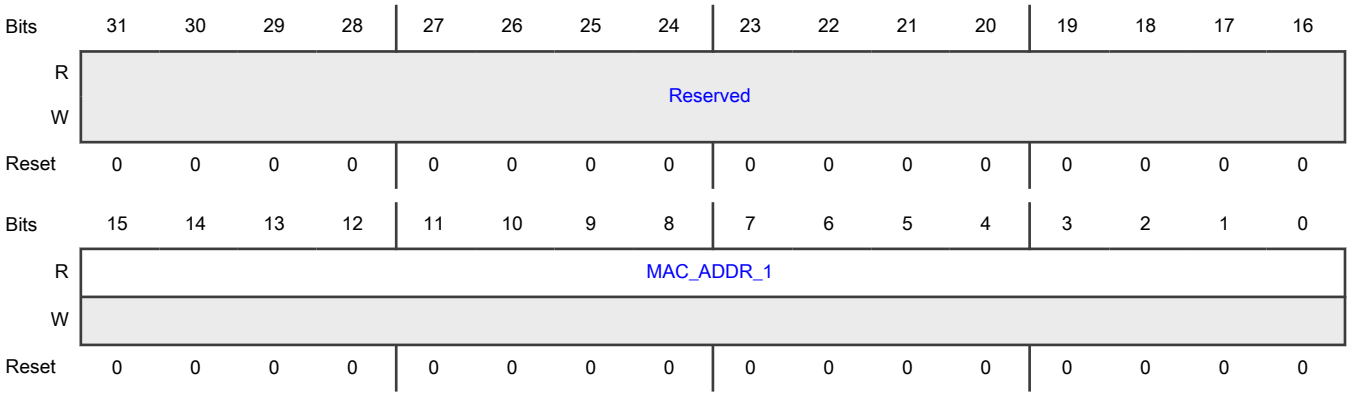
Function

This is the port's MAC address register 0 which is used for transmit PAUSE frame generation and receive magic packet detection.

NOTE

This value is taken directly from the port PMAR1 register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 MAC_ADDR_1	MAC address 1 This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 2 least significant bytes of the MAC address (least significant byte is stored in register bit offset 8-15). For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then PM*a*_MAC_ADDR_1 equals xxxx1615h (where x should be set to 0).

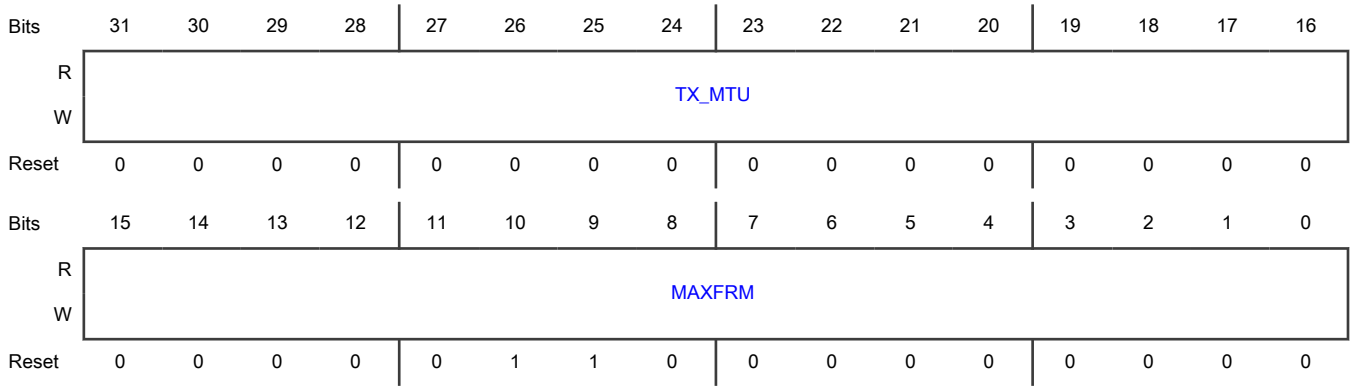
53.4.6.9.5 Port MAC a Maximum Frame Length Register (PM0_MAXFRM - PM1_MAXFRM)

Offset

Register	Offset
PM0_MAXFRM	14h
PM1_MAXFRM	414h

Function
MAC Maximum Frame Length Register

Diagram



Fields

Field	Function
31-16 TX_MTU	Maximum transmit frame length Specifies the different maximum length on transmit. It is used for statistical purposes, see T1523Xn counter (etherStatsPkts1523toXn), and to check for frame size error during transmit. Note that when a frame exceeds this stated maximum, the frame is not dropped. When set to 0 MAXFRM is used instead which is also the default setting.
15-0 MAXFRM	Maximum supported received frame length. The MAC supports reception of any frame size up to 2,000 bytes (0x07D0). Typical settings are 0x05EE (1,518 bytes) for standard untagged frames. Default setting is 0x0600 (1,536 bytes). Received frames that exceed this stated maximum are truncated.(A truncated frame which is anyway corrupted can be in the range of (MAXFRM+4) to (MAXFRM-7). When not using crc forwarding a truncated frame can be in the range of MAXFRM to (MAXFRM-7)).

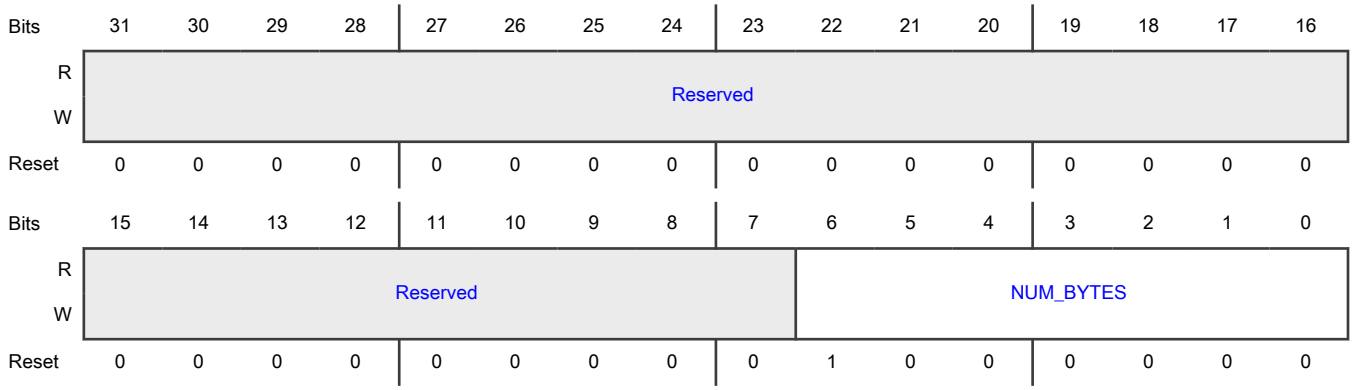
53.4.6.9.6 Port MAC a Minimum Frame Length Register (PM0_MINFRM - PM1_MINFRM)

Offset

Register	Offset
PM0_MINFRM	18h
PM1_MINFRM	418h

Function
MAC Minimum Frame Length Register

Diagram



Fields

Field	Function
31-7 —	Reserved
6-0 NUM_BYTES	Receive Minimum Frame Length size in bytes. Received frames greater than or equal to 18B and less than this value are discarded. Received frames shorter than 18B are discarded silently. The discarded frame count is reported in PM*a*_RUNDn stat register **NOTE** Frame includes MAC Header, payload and FCS. Setting the minimum frame length below 64B requires either full duplex or collision free half-duplex operation.

53.4.6.9.7 Port MAC 0 Internal MDIO Configuration Register (PM0_MDIO_CFG)

Offset

Register	Offset
PM0_MDIO_CFG	30h

Function

Internal MDIO is used to access RevMII registers.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

Fields

Field	Function
31 BUSY	MDIO busy bit. The state of this bit is also reflected in MDIO_CFG[BSY]. 0 MDIO_DATA[MDIO_DATA] contains valid read data. 1 MDIO write transaction in progress; MDIO_DATA[MDIO_DATA] data is invalid.
30-16 —	Reserved
15-0 MDIO_DATA	16-bit MDIO data. Writing to this register initiates a write transaction to the PHY. For proper operation, the MDIO_CTL register must have been initialized first. The MDIO_CFG[BUSY] status bit is set immediately and cleared when the write transaction has completed. Reading this register returns data read from the PHY register specified in MDIO_CTL after a read transaction has completed. Read transactions are initiated by writing a 1 to MDIO_CTL[READ] or MDIO_CTL[POST_INC]. Read data is invalid if MDIO_CFG[BUSY] is set.

53.4.6.9.10 Port MAC a Interrupt Event Register (PM0_IEVENT - PM1_IEVENT)

31-29 —	Reserved
28 MRG_AERR	MAC merge frame assembly error event The count register for this error is the MAC Merge Frame Assembly Error Count Register (MAC_MERGE_MMFAECR).
27 MRG_SERR	MAC merge frame SMD error received event The count register for this error is the MAC Merge Frame SMD Error Count Register (MAC_MERGE_MMFSECR).
26-24 —	Reserved
23 SPD_DUP	Speed/Duplex Change 0 No speed/duplex change detected 1 Speed/Duplex change detected for RGMII or serial modes.
22 RX_CSD	Rx Clock Stop Detection 0b - Rx clock is running

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Rx clock has stopped. This flag is set if the Rx clock for the selected interface becomes inactive for 64 byte times. This flag is not set when Rx is disabled (PMa_COMMAND_CONFIG[RX_EN] = 0). **NOTE** For RGMII, this flag is not set when the Rx clock is stopped due to low power idle clock stop mode.
21 TX_CSD	Tx Clock Stop Detection 0b - Tx clock is running 1b - Tx clock has stopped. This flag is set if the Tx clock for the selected interface becomes inactive for 64 byte times. This flag is not set when Tx is disabled (PMa_COMMAND_CONFIG[TX_EN] = 0). **NOTE** For RGMII, this flag is not set when the Tx clock is stopped due to low power idle with clock stop mode enabled (PMa_IF_MODE[CLK_STOP] = 1).
20-15 —	Reserved
14 MGI	Magic packet detection indication event 0 Magic packet was not detected. 1 Magic packet was detected when PM*a*_COMMAND_CONFIG[MG] was set. PM*a*COMMAND_CONFIG[MG] is cleared upon magic packet detection.
13 —	Reserved
12 RX_OVFL	Receive FIFO overflow event. 0 The receive FIFO has not overflowed. 1 The receive FIFO overflowed. RxFIFO overflow is a non-fatal error.
11 TX_UNFL	Transmit FIFO underflow event. 0 The transmit FIFO has not underflowed. 1 The transmit FIFO underflowed. TxFIFO underflow is a non-fatal error.
10 TX_OVFL	Transmit FIFO overflow event. 0 The transmit FIFO has not overflowed. 1 The transmit FIFO overflowed. TxFIFO overflow is a fatal error and requires FLR to recover normal operation.
9-7	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
6 RX_EMPTY	Receive idle event 0 Rx is not idle: Rx fifo not empty or Rx packet receive in process 1 Rx is idle: Rx fifo is empty and no Rx packet receive in process.
5 TX_EMPTY	Transmit fifo empty event 0 TxFIFO is not empty 1 TxFIFO is empty. To ensure Tx is idle, wait 64 byte time after TX_EMPTY asserts.
4 —	Reserved
3-0 —	Reserved

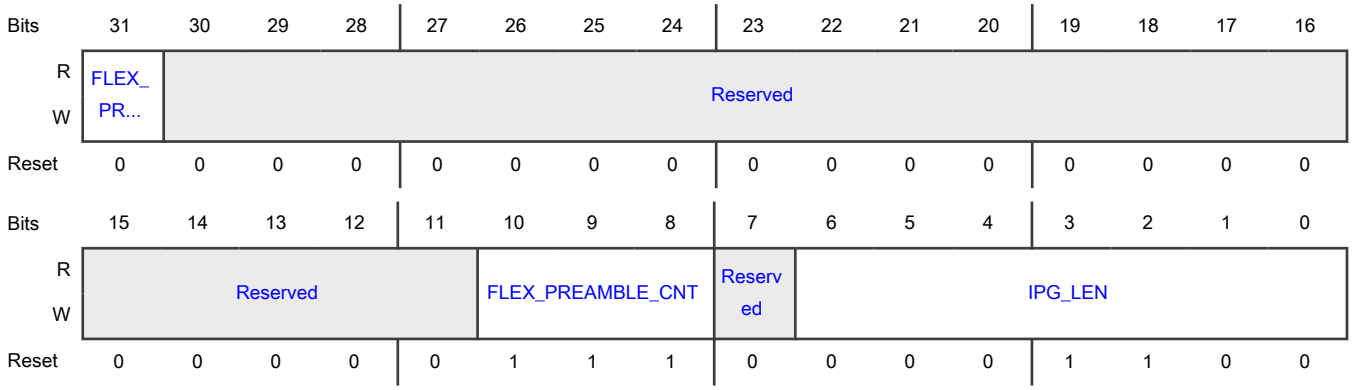
53.4.6.9.11 Port MAC a Transmit Inter-Packet Gap Length and Flexible Preamble length Register (PM0_TX_IPG_PREAMBLE - PM1_TX_IPG_PREAMBLE)

Offset

Register	Offset
PM0_TX_IPG_PREAMBLE	44h
PM1_TX_IPG_PREAMBLE	444h

Function
MAC Transmit Inter-Packet Gap Length and Preamble Length Control Register

Diagram



Fields

Field	Function
31 FLEX_PREAMBLE_EN	Enable Flexible Preamble Count Enables the insertion of less than 7bytes of 8'h55 in the Preamble
30-11 —	Reserved
10-8 FLEX_PREAMBLE_CNT	Flexible Preamble Count When enabled, this field determines the number of bytes of 8'h55 sent out as part of preamble. Valid values are 1 to 7, with 7 being default **NOTE** Generated pause frames always have 7B of preamble, regardless of the setting of FLEX_PREAMBLE_CNT.
7 —	Reserved
6-0 IPG_LEN	Transmit inter-packet gap value. IPG_LEN represents the minimum number of octets between packets. Valid values are 4..24. The default of 0xC (12 octets) is required to conform to IEEE 802.3.

53.4.6.9.12 Port MAC a Interrupt Mask Register(INT_MASK) (PM0_IMASK - PM1_IMASK)

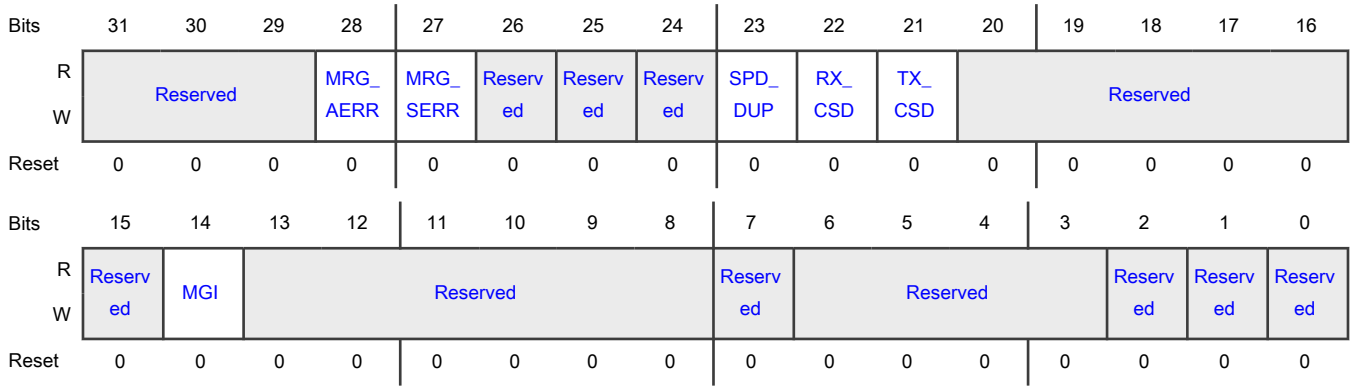
Offset

Register	Offset
PM0_IMASK	4Ch
PM1_IMASK	44Ch

Function

MAC Interrupt Mask Register(INT_MASK)

Diagram



Fields

Field	Function
31-29 —	Reserved
28 MRG_AERR	MAC merge frame assembly error event interrupt mask 0 masked 1 enabled
27 MRG_SERR	MAC merge frame SMD error received event interrupt mask 0 masked 1 enabled
26 —	Reserved
25 —	Reserved
24 —	Reserved
23 SPD_DUP	Speed/Duplex change event mask. 0 masked 1 enabled
22	Rx Clock Stop Detection

Table continues on the next page...

Table continued from the previous page...

Field	Function
RX_CSD	0 masked 1 enabled
21 TX_CSD	Tx Clock Stop Detection 0 masked 1 enabled
20-15 —	Reserved
14 MGI	Magic packet detection indication event mask. 0 masked 1 enabled
13-8 —	Reserved
7 —	Reserved
6-3 —	Reserved
2 —	Reserved

0 —	Reserved

53.4.6.9.13 Port MAC a Pause Quanta Register (PM0_PAUSE_QUANTA - PM1_PAUSE_QUANTA)

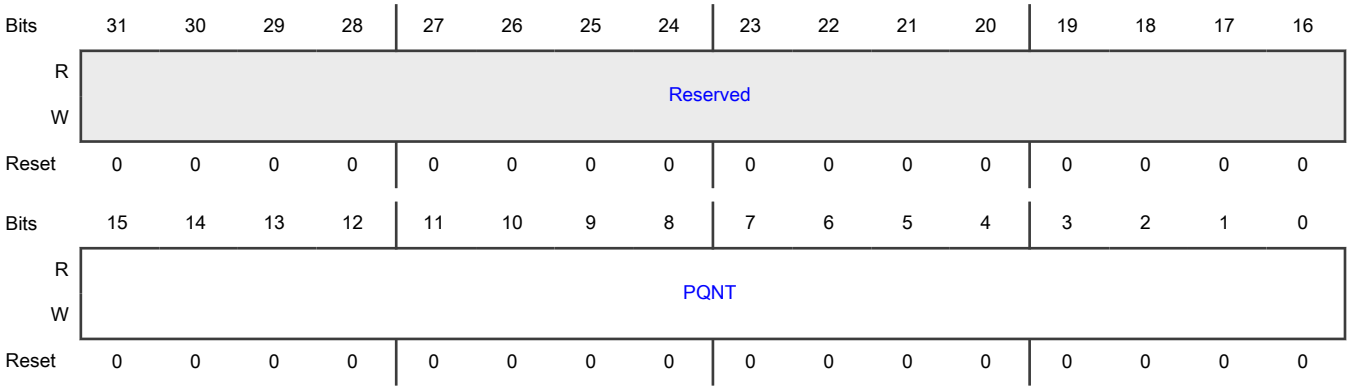
Offset

Register	Offset
PM0_PAUSE_QUANTA	54h
PM1_PAUSE_QUANTA	454h

Function

This is the port MAC pause quanta register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PQNT	Value to be used for the quanta value when XOFF is triggered.

53.4.6.9.14 Port MAC a Pause Quanta Threshold Register (PM0_PAUSE_THRESH - PM1_PAUSE_THRESH)

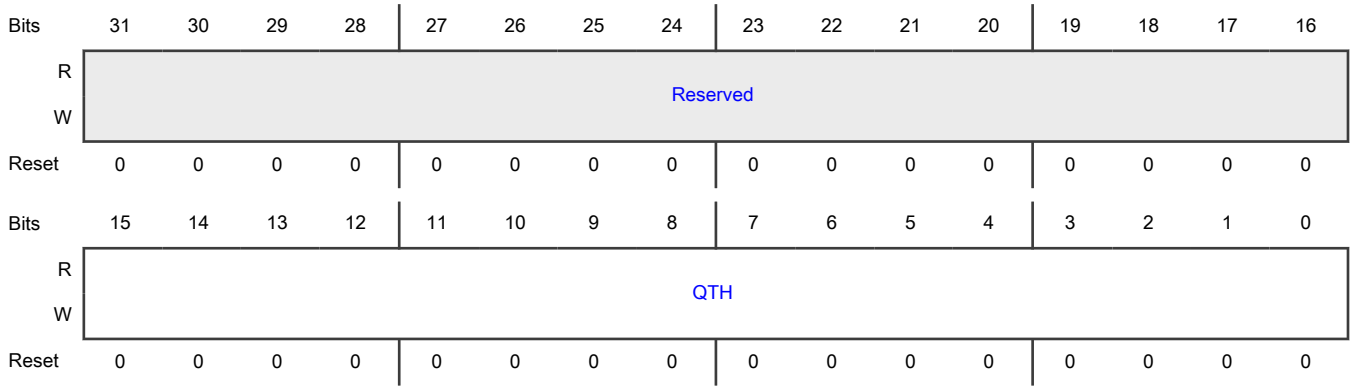
Offset

Register	Offset
PM0_PAUSE_THRESH	64h
PM1_PAUSE_THRESH	464h

Function

MAC Pause Quanta Threshold Register

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 QTH	Quanta threshold. When a quanta timer counts down and reaches this value, the MAC sends a refresh PAUSE frame with the programmed full quanta value if a pause condition still exists. Value must be greater or equal to 2 and less than PQNT. Since the refresh pause frame may be delayed by the transmission of an application frame always in progress, the recommended setting of QTH should take into account worst-case transmission delay to ensure the pause quanta does not expire before it can be refreshed.

53.4.6.9.15 Port MAC a Receive Pause Status Register (PM0_RX_PAUSE_STATUS - PM1_RX_PAUSE_STATUS)

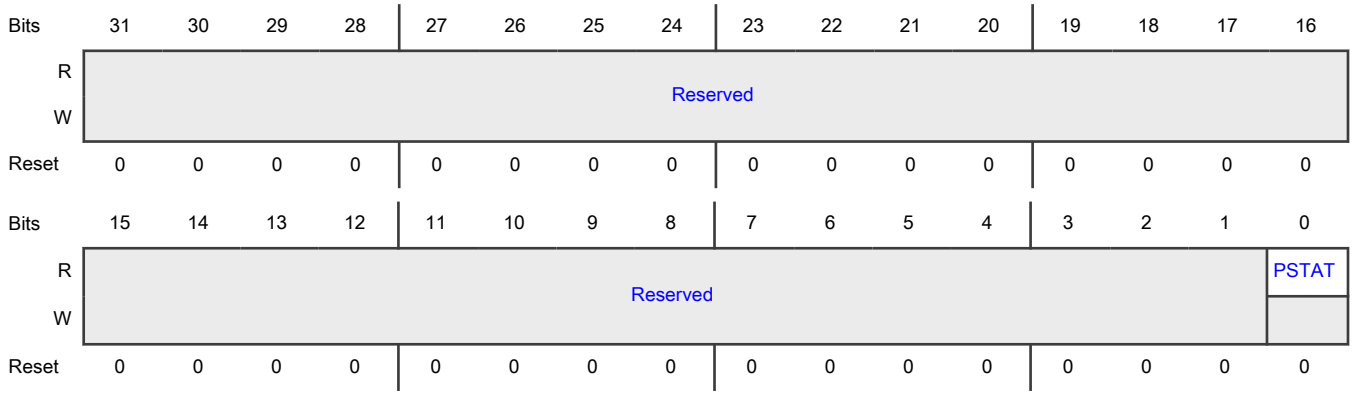
Offset

Register	Offset
PM0_RX_PAUSE_STATUS	74h
PM1_RX_PAUSE_STATUS	474h

Function

MAC Receive Pause Status Register

Diagram



Fields

Field	Function
31-1 —	Reserved
0 PSTAT	Pause status.

53.4.6.9.16 Port MAC a EEE Low Power Wakeup Timer Register (PM0_LPWAKE_TIMER - PM1_LPWAKE_TIMER)

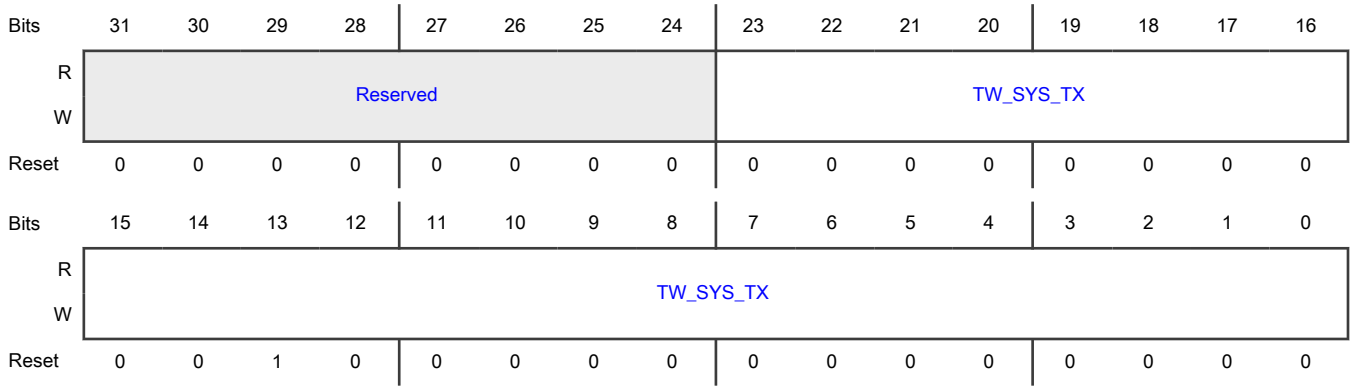
Offset

Register	Offset
PM0_LPWAKE_TIMER	B8h
PM1_LPWAKE_TIMER	4B8h

Function

MAC EEE Low Power Wakeup Timer Register

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 TW_SYS_TX	EEE System transmit wait time Defines the number of NETC cycles (which represents time) required by the PHY to wait before transmitting a new frame after the application has indicated it wants to end the low power state.

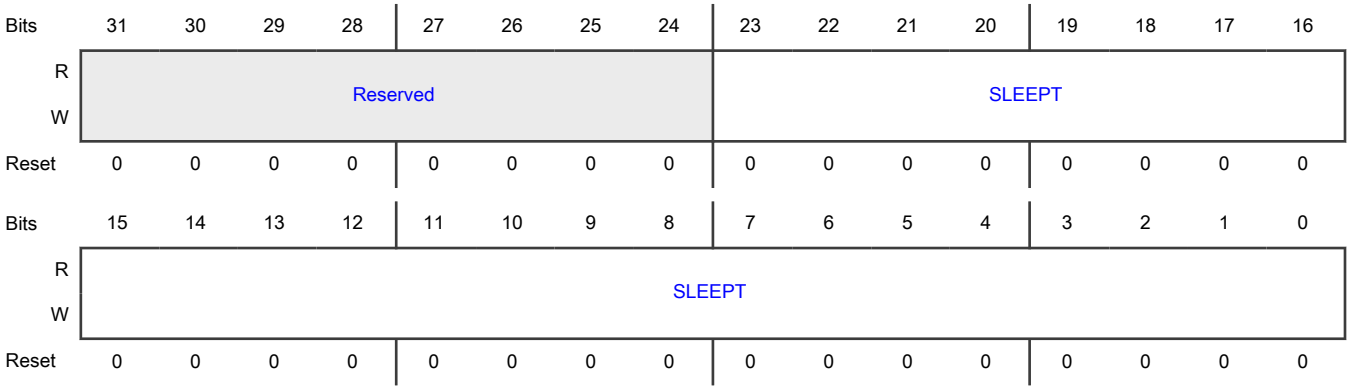
53.4.6.9.17 Port MAC a Transmit EEE Low Power Timer Register (PM0_SLEEP_TIMER - PM1_SLEEP_TIMER)

Offset

Register	Offset
PM0_SLEEP_TIMER	BCh
PM1_SLEEP_TIMER	4BCh

Function
MAC Transmit EEE Low Power Timer Register

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 SLEEPT	Defines the number of NETC cycles (which represents time) where Tx is idle before mac transmits low power EEE.A value of 0 does not activate low power EEE transmission.

53.4.6.9.18 Port MAC a IEEE1588 Single-Step Control Register (PM0_SINGLE_STEP - PM1_SINGLE_STEP)

Offset

Register	Offset
PM0_SINGLE_STEP	C0h
PM1_SINGLE_STEP	4C0h

Function
MAC IEEE1588 Single-Step Control Register

Diagram

R	Reserved				HD_BP_OFF_MIN											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0

Fields

Field	Function
31-28 —	Reserved
27-16 HD_BP_ON_MAX	Half-Duplex Back-Pressure On Maximum Maximum amount of time backpressure can stay asserted before stopping to prevent excess defer on link partner, in byte times. Per spec, maximum can be 3036 byte times (2*max basic frame size of 1518B).
15-12 —	Reserved
11-0 HD_BP_OFF_MIN	Half-Duplex Back-Pressure Off Minimum Minimum amount of time backpressure will stay off after reaching the ON max, before backpressure can reassert after checking if icm_pause_notification is still or again asserted, in byte times. Minimum is 20 byte times (normal IPG + normal preamble).

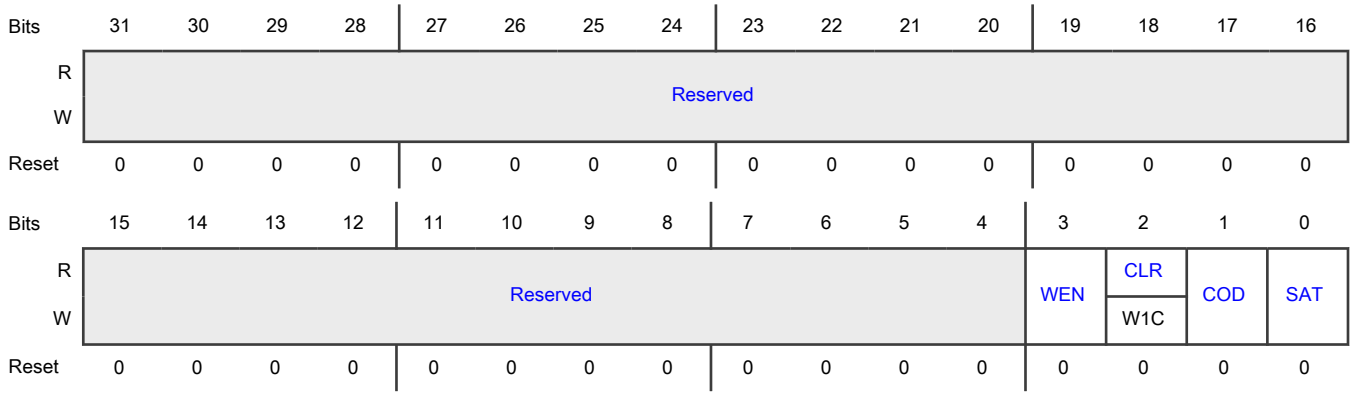
53.4.6.9.21 Port MAC a Statistics Configuration Register (PM0_STATN_CONFIG - PM1_STATN_CONFIG)

Offset

Register	Offset
PM0_STATN_CONFIG	E0h
PM1_STATN_CONFIG	4E0h

Function
MAC Statistics Configuration Register

Diagram



Fields

Field	Function
31-4 —	Reserved
3 WEN	Write enable for Tx/Rx stats registers 0 Attempted writes to Tx/Rx stats are ignored (default) 1 Writes to Tx/Rx stats are permitted
2 CLR	1 - all counters will be reset to 0. Note that this takes at least 32 NETC cycles. Self resetting bit, reads 0 always. The soft-reset from command config will also trigger this counter clear function.
1 COD	0 - (default) counters are not affected by read. 1 - a read to a counter resets it to 0.
0 SAT	0 - (default) counters are wrapping around 1- the counters saturate at the maximum value. Typically used in combination with CLR_ON_RD.

53.4.6.9.22 Port MAC a Receive Ethernet Octets Counter(etherStatsOctetsn) (PM0_REOCTn - PM1_REOCTn)

Offset

Register	Offset
PM0_REOCTn	100h
PM1_REOCTn	500h

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
63-0 ROVRn	Incremented for each packet which is larger than the maximum frame length specified in the MAXFRM(FRAME_LENGTH) register (excluding framing bits, but including FCS octets) received with a good frame check sequence.

Table continues on the next page...

Field	Function
	NOTE Packets received which are larger than the maximum length specified in PM0_MAXFRM are truncated at length=MAXFRM and forwarded immediately to the upper layers with FCS error. The Rx stats associated with this oversized packet are not updated until the actual end of packet is received by the MAC.

53.4.6.9.43 Port MAC a Receive Jabber Packet Counter Register(etherStatsJabbersn) (PM0_RJBRn - PM1_RJBRn)

R	RDRNTPn															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
63-0 RDRNTPn	Incremented for each fully dropped packet (not truncated) due to internal errors of the MAC client. Occurs when a receive FIFO overflows.

53.4.6.9.47 Port MAC a Receive Valid Small Packet Counter Register (PM0_RMIN63n - PM1_RMIN63n)

Offset

Register	Offset
PM0_RMIN63n	1D0h
PM1_RMIN63n	5D0h

Function

MAC Receive Packet Counter for Small Packets with valid CRC

Diagram

R	TERRn															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
63-0 TERRn	Transmit frame error count Incremented for each frame transmitted with an error (i.e. frame is transmitted with a bad FCS): • FIFO overflow error • FIFO underflow error • memory double ECC errors • Parity errors • late-collision or excessive collisions (half-duplex only) • Request by the Ethernet I/F Tx function to set the frame FCS field to a bad CRC value. Possible causes: end_of_frame receive errors for cut-through frames, internal faults

53.4.6.9.55 Port MAC a Transmit Unicast Frame Counter Register(ifOutUcastPktsn) (PM0_TUCAn - PM1_TUCAn)

Offset

Register	Offset
PM0_TUCAn	240h
PM1_TUCAn	640h

Function

MAC Transmit Unicast Frame Counter Register(ifOutUcastPktsn)

3 REVMII	Reverse Mode 0b - Reverse mode disabled - port is in MAC mode 1b - Reverse mode enabled - port is in PHY mode
2-0 IFMODE	Interface mode 001 - MII mode 010 - GMII mode 011 - RMII mode 100 - RGMII mode All other values reserved.

53.4.6.9.74 Port MAC Merge Control and Status Register (MAC_MERGE_MMCSR)

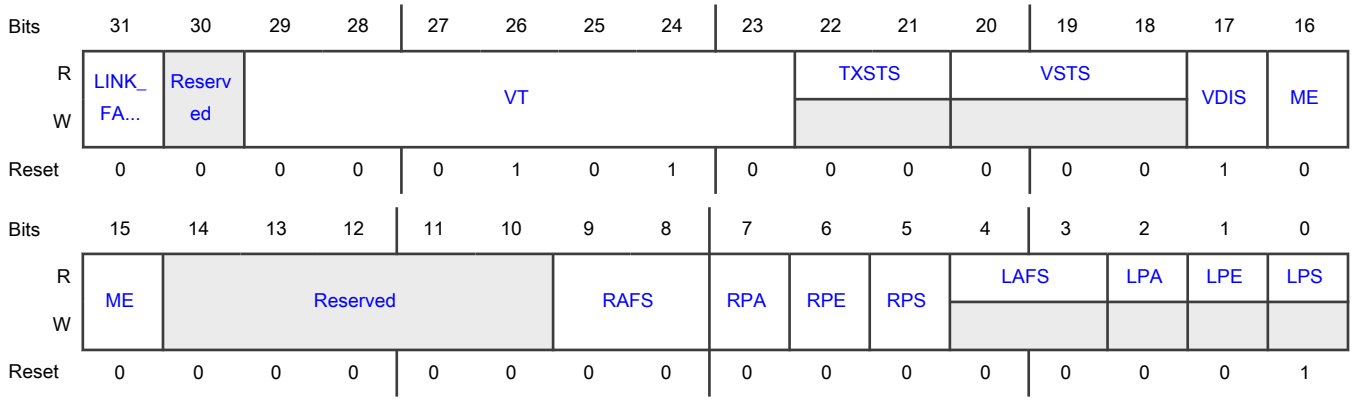
Offset

Register	Offset
MAC_MERGE_MMCSR	800h

Function

The individual fields in this register correspond to the capabilities necessary to claim conformance to the IEEE 802.3-2018 handling of interspersed express traffic.

Diagram



Fields

Field	Function
31 LINK_FAIL	Link Fail Software may set this bit to indicate to the mac merge layer that there has been a failure on the link. If set, the mac merge layer disables the preemption of frames. The mac merge layer will resume preempting frames if software subsequently sets this bit to 0.
30 —	Reserved
29-23 VT	Verify Time The value of this field defines the nominal wait time between verification attempts in milliseconds. Valid range is 1 to 127 inclusive. The default value is 10.
22-21 TXSTS	Merge status This read-only status field provides the state of the mac merge sublayer transmit status as defined in IEEE Std 802.3-2018 Clause 99. 00 Transmit preemption is inactive 01 Transmit preemption is active 10 Reserved 11 Reserved
20-18 VSTS	Verify status This read-only status field provides the state of the mac merge sublayer with respect to verification as defined in IEEE Std 802.3-2018 Clause 99. 000 Verification is disabled 001 Reserved 010 Verification is in progress 011 Verification was successful 100 Verification failed 101 Verification is in an undefined state 110 Reserved 111 Reserved
17 VDIS	Verify disabled Once enabled, the port must perform the verify process described in IEEE Std 802.3-2018 Clause 99 with the remote port. Verification should only be disabled for a closed system. In most systems, software should set this bit to a zero when setting MMCSR[ME]. Note: On start-up, software should wait for the verification process to complete (MMCSR[VSTS]=011) before initiating traffic.
16-15	Merge enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
ME	0 Frame preemption is not enabled 1: Frame preemption supported, transmit preempts frames on any byte boundary post the MinimumFragmentSize 2: Frame preemption supported, transmit preempts frames on 4B boundaries post the MinimumFragmentSize Preemption is disabled by default. Software must set this bit in order for preemption to occur. When 0, the mac merge layer will not preempt PMAC (MAC 1) frames. When set to 1, PMAC frames may be preempted by EMAC (MAC 0) frames.
14-10 —	Reserved
9-8 RAFS	Remote additional fragment size This writeable status field indicates the minimum size of non-final fragments supported by the remote port. The value is expressed in units of 64 octets of additional frame length. The minimum non-final fragment size is ((RAFS + 1) x 64 octets). This value indicates to the local preemption control block the smallest sized fragments that can be sent on TX. Can be used by software to store the value received by the Link Layer Discovery Protocol (LLDP) when receiving an Additional Ethernet Capabilities TLV.
7 RPA	Remote preemption active This writeable status bit indicates whether preemption is active for the remote port. Can be used by software to store the value received by the Link Layer Discovery Protocol (LLDP) when receiving an Additional Ethernet Capabilities TLV.
6 RPE	Remote preemption enabled This writeable status bit indicates whether preemption has been enabled for the remote port. Can be used by software to store the value received by the Link Layer Discovery Protocol (LLDP) when receiving an Additional Ethernet Capabilities TLV.
5 RPS	Remote preemption supported This writeable status bit indicates whether preemption capability is supported for the remote port. Can be used by software to store the value received by the Link Layer Discovery Protocol (LLDP) when receiving an Additional Ethernet Capabilities TLV.
4-3 LAFS	Local additional fragment size This read-only status field indicates the minimum size of non-final fragments supported by this port. The value is expressed in units of 64 octets of additional frame length. The minimum non-final fragment size is ((LAFS + 1) x 64 octets). This implementation is designed to be able to receive a minimum 64 octet fragment size. Write capability was added to this field to permit software to override the value sent to with the system. Can be used by the Link Layer Discovery Protocol (LLDP) when composing a Additional Ethernet Capabilities TLV.
2 LPA	Local preemption active

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This read-only status bit indicates whether preemption is active for this port. This bit will be set if preemption is both enabled and has completed the verification process. Can be used by the Link Layer Discovery Protocol (LLDP) when composing a Additional Ethernet Capabilities TLV. **NOTE** This bit may also read as 1 when preemption is enabled, but verification has failed. When composing a Additional Ethernet Capabilities TLV, this bit should qualified with successful verification status in VSTS. For example, LPA' = LPA && (VSTS == 3).
1 LPE	Local preemption enabled This read-only status bit indicates whether preemption has been enabled for this port. This bit is a reflection of the MMCSR[ME] control bit. Can be used by the Link Layer Discovery Protocol (LLDP) when composing a Additional Ethernet Capabilities TLV.
0 LPS	Local preemption supported This read-only status bit indicates whether preemption capability is supported for this port. This implementation supports preemption, so the value of the bit defaults to 1. Can be used by the Link Layer Discovery Protocol (LLDP) when composing a Additional Ethernet Capabilities TLV.

53.4.6.9.75 Port MAC Merge Frame Assembly Error Count Register (MAC_MERGE_MMFAECR)

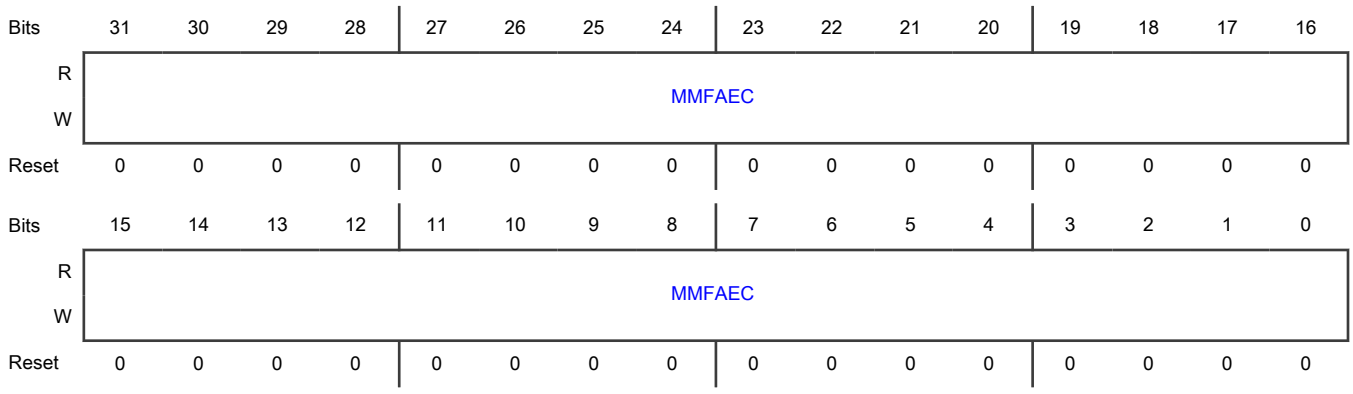
Offset

Register	Offset
MAC_MERGE_MMFAECR	808h

Function

A count of MAC frames with reassembly errors.

Diagram



Fields

Field	Function
31-0 MMFAEC	A count of MAC frames with reassembly errors.

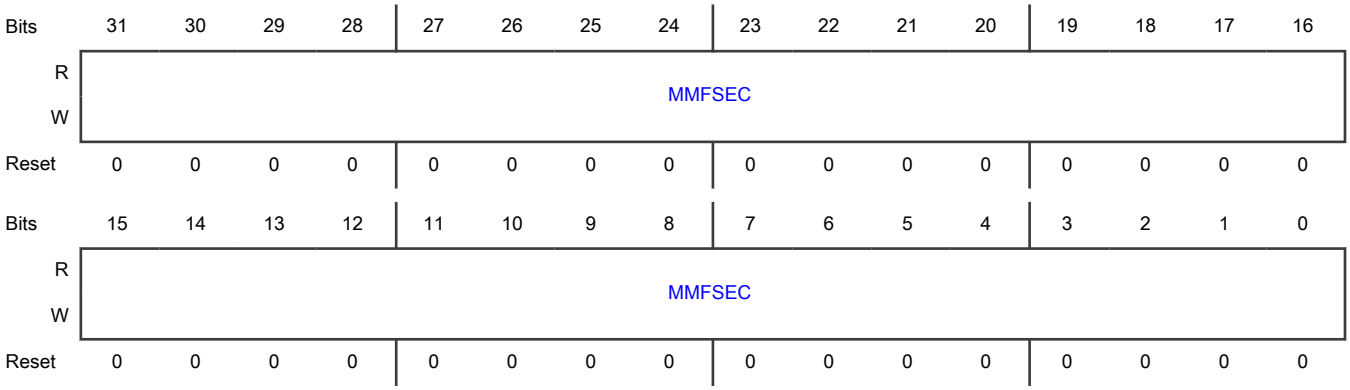
53.4.6.9.76 Port MAC Merge Frame SMD Error Count Register (MAC_MERGE_MMFSECR)

Offset

Register	Offset
MAC_MERGE_MMFSECR	80Ch

Function
A count of received MAC frames / MAC frame fragments rejected due to unknown SMD value or arriving with an SMD-C when no frame is in progress.

Diagram



Fields

Field	Function
31-0 MMFSEC	A count of received MAC frames / MAC frame fragments rejected due to unknown SMD value or arriving with an SMD-C when no frame is in progress.

53.4.6.9.77 Port MAC Merge Frame Assembly OK Count Register (MAC_MERGE_MMFAOCR)

Offset

Register	Offset
MAC_MERGE_MMFAOCR	810h

Function
A count of MAC frames that were successfully reassembled and delivered to the MAC.

Diagram

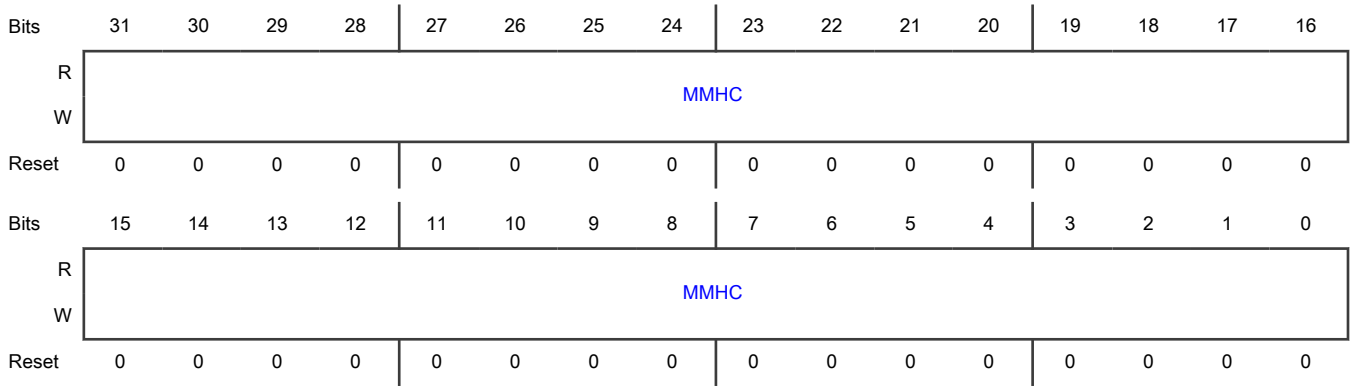
53.4.6.9.80 Port MAC Merge Hold Count Register (MAC_MERGE_MMHCR)

Offset

Register	Offset
MAC_MERGE_MMHCR	81Ch

Function
A count of the number of times the variable hold transitions from false to true.

Diagram



Fields

Field	Function
31-0 MMHC	A count of the number of times the variable hold transitions from false to true.

53.4.6.9.81 Port external MDIO configuration register (PEMDIOCR)

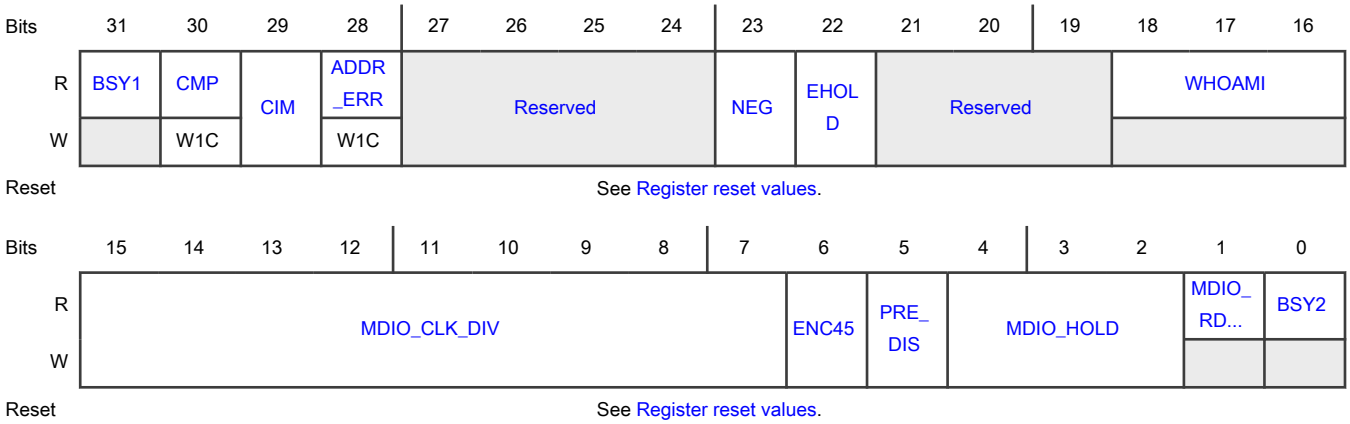
Offset

Register	Offset
PEMDIOCR	C00h

Function

Port external MDIO configuration register for access to the off-chip PHY.

Diagram



Register reset values

Register	Reset value
PEMDIOCR	ENETC0_ETH_MAC_PORT: 0004_1448h SW0_ETH_MAC_PORT0: 0000_1448h SW0_ETH_MAC_PORT1: 0001_1448h SW0_ETH_MAC_PORT2: 0002_1448h SW0_ETH_MAC_PORT3: 0003_1448h

Fields

Field	Function
31 BSY1	Busy 1 Indicates whether MDIO is busy. 0b - An MDIO transaction is not occurring; software may access other MDIO registers. 1b - An MDIO transaction is occurring.
30 CMP	MDIO Command Completion Bit is cleared by writing 1b. 0b - An MDIO command completion did not occur. 1b - An MDIO command completion occurred.
29 CIM	MDIO Command Completion Interrupt Mask 0b - Masked 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 ADDR_ERR	Address Error 0b - Normal 1b - Error. An access control violation has occurred. The request address used does not match the MDIO PHY's address (clause 22) or MDIO port address (clause 45) assigned.
27-24 —	Reserved
23 NEG	Negative Edge 0b - normal operation - positive edge 1b - MDIO is driven by master on MDC negative edge (default for external MDIOs)
22 EHOLD	Extended HOLD **NOTE** For Extended operation, MDIO hold time for MDIO_HOLD is specified as follows: 000b - 1 NETC cycle 001b - 9 NETC cycles 010b - 17 NETC cycles 011b - 25 NETC cycles 100b - 33 NETC cycles 101b - 41 NETC cycles 110b - 49 NETC cycles 111b - 57 NETC cycles 0b - Normal operation, MDIO hold time is as specified in PEMDIOCR[MDIO_HOLD]. 1b - Extended operation
21-19 —	Reserved
18-16 WHOAMI	Returns the link ID
15-7 MDIO_CLK_DIV	MDIO Clock Divisor A value of 5-511 can be set to configure the MDIO clock frequency relative to NETC clock. Ratio is (2*MDIO_CLK_DIV)+1. Setting the divisor to 0 disables MDC. The minimum value which should be written to this bit field is 2, which corresponds to a clock divide ratio of 5. **NOTE** The default is 40. For external MDIO Ethernet management interface, the default is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 ENC45	Enable Clause 45 Support 0b - Clause 22 transactions are used. 1b - Clause 45 transactions are used.
5 PRE_DIS	MDIO Preamble Disable 0b - Generation of MDIO preamble is enabled (default operation). 1b - Generation of MDIO preamble is disabled.
4-2 MDIO_HOLD	MDIO Hold Time 000b - 1 NETC cycle 001b - 3 NETC cycles 010b - 5 NETC cycles (default - recommended value) 011b - 7 NETC cycles 100b - 9 NETC cycles 101b - 11 NETC cycles 110b - 13 NETC cycles 111b - 15 NETC cycles
1 MDIO_RD_ER	MDIO Read (and write) Error 0b - No error on last MDIO transaction (read or write). 1b - An error was detected on the last MDIO transaction (read or write). Errors on internal MDIO accesses can be triggered by an access to an invalid device, or by a write to a shared on-die PHY device that has not been locked.
0 BSY2	Busy 2 (same as bit 31) Indicates whether MDIO is busy. 0b - An MDIO transaction is not occurring; software may access other MDIO registers. 1b - An MDIO transaction is occurring.

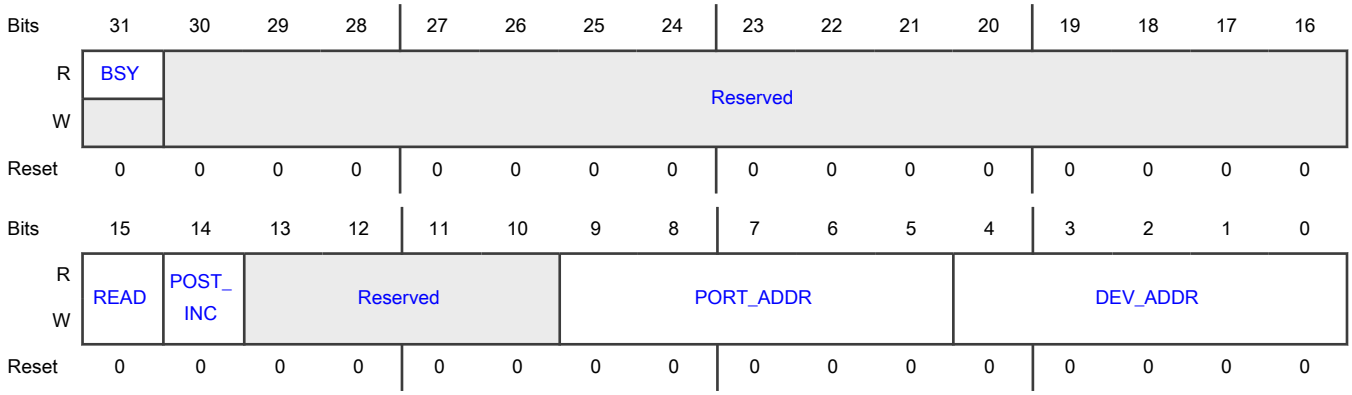
53.4.6.9.82 Port external MDIO interface control register (PEMDIOICR)

Offset

Register	Offset
PEMDIOICR	C04h

Function
This is the port external MDIO interface control register.

Diagram



Fields

Field	Function
31 BSY	MDIO busy 0 An MDIO transaction is not occurring; software may access other MDIO registers. 1 An MDIO transaction is occurring.
30-16 —	Reserved
15 READ	MDIO read initiation. 1 A normal MDIO read transaction is initiated. Self-clearing once transaction is complete.
14 POST_INC	MDIO read with address post-increment initiation. Self-clearing once transaction is complete. 0 (default operation) 1 An MDIO read with Clause 45 address post-increment transaction is initiated (Post-incrementation is performed in the PHY internal address register.)
13-10 —	Reserved
9-5 PORT_ADDR	5-bit MDIO port address (Clause 45) / PHY address (Clause 22)
4-0 DEV_ADDR	5-bit MDIO device address (Clause 45) / register address (Clause 22)

53.4.6.9.83 Port external MDIO interface data register (PEMDIOIDR)

Offset

Register	Offset
PEMDIOIDR	C08h

Function
This is the port external MDIO interface data register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MDIO_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15-0 MDIO_DATA	16-bit MDIO data. Writing to this register initiates a write transaction to the PHY. For proper operation, the MDIO_CTL register must have been initialized first. The PEMDIOCR[BUSY] status bit is set immediately and cleared when the write transaction has completed. Reading this register returns data read from the PHY register specified in PEMDIOICR after a read transaction has completed. Read transactions are initiated by writing a 1 to PEMDIOICR[READ] or PEMDIOICR[POST_INC]. Read data is invalid if PEMDIOCR[BUSY] is set.

53.4.6.9.84 Port external MDIO register address register (PEMDIORAR)

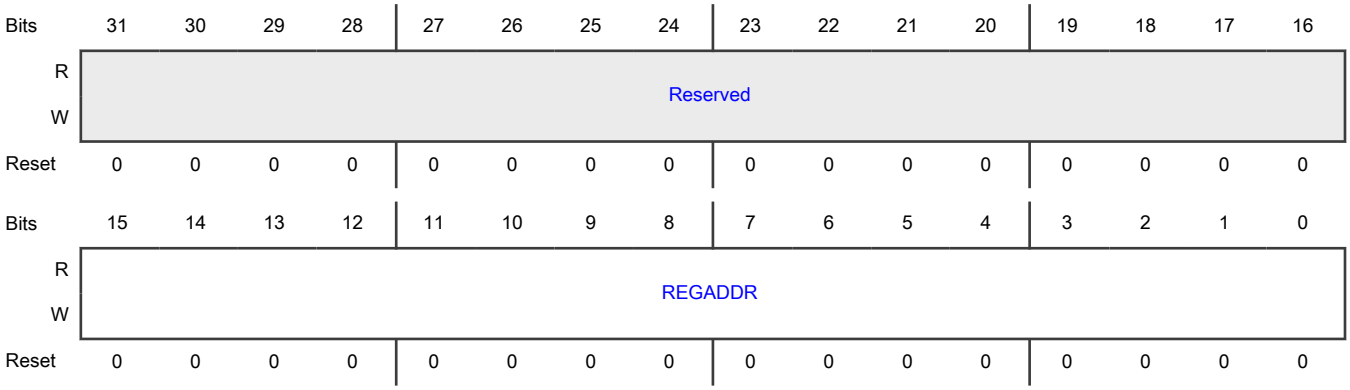
Offset

Register	Offset
PEMDIORAR	C0Ch

Function

This is the port external MDIO register address register, and is used to communicate with an attached Clause 45 PHY.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 REGADDR	MDIO PHY register address. MDIO PHY register address. Address of the register within the Clause 45 PHY device from which data is to be read or to which data is to be written. Writing to this register initiates an address-write transaction to set the PHY's internal address register to the value specified in PEMDIORAR[REGADDR]. For proper operation, the PEMDIOICR register must have been initialized prior to writing to this register.

53.4.6.9.85 Port external MDIO status register (PEMDIOSR)

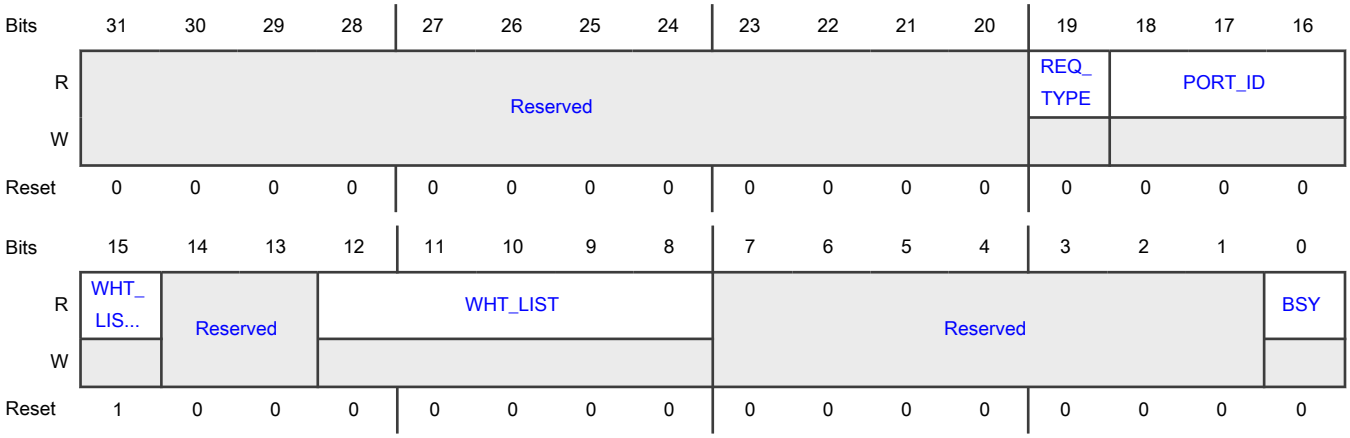
Offset

Register	Offset
PEMDIOSR	C10h

Function

This is the port external MDIO status register.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 REQ_TYPE	Port ID Returns the request type of the active virtual port. 0 MDIO request 1 PHY polling
18-16 PORT_ID	Port ID Returns the port ID of the active virtual port. Matches the value PEMDIOCR[WHOAMI] of active port.
15 WHT_LIST_ENA	PHY white list enable Returns the PHY white list enable of the active virtual port.
14-13 —	Reserved
12-8 WHT_LIST	PHY white list Returns the PHY white list address of the active virtual port.
7-1 —	Reserved
0 BSY	Global MDIO busy 0 An MDIO transaction is not occurring; software may access other MDIO registers. 1 An MDIO transaction is occurring.

53.4.6.9.86 PHY status configuration register (PPSCR)

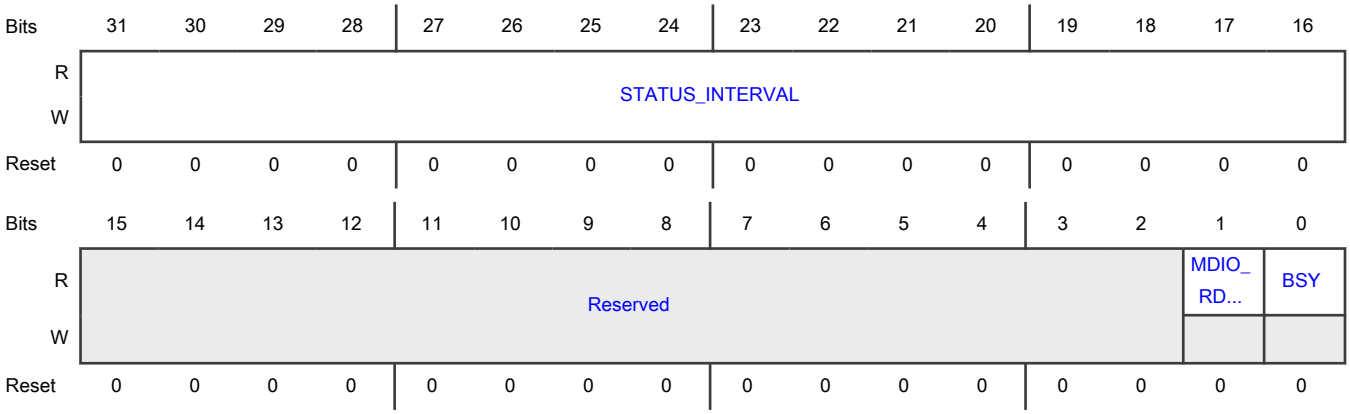
Offset

Register	Offset
PPSCR	C20h

Function

This is the PHY status configuration register.

Diagram



Fields

Field	Function
31-16 STATUS_INTERVAL	PHY status read interval Amount of time to wait between PHY status reads, in units of 1-2 ms. A value of 0 indicates auto PHY automatic status reads are disabled.
15-2 —	Reserved
1 MDIO_RD_ER	MDIO read error 1 The last read transaction received no response from a PHY; any data read should be considered invalid. (for example, The PHY address does not match any PHY available on the MDIO bus.)
0 BSY	MDIO busy 0 An MDIO transaction is not occurring; software may access other MDIO registers. 1 An MDIO transaction is occurring.

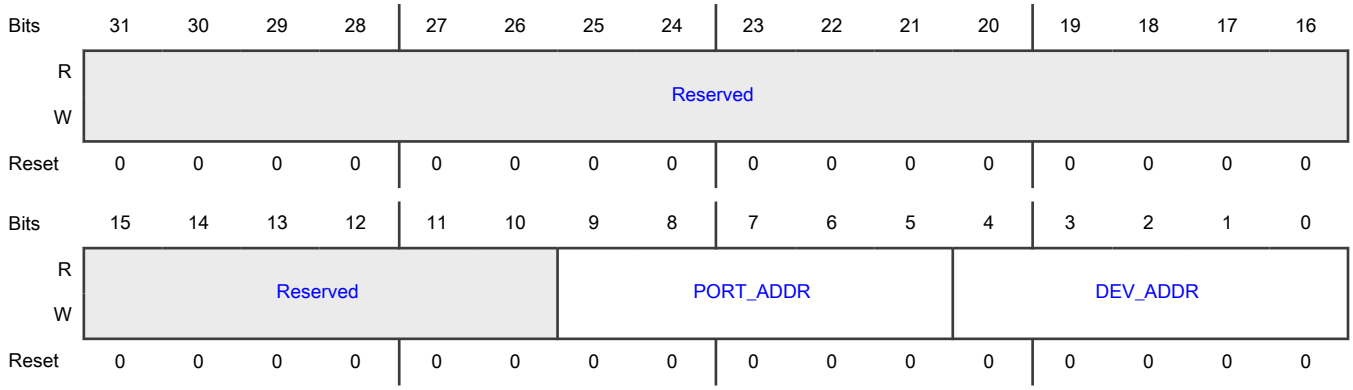
53.4.6.9.87 Port PHY status control register (PPSCTRLR)

Offset

Register	Offset
PPSCTRLR	C24h

Function
This is the port PHY status control register.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-5 PORT_ADDR	5-bit MDIO port address (Clause 45) / PHY address (Clause 22)
4-0 DEV_ADDR	5-bit MDIO device address (Clause 45) / register address (Clause 22)

53.4.6.9.88 Port PHY status data register (PPSDR)

Offset

Register	Offset
PPSDR	C28h

Function
This is the port PHY status data register.

Diagram

Fields

Field	Function
31-16 —	Reserved
15-0 REGADDR	MDIO PHY register address. Address of the register within the Clause 45 PHY device from which data is to be read.

53.4.6.9.90 Port PHY status event register (PPSER)

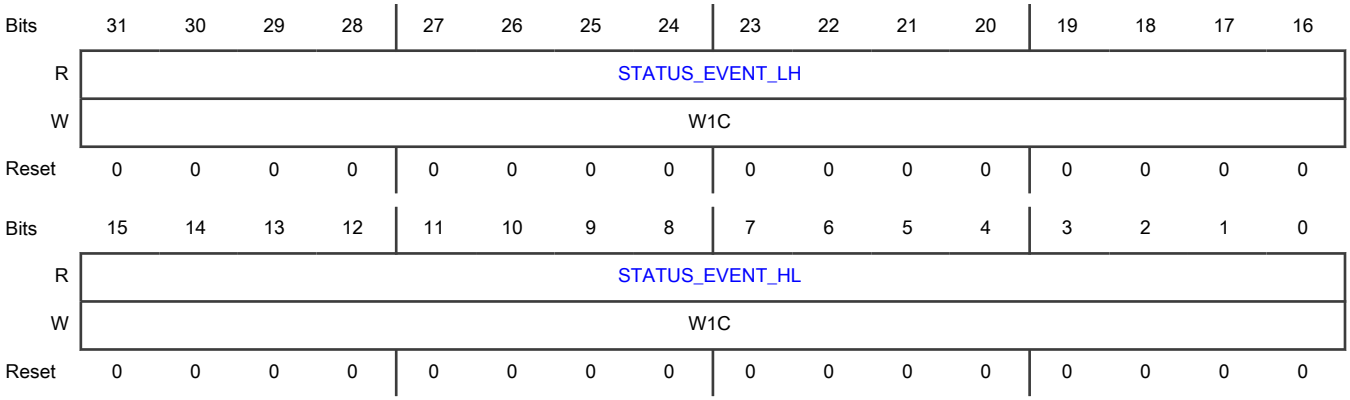
Offset

Register	Offset
PPSER	C30h

Function

This is the port PHY status event register, and is used to detect transitions in the data bits. Used in conjunction with the mask register to signal interrupts.

Diagram



Fields

Field	Function
31-16 STATUS_EVENT_LH	Status event low-to-high. Set to 1 if a 0->1 transition on a corresponding data bit has occurred. Write 1 to clear.
15-0 STATUS_EVENT_HL	Status event high-to-low. Set to 1 if a 1->0 transition on a corresponding data bit has occurred. Write 1 to clear.

53.4.6.9.91 Port PHY status mask register (PPSMR)

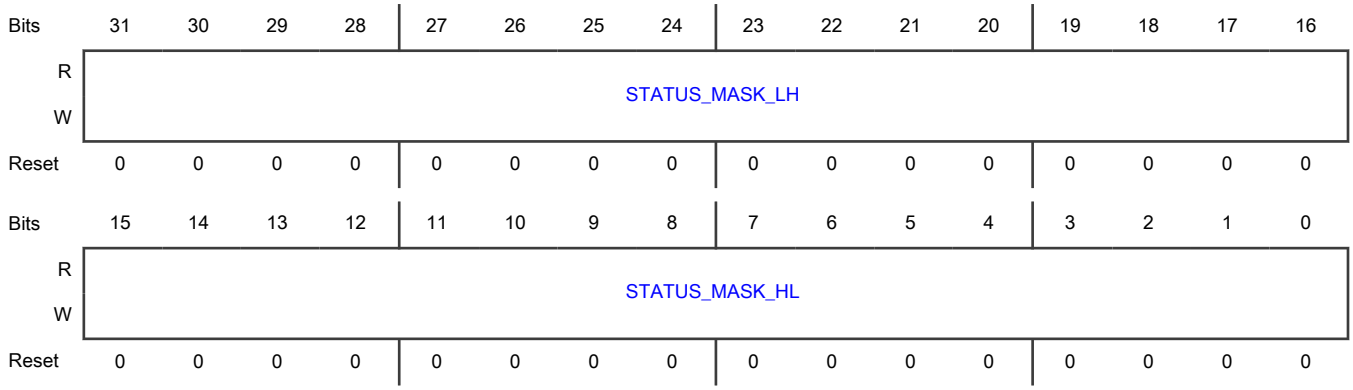
Offset

Register	Offset
PPSMR	C34h

Function

This is the port PHY status mask register, and is used in conjunction with the event register to signal interrupts.

Diagram



Fields

Field	Function
31-16 STATUS_MASK_LH	Status mask low-to-high. If set to 1, assert an interrupt if the corresponding event bit is set.
15-0 STATUS_MASK_HL	Status high-to-low mask. If set to 1, assert an interrupt if the corresponding event bit is set.

53.4.6.10 Pseudo MAC port register descriptions

This section describes the pseudo MAC port registers. The pseudo MAC registers exists whenever two ENETC and switch instances are connected together.

53.4.6.10.1 Pseudo_MAC_port memory map

Instance	Address space	Offset
ENETC1_PSEUDO_MAC_PORT	PCI_F4_BAR_0	60B5_5000h
SW0_PSEUDO_MAC_PORT4	PCI_F2_BAR_0	60A1_5000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Port pseudo MAC status register (PPMSR)	32	R	0000_0101h
10h	Port pseudo MAC configuration register (PPMCR)	32	RW	0001_0000h
80h - 84h	Port pseudo MAC receive octets counter (PPMROCR0 - PPMROCR1)	32	R	0000_0000h
88h - 8Ch	Port pseudo MAC receive unicast frame counter register (PPMRUFCR0 - PPMRUFCR1)	32	R	0000_0000h
90h - 94h	Port pseudo MAC receive multicast frame counter register (PPMRMFCR0 - PPMRMFCR1)	32	R	0000_0000h
98h - 9Ch	Port pseudo MAC receive broadcast frame counter register (PPMRBFCR0 - PPMRBFCR1)	32	R	0000_0000h
C0h - C4h	Port pseudo MAC transmit octets counter (PPMTOCR0 - PPMTOCR1)	32	R	0000_0000h
C8h - CCh	Port pseudo MAC transmit unicast frame counter register (PPMTUFCR0 - PPMTUFCR1)	32	R	0000_0000h
D0h - D4h	Port pseudo MAC transmit multicast frame counter register (PPMTMFCR0 - PPMTMFCR1)	32	R	0000_0000h
D8h - DCh	Port pseudo MAC transmit broadcast frame counter register (PPMTBFCR0 - PPMTBFCR1)	32	R	0000_0000h

53.4.6.10.2 Port pseudo MAC status register (PPMSR)

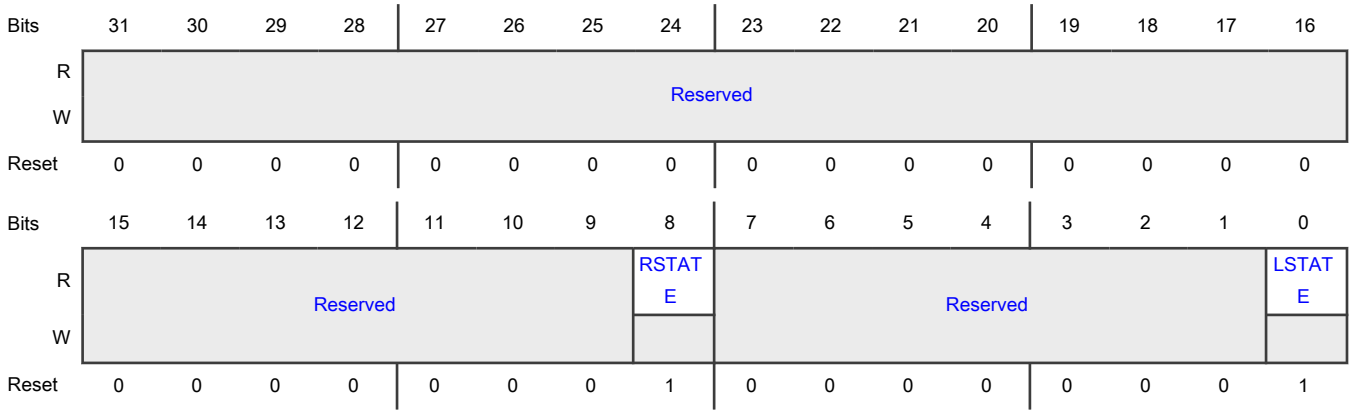
Offset

Register	Offset
PPMSR	0h

Function

This is the port pseudo MAC status register.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 RSTATE	Remote link end's state 0 - Link is down 1 - Link is up **NOTE** The operational state is always "Link is up" for the pseudo link. RSTATE will always return 1.
7-1 —	Reserved
0 LSTATE	Local link end's state 0 - Link is down 1 - Link is up **NOTE** The operational state is always "Link is up" for the pseudo link. LSTATE will always return 1.

53.4.6.10.3 Port pseudo MAC configuration register (PPMCR)

Offset

Register	Offset
PPMCR	10h

Function

This is the port pseudo MAC configuration register.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC1_PSEUDO_MAC_PORT	PPMCR	—
SW0_PSEUDO_MAC_PORT4	—	PPMCR

Diagram

Fields

Field	Function
31-17 —	Reserved
16 TXPAD	Transmit Padding When set, HTA transmit will pad the frame to a minimum of 60 bytes with pad bytes of zeros after performing frame modifications, if any. It will then append the calculated FCS to the frame.
15-0 —	Reserved

53.4.6.10.4 Port pseudo MAC receive octets counter (PPMROCR0 - PPMROCR1)

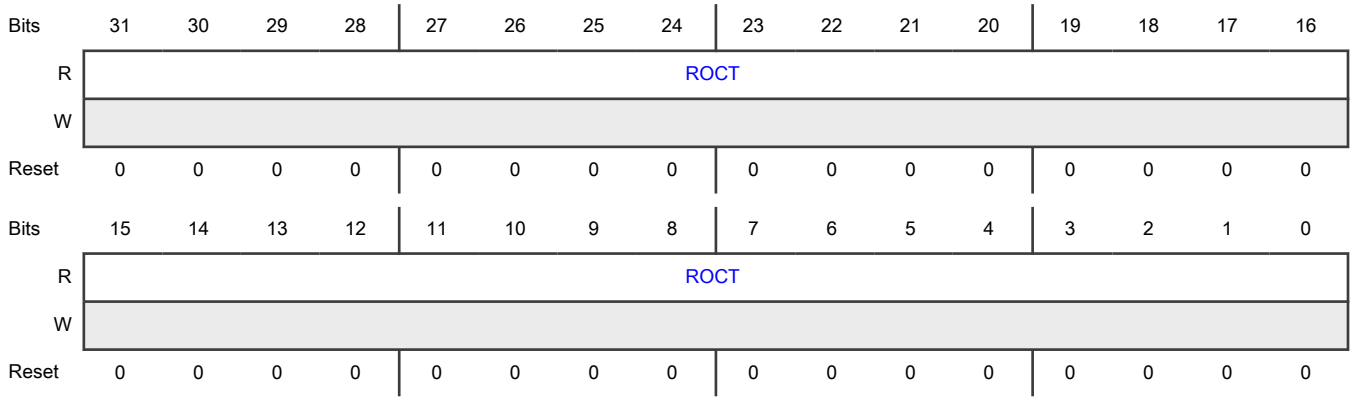
Offset

Register	Offset
PPMROCR0	80h
PPMROCR1	84h

Function

This is the port pseudo MAC receive octets counter. Register xCR0 corresponds to the lower 32b of the counter. xCR1 corresponds to the upper 32b. xCR0 must be read first, followed by a read to xCR1.

Diagram



Fields

Field	Function
31-0 ROCT	Incremented for each octet received (on the link) (that is, Ethernet header, payload, pad and FCS).

53.4.6.10.5 Port pseudo MAC receive unicast frame counter register (PPMRUFCR0 - PPMRUFCR1)

Offset

Register	Offset
PPMRUFCR0	88h
PPMRUFCR1	8Ch

Function

This is the port pseudo MAC receive unicast frame counter register. Register xCR0 corresponds to the lower 32b of the counter. xCR1 corresponds to the upper 32b. xCR0 must be read first, followed by a read to xCR1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 RUCA	Incremented for each valid frame received (on the link) in which bit 0 of the destination address was 0.

53.4.6.10.6 Port pseudo MAC receive multicast frame counter register (PPMRMFCR0 - PPMRMFCR1)

Offset

Register	Offset
PPMRMFCR0	90h
PPMRMFCR1	94h

Function

This is the port pseudo MAC receive multicast frame counter register. Register xCR0 corresponds to the lower 32b of the counter. xCR1 corresponds to the upper 32b. xCR0 must be read first, followed by a read to xCR1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	RMCA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 RMCA	Incremented for each frame received (on the link) in which bit 0 of the destination address was 1 but not the broadcast address (all bits set to 1).

53.4.6.10.7 Port pseudo MAC receive broadcast frame counter register (PPMRBFCR0 - PPMRBFCR1)

Offset

Register	Offset
PPMRBFCR0	98h
PPMRBFCR1	9Ch

Function

This is the port pseudo MAC receive broadcast frame counter register. Register xCR0 corresponds to the lower 32b of the counter. xCR1 corresponds to the upper 32b. xCR0 must be read first, followed by a read to xCR1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 TOCT	Incremented for each octet transmitted (on the link) (that is, Ethernet header, payload, pad and FCS).

53.4.6.10.9 Port pseudo MAC transmit unicast frame counter register (PPMTUFCR0 - PPMTUFCR1)

Offset

Register	Offset
PPMTUFCR0	C8h
PPMTUFCR1	CCh

Function

This is the port pseudo MAC transmit unicast frame counter register. Register xCR0 corresponds to the lower 32b of the counter. xCR1 corresponds to the upper 32b. xCR0 must be read first, followed by a read to xCR1.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TUCA	Incremented for each frame transmitted (on the link) in which bit 0 of the destination address was 0.

53.4.6.10.10 Port pseudo MAC transmit multicast frame counter register (PPMTMFCR0 - PPMTMFCR1)

Offset

Register	Offset
PPMTMFCR0	D0h
PPMTMFCR1	D4h

Function

This is the port pseudo MAC transmit multicast frame counter register. Register xCR0 corresponds to the lower 32b of the counter. xCR1 corresponds to the upper 32b. xCR0 must be read first, followed by a read to xCR1.

R	TMCA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TMCA	Incremented for each frame transmitted (on the link) in which bit 0 of the destination address was 1 but not the broadcast address (all bits set to 1).

53.4.6.10.11 Port pseudo MAC transmit broadcast frame counter register (PPMTBFCR0 - PPMTBFCR1)

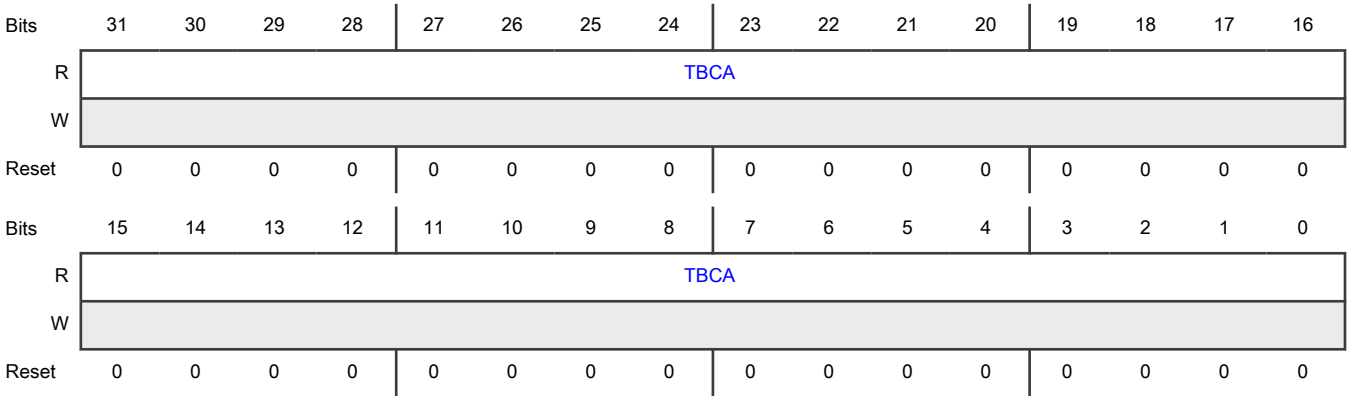
Offset

Register	Offset
PPMTBFCR0	D8h
PPMTBFCR1	DCh

Function

This is the port pseudo MAC transmit broadcast frame counter register. Register xCR0 corresponds to the lower 32b of the counter. xCR1 corresponds to the upper 32b. xCR0 must be read first, followed by a read to xCR1.

Diagram



Fields

Field	Function
31-0 TBCA	Incremented for each frame transmitted (on the link) in which all bits of the destination address were 1.

53.4.6.11 ENETC Station Interface register descriptions

This section describes ENETC station interface device registers for one or more base/physical functions.

There may be differences in actual implemented registers or register fields as well as reset values between functions that is, SI0 is the physical station interface while SI1+ are virtual station interfaces.

The physical station interface function's base address register value can be discovered from reading the PCIe Enhanced Allocation Base Address Register Equivalent Index 0 (EA BEI 0). Virtual station interfaces uses the PCIe Enhanced Allocation Base Address Register Equivalent Index 9 (EA BEI 9).

53.4.6.11.1 Station_Interface memory map

Instance	Address space	PCIe EA BEI offset
ENETC0_SI0	PCI_F3_BAR_0	60B0_0000h
ENETC1_SI0	PCI_F4_BAR_0	60B4_0000h
ENETC1_SI1	PCI_F4_BAR_9	60C1_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Station interface mode register (SIMR)	32	RW	See section
4h	Station interface status register (SISR)	32	R	0000_001Eh
18h	Station interface current time register 0 (SICTR0)	32	R	0000_0000h
1Ch	Station interface current time register 1 (SICTR1)	32	R	0000_0000h
20h	Station interface port capability register 0 (SIPCAPR0)	32	R	See section
24h	Station interface port capability register 1 (SIPCAPR1)	32	R	See section
30h	Station interface timer status register (SITSR)	32	R	0000_0000h
38h	Station interface receive BDR group control register (SIRBGCR)	32	RW	0000_0000h
40h	Station interface buffer cache attribute register (SIBCAR)	32	RW	0202_0202h
44h	Station interface message cache attribute register (SIMCAR)	32	RW	0002_0002h
48h	Station interface command cache attribute register (SICCAR)	32	RW	0202_0202h
80h	Station interface primary MAC address register 0 (SIPMAR0)	32	R	0000_0000h
84h	Station interface primary MAC address register 1 (SIPMAR1)	32	R	0000_0000h
90h	Station interface custom VLAN register 1 (SICVLANR1)	32	R	0000_0000h
94h	Station interface custom VLAN register 2 (SICVLANR2)	32	R	0000_0000h
100h	Station interface VLAN to IPV mapping register 0 (SIVLANIPVMR0)	32	RW	0000_0000h
104h	Station interface VLAN to IPV mapping register 1 (SIVLANIPVMR1)	32	RW	0000_0000h
150h	Station interface IPV to ring mapping register (SIIPVBDRMR0)	32	RW	0000_0000h
204h	Physical station interface message receive register (PSIMSGRR)	32	RW	0000_0000h
204h	Virtual station interface message send register (VSIMSGSR)	32	R	0000_0000h
208h	Physical station interface message send register (PSIMSGSR)	32	RW	0000_0000h
208h	Virtual station interface message receive register (VSIMSGRR)	32	R	0000_0000h
210h	PSI VSI 1 message receive address register 0 (PSIV1MSGRCVAR0)	32	RW	0000_0000h

53.4.6.11.2 Station interface mode register (SIMR)

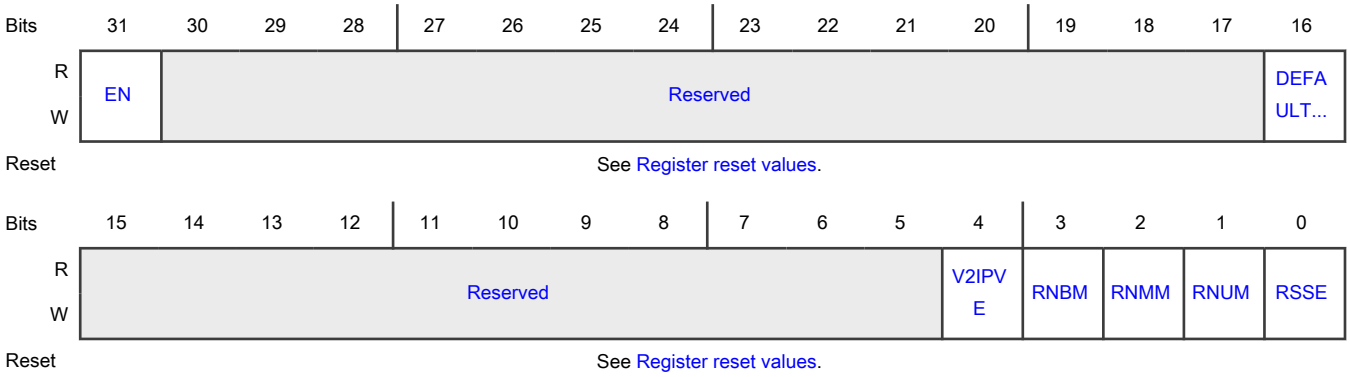
Offset

Register	Offset
SIMR	0h

Function

This is the SI mode register.

Diagram



Register reset values

Register	Reset value
SIMR	ENETC0_SI0,ENETC1_SI0: 8000_0000h ENETC1_SI1: 0000_0000h

Fields

Field	Function
31 EN	Enable station interface. This is the enable for the station interface. The port has a master enable which is ANDed with this bit to determine the final setting. 0 Station interface is disabled. Transmit descriptor rings are not processed and all received frames are dropped. Station interface counters are not updated. If received packets had started processing when the station interface was disabled, they will complete. 1 Station interface is enabled. Received frames and transmit descriptor ring entries are accepted. **NOTE** It is not safe to clear this bit while transmit rings in this SI are actively transmitting frames. Software should only disable the SI after all pending ring entries have been consumed (i.e. when PI = CI). Disabling a transmit ring (or its SI) that is actively processing BDs risks a HW-SW race hazard whereby a hardware resource becomes assigned to work on one or more ring entries only to have those entries be removed due to the ring becoming disabled. Enabled CBD rings within an SI remain operational when the SI is disabled.
30-17 —	Reserved
16 DEFAULT_RX_GROUP	Default receive group The default receive group is used when there is no match for RFS and RSS is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-5 —	Reserved
4 V2IPVE	VLAN to IPV mapping enable Maps the VLAN PCP/DEI to internal priority value (IPV). 0 Disabled. Default IPV is selected from PQOSMR[DIPV]. 1 Enabled
3 RNBM	Receive no broad-cast mode Suppresses broad-cast receive for the SI. When broad-cast receive is suppressed, the SI will not receive broad-cast packets. 0 Disabled 1 Enabled
2 RNMM	Receive no multi-cast mode Suppresses multi-cast receive for the SI. When multi-cast receive is suppressed, the SI will not receive multi-cast packets even if accepted by MAC multi-cast hash table. 0 Disabled 1 Enabled
1 RNUM	Receive no unicast-cast mode Suppresses uni-cast receive for the SI. When uni-cast receive is suppressed, the SI will not receive uni-cast packets even if accepted by MAC uni-cast address table. 0 Disabled 1 Enabled
0 RSSE	RSS classification enable 0 RSS classification is disabled 1 RSS classification is enabled This field is valid if SIPCAPR0[RSS] is set to 1.

53.4.6.11.3 Station interface status register (SISR)

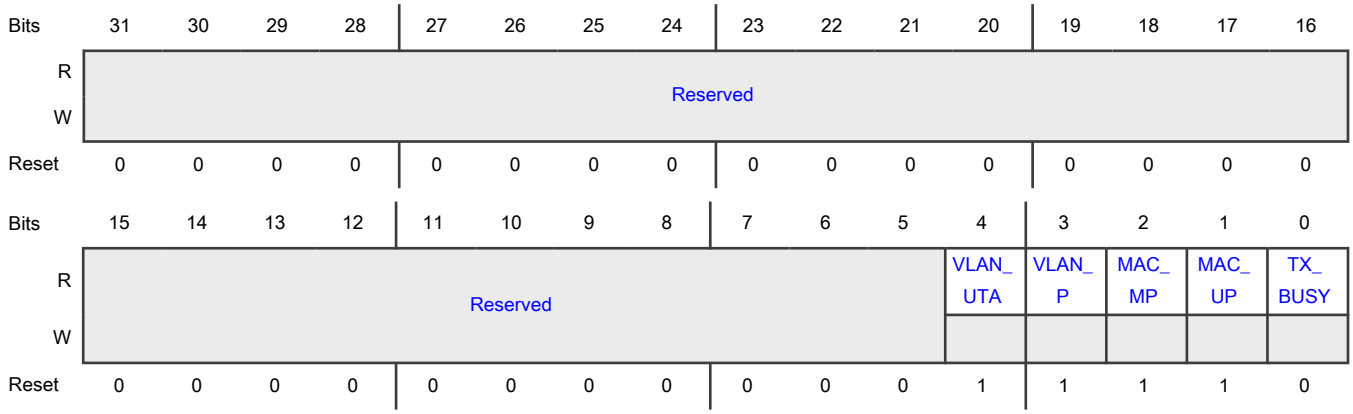
Offset

Register	Offset
SISR	4h

Function

This is the SI status register.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 VLAN_UTA	SI VLAN untagged frames accepted. If set, SI qualifies for reception of untagged frames. This bit is a reflection of the setting in PSIPVMR.
3 VLAN_P	SI VLAN promiscuous. If set, SI qualifies for reception of all VLAN tags. This bit is a reflection of the setting in PSIPVMR.
2 MAC_MP	SI MAC multicast promiscuous. If set, SI qualifies for reception of multicast frames regardless of their MAC address, except when source MAC address matches any of the receiving SI's unicast MAC addresses. This bit is a reflection of the setting in PSIPMMR.
1 MAC_UP	SI MAC unicast promiscuous. If set, SI qualifies for reception of unicast frames regardless of their MAC address. This bit is a reflection of the setting in PSIPMR.
0 TX_BUSY	Transmit busy. The station interface is busy transmitting frames or processing CBD Class 5 command. To quiesce the interface, the associated transmit rings should be disabled. 0 Idle 1 Busy

53.4.6.11.4 Station interface current time register 0 (SICTR0)

Offset

Register	Offset
SICTR0	18h

Function

SICTR0/SICTR1 indicates either the default running time (copy of TMR_DEF_CNT_L/H) or the 1588 running time (copy of TMR_CUR_TIME_L/H). The default running time is shown when TMR_CTRL[TE]=0, whereby the 1588 running time is shown when TMR_CTRL[TE]=1. Reading the low order 32-bits from SICTR0 will capture the time such that a subsequent read to SICTR1 will provide the correct 64-bit time value.

53.4.6.11.9 Station interface receive BDR group control register (SIRBGCR)

Offset

Register	Offset
SIRBGCR	38h

Function

The station interface receive BDR group control register assigns group numbers to the receive BD rings owned by the station interface. This is done by providing the total number of groups used and the number of rings per group (set once per SI and not per group within an SI).

The following rules apply:

- There is a maximum of 8 rings per group.

- Groups are numbered 0 to NUM_GROUPS-1. When one or more groups are configured to be used (NUM_GROUPS is set to a non-zero value), ring 0 is assigned to group 0 and subsequent rings are assigned to the same group in a contiguous manner till the maximum number of rings per group is reached (RINGS_PER_GROUP). Next rings are then assigned to the next higher group number following the same assignment method. The last group may have less rings if the number of rings per group is not an integer divider to the total number of rings.
- Not all rings have to be part of a group. Unassigned rings can only be reached by RFS. Rings assigned to a group can also be directly reached by RFS.
- Steering a received frame to a non existing group will result in a programming error and a dropped frame.
- Steering a received frame to a non existing ring within a group will result in a programming error and a dropped frame if the ring is outside the range of total number of rings. In all other cases, the wrong group/ring may receive the frame.

R	Reserved														NUM_GROUPS	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-19 —	Reserved
18-16 RINGS_PER_GROUP	Number of rings per group The number of rings per groups is RINGS_PER_GROUP + 1, e.g. a value of 7 indicates 8 rings per group.
15-2 —	Reserved
1-0 NUM_GROUPS	Number of groups Number of groups used, 0-2. A value of 0 indicates groups are not used. A value of 1 is useful for providing QoS based on IPV to BD mapping within the group. Maximum number of groups supported is indicated in SICAPR1[NUM_RX_GRP].

53.4.6.11.10 Station interface buffer cache attribute register (SIBCAR)

Offset

Register	Offset
SIBCAR	40h

Function

This is the SI buffer cache attribute register. It determines the system interface attribute setting used for reads and writes of Tx/Rx buffer descriptors and frame data.

Table 779. System Interface Read Transaction Attribute Definitions

RDSNP	RDDOMAIN[1:0]	RDCACHE[3:0]	Memory Type and System Behavior			
			Memory Type	Snoop?	Downstream cache lookup/allocate?	Description
0	b11	b0000	device	no	no / no	Non-cacheable non-coherent/register space access
0	b00	b0010	memory	no	no / no	Non-coherent copy of cacheable memory, do not look up or allocate in downstream cache, non-bufferable
0	b00	b0011	memory	no	no / no	Non-coherent copy of cacheable memory, do not look up or allocate in downstream cache, bufferable
0	b10	b0111	memory	yes	yes / yes	Coherent copy of cacheable memory, look up in downstream cache, allocate on miss
0	b00	b0111	memory	no	yes / yes	Non-coherent copy of cacheable memory, look up in downstream cache, allocate on miss
0	b10	b1011	memory	yes	yes / no	Coherent copy of cacheable memory, look up in downstream cache, no allocate on miss
0	b00	b1011	memory	no	yes / no	Non-coherent copy of cacheable memory, look up in downstream cache, no allocate on miss
all other combinations						Illegal.

53.4.6.11.13 Station interface primary MAC address register 0 (SIPMAR0)

Offset

Register	Offset
SIPMAR0	80h

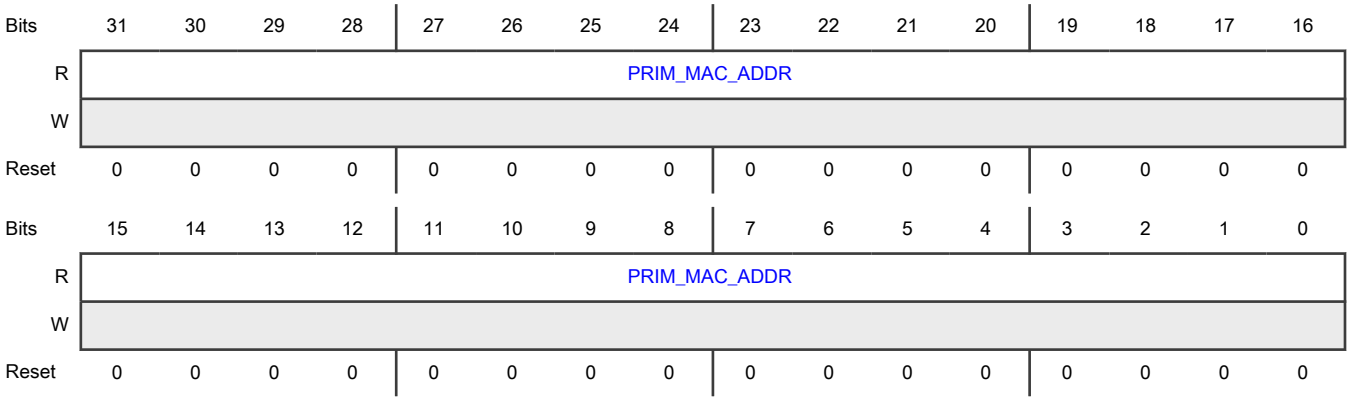
Function

This is the SI's primary MAC address register 0 as set by the port. Ingress frames addressed to this MAC address are not subject to further MAC address filtering, and are delivered to the SI only subject to VLAN filtering.

NOTE

The port will sample the IERB value when PCIe Memory Access bit is set (b1). All updates after this must be done through the port register (PMAR0 for SI 0 and PSI*a*PMAR0 for SI 1,2 .. n)

Diagram



Fields

Field	Function
31-0 PRIM_MAC_ADDR	Primary MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset (register bit offset 0-7). This field contains the 4 most significant bytes of the MAC address. For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then SIPMAR0 equals 14131211h.

53.4.6.11.14 Station interface primary MAC address register 1 (SIPMAR1)

Offset

Register	Offset
SIPMAR1	84h

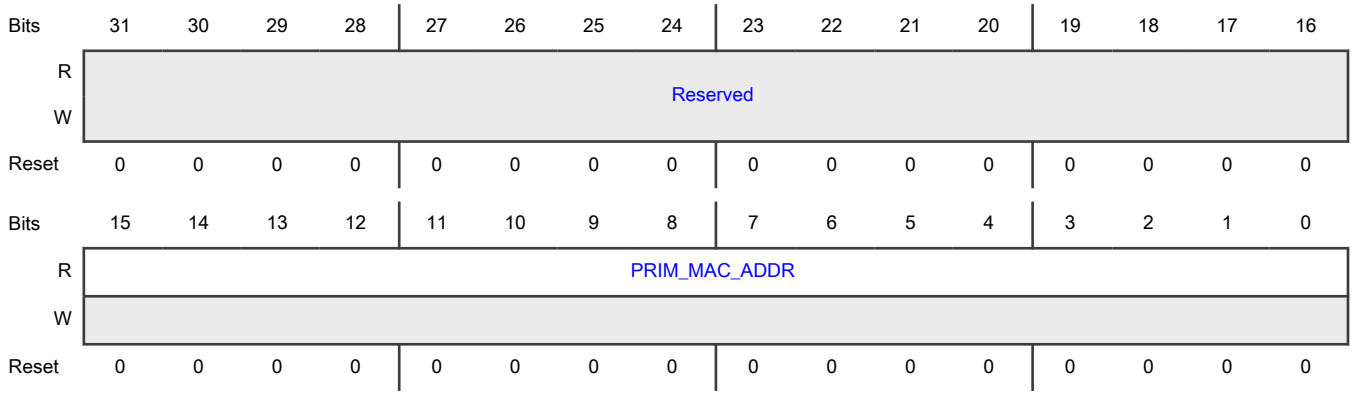
Function

This is the SI's primary MAC address register 1 as set by the port.

NOTE

The port will sample the IERB value when PCIe Memory Access bit is set (b1). All updates after this must be done through the port register (PMAR1 for SI 0 and PSI*a*PMAR1 for SI 1,2 .. n)

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PRIM_MAC_ADDR	Primary MAC address This field is defined in network byte order (big-endian). Most significant byte of the MAC address is stored at the lowest byte offset. This field contains the 2 least significant bytes of the MAC address (least significant byte is stored in register bit offset 8-15). For example if MAC address equals 11:12:13:14:15:16 (11 being the most significant byte), then SIPMAR1 equals xxxx1615h (where x should be set to 0).

53.4.6.11.15 Station interface custom VLAN register 1 (SICVLANR1)

Fields

Field	Function
31-16 MC	Message code This field provides a user defined 16-bit message value. It will be copied to all VSIs that have the MS bit set, allowing multiple VSIs to receive the same message in one command. This field can be read to see the last message sent.
15-2 —	Reserved
1-1 MSn	Message sent to VSI *a* When this bit is set (b1), from a clear state (b0), the message code provided in the MC field will be sent to the VSI. This bit will clear when the VSI reads the message or when the VSI issues a Function Level Reset (FLR), allowing the PSI to keep track of which VSI has processed the message. Writing a 1 when the bit is already set is undefined. Writing a 0 has no effect.
0 —	Reserved

53.4.6.11.23 Virtual station interface message receive register (VSIMSGRR)

Offset

Register	Offset
VSIMSGRR	208h

Function

This is the message receive register for the Virtual Station Interface (VSI) which indicates if there is a pending messages from the PSI in the form of a 16-bit message code. Reading this register acknowledges to the PSI that the message was received and another message can be sent.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

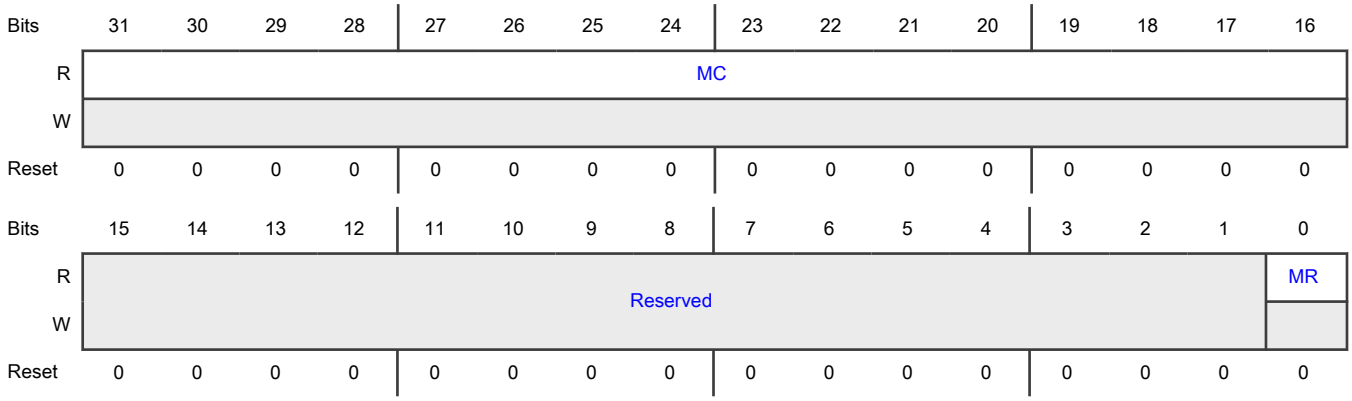
Diagram



Fields

Field	Function
31-0 ADDRH	Upper address bits 63-32.

53.4.6.11.50 Station interface command BDR producer index register (SICBDRPIR)

Offset

Register	Offset
SICBDRPIR	818h

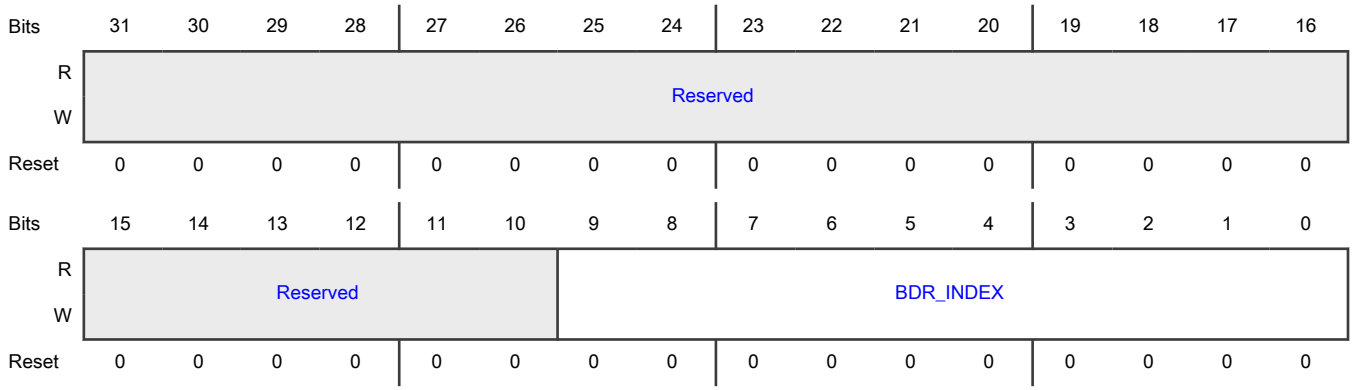
Function

This is the command BDR producer index register. When the BD ring is enabled the value of this register and the consumer index register, SICBDRCIR, determines NETC's unprocessed BDs of the ring. This value also determines how many BD's are committed to the BDR by software. Software should initialize this register while the ring is disabled to reflect an empty state or a pre-loaded BDR state.

To add one or more buffer descriptors to an enabled control ring, software should first check to make sure the ring is not full by reading SICBDRCIR. Note that maximum number of BDs allowed on a ring is one less than the ring size. A memory barrier must be used to guarantee update of the BD(s) to memory before writing the producer index register.

There is no wrap bit to indicate full/empty. One entry is used to differentiate between full and empty. When producer index + 1 equals consumer index, the ring is considered full. When the producer/consumer indices match, the ring is always considered empty.

Diagram



Fields

Field	Function
31-10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9-0 BDR_INDEX	Command buffer descriptor ring producer index. Range of index depends on ring size SICBDRLENR[LENGTH].

53.4.6.11.51 Station interface command BDR consumer index register (SICBDRCIR)

Offset

Register	Offset
SICBDRCIR	81Ch

Function

This is the command BDR consumer index register. It reflects the next BD to be processed by NETC and trails the SICBDRPIR index value. Software should only update/reset this value when the BD ring is re-initialized. Disabling the BD ring has no effect on this register. Software can calculate available entries in the ring by using the software producer index and this register value.

53.4.6.11.60 Physical station interface interrupt detect register (PSIIDR)

Offset

Register	Offset
PSIIDR	A08h

Function

This is the interrupt detect register for the PSI which provides a summary for all functional events detected. Writing a 1 to any of the fields will clear the event. It is recommended that the PSIIER be cleared prior to servicing events in the PSIIDR, then re-enabled upon service routine exit. This will ensure generation of a new interrupt in the event of a set/clear collision in any of the message or FLR source bits.

NOTE

Each module instance supports a different number of registers.

53.4.6.11.64 Station interface MSI-X vector register (SIMSIVR)

Offset

Register	Offset
SIMSIVR	A30h

Function

This is the MSI-X vector register which defines the vector used for address/data lookup in the MSI-X Table. The total number of vectors supported for the station interface is determined by SIPCAPR1[NUM_MSIX].

The following interrupt sources uses this vector:

- Message received from VSI
- FLR initiated by VSI

NOTE

Each module instance supports a different number of registers.

TB4MR–TB9MR	ENETC0_SI0: Register not supported ENETC1_SI0,ENETC1_SI1: 0000_0000h

Fields

Field	Function
31 EN	Enable transmit buffer descriptor ring 0: Disabled. 1: Enabled. When the ring is non-empty, transmit packets will be processed. **NOTE** It is not safe to clear this bit while the ring is actively transmitting frames. Software should only disable an active ring after all pending ring entries have been consumed (i.e. when PI = CI). Disabling a transmit ring that is actively processing BDs risks a HW-SW race hazard whereby a hardware resource becomes assigned to work on one or more ring entries only to have those entries be removed due to the ring becoming disabled.
30-10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 VIH	VLAN Insert Hint If set (b1) then SW intends to use VLAN insertion offload by providing VLAN tag data in the Tx BD. When set, calculations performed by hardware in the transmit scheduler involving the size of the frame (e.g. credit based shaper) will account for the extra 4 bytes of VLAN information in their calculations regardless of whether descriptor-based VLAN insertion offload is used or not used.
8 CRC	User CRC provided Determines if user provides CRC32 (FCS) at the end of the frame. 0: User CRC (FCS) is not provided (calculated and appended by the hardware). Calculations performed by hardware in the transmit scheduler involving the size of the frame (e.g. credit based shaper) will account for the extra 4 bytes of FCS in their calculations. 1: User CRC (FCS) is provided; the hardware does not append any FCS to the frame. If the port is configured to pad frames to the minimum length of 64 bytes (PPMCR[TXPAD]=1 for pseudo MAC or PMa_COMMAND_CONFIG[TXP]=1 for Ethernet MAC), frames (with FCS) provided by the user must be 64 bytes or longer. If frames are shorter than 64 bytes, frames will be padded to 64 bytes and transmitted with a bad FCS. **NOTE** If this field is set to 1 (user CRC provided) and offloading of VLAN tag insertion is requested (i.e. SI-Based VLAN insertion or descriptor-based VLAN insertion), then the frame will not be transmitted as the FCS would be bad due to the frame modification. The STATUS field of host transmit descriptor is updated with Programming Error flag set to 1.
7 —	Reserved
6-4 WRR	WRR weight Weight used for arbitration when two or more rings have the same priority within the same VSI. A higher value indicates more bandwidth. 000 Weight of 1 001 Weight of 2 ... 110 Weight of 7 111 Weight of 8

Fields

Field	Function
31-0 ADDRH	Upper address bits 63-32.

53.4.6.11.95 Tx BDR a producer index register (TB0PIR - TB9PIR)

Offset

For a = 0 to 9:

Register	Offset
TBaPIR	8018h + (a × 200h)

Function

This is the transmit BDR producer index register. When the BD ring is enabled the value of this register and TB*a*CIR determines NETC's unprocessed BDs of the ring. This value also determines how many BD's are committed to the BDR by software. Software should initialize this register while the ring is disabled to reflect an empty state or a pre-loaded BDR state. Software can calculate available entries in the ring by using the software consumer index and this register value.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_SI0	TB0PIR–TB3PIR	TB4PIR–TB9PIR

Fields

Field	Function
31-16 —	Reserved
15-0 BDR_INDEX	Transmit buffer descriptor ring producer index. Range of index depends on ring size TB*a*LENR[TBLENR].

53.4.6.11.96 Tx BDR a consumer index register (TB0CIR - TB9CIR)

Offset

For a = 0 to 9:

Register	Offset
TBaCIR	801Ch + (a × 200h)

Function

This is the transmit BDR consumer index register. It reflects the next BD to be processed by NETC and trails the TB*a*PIR index value. Software should only update/reset this value when the BD ring is re-initialized. Disabling the BD ring has no effect on this register. During operation, hardware updates the consumer index to reflect frames that have completed transmission and whose BDs are committed to memory, i.e. status/timestamp updated.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

53.4.6.11.99 Tx BDR a interrupt detect register (TB0IDR - TB9IDR)

Offset

For a = 0 to 9:

Register	Offset
TBaIDR	80A4h + (a × 200h)

Function

This is the interrupt detect register for the transmit buffer descriptor ring. Reading will automatically clear all events. Register SITXIDR provides a non-destructive read access. It is not necessary to clear/set the TBaIER register upon entry/exit of the service routine. A new interrupt is generated in the event of a set/clear collision in this register.

TBaIDR should not be polled if interrupt coalescing is enabled. Polling reads of TBaIDR clear the frame counter and reset the interrupt timer prematurely, preventing an interrupt from occurring.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

TB4ICR1–TB9ICR1	ENETC0_SI0: Register not supported ENETC1_SI0,ENETC1_SI1: 0000_0000h

Fields

Field	Function
31-0 ICTT	Interrupt coalescing timer threshold, specified in units of NETC clock cycles. When interrupt coalescing is enabled, TB*a*ICR0[ICEN]=1, this value determines the maximum amount of time allowed between a first transmitted packet until the TB*a*ICR0[ICPT] threshold is reached. If the timer expires before threshold reached, the interrupt event TB*a*IDR[TXT] is asserted. The timer operates on the NETC platform clock. A register value of zero indicates the timer is disabled. One of the following conditions will reset the timer: • Disabling transmit ring (TB*a*MR[EN]=0) • Reading TB*a*IDR • Writing a 1 to SITXIDR[TXT*a*] **NOTE** If timer threshold is used it should be set when TB*a*ICR0[ICEN]=0 to avoid missing a "first packet" transmitted condition which starts the timer.

53.4.6.11.102 Rx BDR a mode register (RB0MR - RB9MR)

Offset

For a = 0 to 9:

Register	Offset
RBaMR	8100h + (a × 200h)

Function

Fields

Field	Function
31 EN	Enable receive buffer descriptor ring 0 Disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1 Enabled.
30-10 —	Reserved
9 —	Reserved
8 CRC	Indicates if CRC32 (FCS) is to be stripped or preserved at the end of the frame. 0: CRC (FCS) is stripped 1: CRC (FCS) is preserved **NOTE** If this field is set to 1 (CRC is preserved) and offloading of VLAN tag removal is requested then the CRC of the frame delivered to the host will be bad as the CRC is not updated as a result of the frame modification.
7 —	Reserved
6 VTPD	VLAN tag presentation disable Controls whether the extracted VLAN tag is provided in the Rx BD. If set (b1) this presentation is disabled. Valid only if the VTE bit in this register is set to 1.
5 VTE	VLAN tag extract enable Controls whether the outer VLAN, as seen by the SI, is extracted. Note that this may be the second VLAN in the frame, if the actual outer VLAN matches the SI-based VLAN for this SI and the PSI has enabled removal of that tag. 0 Disabled 1 Enabled
4 CM	Congestion mode Determines the congestion scheme for the receive ring. In lossless mode, when a frame encounters lack of buffers to complete writing the frame to memory, it will back-pressure to the Ingress Congestion Manager (ICM) which in turn can start generating PAUSE frames when received frames are starting to consume too much of the internal frame memory. In lossy mode, tail drop is invoked to handle fullness of the ring. 0 Lossy 1 Lossless

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field is not applicable to transmit timestamp reference responses which are identified by their Host Reason code (0x3 Timestamp Response). If a receive BD ring reaches full level (i.e. no BDs/buffers are available when a transmit timestamp reference response is ready to be delivered to the host), HTA will wait for more BDs to be added to the ring by software; the transmit timestamp reference response will not be dropped.
3 —	Reserved
2 BDS	BD Size A BD ring can use either the standard 16B or extended 32B buffer descriptor format. 0 16B buffer descriptors format 1 32B buffer descriptors format
1 —	Reserved
0 AL	Header alignment If set, an additional 2-byte alignment is applied to the header in the 1st buffer descriptor. It can be used to align the IP address in the frame. 0 No alignment added 1 +2B alignment added to frame.

53.4.6.11.103 Rx BDR a status register (RB0SR - RB9SR)

Offset

For a = 0 to 9:

Register	Offset
RBaSR	8104h + (a × 200h)

Function

This is the status register for a receive buffer descriptor ring.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

Fields

Field	Function
31-17 —	Reserved
16 SBE	System bus error A system bus error has occurred during one or more transactions related to this receive ring, including possibly the receive BD writeback entry itself. To avoid the possibility of referencing unreliable BD writeback contents, SBE can be checked at every observed RB*a*PIR movement. See error detect register SIUNSBESR/SIUFSBESR for more information. Write 1 to clear.
15-1 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 EMPTY	Ring is empty Indicates the ring is empty of received BDs. Valid when RB*a*MR[EN]=1.

53.4.6.11.104 Rx BDR a buffer size register (RB0BSR - RB9BSR)

Offset

For a = 0 to 9:

Register	Offset
RBaBSR	8108h + (a × 200h)

Function

This is the buffer size register for the receive buffer descriptor ring. All buffers in the receive ring have the same size which allows the first buffer descriptor to indicate the total packet size.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_SI0	RB0BSR–RB3BSR	RB4BSR–RB9BSR

Fields

Field	Function
31-16 —	Reserved
15-0 BSIZE	Buffer size Indicates the buffer size for the buffer pool used. 0x0000 64 KB 0x0080 128 bytes 0x0081 129 bytes ... 0x0100 256 bytes ... 0xFFFF 64 KB - 1 Minimum buffer size is 128 bytes. For better performance, it is recommended not to use a buffer size smaller than 256 bytes.

53.4.6.11.105 Rx BDR a consumer index register (RB0CIR - RB9CIR)

Offset

For a = 0 to 9:

Register	Offset
RBaCIR	810Ch + (a × 200h)

Function

This is the receive ring consumer index register which indicates the next BD to be released to NETC for received frames. Software will initialize the buffer address in the BD and provide to hardware. Whenever the consumer index matches the value of the producer index, all BDs in the ring are considered initialized. Software writes this register during operation of the ring to indicate that any receive data occupied in the BD has been processed and it has been prepared for new data.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_SI0	RB0CIR–RB3CIR	RB4CIR–RB9CIR

Fields

Field	Function
31-0 ADDRH	Upper address bits 63-32.

53.4.6.11.108 Rx BDR a producer index register (RB0PIR - RB9PIR)

Offset

For a = 0 to 9:

Register	Offset
RBaPIR	8118h + (a × 200h)

Function

This is the producer index which indicates the BD used for the data of the next received frame. The producer index is initially configured by software but owned by hardware after the ring has been enabled. Hardware increments the index when a frame is received which may consume one or more BDs. Hardware is not allowed to increment the producer index to match the consumer index (RB*a*CIR) since ring can hold at most RB*a*LENR[LENGTH]*8-1 received BDs. Whenever the producer index matches the value of the consumer index, the ring has no unprocessed received frames and all BDs in the ring have been initialized/prepared by software, i.e. hardware owns all BDs in the ring.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_SI0	RB0PIR–RB3PIR	RB4PIR–RB9PIR

Fields

Field	Function
31-16 —	Reserved
15-0 BDR_INDEX	Receive buffer descriptor ring producer index. Range of index depends on ring size RB*a*LENR[LENGTH].

53.4.6.11.109 Rx BDR a length register (RB0LENR - RB9LENR)

Offset

For a = 0 to 9:

Register	Offset
RBaLENR	8120h + (a × 200h)

Function

This is the receive BDR length register. It determines the size of the receive ring in sets of 8 BDs. The receive ring can only hold RB*a*LENR[LENGTH]*8-1 frames since no wrap bit is used to calculate full/empty conditions from consumer/producer indices.

One entry is used to differentiate between full and empty ring. When producer index + 1 equals consumer index, the ring is considered full. When the producer/consumer indices match, the ring is always considered empty.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

Field	Function
31-1 —	Reserved
0 RXTIE	Receive threshold interrupt enable 0 Disabled 1 Enabled

53.4.6.11.112 Rx BDR a interrupt detect register (RB0IDR - RB9IDR)

Offset

For a = 0 to 9:

Register	Offset
RBaIDR	81A4h + (a × 200h)

Function

This is the interrupt detect register for the receive buffer descriptor ring. Reading will automatically clear all events. Register SIRXIDR provides a non-destructive read access. It is not necessary to clear/set the RBaIER register upon entry/exit of the service routine. A new interrupt is generated in the event of a set/clear collision in this register.

RBaIDR should not be polled if interrupt coalescing is enabled. Polling reads of RBaIDR clear the frame counter and reset the interrupt timer prematurely, preventing an interrupt from occurring.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENETC0_SI0	RB0IDR–RB3IDR	RB4IDR–RB9IDR

RB4ICR0–RB9ICR0	ENETC0_SI0: Register not supported ENETC1_SI0,ENETC1_SI1: 0000_0000h

Fields

Field	Function
31 ICEN	Interrupt coalescing enable 0 Interrupt coalescing is disabled 1 Interrupt coalescing is enabled. If the receive ring threshold interrupt is enabled (RB*a*IER[RXTIE] is set), an interrupt is raised when the threshold number of packets is reached (as defined by RB*a*ICR0[ICPT]) or when the threshold timer expires (as defined by RB*a*ICR1[ICTT]).
30-9 —	Reserved
8-0	Interrupt coalescing packet threshold

Table continues on the next page...

Table continued from the previous page...

Field	Function
ICPT	While interrupt coalescing is enabled, ICEN=1, this values determines the minimum number of packets received before raising an interrupt. The counter starts when ICEN is first set and one of the following events will restart the threshold counter: • Disabling receive ring (RB*a*MR[EN]=0) • Writing RB*a*ICR0 • Reading RB*a*IDR • Writing a 1 to SIRXIDR[RXT*a*] Settings: b0_0000_0000 Disabled b0_0000_0001 1 packet received b0_0000_0010 2 packets received b0_0000_0011 3 packets received ... b1_1111_1111 511 packets received **NOTE** If timer threshold is used it should be set when RB*a*ICR0[ICEN]=0 to avoid missing a "first packet" received condition which starts the timer. The threshold is based on received packets and does not include packets already present in the ring as a starting condition, therefore software should process all BDs in the ring and not just a number based on the threshold value.

53.4.6.11.114 Rx BDR a interrupt coalescing register 1 (RB0ICR1 - RB9ICR1)

Offset

For a = 0 to 9:

Register	Offset
RBaICR1	81ACh + (a × 200h)

Function

The receive ring interrupt coalescing register enables and configures the parameters for interrupt coalescing associated with received packets.

NOTE

Each module instance supports a different number of registers.

Fields

Field	Function
31-0 ICTT	Interrupt coalescing timer threshold ,specified in units of NETC clock cycles. When interrupt coalescing is enabled, RB*a*ICR0[ICEN]=1, this value determines the maximum amount of time allowed between a first received packet until RB*a*ICR0[ICPT] threshold is reached. If the timer expires before threshold reached, the interrupt event RB*a*IDR[RXT] is asserted. The timer operates on the NETC platform clock. A register value of zero indicates the timer is disabled. One of the following conditions will reset the timer: • Disabling receive ring (RB*a*MR[EN]=0) • Reading RB*a*IDR • Writing a 1 to SIRXIDR[RXT*a*]

Table continues on the next page...

Field	Function
	NOTE If timer threshold is used it should be set when RB*a*ICR0[ICEN]=0 to avoid missing a "first packet" received condition which starts the timer.

53.4.6.12 NETC EMDIO base function register descriptions

This section describes the NETC device registers for the EMDIO base PCIe function.

The base address listed is relative to the PCIe function's base address register value can be discovered from reading the PCIe Enhanced Allocation Base Address Register Equivalent Index 0 (EA BEI 0).

4-0 DEV_ADDR	5-bit MDIO device address (Clause 45) / register address (Clause 22)

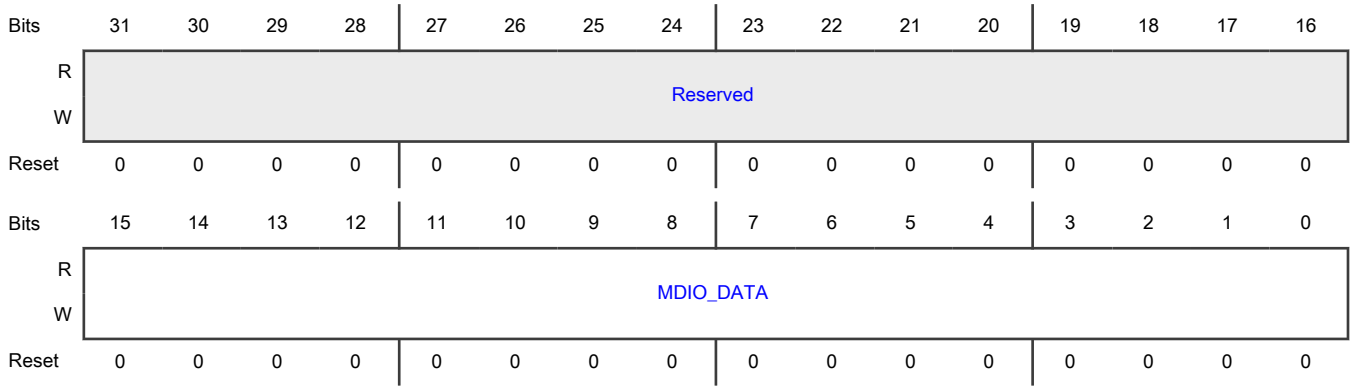
53.4.6.12.4 External MDIO interface data register (EMDIO_DATA)

Offset

Register	Offset
EMDIO_DATA	1C08h

Function
This is the external MDIO interface data register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 MDIO_DATA	16-bit MDIO data. Writing to this register initiates a write transaction to the PHY. For proper operation, the EMDIO_CTL register must have been initialized first. The EMDIO_CFG[BUSY] status bit is set immediately and cleared when the write transaction has completed. Reading this register returns data read from the PHY register specified in EMDIO_CTL after a read transaction has completed. Read transactions are initiated by writing a 1 to EMDIO_CTL[READ] or EMDIO_CTL[POST_INC]. Read data is invalid if EMDIO_CFG[BUSY] is set.

53.4.6.12.5 External MDIO register address register (EMDIO_ADDR)

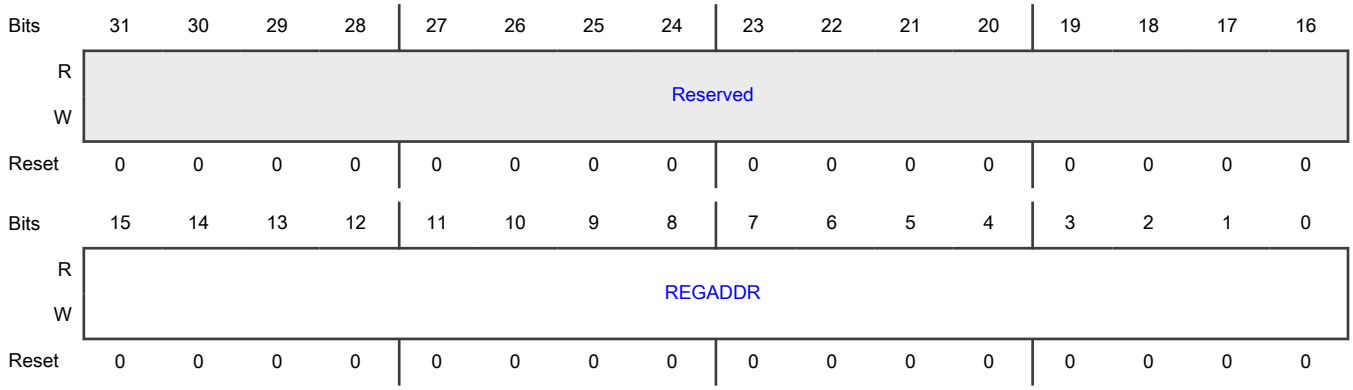
Offset

Register	Offset
EMDIO_ADDR	1C0Ch

Function

This is the external MDIO register address register, and is used to communicate with an attached Clause 45 PHY.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 REGADDR	MDIO PHY register address. Address of the register within the Clause 45 PHY device from which data is to be read or to which data is to be written. Writing to this register initiates an address-write transaction to set the PHY's internal address register to the value specified in EMDIO_ADDR[REGADDR]. For proper operation, the EMDIO_CTL register must have been initialized prior to writing to this register.

53.4.6.12.6 External MDIO status register (EMDIO_STAT)

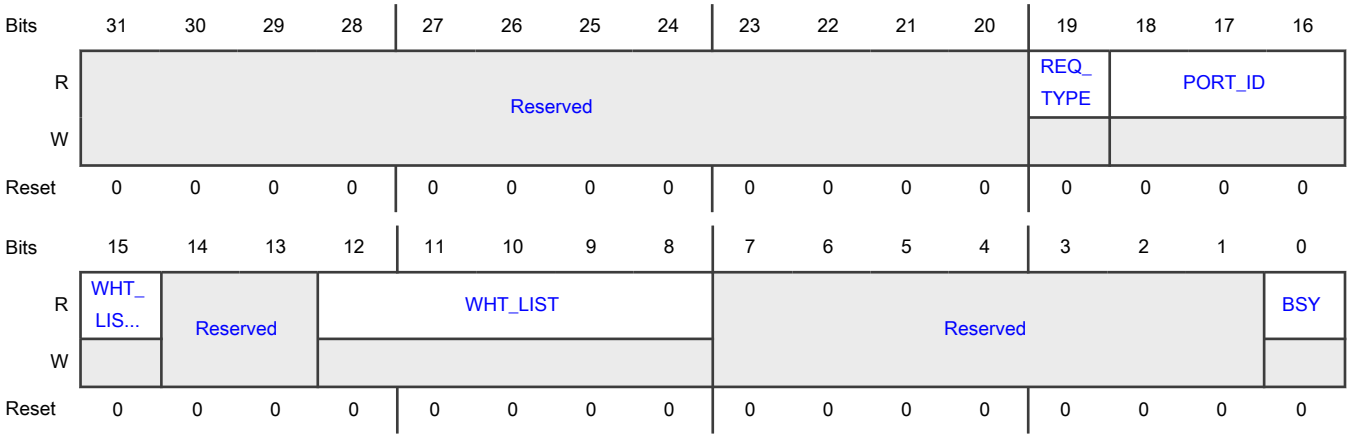
Offset

Register	Offset
EMDIO_STAT	1C10h

Function

This is the external MDIO status register.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 REQ_TYPE	Port ID Returns the request type of the active virtual port. 0 MDIO request 1 PHY polling
18-16 PORT_ID	Port ID Returns the port ID of the active virtual port. Matches the value EMDIO_CFG[WHOAMI] of active port.
15 WHT_LIST_ENA	PHY white list enable Returns the PHY white list enable of the active virtual port.
14-13 —	Reserved
12-8 WHT_LIST	PHY white list Returns the PHY white list address of the active virtual port.
7-1 —	Reserved
0 BSY	Global MDIO busy 0 An MDIO transaction is not occurring; software may access other MDIO registers. 1 An MDIO transaction is occurring.

53.4.6.12.7 PHY status configuration register (PHY_STATUS_CFG)

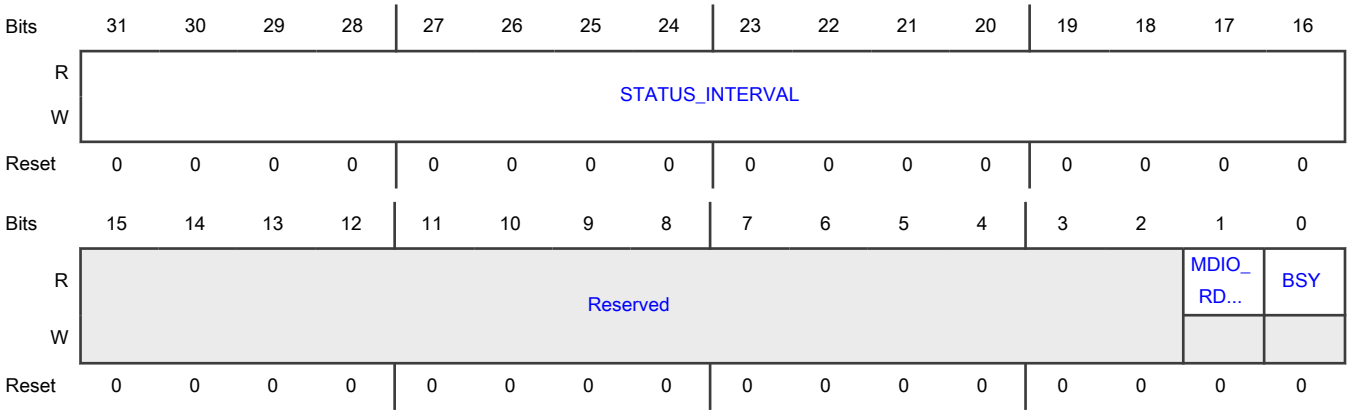
Offset

Register	Offset
PHY_STATUS_CFG	1C20h

Function

This is the PHY status configuration register.

Diagram



Fields

Field	Function
31-16 STATUS_INTERVAL	PHY status read interval Amount of time to wait between PHY status reads, in units of 1-2 ms. A value of 0 indicates auto PHY automatic status reads are disabled.
15-2 —	Reserved
1 MDIO_RD_ER	MDIO read error 1 The last read transaction received no response from a PHY; any data read should be considered invalid. (for example, The PHY address does not match any PHY available on the MDIO bus.)
0 BSY	MDIO busy 0 An MDIO transaction is not occurring; software may access other MDIO registers. 1 An MDIO transaction is occurring.

53.4.6.12.8 PHY status control register (PHY_STATUS_CTL)

Offset

Register	Offset
PHY_STATUS_CTL	1C24h

Function
This is the PHY status control register.

Diagram

53.4.6.13 Timer register descriptions

This section describes the Timer registers to support the IEEE 1588 embedded PCIe function.

The base address listed is relative to the PCIe function's base address register value discovered from reading the PCIe Enhanced Allocation Base Address Register Equivalent Index 0 (EA BEI 0).

NOTE

Timer does not return an error on invalid register accesses, but returns 0's on reads in invalid registers, and silently drops writes to invalid or read-only registers.

26 PP2L	Fiper2 pulse loop back mode enabled 0 Trigger2 input is based upon normal external trigger input 1 Fiper2 pulse is looped back into Trigger2 input
25-16 TCLK_PERIOD	1588 timer reference clock period The value programmed by user in this field ideally represents the frequency of the phase adjusted clock period. The timer clock counter will increment by TCLK_PERIOD every clock cycle. When this field is being used to track time, this clock period must be equal to the clock period of the timer reference clock. For applications where user does not want the clock period to be added, they can program this field to 1 to count the clock ticks. Note: For customers sensitive to consistency in time-stamp values, it is recommended the selected frequency is fixed at a period that is an integer multiple value.
15 COMP_MODE	Mode bit to allow atomic writes to TCLK_PERIOD and TMR_ADD If drift compensation requires updates to TCLK_PERIOD and TMR_ADD, the resulting time will be inconsistent for the time it takes to do the two register writes. Setting this Compensation Mode bit makes the writes atomic. An update to TCLK_PERIOD doesn't take effect until TMR_ADD is written. That would allow writes to TMR_ADD alone, or TMR_CTRL[TCLK_PERIOD]+TMR_ADD. 0 Atomic updates to TMR_PERIOD and TMR_ADD disabled 1 Allow atomic updates to TMR_PERIOD and TMR_ADD

53.4.6.13.11 Timer Event Register (TMR_TEVENT)

Offset

Register	Offset
TMR_TEVENT	84h

Function

The IEEE 1588 timer implementation requires several interrupt event signals. Software may poll this register at any time to check for pending interrupts. If an event occurs and its corresponding enable bit is set in the event mask register (TEMASK), the event also causes a hardware interrupt. A bit in the timer event register is cleared by writing a 1 to that bit position.

TMR_TEMASK	88h

Function

Timer event mask register. The event mask register provides control over which possible interrupt events in the TMR_TEVENT register are permitted to participate in generating hardware interrupts to the PIC. All implemented bits in this register are R/W and cleared upon a hardware reset.

Diagram

53.4.6.13.13 Timer status register (TMR_STAT)

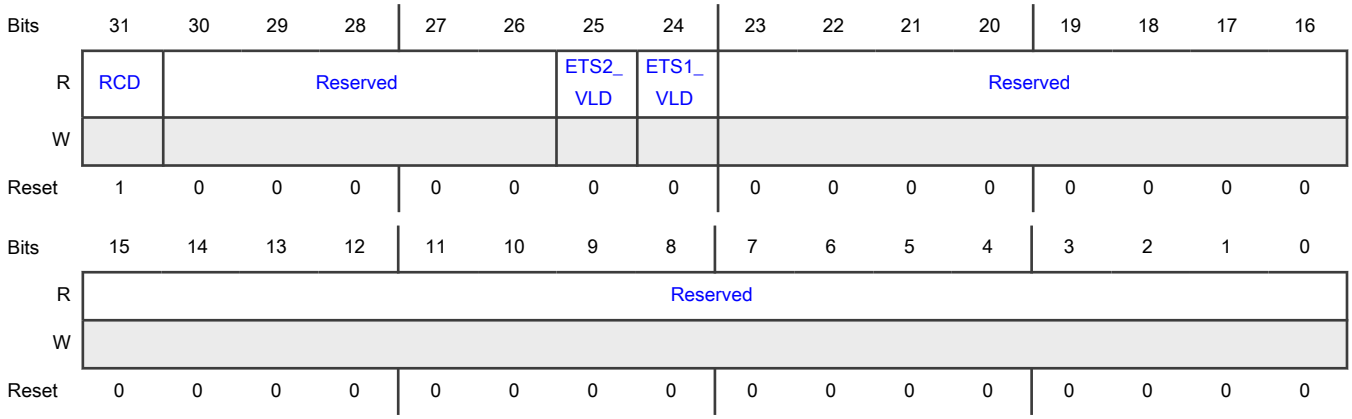
Offset

Register	Offset
TMR_STAT	94h

Function

The timer TMR_STAT register returns relevant dynamic timer status that does not generate an interrupt. This register is read only.

Diagram



Fields

Field	Function
31 RCD	Timer Reference Clock Detected The selected timer clock, TMR_CTRL[CK_SEL], is sensed as being active. When it is not active, register read/write accesses to timer clock domain registers will not be allowed. Refer to Table "Timer Clock Domain Register List" and Table "Platform Clock Domain Register List". **NOTE** This bit is not functional when the external system clock selected is not active. Access to the TMR registers in IEEE1588 clock domain will cause a hang. The bit is not functional if the external clock selected becomes inactive after RCD is set to 1. 0b - Reference Clock has not been detected as active. Registers in timer clock domain are not allowed to be accessed; reads return 0, writes are ignored. 1b - Reference Clock has been detected as active. Registers in timer clock domain are allowed to be accessed.
30-26 —	Reserved
25 ETS2_VLD	External trigger 2 Valid time-stamp 0 all valid external trigger time-stamps have been read 1 external trigger has an unread valid time-stamp value
24 ETS1_VLD	External trigger 1 Valid time-stamp 0 all valid external trigger time-stamps have been read 1 external trigger has an unread valid time-stamp value
23-0 —	Reserved

53.4.6.13.14 Timer counter low register (TMR_CNT_L)

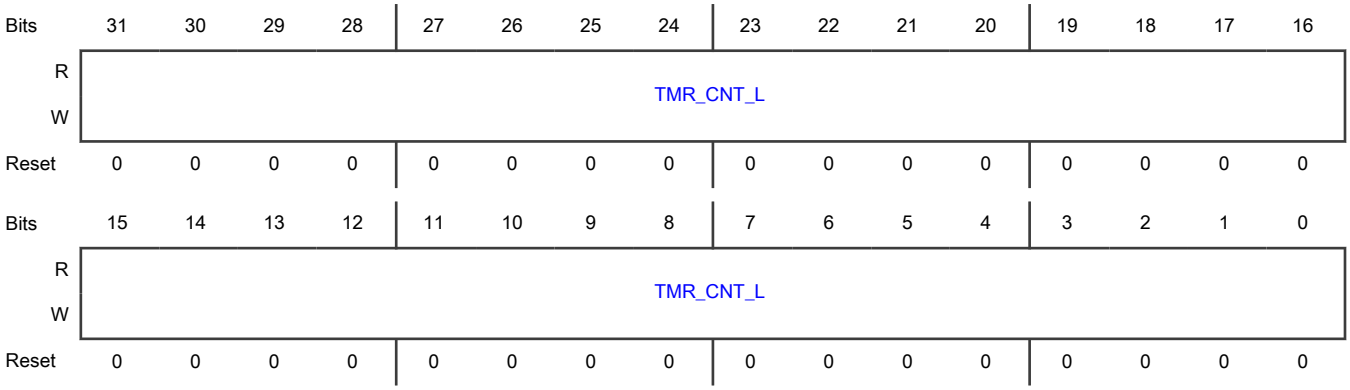
Offset

Register	Offset
TMR_CNT_L	98h

Function

If the timer module is in master mode, the timer register (TMR_CNT_H/L) represents accurate time in terms of nanoseconds. Writes to these registers will override the previous time. This is a read/write register.

Diagram



Fields

Field	Function
31-0 TMR_CNT_L	Timer counter register. Current time is calculated by adding TMROFF_H/L with the TMR_CNT_H/L counter. This register can be written through the register writes. Writes to the TMR_CNT_L register copies the written value into the shadow TMR_CNT_L register. Writes to the TMR_CNT_H register copies the values written into the shadow TMR_CNT_H register. Contents of the shadow registers are copied into the TMR_CNT_L and TMR_CNT_H registers following a write into the TMR_CNT_H register. Writes to these registers have precedence over the timer increment. The user must write to TMR_CNT_L register first. Reads from the TMR_CNT_L register copies the entire 64-bit clock time of the read enable into the TMR_CNT_H/L shadow registers. Read instruction from the TMR_CNT_H register reads the value stored in the TMR_CNT_H shadow register. The user must read the TMR_CNT_L register first to get correct 64-bit TMR_CNT_H/L counter values.

53.4.6.13.15 Timer counter high register (TMR_CNT_H)

Offset

Register	Offset
TMR_CNT_H	9Ch

Function

If the timer module is in master mode, the timer register (TMR_CNT_H/L) represents accurate time in terms of nanoseconds. Writes to these registers will override the previous time. This is a read/write register.

Diagram

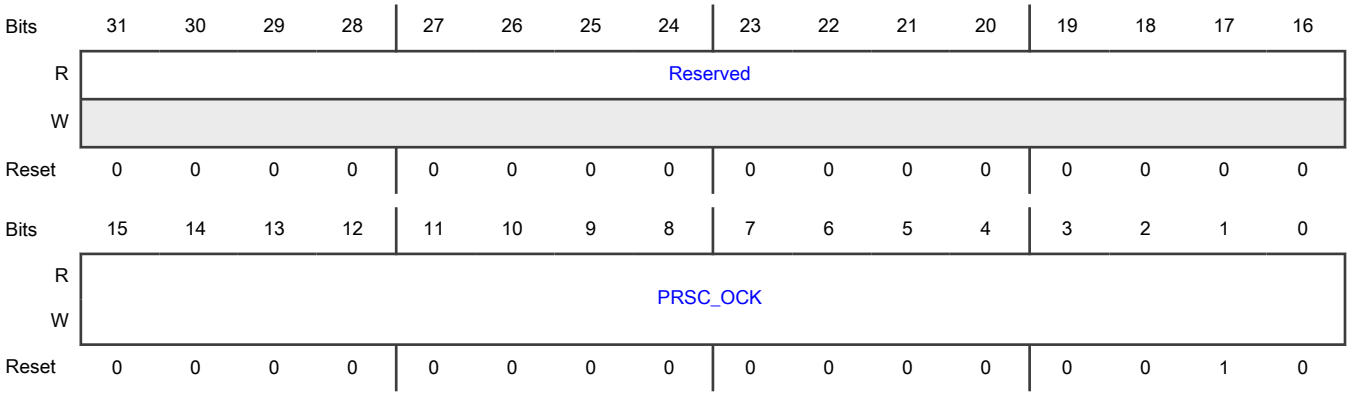
53.4.6.13.18 Timer prescale register (TMR_PRSC)

Offset

Register	Offset
TMR_PRSC	A8h

Function
TMR_PRSC Register Definition

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PRSC_OCK	Output clock division prescale factor. Output FIPER pulse clock (TMR_GCLK) is generated by dividing the timer input clock by this number. PRSC_OCK must be an even value.

53.4.6.13.19 Extended timer control register (TMR_ECTRL)

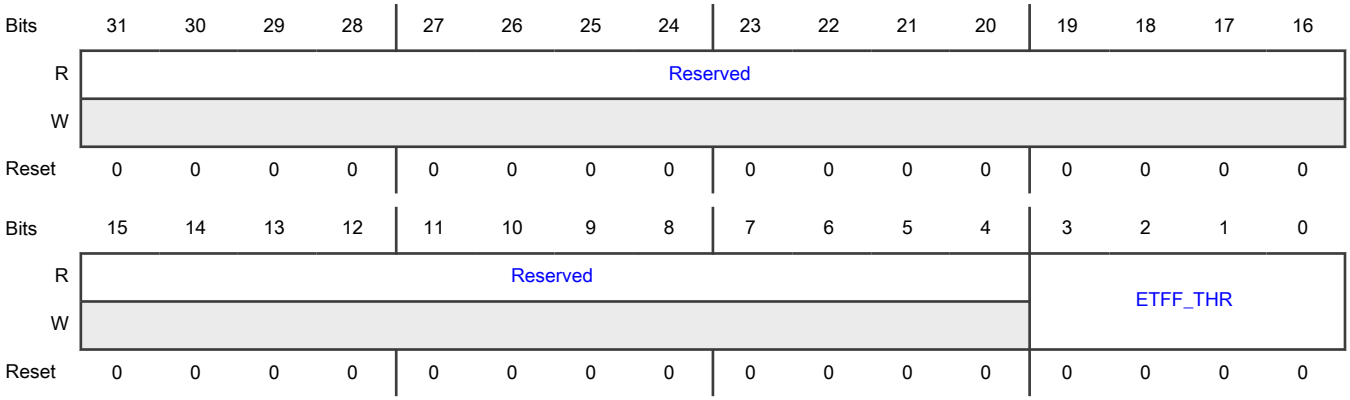
Offset

Register	Offset
TMR_ECTRL	ACh

Function

The Extended Control register provides user additional control of the Timer unit. This sections figure describes the definition for the TMR_ECTRL register.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 ETFF_THR	External trigger FIFO threshold. The External Trigger FIFO Threshold register can control when the TMR_TEVENT[ETTSn] interrupt will assert. It can be used to know when the 16-deep entry FIFO is near full, or to gather several ETTn Time-Stamps before being serviced.0000 - Set TMR_TEVENT[ETTn] when 1 or more entry is in ETTSn FIFO, clear if less0001 - Set TMR_TEVENT[ETTn] when 2 or more entries are in ETTSn FIFO, clear if less0010 - Set TMR_TEVENT[ETTn] when 3 or more entries are in ETTSn FIFO, clear if less...1110 - Set TMR_TEVENT[ETTn] when 15 or more entries are in ETTSn FIFO, clear if less1111 - Set TMR_TEVENT[ETTn] when 16 entries are in ETTSn FIFO, clear if less

53.4.6.13.20 Timer offset low register (TMROFF_L)

Offset

Register	Offset
TMROFF_L	B0h

Function

The timer offset register is used to adjust current time by adding its value to the clock counter. Value is in ns.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 TMROFF_H	Offset value of the clock counter. Current time in is calculated by adding TMROFF_H/L with the timer's counter TMR_CNT_H/L register.

53.4.6.13.22 Alarm 1 time comparator low register (TMR_ALARM1_L)

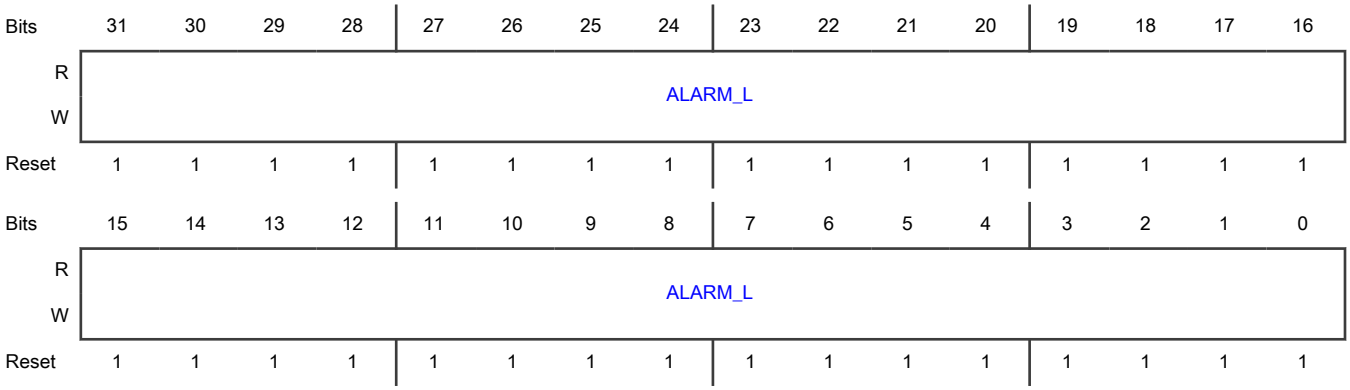
Offset

Register	Offset
TMR_ALARM1_L	B8h

Function

This register holds alarm time for comparison with the current time counter. There are two registers - one per alarm, for the 1588 timer.

Diagram



Fields

Field	Function
31-0 ALARM_L	Alarm time comparator register. The corresponding alarm event in TMR_TEVENT is set when the current time counter becomes equal to or greater than the alarm time compare value in TMR_ALARMn_L/H. By default, once the timer is enabled, the Alarm is armed and will fire if it is not deactivated. Writing the TMR_ALARMn_L register deactivates the alarm event after it has fired. Writing the TMR_ALARMn_L followed by the TMR_ALARMn_H register rearms the alarm function with the new compare value. The value programmed in this register must be an integer multiple of TMR_CTRL[TCLK_PERIOD] in order to get correct result. This register is reset to all ones to avoid false alarm after reset. In FS mode the alarm trigger is used as an indication to the fiper start down counting. Only alarm 1 supports this mode. In FS mode, alarm polarity bit should be configured to 0 (rising edge).

53.4.6.13.23 Alarm 1 time comparator high register (TMR_ALARM1_H)

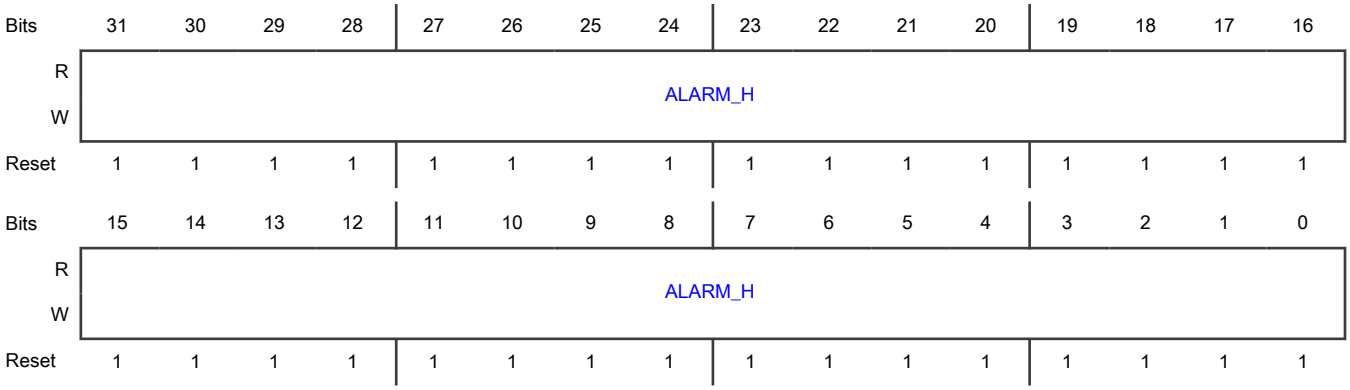
Offset

Register	Offset
TMR_ALARM1_H	BCh

Function

This register holds alarm time for comparison with the current time counter. There are two of these registers for the 1588 timer IP.

Diagram



Fields

Field	Function
31-0 ALARM_H	Alarm time comparator register. The corresponding alarm event in TMR_TEVENT is set when the current time counter becomes equal to or greater than the alarm time compare value in TMR_ALARMn_L/H. By default, once the timer is enabled, the Alarm is armed and will fire if it is not deactivated. Writing the TMR_ALARMn_L register deactivates the alarm event after it has fired. Writing the TMR_ALARMn_L followed by the TMR_ALARMn_H register rearms the alarm function with the new compare value. R W	FIPER															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
31-0 FIPER	Fixed Interval Pulse Period Controls the interval of FIPER pulses. Set to desired FIPER interval in ns - TCLK_PERIOD. This register is reset with 0xFFFF_FFFF. FIPER must be at least 4*PRSC_OCK*TIMER_CLK period. See Generating periodic pulses for more details on generating periodic pulses with FIPER.

53.4.6.13.28 Timer FIPER Control Register (TMR_FIPER_CTRL)

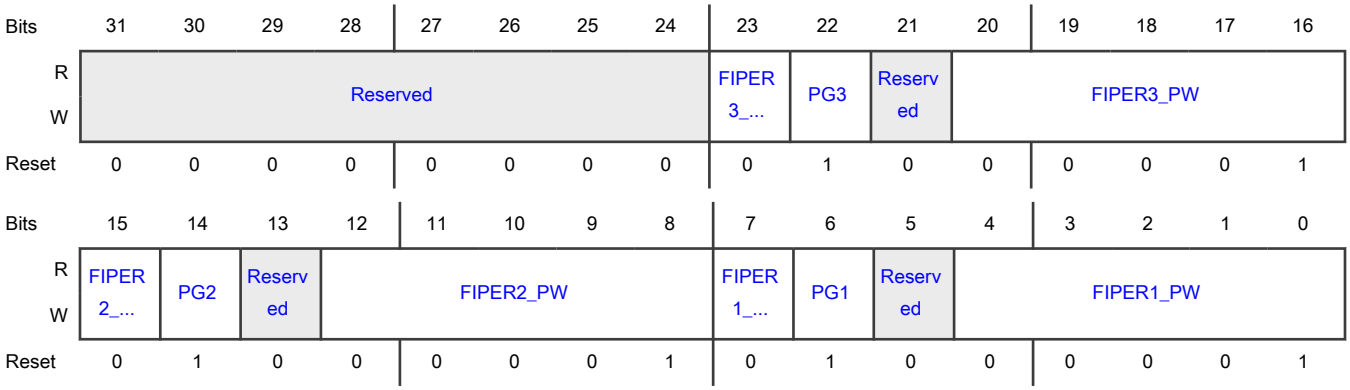
Offset

Register	Offset
TMR_FIPER_CTRL	DCh

Function

This register is used to configure, FIPER1, FIPER2, and FIPER control details.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 FIPER3_DIS	FIPER3 disable Disables FIPER 3 generation. Generation must be disabled before changing FIPER configuration. 0 - FIPER 3 is enabled, and will assert as configured 1 - FIPER 3 is disabled.
22 PG3	FIPER3 pulse generation time Selects whether FIPER3 output is asserted aligned to TMR_GCLK. FIPER3 deassertion is always aligned to TMR_GCLK 0 - FIPER 3 output asserted immediately after interval timer expires. 1 - FIPER 3 output asserted synchronous to timer generated clock. (Default)
21 —	Reserved
20-16	FIPER 3 pulse width selection

Table continues on the next page...

Table continued from the previous page...

Field	Function
FIPER3_PW	FIPER pulse width, in multiples of TMR_GCLK period. The default value is 1. Actual pulse width may be less than FIPER3_PW by up to 1 TMR_GCLK period if PG1=0. The pulse width value must be less than the FIPER interval, with recommended setting less than half of FIPER interval. For example: If PRSC_OCK = 2, timer clock is 200 MHz and FIPERn register is programmed to 200 ns, FIPERn_PW must not be > 20, and recommended value is < 10. 5'h00 : Reserved 1 - 31 : Number of timer generated clocks the FIPER will be active for.
15 FIPER2_DIS	FIPER2 disable Disables FIPER 2 generation. Generation must be disabled before changing FIPER configuration. 0 - FIPER 2 is enabled, and will assert as configured 1 - FIPER 2 is disabled.
14 PG2	FIPER2 pulse generation time Selects whether FIPER2 output is asserted aligned to TMR_GCLK. FIPER2 deassertion is always aligned to TMR_GCLK 0 - FIPER 2 output asserted immediately after interval timer expires. 1 - FIPER 2 output asserted synchronous to timer generated clock. (Default)
13 —	Reserved
12-8 FIPER2_PW	FIPER 2 pulse width selection FIPER pulse width, in multiples of TMR_GCLK period. The default value is 1. Actual pulse width may be less than FIPER2_PW by up to 1 TMR_GCLK period if PG1=0. The pulse width value must be less than the FIPER interval, with recommended setting less than half of FIPER interval. For example: If PRSC_OCK = 2, timer clock is 200 MHz and FIPERn register is programmed to 200 ns, FIPERn_PW must not be > 20, and recommended value is < 10. 5'h00 : Reserved 1 - 31 : Number of timer generated clocks the FIPER will be active for.
7 FIPER1_DIS	FIPER1 disable Disables FIPER 1 generation. Generation must be disabled before changing FIPER configuration. 0 - FIPER 1 is enabled, and will assert as configured 1 - FIPER 1 is disabled.
6 PG1	FIPER1 pulse generation select Selects whether FIPER1 output is asserted aligned to TMR_GCLK. FIPER1 deassertion is always aligned to TMR_GCLK 0 - FIPER 1 output asserted immediately after interval timer expires. 1 - FIPER 1 output asserted synchronous to timer generated clock. (Default)

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 —	Reserved
4-0 FIPER1_PW	FIPER 1 pulse width selection FIPER pulse width, in multiples of TMR_GCLK period. The default value is 1. Actual pulse width may be less than FIPER1_PW by up to 1 TMR_GCLK period if PG1=0. The pulse width value must be less than the FIPER interval, with recommended setting less than half of FIPER interval. For example: If PRSC_OCK = 2, timer clock is 200 MHz (period = 5 ns) and FIPERn register is programmed to 200 ns, FIPERn_PW must not be > 20, and recommended value is < 10. 5'h00 : Reserved 1 - 31 : Number of timer generated clocks the FIPER will be active for.

53.4.6.13.29 External trigger stamp register (TMR_ETTS1_L)

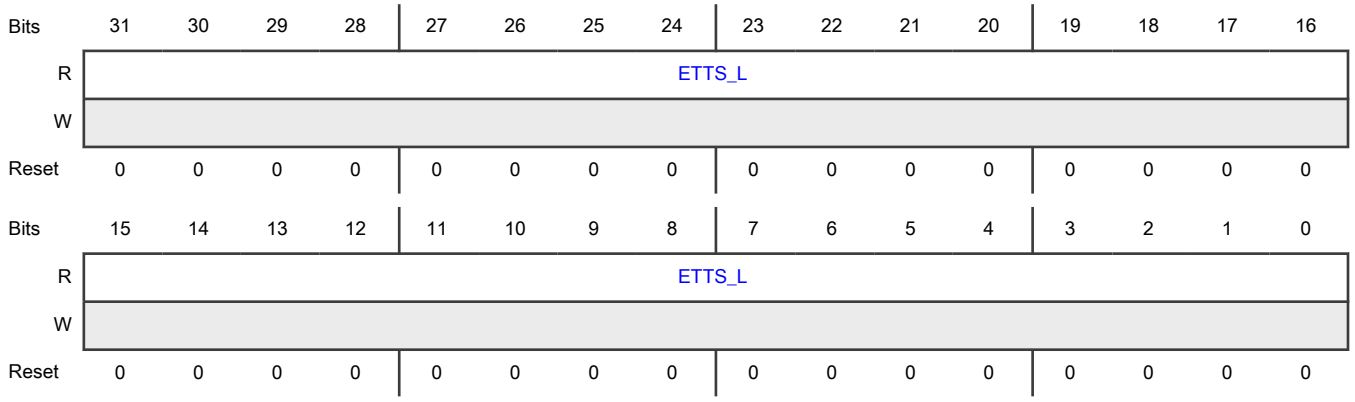
Offset

Register	Offset
TMR_ETTS1_L	E0h

Function

General purpose external trigger-stamp register (TMR_ETTSn_H/L). This register holds time at the programmable edge of the external trigger. This register is read only.

Diagram



Fields

Field	Function
31-0 ETTS_L	Time stamp field at the programmable edge of the external trigger. For time-stamping of back-2-back trigger events, the trigger falling edge can be no closer than 5 timer clocks to next trigger rising edge. There can be as many as 16 time-stamps queued up to be read. To properly read the external trigger time-stamps, user must wait till TMR_TEVENT[ETSn] bit or TMR_TEVENT[ETSn_THR] bit is set before reading the register. Note, both TMR_ETTSn_H and TMR_ETTSn_L must be read as a pair before the next time-stamp in the queue can be read. Else user will be re-reading the same value. For instance, a read to TMR_ETTS1_L, followed by another read to TMR_ETTS1_L, will result in a read of the same value; not until TMR_ETTS1_H is read, in this case, then a new read to TMR_ETTS1_L will return next time-stamp value in the queue. To read till empty, poll TMR_STAT[ETSn_VLD] bit in between reads to the TMR_ETTSn_H/L registers When it is clear, the time-stamp queue is empty. If the ETTSn time-stamp queue overflows, TMR_TEVENT[ETSn_OV] bit will be set, and newer time-stamps will be discarded until space is made available in the queue by a read of ETTSn_H/L pair. Hardware does not provide atomic access to this register. User must insure it is able to read the accurate time-stamp value before the next trigger event occurs.

53.4.6.13.30 External trigger stamp register (TMR_ETTS1_H)

Offset

Register	Offset
TMR_ETTS1_H	E4h

Function

General purpose external trigger-stamp register (TMR_ETTSn_H/L). This register holds time at the programmable edge of the external trigger. This register is read only.

There can be as many as 16 time-stamps queued up to be read. To properly read the external trigger time-stamps, user must wait till TMR_TEVENT[ETSn] bit or TMR_TEVENT[ETSn_THR] bit is set before reading the register. Note, both TMR_ETTSn_H and TMR_ETTSn_L must be read as a pair before the next time-stamp in the queue can be read. Else user will be re-reading the same value. For instance, a read to TMR_ETTS1_L, followed by another read to TMR_ETTS1_L, will result in a read of the same value; not until TMR_ETTS1_H is read, in this case, then a new read to TMR_ETTS1_L will return next time-stamp value in the queue. To read till empty, poll TMR_STAT[ETSn_VLD] bit in between reads to the TMR_ETTSn_H/L registers When it is clear, the time-stamp queue is empty. If the ETTSn time-stamp queue overflows, TMR_TEVENT[ETSn_OV] bit will be set, and newer time-stamps will be discarded until space is made available in the queue by a read of ETTSn_H/L pair. Hardware does not provide atomic access to this register. User must ensure it is able to read the accurate time-stamp value before the next trigger event occurs.

53.4.6.13.31 External trigger stamp register (TMR_ETTS2_L)

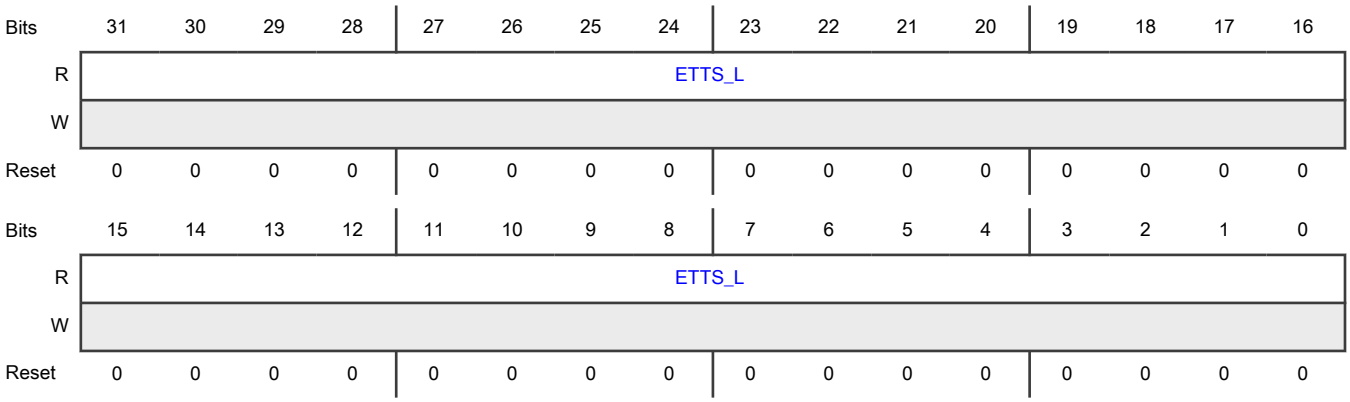
Offset

Register	Offset
TMR_ETTS2_L	E8h

Function

General purpose external trigger-stamp register (TMR_ETTSn_H/L). This register holds time at the programmable edge of the external trigger. This register is read only.

Diagram



Fields

Field	Function
31-0 ETTS_L	Time stamp field at the programmable edge of the external trigger. For time-stamping of back-2-back trigger events, the trigger falling edge can be no closer than 5 timer clocks to next trigger rising edge. There can be as many as 16 time-stamps queued up to be read. To properly read the external trigger time-stamps, user must wait till TMR_TEVENT[ETSn] bit or TMR_TEVENT[ETSn_THR] bit is set before reading the register. Note, both TMR_ETTSn_H and TMR_ETTSn_L must be read as a pair before the next time-stamp in the queue can be read. Else user will be re-reading the same value. For instance, a read to TMR_ETTS1_L, followed by another read to TMR_ETTS1_L, will result in a read of the same value; not until TMR_ETTS1_H is read, in this case, then a new read to TMR_ETTS1_L will return next time-stamp value in the queue. To read till empty, poll TMR_STAT[ETSn_VLD] bit in between reads to the TMR_ETTSn_H/L registers When it is clear, the time-stamp queue is empty. If the ETTSn time-stamp queue overflows, TMR_TEVENT[ETSn_OV] bit will be set, and newer time-stamps will be discarded until space is made available in the queue by a read of ETTSn_H/L pair. Hardware does not provide atomic access to this register. User must insure it is able to read the accurate time-stamp value before the next trigger event occurs.

53.4.6.13.32 External trigger stamp register (TMR_ETTS2_H)

Offset

Register	Offset
TMR_ETTS2_H	ECh

Function

General purpose external trigger-stamp register (TMR_ETTSn_H/L). This register holds time at the programmable edge of the external trigger. This register is read only.

53.4.6.14 NETC global register descriptions

This section describes NETC global device registers which are accessible by all NETC base functions, except where noted, and is applicable to NETC as a whole.

The base address(es) listed is per function and is relative to the PCIe function's base address register value can be discovered from reading the PCIe Enhanced Allocation Base Address Register Equivalent Index 0 (EA BEI 0).

53.4.6.14.1 Global memory map

Instance	Address space	PCIe EA BEI 0 offset
EMDIO_GLOBAL	PCI_F1_BAR_0	60BB_0000h
ENETC0_GLOBAL	PCI_F3_BAR_0	60B2_0000h
ENETC1_GLOBAL	PCI_F4_BAR_0	60B6_0000h
SW0_GLOBAL	PCI_F2_BAR_0	60A8_0000h
TMR0_GLOBAL	PCI_F0_BAR_0	60B9_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Shared memory capability register (SMCAPR)	32	R	0000_1FB0h

53.4.6.14.2 Shared memory capability register (SMCAPR)

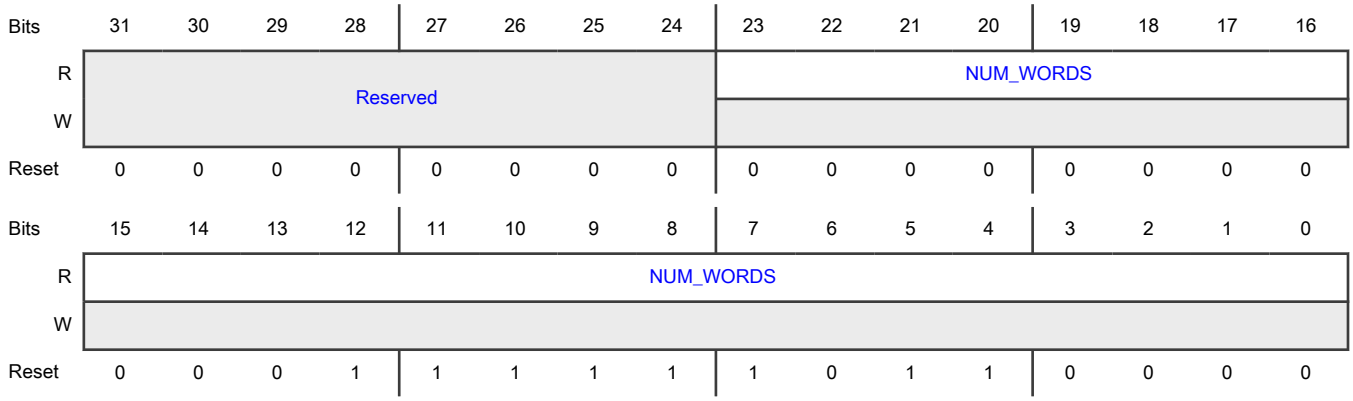
Offset

Register	Offset
SMCAPR	0h

Function

This is the shared memory capability register.

Diagram



Fields

Field	Function
31-24	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
23-0 NUM_WORDS	Total amount of words in common memory available for free list to NETC buffers, frame descriptors and hash tables. **NOTE** Value derived from IERB as follows: CMCAPR[NUM_WORDS] - HBTMAR[NUM_WORDS] - GHTEMCAPR[NUM_WORDS] - S*a*ltMAR[NUM_WORDS] - E*a*ltMAR[NUM_WORDS]

53.4.6.14.3 Shared memory depletion threshold register (SMDTR)

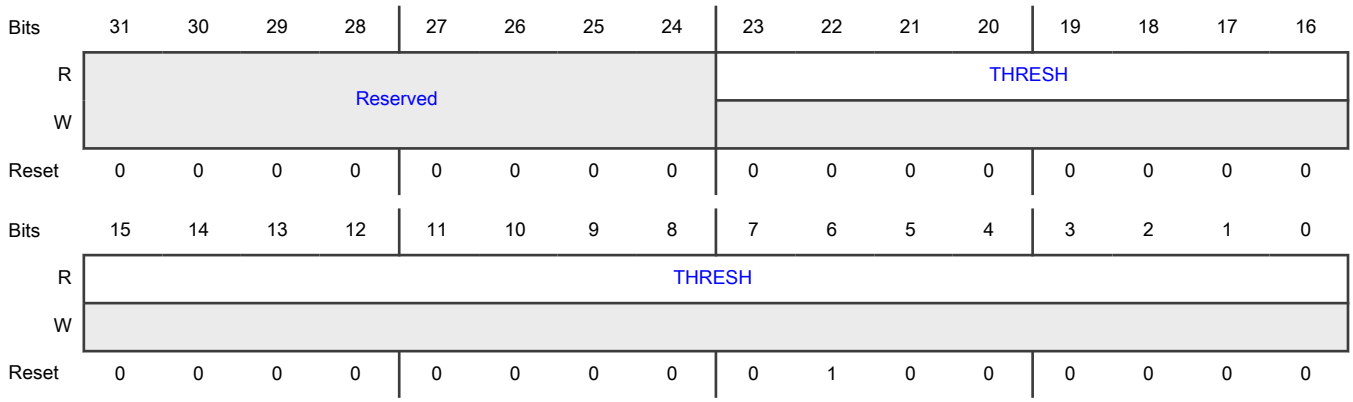
Offset

Register	Offset
SMDTR	4h

Function

This is the shared memory depletion threshold register.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 THRESH	Shared memory depletion threshold in Words.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This sets the minimum amount of free memory that should be maintained in the datapath sub system, and when the amount of shared memory falls below this threshold, a depletion indication is asserted, which may trigger "intelligent drop" of frames from the ingress queues in the ICM. Setting this field to 0 disables dropping of frames by Ingress Congestion Manager (ICM) due to internal shared memory depletion. This value is writable in IERB (by pre-boot initialization), and is immediately reflected here.

53.4.6.14.4 Shared memory available count register (SMACR)

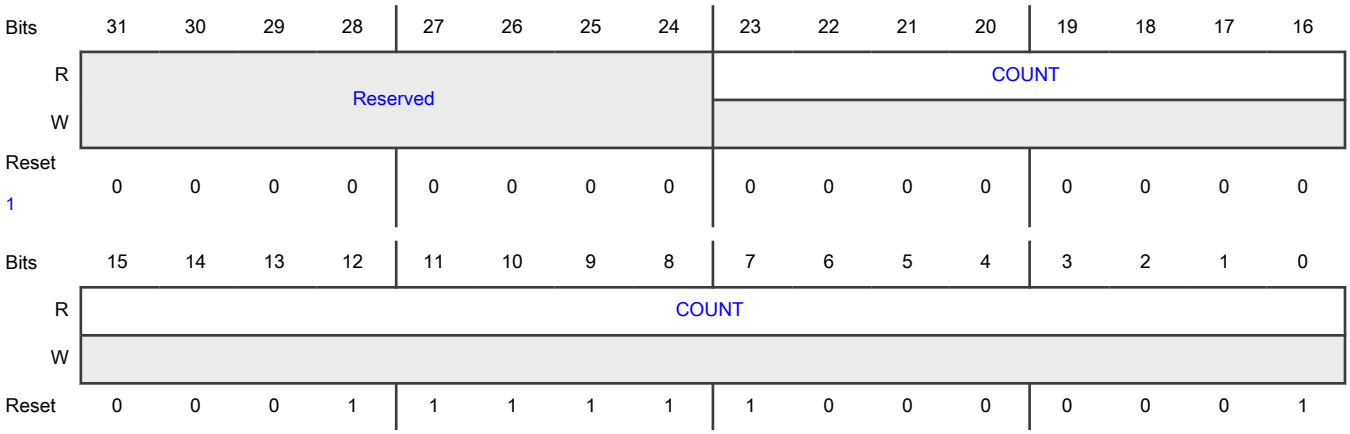
Offset

Register	Offset
SMACR	8h

Function

This is the shared memory available count register.

Diagram



1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-24 —	Reserved
23-0 COUNT	Shows the current amount of available shared memory in words.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Reset value is defined by SMCAPR - SMBUCR.

53.4.6.14.5 Shared memory count low watermark register (SMCLWMR)

Offset

Register	Offset
SMCLWMR	10h

Function

This is the shared memory count low watermark register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	WATERMARK															
W																
Reset	0	0	0	1	1	1	1	1	1	0	0	0	0	0	0	1

1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-24 —	Reserved
23-0 WATERMARK	Shows the low watermark for shared memory in words since the last read of this register. When register is read, value is reset to SMACR.

53.4.6.14.6 Shared memory buffer unassigned count register (SMBUCR)

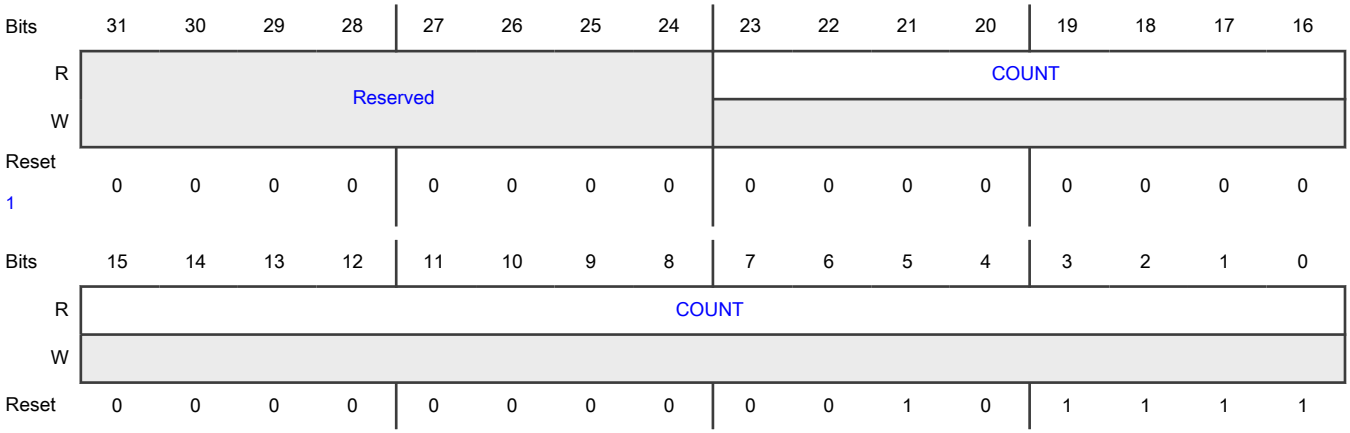
Offset

Register	Offset
SMBUCR	14h

Function

This is the shared memory buffer unassigned count register.

Diagram



1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-24 —	Reserved
23-0 COUNT	Shows the current amount of unassigned Shared memory buffer, in words. This tracks buffer memory from the shared memory partition that has been acquired (i.e. is no longer Free) but has not yet been assigned to switch frame buffering or ENETC frame buffering. This includes all buffer memory used by frames that are in transit between functions, for example in small queues between the receive MAC and the switch or ENETC queues, as well as the shared memory used for hash table entries. Unlike the other budgets, there is no allocation limit for the unassigned buffer memory. In effect, unassigned buffer memory gets to use whatever allocation is left over in the shared memory partition. It is important to note that the datapath sub-system always requires some amount of unassigned buffer memory for in-transit functions, therefore the sum of the switch, ENETC Rx, and hash table allocations must be less than the total available shared buffer memory.

53.4.6.14.7 Shared memory buffer unassigned count high watermark register (SMBUCHWMR)

Offset

Register	Offset
SMBUCHWMR	18h

Function

This is the shared memory buffer unassigned count high watermark register which shows the high watermark for unassigned memory.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1																

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WATERMARK															
W																
Reset	0	0	0	0	0	0	0	0	0	0	1	0	1	1	1	1

1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-24 —	Reserved
23-0 WATERMARK	Shows the high watermark for unassigned memory since the last read of this register, in words. After a read, this register is set equal to SMBUCR.

53.4.6.14.8 Shared memory loss count register (SMLCR)

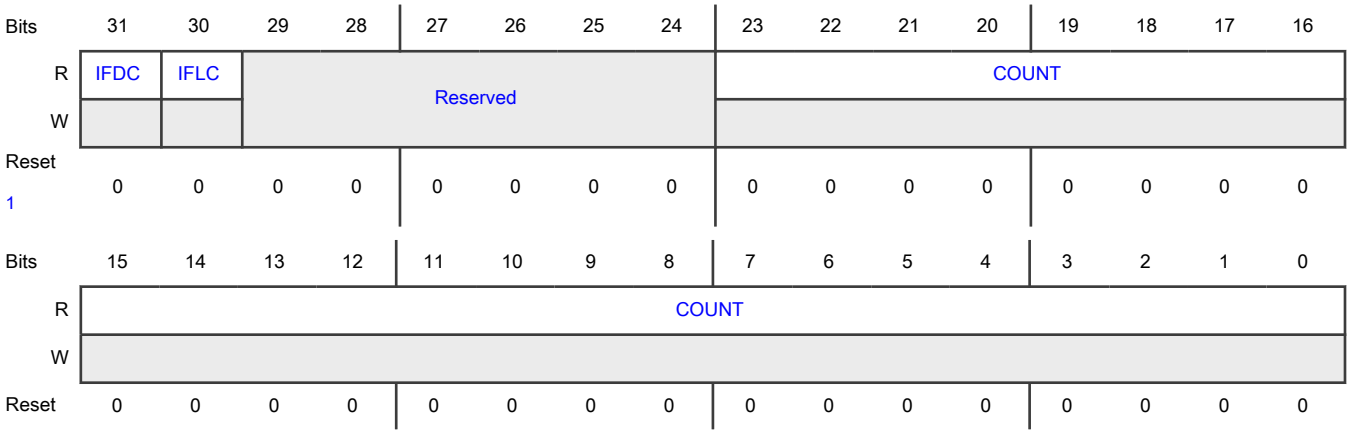
Offset

Register	Offset
SMLCR	1Ch

Function

This is the shared memory loss count register. Read-only count of the amount of shared memory in words (IMUs) lost due to multi-bit ECC memory error.

Diagram



1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31 IFDC	Indeterminate frame descriptor corruption Number of words lost due to frame's key meta data (reference count or number of IMUs) corruption. After a read operation, the field's value clears to 0.
30 IFLC	Indeterminate free list corruption Number of words lost due to free list corruption. Indeterminate number of words lost due to corruption to one of the free list. 1 = one or more IMU free lists has been disabled due to multi-bit ECC error corruption of its link pointers. After a read operation, the field's value clears to 0.
29-24 —	Reserved
23-0 COUNT	Determinate number of lost words. This is a determinate count incremented due to buffer pointer corruption.

53.4.6.14.9 Hash bucket table capability register (HBTCAPR)

Offset

Register	Offset
HBTCAPR	20h

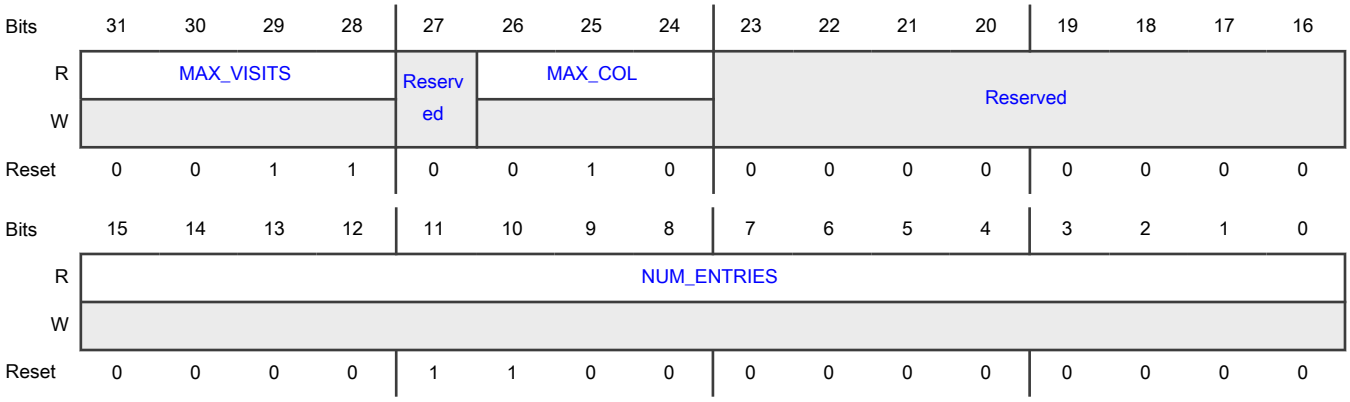
Function

This is the hash bucket table capability register.

NOTE

A write to this read-only register will return an error.

Diagram



Fields

Field	Function
31-28 MAX_VISITS	Specifies the maximum number of hash entries visited during a table management search command. Range: 64..1K Formula: 64*(n+1) n=0..15 Reset value determined by IERB register HBTCR.
27 —	Reserved
26-24 MAX_COL	Specifies the maximum exact match hash collisions chain allowed. Range: 1..3 Formula: MAX_COL+1 Entries are not allowed to be added if the hash collisions chain has reached the limit specified in this field. Reset value determined by IERB register HBTCR.
23-16 —	Reserved
15-0 NUM_ENTRIES	Specifies the total number of allocate bucket entries for use.

53.4.6.14.10 Hash bucket table operational register 0 (HBTOR0)

Offset

Register	Offset
HBTOR0	24h

Function

This is the hash bucket table operational register 0.

Diagram

1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-20 —	Reserved
19-16 HWM_COL	Length of the longest hash collision chain noticed since the last read. Range: 0..8 After a read operation, the field's value clears to 0.
15-8 RUN_AVG_INT	The integer portion of the running average length of hash lookup. This is to determine the exponential moving average latency of our hash lookup for the various tables being used. After a read operation, the field is set to 1.
7-0 RUN_AVG_FRACT	The fractional portion of the running average length of hash lookup. This is to determine the exponential moving average latency of our hash lookup for the various tables being used. After a read operation, the field's value clears to 0.

53.4.6.14.12 Shared memory ENETC receive buffer capability register (SMERBCAPR)

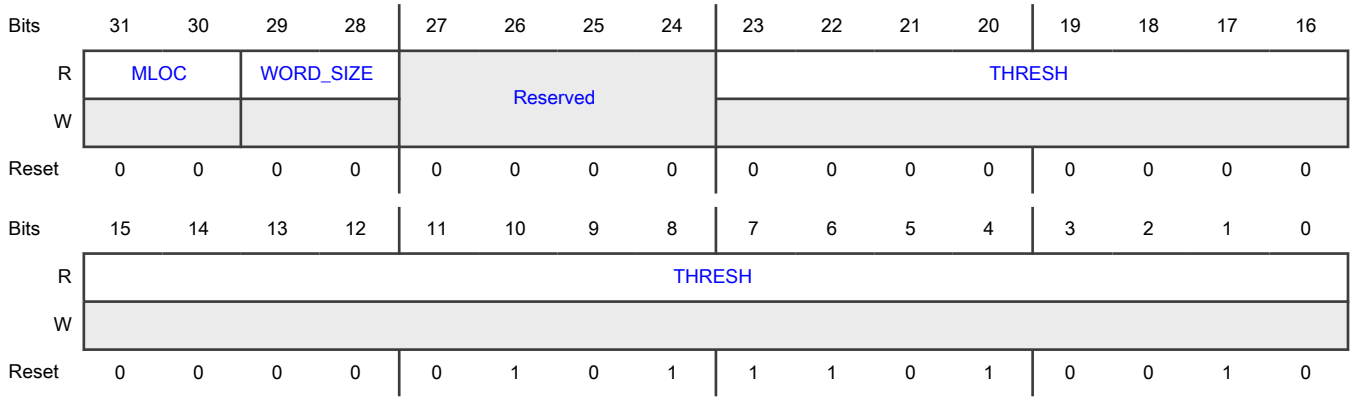
Offset

Register	Offset
SMERBCAPR	40h

Function

This is the shared memory ENETC receive buffer capability register.

Diagram



Fields

Field	Function
31-30 MLOC	Indicates memory location 0: Common memory 1-3: Reserved
29-28 WORD_SIZE	Word size in bytes. 0: 24 Bytes 1-3: reserved
27-24 —	Reserved
23-0 THRESH	Threshold in words of receive buffer memory used by all ENETC functions. If this threshold is exceeded, smart-drop from ICM queues may be triggered. Reset value from IERB ERSMBAR.

53.4.6.14.13 Shared memory ENETC receive buffer operational register 0 (SMERBOR0)

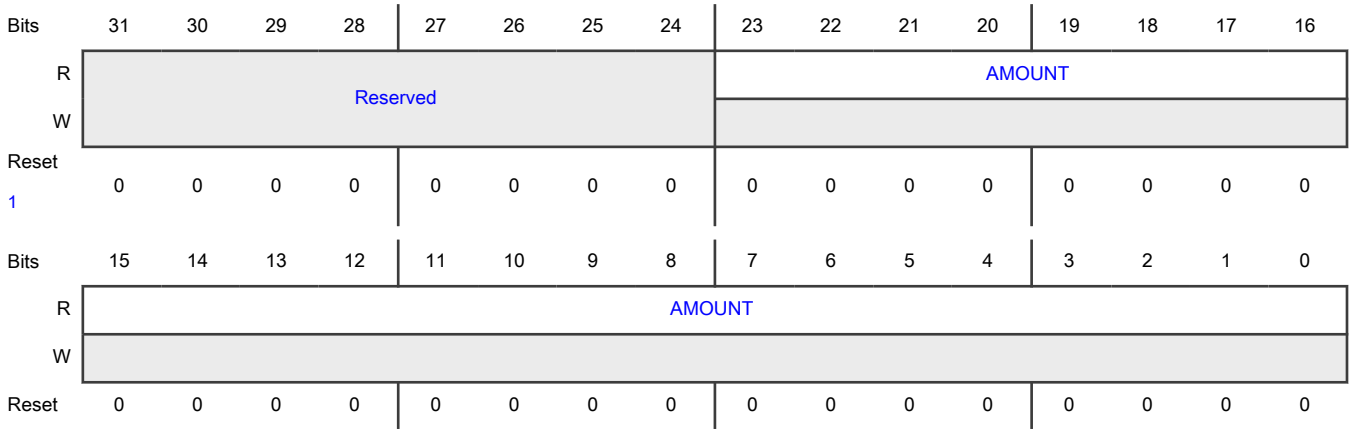
Offset

Register	Offset
SMERBOR0	44h

Function

This is the shared memory ENETC receive buffer operational register 0.

Diagram



1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-24 —	Reserved
23-0 AMOUNT	Number of words in use for buffers and frame descriptors.

53.4.6.14.14 Shared memory ENETC receive buffer operational 1 (SMERBOR1)

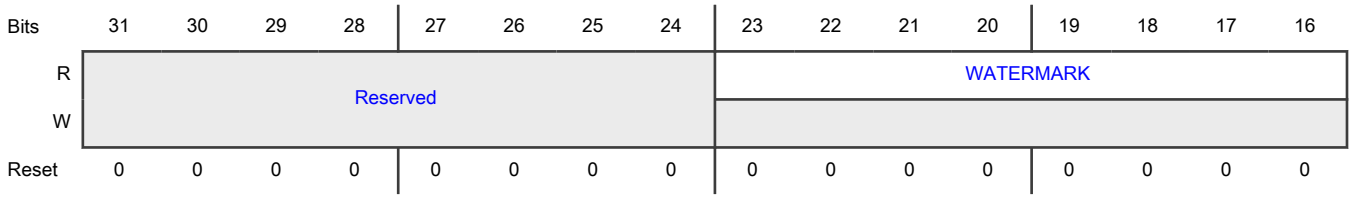
Offset

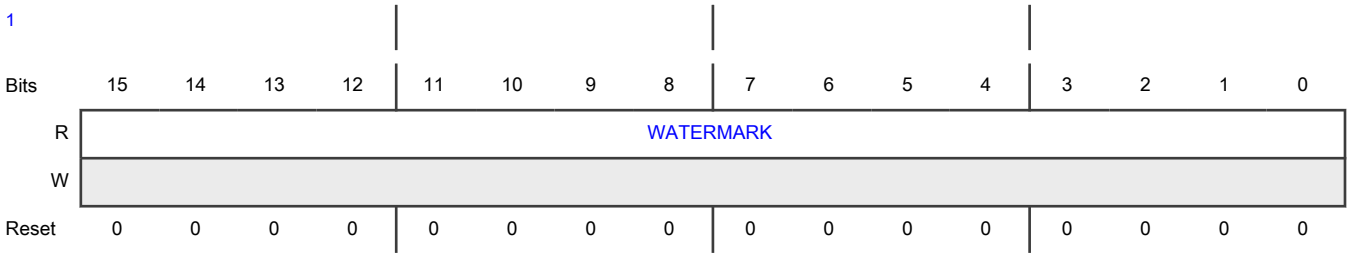
Register	Offset
SMERBOR1	48h

Function

This is the shared memory ENETC receive buffer operational register 1.

Diagram





1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-24 —	Reserved
23-0 WATERMARK	High watermark of words in use by buffers and frame descriptors since the last read. **NOTE** Value reset to AMOUNT after a read.

53.4.6.14.15 PCE 0 operational register (PCE0OR)

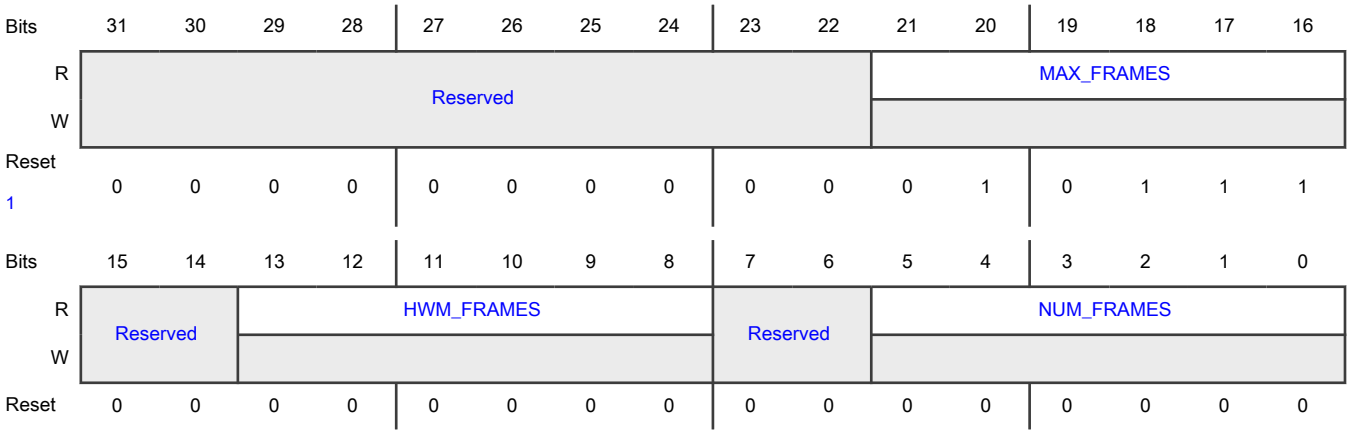
Offset

Register	Offset
PCE0OR	100h

Function

This is the Parse Classifier Engine (PCE) block operational register. The PCE realizes the Ingress Packet Processing (Switch) and Ingress Port Processing (ENETC) functional blocks.

Diagram



1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-22 —	Reserved
21-16 MAX_FRAMES	Maximum number of concurrent frames that can be processed by the PCE block. There are 8 threads per multi-threaded hardware engine. One or more per multi-threaded hardware engines is instantiated inside the PCE hardware block depending on the requirements e.g. number of ports, port speeds. Total number of threads available is equal to 8 multiply by the number of engines. One thread is reserved for processing table management commands. The remaining threads are used to process received frames, with each thread handling a single frame.
15-14 —	Reserved
13-8 HWM_FRAMES	High watermark of concurrent frames being processed since the last read of this register. **NOTE** When register is read, value is equal to NUM_FRAMES.
7-6 —	Reserved
5-0 NUM_FRAMES	Number of active frames currently being processed by the Parse Classifier Engine.

53.4.6.14.16 Replication Forwarding Engine 0 operational register (RFE0OR)

Offset

Register	Offset
RFE0OR	104h

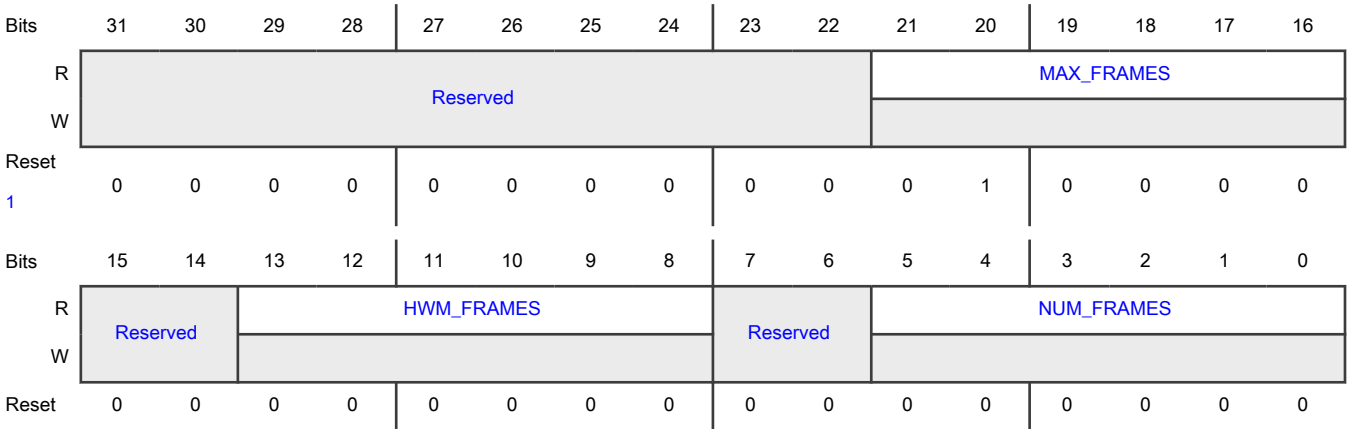
Function

This is the Replication Forwarding Engine (RFE) operational register. RFE realizes the Replication and Egress Packet Processing functional block.

NOTE

A write to this read-only register will return an error.

Diagram



1. Not affected by FLR, requires soft reset.

Fields

Field	Function
31-22 —	Reserved
21-16 MAX_FRAMES	Maximum number of concurrent frames that can be processed by the RFE block. There are 16 threads per multi-threaded hardware engine, where each thread is handling a single frame. One or more per multi-threaded hardware engines is instantiated inside the RFE hardware block depending on the requirements e.g. number of ports, port speeds. Total number of threads available is equal to 16 multiply by the number of engines.
15-14 —	Reserved
13-8 HWM_FRAMES	High watermark of concurrent frames being processed since the last read of this register. **NOTE** When register is read, value is equal to NUM_FRAMES.
7-6 —	Reserved
5-0 NUM_FRAMES	Number of active frames currently being processed by the Replication and Forwarding Engine.

53.4.6.14.17 NETC clock register (NETCCLKR)

Offset

Register	Offset
NETCCLKR	164h

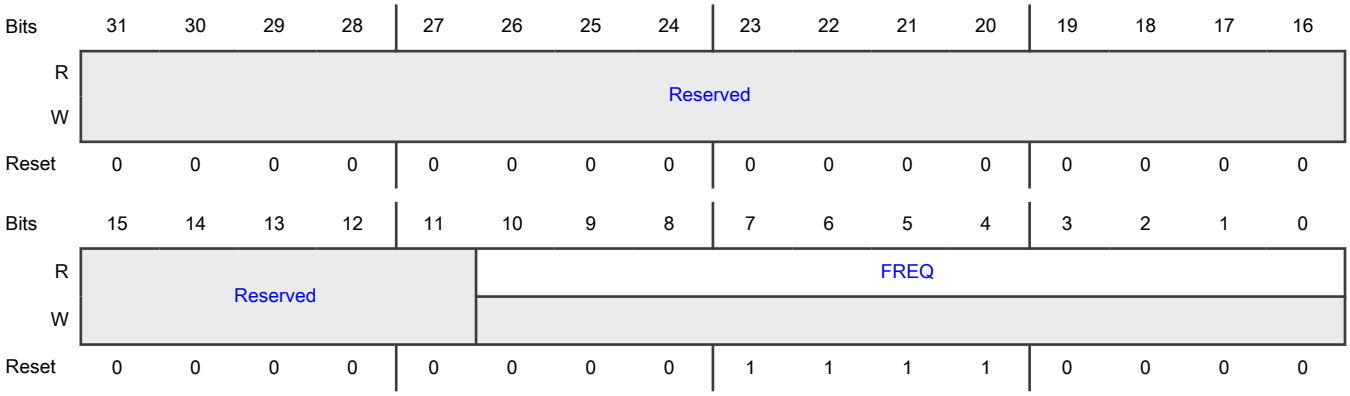
Function

This is the NETC clock register.

NOTE

A write to this read-only register will return an error.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-0 FREQ	Frequency This is the NETC clock frequency in MHz.

53.4.6.14.18 HTA 0 capability register (HTA0CAPR)

Offset

Register	Offset
HTA0CAPR	200h

Function

This is the HTA capability register.

The HTA hardware block realizes the HTA Transmit functional block and the HTA Receive functional block for the ENETC instances. The HTA hardware block is implemented using multi-threaded hardware engine(s) where each engine implements a finite state machine (FSM) which operates on a plurality of receive and transmit threads with each thread handling a single frame. One or more per multi-threaded hardware engines is instantiated inside the HTA hardware block depending on the requirements e.g. number of ports, port speeds. There are 8 receive threads and 8 transmit threads per multi-threaded hardware engine.

53.4.6.14.23 Root complex 0 system bus read latency average register (RC0SBRLAR)

Offset

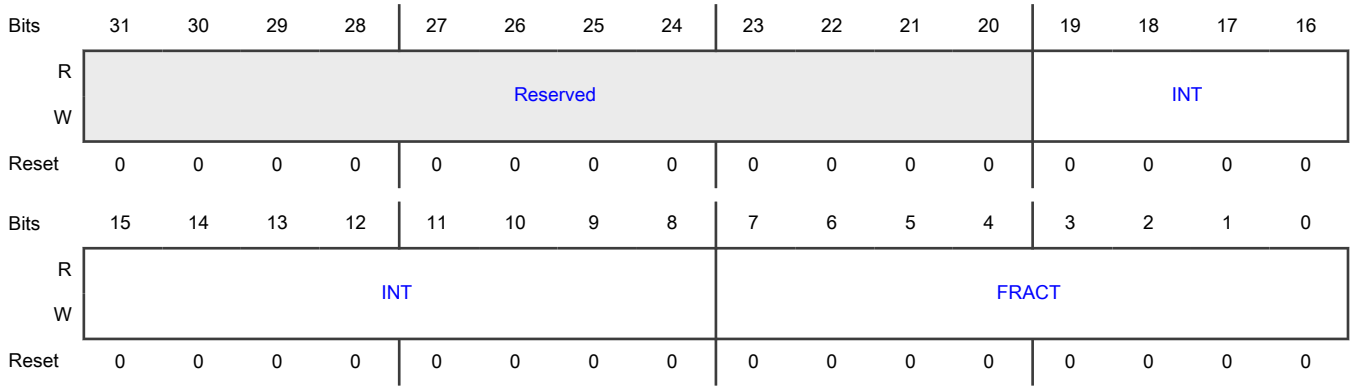
Register	Offset
RC0SBRLAR	300h

Function

The Exponentially Weighted Moving Average (EWMA) is calculated with every latency sample: EWMAnew = (1 - a) * EWMAcurrent + Sample * a; (where a = 1/256). The latency samples are 12-bit integer values (0 to 4095 NETC clock cycles) and a power of 2 weight (1/256). The actual implementation is as follows: Avg_latency_20_bit = Avg_latency_20_bit - (Avg_latency_20_bit >> 8) + sample_12_bit.

Note that after reset, the average value is 0, following which a sufficient number of samples must be taken to arrive at a statistically significant average value reading. To speed up the process of arriving at a significant average value, the average can be initialized to an expected value by writing to this register.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-8 INT	Integer portion of the latency value.
7-0 FRACT	Fractional portion of the latency value.

53.4.6.14.24 Root complex 0 system bus read latency high watermark register (RC0SBRLHWMR)

Offset

Register	Offset
RC0SBRLHWMR	304h

Function

A read of this register resets the high watermark.

53.4.6.15 RevMII MDIO Register Map

This section provides a detailed description of RevMII MDIO registers. Registers are not memory mapped but accessible from:

- External RevMII MDIO slave interface
- Internal MAC MDIO interface

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

53.4.6.15.1 REVMII MDIO register descriptions

This section describes the RevMII MDIO specific registers for one or more ports.

NOTE

LaBCR[MDIO_PHYAD_PRTAD] determines the PHY address of the slave MDIO interface.

53.4.6.15.1.1 REVMII memory map

Instance	Address space	MDIO PHY Address
ENETC0_REVMII_MAC	LINK4_REVMII_MDIO	1Fh
ENETC0_REVMII_PHY	LINK4_REVMII_MDIO	0h
SW_REVMII_MAC2	LINK2_REVMII_MDIO	1Fh
SW_REVMII_MAC3	LINK3_REVMII_MDIO	1Fh

Chapter 54
Message Interrupt (MSGINTR)

54.1 Introduction

The Message Interrupt (MSGINTR) module converts memory mapped write transactions to interrupt signals.

Writes to the MSIIR register will simultaneously generate an interrupt signal and set a bit in the MSIR register associated with each interrupt so that multiple “messages” can be sent and processed separately.

There will be three sets of MSIIR/MSIR registers and three associated interrupts.

54.1.1 Overview

The block diagram of MSGINTR is shown below as would be instantiated within a system. The APB interface and the interrupt outputs are clocked at "apb_clk" rate.

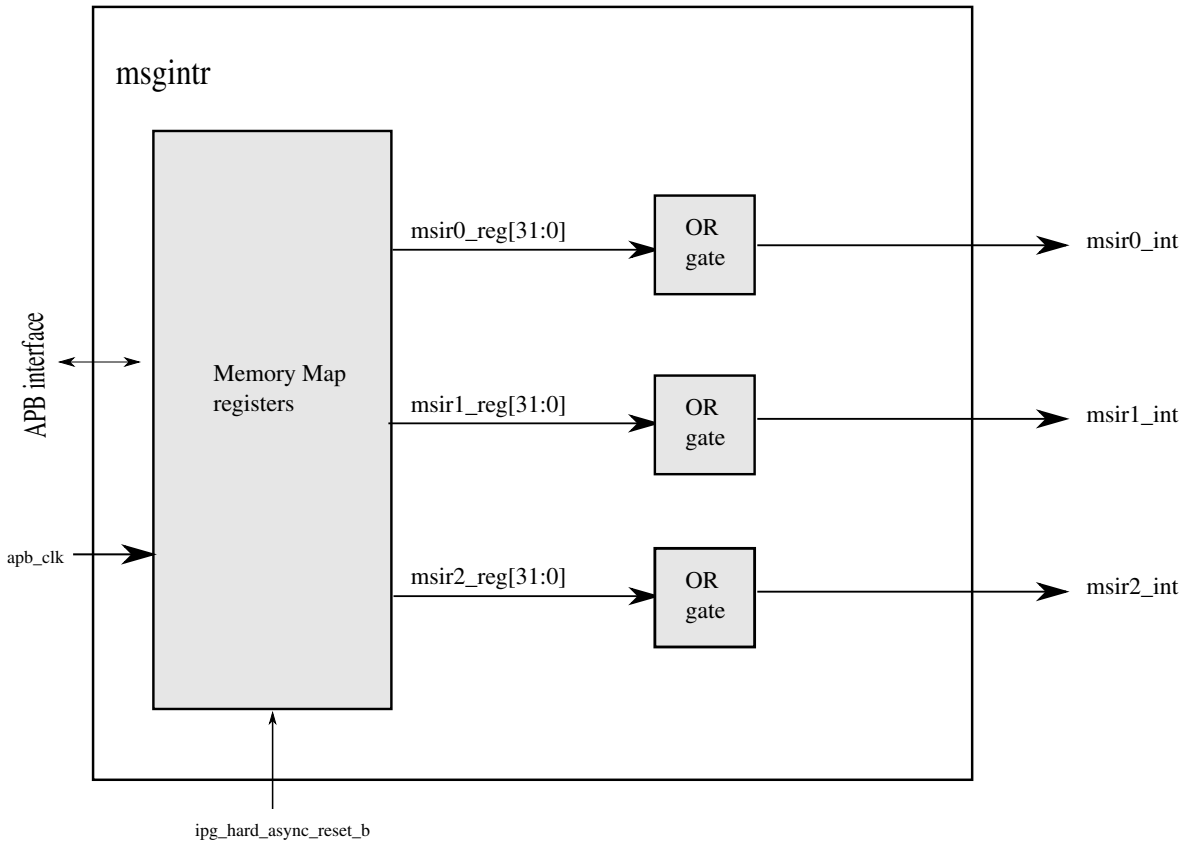

Figure 369. MSGINTR Block Diagram

54.2 External Signal Description

There are no external signals for MSGINTR block.

54.3 Memory Map

This section provides a detailed description of all accessible MSGINTR memory and registers. Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

MSGINTR uses a contiguous 64KB memory page as shown in Memory Map.

54.4 MSGINTR register descriptions

The table shows the memory map of MSGINTR resources.

54.4.1 MSGINTR memory map

MSGINTR1 base address: 428A_0000h

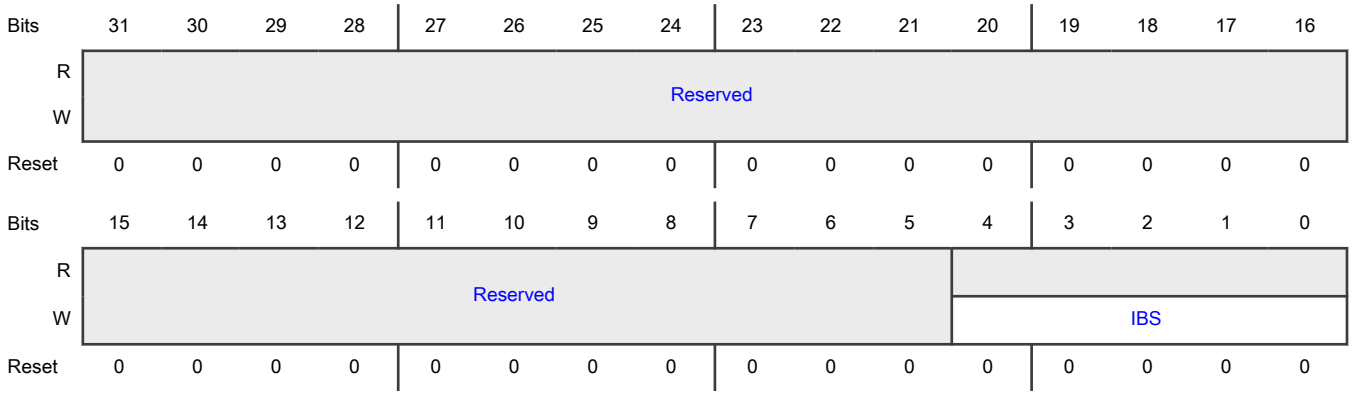
Diagram



Fields

Field	Function
31-0 SHn	Message sharer n has a pending interrupt.

54.5 Functional Description

MSGINTR converts a memory write transaction to an interrupt event. It has 3 sets of MSIIR/MSIR registers.

A write to the MSIIRn[IBS] will set the bit (indexed by IBS) in the MSIRn register and trigger the interrupt associated with MSIRn. A read to the MSIIRn will return 0s and has no effect.

A read to MSIRn will clear all bits in the MSIRn register and hence de-assert the associated interrupt.

55.2 Overview

An EtherCAT® Subordinate Controller (ESC) takes care of the EtherCAT communication as an interface between the EtherCAT fieldbus and slave application.

55.2.1 Block diagram

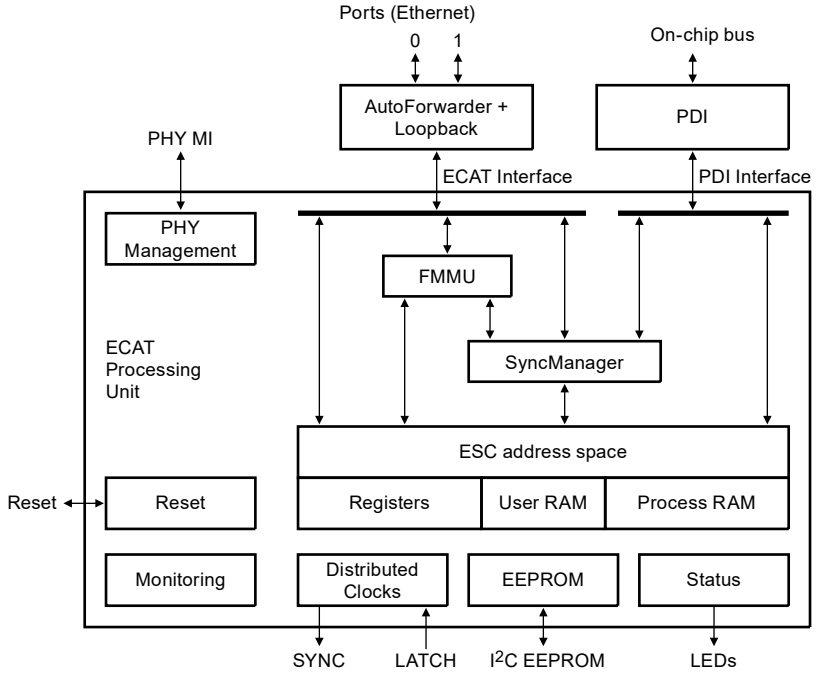

Figure 370. ESC block diagram

The block diagram above shows the general functionality of EtherCAT.

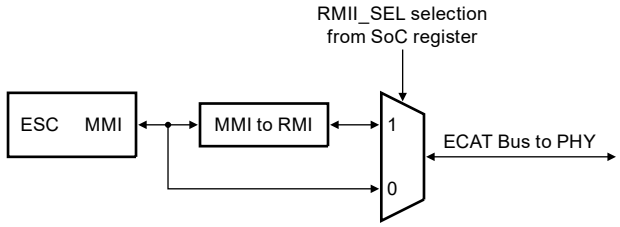

Figure 371. ESC wrapper

55.2.2 Features

This sections lists the features of the EtherCAT block.

- 2 EtherCAT Ports
- 8 FMMUs
- 8 Sync Managers
- Process Data RAM 8Kbyte
- User RAM 128Byte
- 64 bits Distributed clocks
- Process data interface is deactivated (no PDI)

55.3 Functional description

EtherCAT supports the following functions:

EtherCAT protocol

- Ethernet frames with Ether type 88A4h
- EtherCAT frames encapsulated in UDP/IP
- EtherCAT frames with VLAN Tag
- Normal Ethernet frames
- **Addressing modes**
  - Device addressing
  - Logical addressing
- **Working counter**
  - Counting the number of read/write from/to the device.
- **EtherCAT command type**
  - Processing the command that master requests slaves to address each addressing mode

Loop control

- Loop control and loop state in eCAT

Shadow buffer

- Shadow buffers function when register is written using frame access.

Circulating frames

- Prevention of circulating frames during the failure

FIFO size reduction

- RX FIFO size reduction because of reduction of propagation delay

Ethernet physical layer

- MII
- RMII
- Back-to-Back MII connection
- MII management interface
- Read/write of the PHY register via MII management interface
- PHY address offset
- Automatic TX clock shift compensation

FMMU

- Mapping between logical address and physical address

SyncManager

- Buffer mode
- Mailbox mode
- Watchdog,Interrupt and latch event generation when a buffer is completely and successfully written or read.
- Repeating mailbox communication
- SyncManager deactivation by the PDI

Distributed clocks

- Clock Synchronization considering propagation delay and drift compensation
- Generation of synchronous output signals (SYNC0 and 1 signals): (1)Cyclic mode (2)Single shot mode;(3)Cyclic acknowledge mode;(4)Single shot acknowledge mode
- Precise time stamping of input events (LATCH0 and 1 signals):(1)Single event mode (2)Continuous mode (3)SyncManager event mode (for debugging)
- Generation of synchronous interrupts
- Exclusive control for the SYNC and LATCH signals of the ECAT and PDI
- Communication Timing: (1) Free run (2)Synchronized to output event (3)Synchronized to SYNC signal

EtherCAT state machine

- Control of state machine / Indication of the status and error code

SII EEPROM

- SII EEPROM commands
- SII EEPROM error indication
- SII EEPROM access interface
- EEPROM size selection

Interrupt

- AL event request (PDI interrupt)
- ECAT event request (ECAT interrupt)

Watchdog

- Process data watchdog
- PDI watchdog

LED signals

- RUN LED signal
- ERR LED signal
- STATE LED and STATE_RUN LED signals
- LINK/ACT LED signals
- RUN/ERR LED override

Process data interface (PDI)

- On-chip bus

ESC reset

- ESC reset from the master or PDI

55.3.1 EtherCAT controller function blocks

- **EtherCAT interfaces (Ethernet)**

  The EtherCAT interfaces or ports connect the ESC to other EtherCAT slaves and the master. The MAC layer is integral part of the ESC. The physical layer may be Ethernet . For Ethernet ports, external Ethernet PHYs connect to the MII/RMII ports of the ESC. Transmission speed for EtherCAT is fixed to 100 Mbit/s with Full Duplex communication. Link state and communication status are reported to the Monitoring device.

  EtherCAT slaves support 2 ports, the logical ports are numbered 0-1, formerly they were denoted by A-B

- **EtherCAT processing unit**

  The EtherCAT Processing Unit (EPU) receives, analyses, and processes the EtherCAT data stream. It is logically located between port 0 and port 1. The main purpose of the EtherCAT Processing unit is to enable and coordinate access to the internal registers and the memory space of the ESC, which can be addressed both from the EtherCAT master and from the local application via the PDI. Data exchange between master and slave application is comparable to a dual-ported memory (process memory), enhanced by special functions e.g. for consistency checking (SyncManager) and data mapping (FMMU). The EtherCAT Processing Units contains the main function blocks of EtherCAT slaves besides Auto-Forwarding, Loop-back function, and PDI.

- **Auto-forwarder**

  The Auto-Forwarder receives the Ethernet frames, performs frame checking and forwards it to the Loop-back function. Time stamps of received frames are generated by the Auto-Forwarder.

- **Loop-back function**

  The Loop-back function forwards Ethernet frames to the next logical port if there is either no link at a port, or if the port is not available, or if the loop is closed for that port. The Loop-back function of port 0 forwards the frames to the EtherCAT Processing Unit. The loop settings can be controlled by the EtherCAT master.

- **FMMU**

  Fieldbus Memory Management Units are used for bitwise mapping of logical addresses to physical addresses of the ESC.

- **SyncManager**

  SyncManagers are responsible for consistent data exchange and mailbox communication between EtherCAT master and slaves. The communication direction can be configured for each SyncManager. Read or write transactions may generate events for the EtherCAT master and an attached Controller respectively. The SyncManagers are responsible for the main difference between and ESC and a dual-ported memory, because they map addresses to different buffers and block accesses depending on the SyncManager state. This is also a fundamental reason for bandwidth restrictions of the PDI.

- **Monitoring**

  The Monitoring unit contains error counters and watchdogs. The watchdogs are used for observing communication and returning to a safe state in case of an error. Error counters are used for error detection and analysis.

- **PHY management**

  The PHY Management unit communicates with Ethernet PHYs via the MII management interface. This is either used by the master or by the slave. The MII management interface is used by the ESC itself for optionally restarting auto negotiation after receive errors with the enhanced link detection mechanism, and for the optional MI link detection and configuration feature.

- **Distributed clock**

  Distributed Clocks (DC) allow for precisely synchronized generation of output signals and input sampling, as well as time stamp generation of events. The synchronization may span the entire EtherCAT network.

- **Memory**

  An EtherCAT slave can have an address space of up to 64Kbyte. The first block of 4 Kbyte (0x0000-0x0FFF) is used for registers and user memory. The memory space from address 0x1000 onwards is used as the process memory (up to 60 Kbyte). The size of process memory depends on the device. The ESC address range is directly addressable by the EtherCAT master and an attached Controller.

- **Process Data Interface (PDI) or Application interface:**

  — Process data interface is deactivated (no PDI)

- **SII EEPROM**

  One non-volatile memory is needed for EtherCAT Slave Information (ESI) storage, typically an I2C EEPROM.

- **Status/LEDs**

The Status block provides ESC and application status information. It controls external LEDs like the application RUN LED/ERR LED and port Link/Activity LEDs.

55.3.2 EtherCAT protocol

EtherCAT uses standard IEEE 802.3 Ethernet frames, thus a standard network controller can be used and no special hardware is required on master side.

EtherCAT has a reserved EtherType of 0x88A4 that distinguishes it from other Ethernet frames. Thus, EtherCAT can run in parallel to other Ethernet protocols.

EtherCAT does not require the IP protocol, however it can be encapsulated in IP/UDP. The EtherCAT Subordinate Controller processes the frame in hardware. Thus, communication performance is independent from processor power.

An EtherCAT frame is subdivided into the EtherCAT frame header followed by one or more EtherCAT datagrams. At least one EtherCAT datagram has to be in the frame. Only EtherCAT frames with Type 1 in the EtherCAT Header are currently processed by the EtherCAT Controllers. The ESC also support IEEE802.1Q VLAN Tags, although the VLAN Tag contents are not evaluated by the ESC.

If the Ethernet frame size falls below 64 byte, padding bytes have to be added until this size is reached. Otherwise the EtherCAT frame is exactly as large as the sum of all EtherCAT datagrams plus EtherCAT frame header.

The figure below shows how an ethernet frame containing EtherCAT data is assembled.

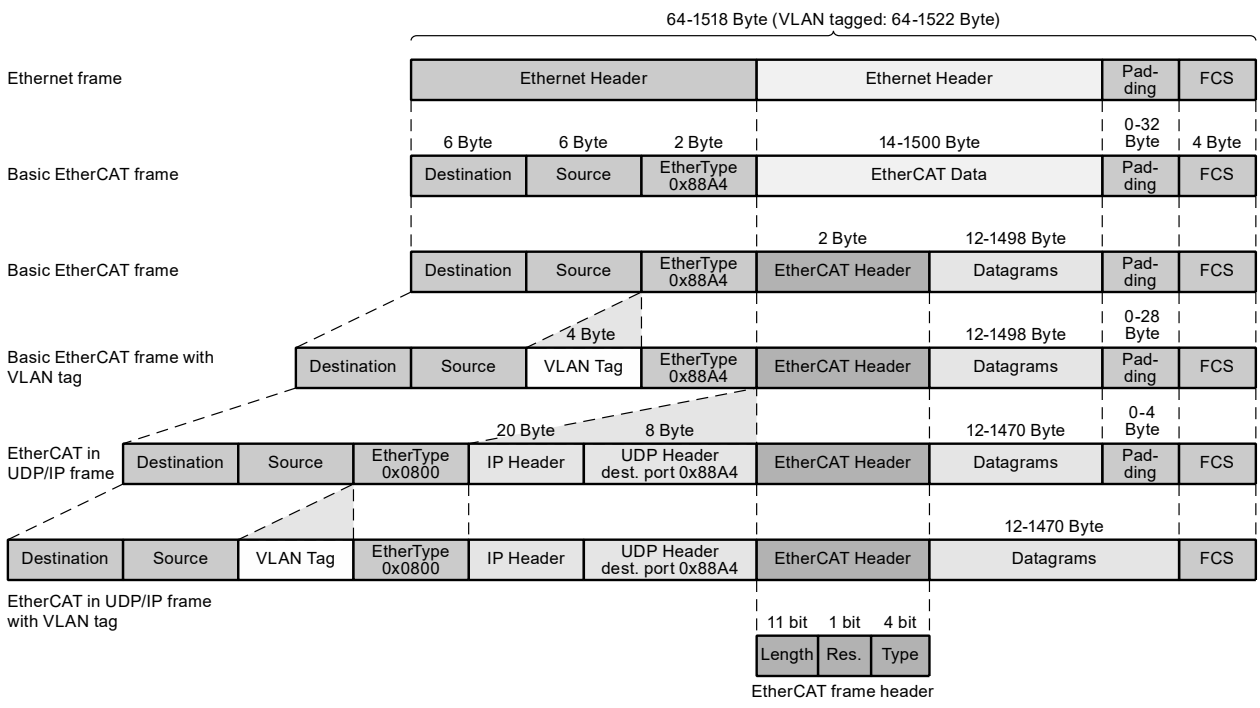

Figure 372. EtherCAT frame with EtherCAT data

Table 782. EtherCAT frame header

Field	Data Type	Description
Length	11 bits	Length of the EtherCAT datagrams (excl. FCS)
Reserved	1 bit	Reserved, 0

Table continues on the next page...

Table 782. EtherCAT frame header (continued)

Field	Data Type	Description
Type	4 bit	Protocol type. Only EtherCAT commands (Type = 0x1) are supported by ESC.

55.3.2.1 EtherCAT datagram

The below figure shows the structure of an EtherCAT datagram.

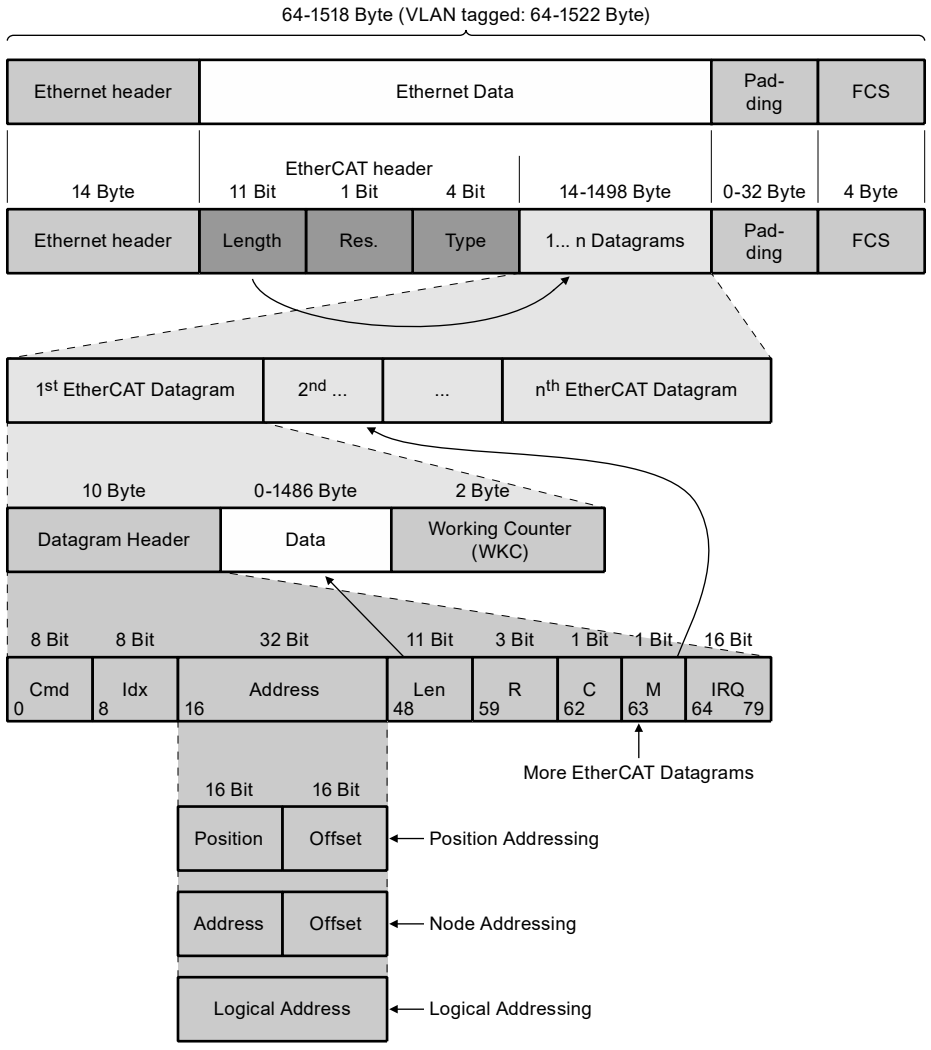

Figure 373. EtherCAT datagram

Table 783. EtherCAT frame header

Field	Data Type	Description
Cmd	BYTE	EtherCAT Command Type
Idx	BYTE	The index is a numeric identifier used by the master for identification of

Table continues on the next page...

Table 783. EtherCAT frame header (continued)

Field	Data Type	Description
		duplicates/lost datagrams. It shall not be changed by EtherCAT slaves
Address	BYTE[4]	Address (Auto Increment, Configured Station Address, or Logical Address, see 2.3)
Len	11 bits	Length of the following data within this datagram
R	3 bits	Reserved, 0
C	1 bit	Circulating frame (see 3.5): • 0: Frame is not circulating • 1: Frame has circulated once
M	1 bit	More EtherCAT datagrams • 0: Last EtherCAT datagram • 1: More EtherCAT datagrams will follow
IRQ	WORD	EtherCAT Event Request registers of all slaves combined with a logical OR
Data	BYTE[n]	Read/Write Data
WKC	WORD	Working Counter

55.3.2.2 EtherCAT addressing modes

Two addressing modes of EtherCAT devices are supported within one segment: device addressing and logical addressing. Three device addressing modes are available: auto increment addressing, configured station address, and broadcast. EtherCAT devices can have up to two configured station addresses, one is assigned by the master (Configured Station Address), the other one is stored in the SII EEPROM and can be changed by the slave application (Configured Station Alias address). The EEPROM setting for the Configured Station Alias address is only taken over at the first EEPROM loading after power-on or reset

Table 784. EtherCAT frame header

Mode	Field	Data Type	Description
Auto Increment Address	Position	WORD	Each slave increments Position. Slave is addressed if Position = 0.
	Offset	WORD	Local register or memory address of the ESC
Configured Station Address	Address	WORD	Slave is addressed if Address matches Configured Station Address or Configured Station Alias (if enabled).
	Offset	WORD	Local register or memory address of the ESC

Table continues on the next page...

Table 784. EtherCAT frame header (continued)

Mode	Field	Data Type	Description
Broadcast	Position	WORD	Each slave increments Position (not used for addressing)
	Offset	WORD	Local register or memory address of the ESC
Logical Address	Address	DWORD	Logical Address (configured by FMMUs) Slave is addressed if FMMU configuration matches Address.

55.3.2.2.1 Device addressing

The device can be addressed via Device Position Address (Auto Increment address), by Node Address (Configured Station Address/Configured Station Alias), or by a Broadcast.

- Position Address / Auto Increment Address: The datagram holds the position address of the addressed slave as a negative value. Each slave increments the address. The slave which reads the address equal zero is addressed and will execute the appropriate command at receive. Position Addressing should only be used during start-up of the EtherCAT system to scan the fieldbus and later only occasionally to detect newly attached slaves. Using Position addressing is problematic if loops are closed temporarily due to hot connecting or link problems. Position addresses are shifted in this case, and e.g., a mapping of error register values to devices becomes impossible, thus the faulty link cannot be localized
- Node Address / Configured Station Address and Configured Station Alias: The configured Station Address is assigned by the master during start up and cannot be changed by the EtherCAT slave. The Configured Station Alias address is stored in the SII EEPROM and can be changed by the EtherCAT slave. The Configured Station Alias has to be enabled by the master. The appropriate command action will be executed if Node Address matches with either Configured Station Address or Configured Station Alias. Node addressing is typically used for register access to individual and already identified devices.
- Broadcast: Each EtherCAT slave is addressed. Broadcast addressing is used e.g. for initialization of all slaves and for checking the status of all slaves if they are expected to be identical.

Each slave device has a 16 bit local address space (address range 0x0000:0x0FFF is dedicated for EtherCAT registers, address range 0x1000:0xFFFF is used as process memory) which is addressed via the Offset field of the EtherCAT datagram. The process memory address space is used for application communication (e.g. mailbox access).

55.3.2.2.2 Logical addressing

All devices read from and write to the same logical 4 Gbyte address space (32 bit address field within the EtherCAT datagram). A slave uses a mapping unit (FMMU, Fieldbus Memory Management Unit) to map data from the logical process data image to its local address space. During start up the master configures the FMMUs of each slave. The slave knows which parts of the logical process data image have to be mapped to which local address space using the configuration information of the FMMUs. Logical Addressing supports bit wise mapping. Logical Addressing is a powerful mechanism to reduce the overhead of process data communication, thus it is typically used for accessing process data.

55.3.2.3 Working counter

Every EtherCAT datagram ends with a 16 Bit Working Counter (WKC). The Working Counter counts the number of devices that were successfully addressed by this EtherCAT datagram. Successfully means that the ESC is addressed and the addressed memory is accessible (e.g., protected SyncManager buffer). EtherCAT Controllers increment the Working Counter in hardware. Each datagram should have an expected Working Counter value calculated by the master. The master can check the valid processing of EtherCAT datagrams by comparing the Working Counter with the expected value.

The Working Counter is increased if at least one byte/one bit of the whole multi-byte datagram was successfully read and/or written. For a multi-byte datagram, you cannot tell from the Working Counter value if all or only one byte was successfully read and/or written. This allows reading separated register areas using a single datagram by ignoring unused bytes.

The Read-Multiple-Write commands ARMW and FRMW are either treated like a read command or like a write command, depending on the address match.

Table 785. Working counter increment

Command	Data Type	Increment
Read command	No success	no change
	Successful read	+1
Write command	No success	no change
	Successful write	+1
ReadWrite command	No success	no change
	Successful read	+1
	Successful write	+2
	Successful read and write	+3

55.3.2.4 EtherCAT command types

All supported EtherCAT Command types are listed in the below table. For ReadWrite operations, the Read operation is performed before the Write operation

Table 786. EtherCAT frame header

CMD	Abbr.	Name	Description
0	NOP	No Operation	Slave ignores command
1	APRD	Auto Increment Read	Slave increments address. Slave puts read data into the EtherCAT datagram if received address is zero.
2	APWR	Auto Increment Write	Slave increments address. Slave writes data into memory location if received address is zero.
3	APRW	Auto Increment Read Write	Slave increments address. Slave puts read data into the EtherCAT datagram and writes the data into the same memory location if received address is zero.
4	FPRD	Configured Address Read	Slave puts read data into the EtherCAT datagram if address matches with one of its configured addresses

Table continues on the next page...

Table 786. EtherCAT frame header (continued)

CMD	Abbr.	Name	Description
5	FPWR	Configured Address Write	Slave writes data into memory location if address matches with one of its configured addresses
6	FPRW	Configured Address Read Write	Slave puts read data into the EtherCAT datagram and writes data into the same memory location if address matches with one of its configured addresses
7	BRD	Broadcast Read	All slaves put logical OR of data of the memory area and data of the EtherCAT datagram into the EtherCAT datagram. All slaves increment position field.
8	BWR	Broadcast Write	All slaves write data into memory location. All slaves increment position field.
9	BRW	Broadcast Read Write	All slaves put logical OR of data of the memory area and data of the EtherCAT datagram into the EtherCAT datagram, and write data into memory location. BRW is typically not used. All slaves increment position field.
10	LRD	Logical Memory Read	Slave puts read data into the EtherCAT datagram if received address matches with one of the configured FMMU areas for reading.
11	LWR	Logical Memory Write	Slaves writes data to into memory location if received address matches with one of the configured FMMU areas for writing.
12	LRW	Logical Memory Read Write	Slave puts read data into the EtherCAT datagram if received address matches with one of the configured FMMU areas for reading. Slaves writes data to into memory location if received address matches with one of

			the configured FMMU areas for writing.
13	ARMW	Auto Increment Read Multiple Write	Slave increments address. Slave puts read data into the EtherCAT datagram if received address is zero, otherwise slave writes the data into memory location.
14	FRMW	Configured Read Multiple Write	Slave puts read data into the EtherCAT datagram if address matches with one of its configured addresses, otherwise slave writes the data into memory location.
15-255	-	reserved	-

55.3.2.5 UDP/IP

The following header fields are evaluated by an ESC to detect an EtherCAT frame encapsulated in UDP/IP:

All other fields if the IP and UDP header are not evaluated, and the UDP checksum is not checked. Since EtherCAT frames are processed on the fly, the UDP checksum cannot be updated by an ESC when the frame content is modified. Instead, the ESC clears the UDP checksum for any EtherCAT frame (regardless of DL Control register 0x0100[0]), which indicates that the checksum is not used. The UDP checksum is forwarded without modification for non-EtherCAT frames if DL Control register 0x0100[0]=0.

Table 787. EtherCAT UDP/IP encapsulation

Field	Expected value for EtherCAT
EtherType	0x800(IP)
IP version	4
IP Header length	5
IP Protocol	0x11(UDP)
UDP destination port	0x88A4

55.3.3 Frame processing

The IP Core slave controllers only support Direct Mode addressing: neither a MAC address nor an IP address is assigned to the ESC, they process EtherCAT frames with any MAC or IP address.

It is not possible to use unmanaged switches between these ESCs or between master and the first slave, because source and destination MAC addresses are not evaluated or exchanged by the ESCs. Only the source MAC address is modified when using the default settings, so outgoing and incoming frames can be distinguished by the master.

NOTE

Attaching an ESC directly to an office network will result in network flooding, since the ESC will reflect any frame especially broadcast frames back into the network (broadcast storm).

The frames are processed by the ESC on the fly, i.e., they are not stored inside the ESC. Data is read and written as the bits are passing the ESC. The forwarding delay is minimized to achieve fast cycle times. The forwarding delay is defined by the receive FIFO size and the EtherCAT Processing Unit delay. A transmit FIFO is omitted to reduce delay times.

The ESCs support EtherCAT, UDP/IP, and VLAN tags. EtherCAT frames and UDP/IP frames containing EtherCAT datagrams are processed. Frames with VLAN tags are processed by the ESCs, the VLAN settings are ignored and the VLAN tag is not modified. The source MAC address is changed for every frame passing the EtherCAT Processing Unit (SOURCE_MAC[1] is set to 1 locally administered address). This helps to distinguish between frames transmitted by the master and frames received by the master

55.3.3.1 Loop control and loop state

Each port of an ESC can be in one of two states: open or closed. If a port is open, frames are transmitted to other ESCs at this port, and frames from other ESCs are received. A port which is closed will not exchange frames with other ESCs, instead, the frames are forwarded internally to the next logical port, until an open port is reached. The loop state of each port can be controlled by the master (ESC DL Control register 0x0100). The ESCs supports four loop control settings, two manual configurations, and two automatic modes:

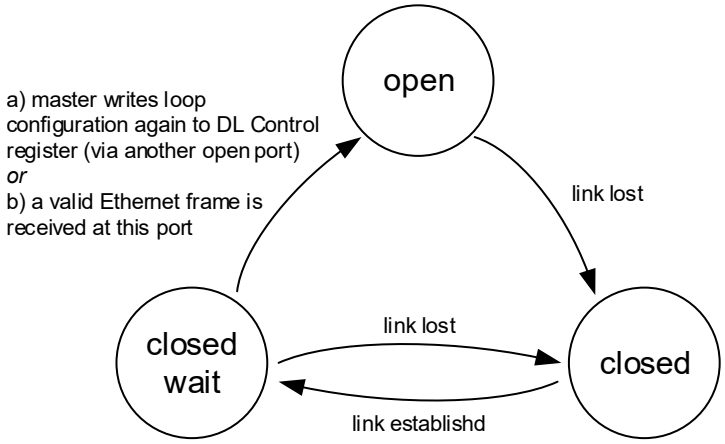

Figure 374. Auto close loop state transitions

- Manual open: The port is open regardless of the link state. If there is no link, outgoing frames will be lost.
- Manual close: The port is closed regardless of the link state. No frames will be sent out or received at this port, even if there is a link with incoming frames.
- Auto: The loop state of each port is determined by the link state of the port. The loop is open if there is a link, and it is closed without a link.
- Auto close (manual open): The port is closed depending on the link state, i.e., if the link is lost, the loop will be closed (auto close). If the link is established, the loop will not be automatically opened, instead, it will remain closed (closed wait state). Typically, the port has to be opened by the master explicitly by writing the loop configuration again to the ESC DL Control register 0x0100. This write access has to enter the ESC via a different open port. There is an additional fallback option for opening the port: if a valid Ethernet frame is received from the external link at the closed port in Auto close mode, it will also be opened after the CRC is received correctly. The content of the frame is not evaluated.

A port is considered open if the port is available, i.e., it is enabled in the configuration, and one of the following conditions is met:

- The loop setting in the DL Control register is Auto and there is an active link at the port.
- The loop setting in the DL Control register is Auto close and there is an active link at the port and the DL Control register was written again after the link was established
- The loop setting in the DL Control register is Auto close and there is an active link at the port and a valid frame was received at this port after the link was established.
- The loop setting in the DL control register is Always open

A port is considered closed if one of the following conditions is met:

- The port is not available or not enabled in the configuration.
- The loop setting in the DL Control register is Auto and there is no active link at the port.
- The loop setting in the DL Control register is Auto close and there is no active link at the port or the DL Control register was not written again after the link was established
- The loop setting in the DL Control register is Always closed

Table 788. Registers for loop control and loop/link status

Register Address	Name	Description
0x0100[15:8]	ESC DL Control	Loop control/loop setting
0x0110[15:4]	ESC DL Status	Loop and link status
0x0518:0x051B	PHY Port status	PHY Management link status

55.3.3.2 Frame Processing Order

The frame processing order of EtherCAT Subordinate Controllers depends on the number of ports (logical port numbers are used):

Table 789. Frame Processing Order

Number of Ports	Frame Processing Order
1	0--> EtherCAT Processing Unit -->0
2	0--> EtherCAT Processing Unit -->1 / 1-->0

The direction through an ESC including the EtherCAT Processing Unit is called "processing" direction, other directions without passing the EtherCAT Processing Unit are called "forwarding" direction. Ports which are not implemented behave similar to closed ports, the frame is forwarded to the next port. Frame processing in general is shown in the below figure:

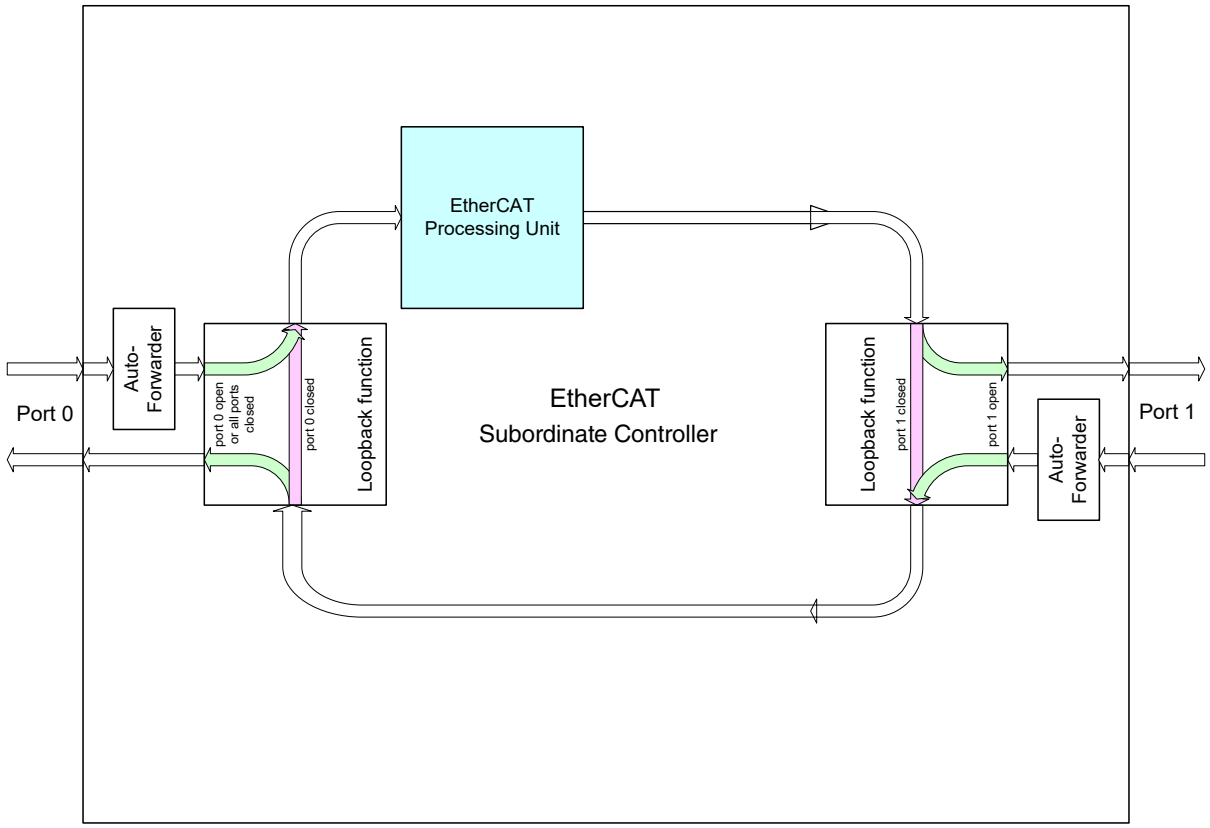

Figure 375. Frame Processing

Example Port Configuration with Ports 0, 1

If there are only ports 0, 1, a frame received at port 0 goes via the Auto-Forwarder and the Loopback function to the EtherCAT Processing Unit which processes it. Then, the frame is sent to port 1. If port 1 is closed, the frame is forwarded by the Loopback function . If port 1 is open, the frame is sent out at port 1. When the frame comes back into port 1, it is handled by the Auto-Forwarder . Then it is handled by the Loopback function and sent out at port 0 - back to the master.

55.3.3.3 Permanent ports and bridge port

The EtherCAT ports of an ESC are typically permanent ports, which are directly available after Power- On. Permanent ports are initially configured for Auto mode, i.e., they are opened after the link is established. This Bridge port becomes available if the EEPROM is loaded successfully, and it is closed initially, i.e., it has to be opened (or set to Auto mode) explicitly by the EtherCAT master.

55.3.3.4 Shadow buffer for register write operations

The ESCs have shadow buffers for write operations to registers (0x0000 to 0x0F7F). During a frame, write data is stored in the shadow buffers. If the frame is received correctly, the values of the shadow buffers are transferred into the effective registers. Otherwise, the values of the shadow buffers are not taken over. As a consequence of this behavior, registers take their new value shortly after the FCS of an EtherCAT frame is received. SyncManagers also change the buffers after the frame was received correctly.

User and Process Memory do not have shadow buffers. Accesses to these areas are taking effect directly. If a SyncManager is configured to User Memory or Process Memory, write data will be placed in the memory, but the buffer will not change in case of an error.

55.3.3.5 Circulating frames

The ESCs incorporate a mechanism for prevention of circulating frames. This mechanism is very important for proper watchdog functionality. This is an example network with a link failure between slave 1 and slave 2:

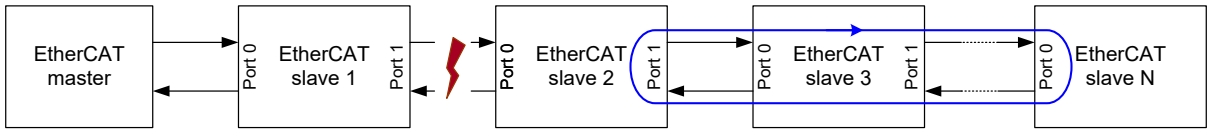

Figure 376. Circulating frames

Both slave 1 and slave 2 detect the link failure and close their ports (port 1 at slave 1 and port 0 at slave 2). A frame currently traveling through the ring at the right side of slave 2 might start circulating. If such a frame contains output data, it might trigger the built-in watchdog of the ESCs, so the watchdog never expires, although the EtherCAT master cannot update the outputs anymore. To prevent this, a slave with loop closed at port 0 and loop control for port 0 set to Auto or Auto close (ESC DL Control register 0x0100) will do the following inside the EtherCAT Processing Unit:

- If the Circulating bit of the EtherCAT datagram is 0, set the Circulating bit to 1
- If the Circulating bit is 1, do not process the frame and destroy it

The result is that circulating frames are detected and destroyed. Since the ESCs do not store the frames for processing, a fragment of the frame will still circulate triggering the Link/Activity LEDs. Nevertheless, the fragment is not processed.

55.3.3.5.1 Unconnected port 0

Port 0 must not be left intentionally unconnected (slave hardware or topology) because of the circulating frame prevention. All frames will be dropped after they have passed an automatically closed Port 0 for the second time, and this can prohibit any EtherCAT communication.

In redundancy operation, only one Port 0 is automatically closed, so the communication remains active.

55.3.3.6 Non-EtherCAT protocols

If non-EtherCAT protocols are used, the forwarding rule in the ESC DL Control register (0x0100[0]) has to be set to forward non-EtherCAT protocols. Otherwise they are destroyed by the eCAT.

55.3.3.7 Special functions of port 0

Port 0 of each EtherCAT is characterized by some special functions in contrast to port 1:

- Port 0 leads to the master, i.e., port 0 is the upstream port.
- The link state of Port 0 influences the Circulating Frame bit, and frames are dropped at port 0 if the bit is set and the link is automatically closed.
- Port 0 loop state is open if all ports are closed (either automatically or manually).

55.3.4 Physical layer common features

EtherCAT supports two basic types of physical layers, Ethernet . It requires 100 Mbit/s links with full duplex communication.

The Ethernet-based physical layer uses standard Ethernet physical layer devices (PHY) according to IEEE 802.3. It supports different flavors like cable (100BaseTX), optical (100BaseFX), and EtherCAT P (100BaseTX-like with power supply).

55.3.4.1 Link status

The link status of each port is available in the ESC DL Status register (0x0110:0x0111), most important are the "Communication established" bits 15, 13, 11, and 9. Additional link information is available in the PHY Port status register (0x0518:0x051B) if MI link detection and configuration is used. All other status bits are mainly for debugging purposes. The link status bits are described in the following table

If all ports are closed (either manually or automatically, e.g., because no port has a communication link), port 0 is automatically opened as the recovery port. Reading and writing via this port is possible, although the DL status register reflects the correct status. This can be used to correct erroneous DL control register settings or to fix LINK_MII polarity configuration.

55.3.4.2 Selecting standard/enhanced link detection

Some ESCs distinguish between standard and enhanced link detection. Enhanced link detection provides additional security mechanisms regarding link establishment and surveillance. Using enhanced link detection is recommended for Ethernet PHY ports. Some ESCs only support global Enhanced Link Detection configuration for all ports, some support port-wise configuration.

After power-on, enhanced link detection is enabled by default. It is disabled or remains enabled after the SII EEPROM is loaded according to the EEPROM setting (register 0x0141). An invalid EEPROM content will also disable enhanced link detection.

The EEPROM setting for enhanced Link detection is only taken over at the first EEPROM loading after power-on or reset. Changing the EEPROM and manually reloading it will not affect the enhanced link detection enable status (register 0x0110[2]), even if the EEPROM could not be read initially. Registers used for Enhanced link detection are listed in the below table.

Table 790. Registers for enhanced link detection

Register Address	Name	Description
0x0141[1]	ESC Configuration	Enable/disable Enhanced link detection for all ports
0x0141[7:4]	ESC Configuration	Enable/disable Enhanced link detection port-wise
0x0110[2]	ESC DL Status	Enhanced link detection status

NOTE

Some of these register bits are set via SII EEPROM/IP Core configuration.

55.3.4.3 FIFO size reduction

The ESCs incorporate a receive FIFO (RX FIFO) for decoupling receive clock and processing clock. The FIFO size is programmable by the EtherCAT master (ESC DL Control register 0x0100). Some ESCs support a default value for the FIFO size loaded from the SII EEPROM. The FIFO size values determine a reduction of the FIFO size, the FIFO cannot be disabled completely. The FIFO size can be reduced considering these three factors:

- Accuracy of the receiver's clock source
- Accuracy of the sender's clock source
- Maximum frame size

The default FIFO size is sufficient for maximum Ethernet Frames and default Ethernet clock source accuracy (100 ppm). If the clock accuracy is 25 ppm or better, the FIFO size can be reduced to the minimum. If the FIFO size was accidentally reduced too much, a short 64 Byte frame should be sent for resetting the FIFO size to the default value, since a smaller frame is not utilizing the FIFO as much as a larger frame.

The FIFO size can be reduced to minimum if both sender and receiver have 25 ppm accuracy of their clock sources, even with maximum frame size.

Since 25 ppm clock accuracy can typically not be guaranteed for the entire life-time of a clock source, the actual clock deviation has to be measured on a regular basis for FIFO size reduction. If a slave does not support Distributed Clocks or the actual deviation is larger than 25 ppm, the FIFO size of all neighbors and the slave itself cannot be reduced. The actual deviation can be measured using Distributed Clocks:

- Compare DC Receive Times over a period of time for slaves which only support DC Receive Times. Do not use this method if both slaves which are compared support DC Time Loop, since the measured deviation will approximate zero if the DC control loop has settled, but the actual deviation determining the FIFO size might be larger than 25 ppm.
- Compare calculated deviation from register Speed Counter Diff (0x0932:0x0933) for adjacent slaves with DC Time Loop support after the DC control loop has settled (i.e., System Time Difference 0x092C:0x092F is at its minimum).

NOTE

Be careful with FIFO size reduction at the first slave if off-the-shelf network interface cards without 25 ppm accuracy are used by master.

Table 791. Registers for FIFO size reduction

Register Address	Name	Description
0x0100[18:16]	ESC DL Control	Current FIFO size setting

55.3.5 Ethernet physical layer

ESCs with Ethernet Physical Layer support use the MII interface, some do also support the RMII interface. Since RMII PHY include FIFOs, they increase the forwarding delay of an EtherCAT slave device as well as the jitter. MII is recommended due to these reasons.

55.3.5.1 PHY reset and link partner notification/loop closing

The main principle of EtherCAT operation in case of link errors is disabling unreliable links by closing loops. This is automatically performed by the ESCs. The ESCs rely on the LINK_MII signal from the PHYs for detecting the link state.

It is crucial that a PHY does not establish a link while the ESC is not operating. Otherwise, the communication partner would also detect a physical link, causing it to open the communication link. Subsequently, all frames will get lost because the ESC is not operating.

So at least the following requirements have to be fulfilled, otherwise frames will be lost:

- ESC in reset state --> PHY disabled

The recommended solution for this issue is to enable the PHY together with the ESC by using the ESCs global reset signal for the PHY, too. If the ESC has individual PHY reset outputs, they should be used instead. This solution prevents the PHYs from establishing a link while the ESCs are not operating. The individual PHY reset signals of an ESC have this functionality:

- Keep the PHY in reset while the ESC is in Reset
- If an FX link is used, and Enhanced link detection is active, a reset for the PHY and the transceiver is applied when too many RX_ERR are received
- The PHY reset is extended to a certain time

55.3.6 MII interface

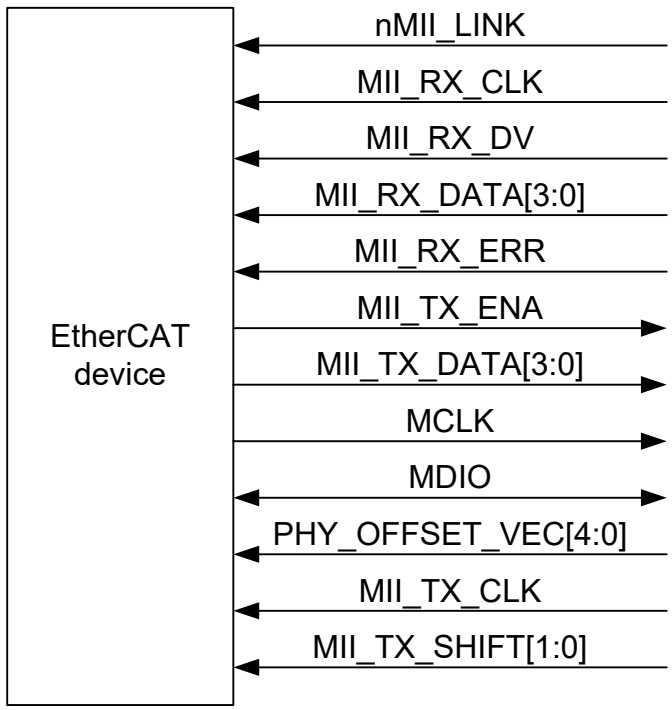

Figure 377. ECAT interrupt masking

Table 792. MII interface signals

Signal	Direction at PHY	Description
nMII_LINK	IN	Input signal provided by the PHY if a 100Mbit/s(Full duplex) link is established (alias Link_MII)
MII_RX_CLK	IN	Receive Clock
MII_RX_DV	IN	Receive data valid
MII_RX_DATA[3:0]	IN	Receive data (alias RXD)
MII_RX_ERR	IN	Receive error (alias RX_ER)
MII_TX_ENA	OUT	Transmit enable (alias TX_EN)
MII_TX_DATA[3:0]	OUT	Transmit data (alias TXD)
MCLK	OUT	Management Interface clock (alias MCLK)
MDIO	BIDIR	Management Interface data (alias MDIO)
PHY_OFFSET_VEC[4:0]	IN	Configuration: PHY address offset
MII_TX_CLK	IN	Transmit Clock for automatic TX Shift compensation
MII_TX_SHIFT[1:0]	IN	Manual TX Shift compensation with additional registers

55.3.6.1 Unused MII port

If an ESC MII interface is not used, LINK_MII has to be tied to a logic value which indicates no link, and RX_CLK, RXD, RX_ER, and especially RX_DV have to be tied to GND. The TX outputs can be left unconnected, unless they are used for ESC configuration.

55.3.7 RMII interface

For more details about the RMII interface, refer to the RMII Specification, available from the RMII consortium.

55.3.7.1 Unused RMII ports

If an ESC RMII interface is not used, LINK_MII has to be tied to a logic value which indicates no link, and RXD, RX_ER, and especially CRS_DV have to be tied to GND. The TX signals can be left unconnected, unless they are used for ESC configuration.

55.3.8 Link detection

The ESCs support different mechanisms for link detection, and some of them are optional. The major goal of the link detection is to detect a link loss very fast. This is required to maintain communication in the rest of the network by appropriately closing communication loops.

The following link status sources are available for Ethernet PHYs:

- LINK_MII signal from an Ethernet PHY
- MI link detection and configuration (MII management interface)
- RX_ERR signal used by Enhanced Link Detection

ECAT support a LINK_MII signal for fast link detection at each Ethernet MII port. EtherCAT IP Core additionally support link detection and configuration via the MII management interface.

The MI link detection is generally not fast enough for EtherCAT when a link loss happens. For many PHYs, the LINK_MII signal is fast enough, but others need Enhanced Link Detection (RX_ERR).

The results of the different link status sources are evaluated inside the ESC according to the DL Control loop setting (register 0x0100):

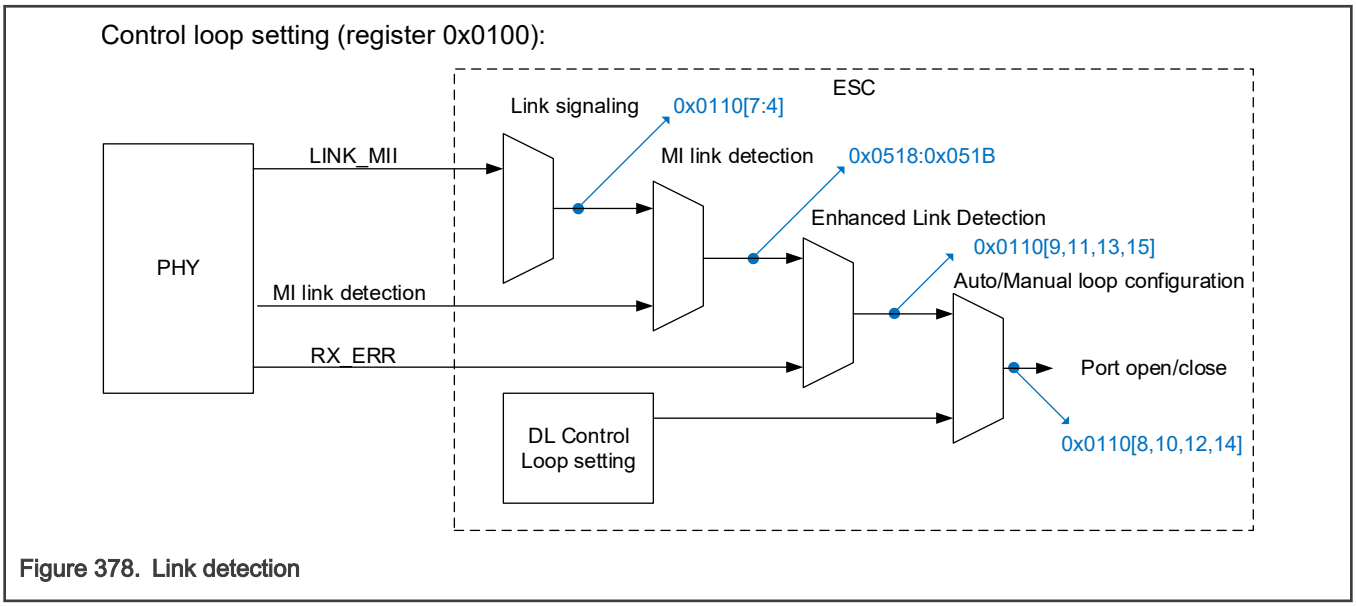

Figure 378. Link detection

The result of the MI link detection is available in the PHY Port Status register 0x0518:0x051B, it is combined with the previous link result.

Enhanced link detection overrides the previous result, if it is enabled and too many RX_ERR have been detected. The result is reflected in the ESC DL Status register (0x0110[15,13,11,9]- Communication established), and it is also used for LINKACT LED.

Finally, the DL Control settings select if the link result is evaluated (and how). The loop state of each port is reflected in the ESC DL Status register (0x0110[14,12,10,8] - Loop open/closed).

Table 793. Registers used for ethernet link detection

Register Address	Name	Description
0x0100:0x0111	ESC DL Control	Link Configuration (manual/auto)
0x0110:0x0111	ESC DL Status	Link Status (LINK_MII)
0x0300:0x0307	RX Error Counter	RX_ERR counter for Enhanced Link Detection
0x0518:0x051B	PHY Port Status	MI Link Detection results

55.3.8.1 Standard link detection

The results of the different sources for Standard MII link detection are combined by a specific logic. The main combinations are shown in the following table.

Table 794. Ethernet link detection combination

LINK_MI	In-band signaling	MI link	MI no link	Link result	Description
no	no	no	no	no link	
yes	no	no	no	link	
no	yes	no	no	link	In-band signaling is used without LINK_MII
yes	yes	no	no	link	LINK_MII is used while In-band signaling is available
yes(one or both)		yes	no	link	MI link detection found valid link, status of LINK_MII/in-band signaling is accepted
don't care		no	yes	no link	MI link detection found invalid link status, either local or at link partner, overrides other status
link down event		yes	no	no link	A link down event (edge) overrides MI link detection
no	no	yes	no	link	Test only, because link-loss reaction time is too slow: MI link is used

Table continues on the next page...

Table 794. Ethernet link detection combination (continued)

LINK_MI	In-band signaling	MI link	MI no link	Link result	Description
					without LINK_MII and without in-band signaling

NOTE

NOTE: "MI link" means that MI link detection successfully read the PHY, and the result is OK. "MI no link" means that MI link detection successfully read the PHY, but the result is not OK. If MI link detection could not properly read from the PHY, the result is undefined.

55.3.8.1.1 LINK_MII signal

The LINK_MII signal used for link detection is typically an LED output signal of the Ethernet PHY. If available, LINK_MII should be connected to a combined signal indicating a 100 Mbit/s Full Duplex link. If such a signal is not available, a signal indicating a 100 Mbit/s link (speed LED) might be used. If only a Link signal is available (link LED), this might be used. Never use (combined) activity signals, e.g., Link/Act LED outputs, because the link state will toggle upon activity.

The main advantage of using a dedicated link signal instead of reading out MII management interface registers is the fast reaction time in case of a link loss. This is crucial for redundancy operation, since only one lost frame is tolerated. The EtherCAT port of an ESC which loses a link has to be closed as fast as possible to maintain EtherCAT communication at the other ports and to reduce the number of lost frames.

55.3.8.1.2 MI link detection and configuration

The EtherCAT IP Core supports link detection and PHY configuration by using the MII management interface. Initially, the PHY configuration is checked and updated if necessary. Afterwards, the link status of each Ethernet port is cyclically polled. PHY accesses of the EtherCAT master are inferred upon request.

The MI Link Configuration mechanism configures the Ethernet PHYs to use Auto negotiation and advertise only 100BASE-TX Full-Duplex connections. ESCs support using Gigabit Ethernet PHYs, which are restricted to 100 Mbit/s links by the MI Link Configuration. ESCs which support FX operation natively are configuring the FX ports to use fixed 100BASE-TX Full-Duplex connections without Auto negotiation

Depending on the physical layer configuration and the supported ESC features (e.g., TX vs. FX), the MI Link Detection will check if the link characteristics fulfill EtherCAT requirements (Auto negotiation, Speed, Duplex, etc.). If all conditions are met, an MI Link is detected.

Since the MI Link Detection does not solely rely on the PHY link status bit (register 1[2]), the local PHY and the remote PHY may indicate a link, but the ESC refuses it because it does not fulfill EtherCAT requirements. The current MI Link Detection state is reflected in the MI Interface registers (PHY Port Status 0x0518:0x051B).

MI Link Detection and Configuration must not be used without link detection via LINK_MII signal , because link loss reaction time would otherwise be to slow for redundancy operation. Enhanced Link Detection might not be a suitable solution in this case if too few RX_ERR are issued to the ESC before the PHY takes down the link

The MI Link Detection and Configuration checks the management communication with Ethernet PHYs. If communication is not possible - e.g. because no PHY is configured for the expected PHY address - the results are ignored. Take care of proper PHY address configuration to prevent erroneous behavior.

NOTE

Proper PHY address settings and PHY address offset configuration is crucial for MI Link Detection and Configuration.

55.3.8.1.3 Enhanced link detection

For Ethernet, the enhanced MII link detection feature is a feature of link error detection and reaction. This has to be distinguished from the actual link detection, which tells the ESC if a physical link is available (i.e., the LINK_MII signal or the MI link detection and configuration mechanism).

Enhanced MII link detection will additionally disconnect a link if at least 32 RX errors (RX_ER) occur in a fixed interval of time (~10 µs). The local loop is closed and the link partner is informed by restarting the Auto-Negotiation mechanism via the MII Management Interface. This informs the link partner of the error condition, and the link partner will close the loop.

The ESC keeps the port closed until the link goes down during Auto-Negotiation and comes up again (the port remains closed if the link does not go down).

The availability of Enhanced MII Link Detection depends on a supported PHY address configuration, otherwise it has to be disabled.

55.3.9 MII Management Interface (MI)

Most EtherCAT Subordinate Controllers with MII/RMII ports use the MII management interface for communication with the Ethernet PHYs. The MII management interface can be used by the EtherCAT master - or the local µController if supported by the eCAT. Enhanced MII link detection uses the management interface for configuration and restarting auto negotiation after communication errors occurred (TX PHYs only). Some ESC can make use of the MII management interface for link detection and PHY configuration. For fast link detection, the ESC require to use a separate signal (LINK_MII).

The ESCs support a shared MII Management Interface for all PHYs, i.e., MCLK and MDIO are connected to the ESC and to all PHYs.

55.3.9.1 PHY addressing/phy address offset

Proper PHY address configuration is crucial for Enhanced Link Detection and MI Link Detection and configuration, because the ESC itself needs to relate logical ports to the corresponding PHY addresses. The EtherCAT master can access the Ethernet PHYs using any address by means of the PHY address register 0x0513.

Typically, the logical port numbers match with the PHY addresses, i.e. the EtherCAT master and the ESC itself use PHY address 0 for accessing the PHY at port 0 (PHY address 1 for the PHY at port 1 and so on).

Depending on the ESC, there are two options for configuring the PHY addresses:

- PHY address offset: The ESC accesses a PHY at logical port x with the address "x + PHY address offset". Depending on the ESC only some or all possible offsets are configurable. The EtherCAT master uses the PHY addresses 0-3 to access the logical ports 0-3. These addresses are incremented by the PHY address offset inside the ESC. If the master uses PHY addresses 4-31, these addresses are also incremented by the PHY address offset inside the ESC.
- Individual PHY address: The ESC accesses a PHY at each logical port with an individual PHY address. The EtherCAT master uses the PHY addresses 0-3 to access the logical ports 0-3. These addresses are replaced with the individual addresses inside the ESC. If the master uses PHY addresses 4-31, these addresses are not translated.

Depending on the ESC the PHY address configuration is a strapped at power-up, configured in advance (IP Core) or configured by signals.

Typically, the PHY address offset should be 0, and the logical port numbers match with the PHY addresses. Some Ethernet PHYs associate a special function with PHY address 0, e.g., address 0 is a broadcast PHY address. In these cases, PHY address 0 cannot be used. Instead, a PHY address offset different from 0 should be selected, preferably an offset which is supported by the ESC. If PHY addresses are chosen which are not supported by the ESC, Enhanced Link Detection and MI Link Detection and Configuration cannot be used and have to be disabled (the PHY address offset should be 0 in these cases). Nevertheless, the EtherCAT master can communicate with the PHYs using the actual PHY addresses, and EtherCAT communication is possible anyway- using the LINK_MII signal. It is recommended that the PHY addresses are selected to be equal to the logical port number plus 1 in this case.

If the PHY address offset configuration of an ESC reflects the actual PHY address settings, the EtherCAT master can use addresses 0-3 in PHY address register 0x0513 for accessing the PHYs of logical ports 0-3, regardless of the PHY address offset.

Table 795. PHY Address configuration matches PHY address settings

Logical Port	Configured address of the PHY		PHY address register value used by EtherCAT master
	PHY address offset = 0	PHY address offset = 16	
0	0	16	0
1	1	17	1
2	2	18	2
3	3	19	3
none	4-15	20-31	4-15
none	16-31	0-15	16-31

If the actual PHY address settings differ from the PHY address configuration of the ESC, the EtherCAT master has to use the actual PHY address mapping, i.e., PHY addresses 1-4 for accessing the PHYs of logical ports 0-3.

Table 796. PHY Address configuration does not match actual PHY address settings

Logical Port	Configured address of the PHY	PHY address register value used by EtherCAT master
0	1	1
1	2	2
2	3	3
3	4	4
none	0, 5-31	0, 5-13

NOTE

PHY address offset is 0 in this case (recommended).

55.3.9.2 Logical interface

The MI of the ESC is typically controlled by EtherCAT via the MI registers

Table 797. PHY address configuration does not match actual PHY address settings

Register Address	Description
0x0510:0x0511	MII Management Control/Status
0x0512	PHY Address
0x0513	PHY Register Address
0x0514:0x0515	PHY Data

The MI supports two commands: write to one PHY register or read one PHY register.

55.3.9.2.1 MI read/write example

The following steps have to be performed for a PHY register access:

- Check if the Busy bit of the MI Status register is cleared and the MI is not busy.
- Write PHY address to PHY Address register.

- Write PHY register number to be accessed into PHY Register Address register (0-31).
- Write command only: put write data into PHY Data register (1 word/2 byte).
- Issue command by writing to Control register. For read commands, write 1 into Command Register Read 0x0510[8]. For write commands, write 1 into Write Enable bit 0x0510[0] and also 1 into Command Register Write 0x0510[9]. Both bits have to be written in one frame. The Write enable bit realizes a write protection mechanism. It is valid for subsequent MI commands issued in the same frame and self- clearing afterwards.
- The command is executed after the EOF, if the EtherCAT frame had no errors.
- Wait until the Busy bit of the MI Status register is cleared.
- Check the Error bits of the MI Status register. The command error bit is cleared with a valid command or by clearing the command register. The read error bit indicates a read error, e.g., a wrong PHY address. It is cleared by writing to the register.
- Read command only: Read data is available in PHY Data register.

NOTE

NOTE: The Command register bits are self-clearing. Manually clearing the command register will also clear the status information.

55.3.9.2.2 MI Interface Assignment to ECAT/PDI

The EtherCAT master controls the MI Interface (default) if the MII Management PDI Access State register 0x0517[0] is not set. The EtherCAT master can prevent PDI control over the MI Interface, and it can force the PDI to release the MI Interface control. After power-on, the PDI can take over MI Interface control without any master transactions.

55.3.9.2.3 MI Protocol

Each MI access begins with a Preamble of "Ones"(32 without preamble suppression, less if both ESC and PHY support preamble suppression), followed by a Start-of-Frame (01) and the Operation Code (01 for write and 10 for read operations). Then the PHY address (5 bits) and the PHY register address (5 bits) are transmitted to the PHY. After a Turnaround (10 for write and Z0 for read operations - Z means MDIO is high impedance), two bytes of data follow. The transfer finishes after the second data byte and at least one IDLE cycle.

55.3.9.2.4 Timing Specifications

Table 798. MII Management Interface timing characteristics

Parameter	Description
t_{clk}	MDC Period
t_{Write}	Write access time
t_{Read}	Read Access time

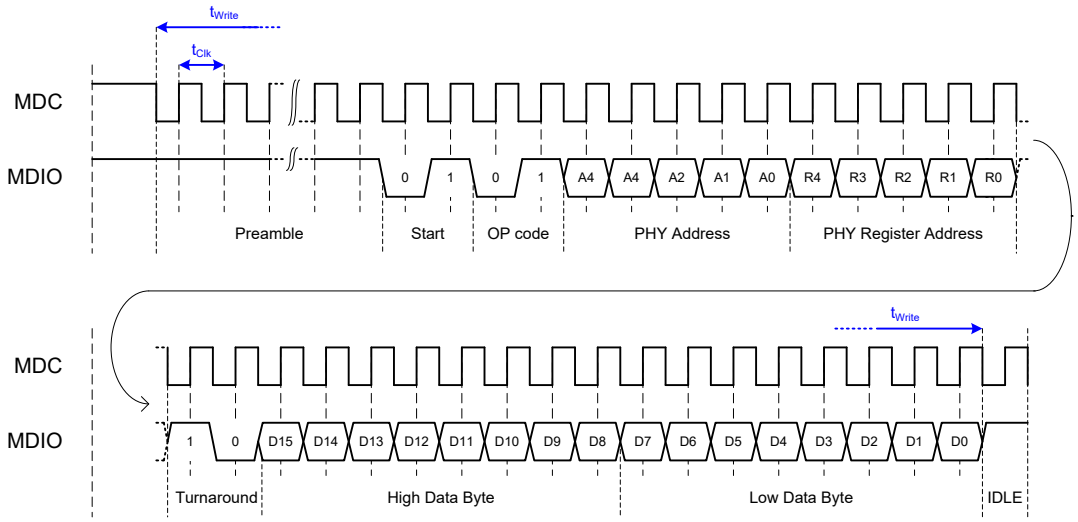

Figure 379. Write Access

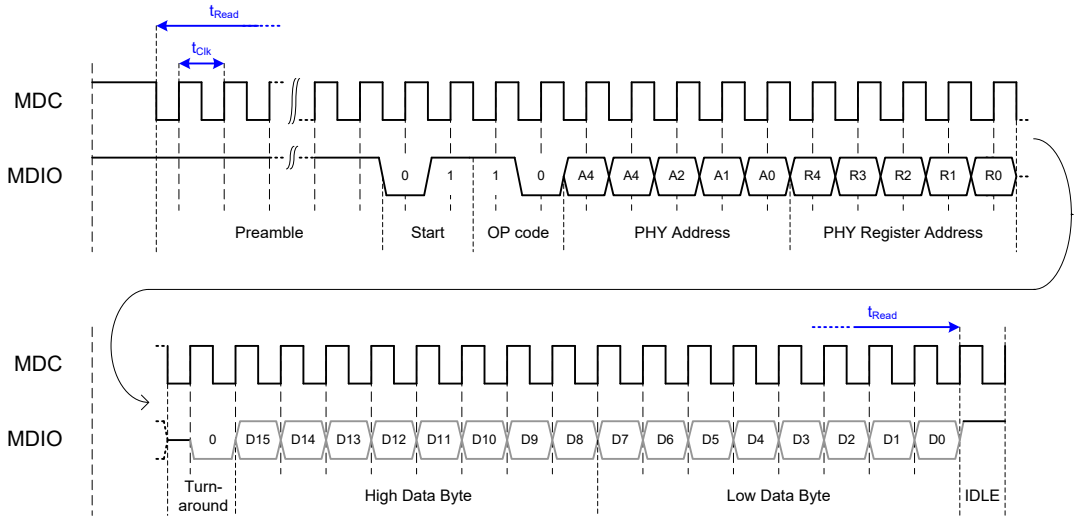

Figure 380. Read Access

55.3.10 MII management example schematic

The MII management interface is a shared bus for all PHYs. The example schematic shows the connection between ESC and PHYs. Take care of proper PHY address configuration

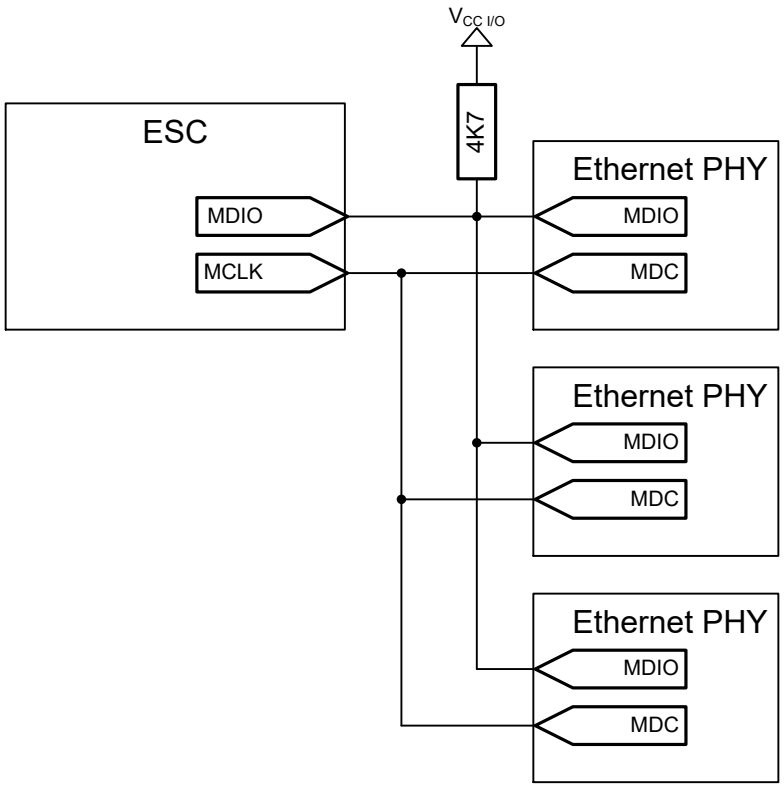

Figure 381. MII management example schematic

55.3.11 Fieldbus Memory Management Units (FMMU)

Fieldbus Memory Management Units (FMMU) convert logical addresses into physical addresses by the means of internal address mapping. Thus, FMMUs allow to use logical addressing for data segments that span several slave devices: one datagram addresses data within several arbitrarily distributed ESCs. Each FMMU channel maps one continuous logical address space to one continuous physical address space of the slave. The FMMUs support bit wise mapping, the number of supported FMMUs depends on the ESC. The access type supported by an FMMU is configurable to be either read, write, or read/write.

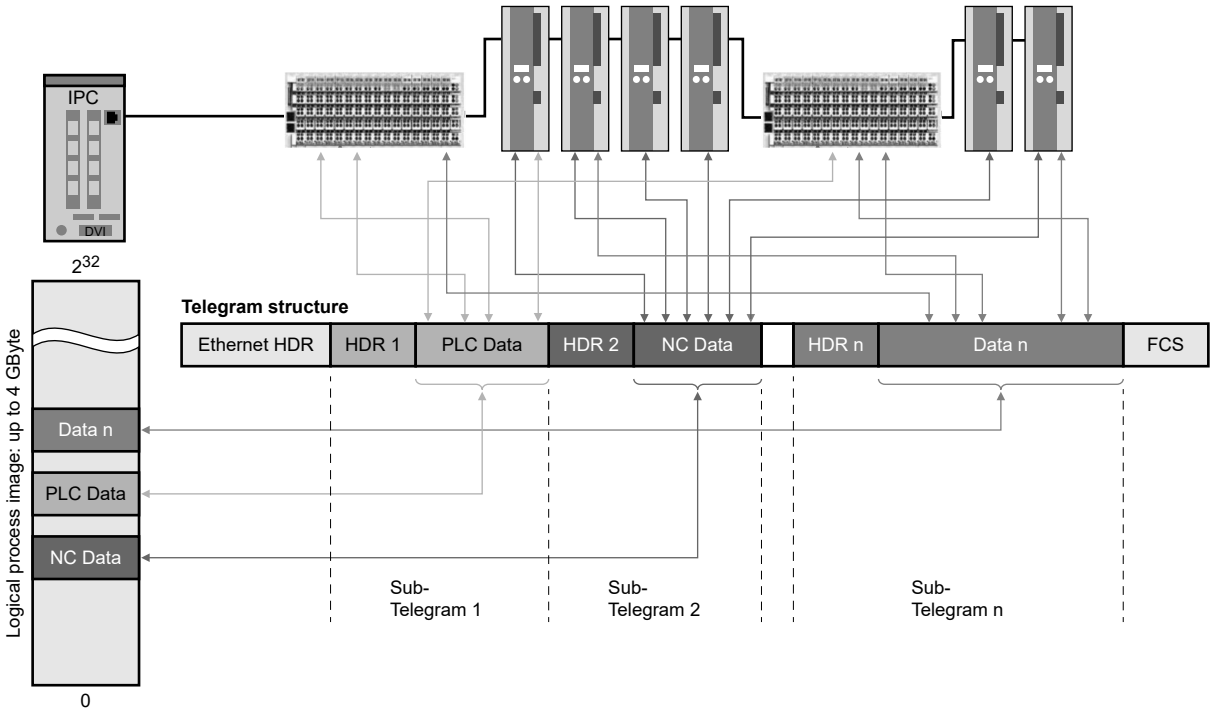

Figure 382. FMMU mapping

NOTE

FMMU configuration registers start at address 0x0600.

Additional FMMU Characteristics:

- Each logical address byte can at most be mapped either by one FMMU(read) plus one FMMU(write), or by one FMMU(read/write). If two or more FMMUs (with the same direction -read or write) are configured for the same logical byte, the FMMU with the lower number (lower configuration address space) is used, the other ones are ignored.
- One or more FMMUs may point to the same physical memory, all of them are used. Collisions cannot occur.
- It is the same to use one read/write FMMU or two FMMUs - one read, the other one write-for the same logical address.
- A read/write FMMU cannot be used together with SyncManagers, since independent read and write SyncManagers cannot be configured to use the same (or overlapping) physical address range.
- Bit-wise reading is supported at any address. Bits which are not mapped to logical addresses are not changed in the EtherCAT datagram. E.g., this allows for mapping bits from several ESCs into the same logical byte.
- A frame/datagram addressing a logical address space which is not configured in the ESC will not change data in the ESC, and no data from the ESC is placed in the frame/datagram.

55.3.12 SyncManager

The memory of an ESC can be used for exchanging data between the EtherCAT master and a local application (on a µController attached to the PDI) without any restrictions. Using the memory for communication like this has some drawbacks which are addressed by the SyncManagers inside the ESCs:

- Data consistency is not guaranteed. Semaphores have to be implemented in software for exchanging data in a coordinated way.
- Data security is not guaranteed. Security mechanisms have to be implemented in software.

- Both EtherCAT master and application have to poll the memory in order to find out when the access of the other side has finished.

SyncManagers enable consistent and secure data exchange between the EtherCAT master and the local application, and they generate interrupts to inform both sides of changes.

SyncManagers are configured by the EtherCAT master. The communication direction is configurable, as well as the communication mode (Buffered Mode and Mailbox Mode). SyncManagers use a buffer located in the memory area for exchanging data. Access to this buffer is controlled by the hardware of the SyncManagers.

A buffer has to be accessed beginning with the start address, otherwise the access is denied. After accessing the start address, the whole buffer can be accessed, even the start address again, either as a whole or in several strokes. A buffer access finishes by accessing the end address, the buffer state changes afterwards and an interrupt or a watchdog trigger pulse is generated (if configured). The end address cannot be accessed twice inside a frame.

Two communication modes are supported by SyncManagers:

- Buffered Mode

  The buffered mode allows both sides, EtherCAT master and local application, to access the communication buffer at any time. The consumer always gets the latest consistent buffer which was written by the producer, and the producer can always update the content of the buffer. If the buffer is written faster than it is read out, old data will be dropped.

  The buffered mode is typically used for cyclic process data.

- Mailbox Mode

  The mailbox mode implements a handshake mechanism for data exchange, so that no data will be lost. Each side, EtherCAT master or local application, will get access to the buffer only after the other side has finished its access. At first, the producer writes to the buffer. Then, the buffer is locked for writing until the consumer has read it out. Afterwards, the producer has write access again, while the buffer is locked for the consumer.

  The mailbox mode is typically used for application layer protocols.

The SyncManagers accept buffer changes caused by the master only if the FCS of the frame is correct, thus, buffer changes take effect shortly after the end of the frame. The configuration registers for SyncManagers are located beginning at register address 0x0800.

Table 799. SyncManager Register overview

Description	Register Address Offset
Physical Start Address	0x0:0x1
Length	0x2:0x3
Control Register	0x4
Status Register	0x5
Activate	0x6
PDI Control	0x7

55.3.12.1 Buffered mode

The buffered mode allows writing and reading data simultaneously without interference. If the buffer is written faster than it is read out, old data will be dropped. The buffered mode is also known as 3-buffer-mode.

Physically, 3 buffers of identical size are used for buffered mode. The start address and size of the first buffer is configured in the SyncManager configuration. The addresses of this buffer have to be used by the master and the local application for reading/writing the data. Depending on the SyncManager state, accesses to the first buffer's (0) address range are redirected to one of the 3 buffers. The memory used for buffers 1 and 2 cannot be used and should be taken into account for configuring other SyncManagers.

One buffer of the three buffers is allocated to the producer (for writing), one buffer to the consumer (for reading), and the third buffer keeps the last consistently written data of the producer. As an example, Figure 24 demonstrates a configuration with start address 0x1000 and Length 0x100. The other buffers shall not be read or written. Access to the buffer is always directed to addresses in the range of buffer 0.

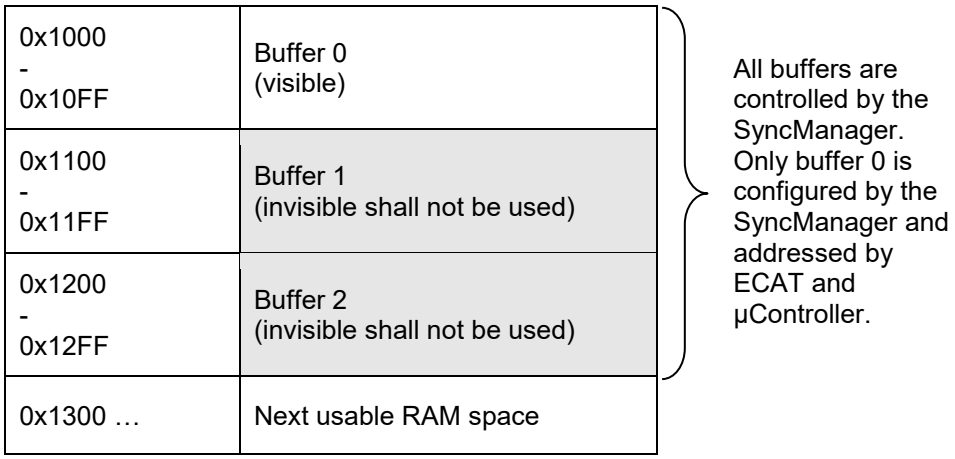

Figure 383. SyncManager buffer allocation

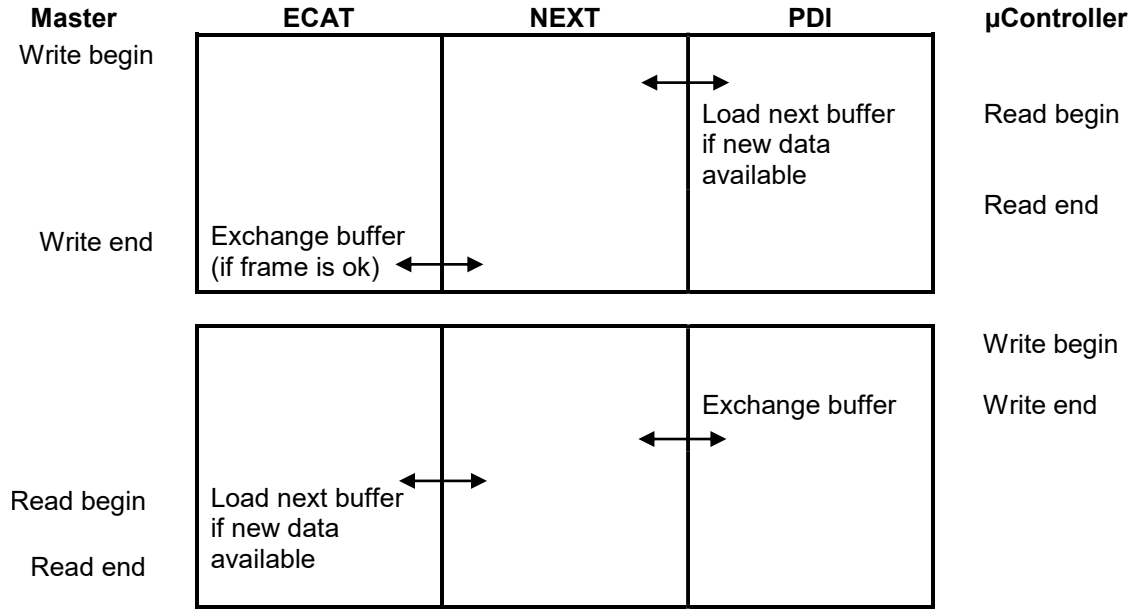

Figure 384. SyncManager mailbox interaction

The Status register of the SyncManager reflects the current state. The last written buffer is indicated (informative only, access redirection is performed by the ESC), as well as the interrupt states. If the SyncManager buffer was not written before, the last written buffer is indicated to be 3 (start/empty).

55.3.12.2 Mailbox mode

The mailbox mode only allows alternating reading and writing. This assures all data from the producer reaches the consumer. The mailbox mode uses just one buffer of the configured size.

At first, after initialization/activation, the buffer (mailbox, MBX) is writeable. Once it is written completely, write access is blocked, and the buffer can be read out by the other side. After it was completely read out, it can be written again. The time it takes to read or write the mailbox does not matter.

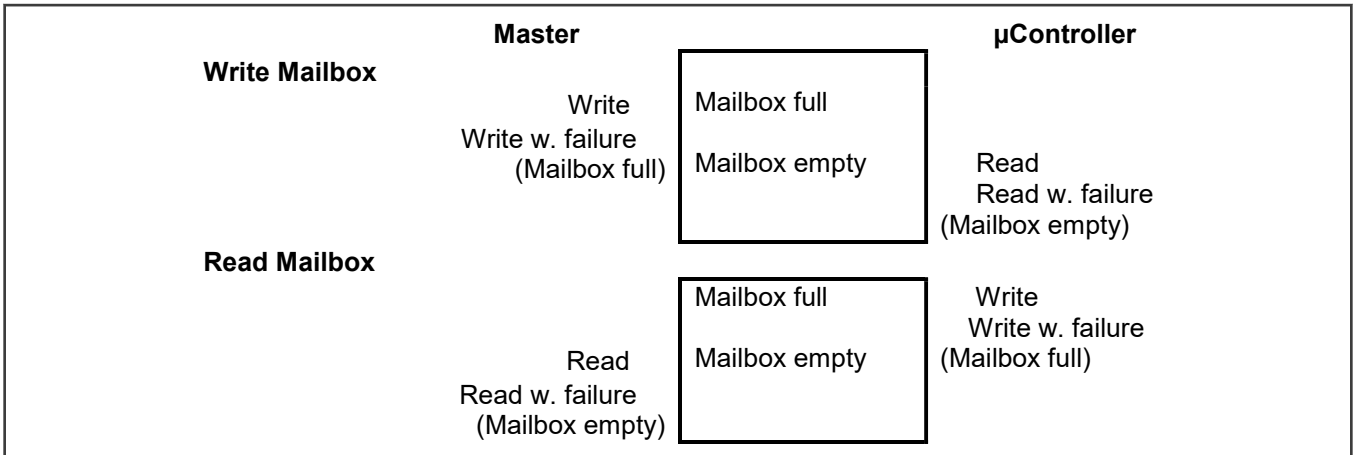

Figure 385. SyncManager mailbox interaction

55.3.12.2.1 Mailbox communication protocols

This is only a brief overview of the mailbox communication protocols.

- **Ethernet over EtherCAT (EoE):** Defines a standard way to exchange or tunnel standard Ethernet Frames over EtherCAT.
- **CAN application layer over EtherCAT (CoE)** Defines a standard way to access a CAN application layer object dictionary and to exchange CAN application layer Emergency and PDO messages on an event driven path.
- **File Access over EtherCAT (FoE)** Defines a standard way to download and upload firmware and other 'files'.
- **Servo Profile over EtherCAT (SoE)** Defines a standard way to access the IEC 61800-7 identifier.
- **Vendor specific Profile over EtherCAT (VoE)** A vendor specific protocol follows after a VoE header that identifies the vendor and a vendor specific type.
- **ADS over EtherCAT (AoE)** AoE defines a standard way to exchange Automation Device Specification (ADS) messages over EtherCAT.

The content of an EtherCAT mailbox header is shown in below figure.

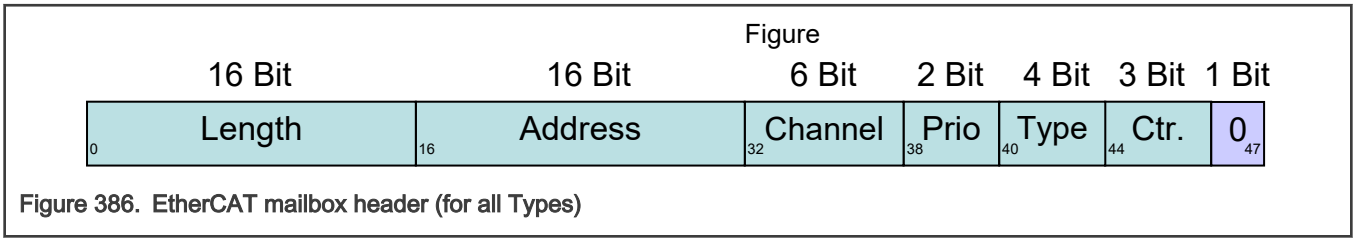

Figure 386. EtherCAT mailbox header (for all Types)

Table 800. EtherCAT mailbox header

Field	Data Type	Value/Description
Length	WORD	Number of Bytes of this mailbox command excluding the mailbox header
Address	WORD	Station Address of originator
Channel	6 bit	0 - reserved for future use
Priority	2 bit	Priority between 0 (lowest) and 3 (highest)
Type	4 bit	Mailbox protocol types:

Table continues on the next page...

Table 800. EtherCAT mailbox header (continued)

Field	Data Type	Value/Description
		• 0x0: Error • 0x1: Vendor specific (AoE -ADS over EtherCAT) • 0x2: EoE (Ethernet over EtherCAT) • 0x3: CoE (CAN application layer over EtherCAT) • 0x4: FoE (File access over EtherCAT) • 0x5: SoE (Servo profile over EtherCAT) • 0xF: Vendor specific (VoE)
Ctr.	3 bit	Sequence number that is used for detection of duplicated frames
Reserved	1 bit	0

55.3.12.3 Interrupt and watchdog trigger generation, latch event generation

Interrupts can be generated when a buffer was completely and successfully written or read. A watchdog trigger signal can be generated to rewind (trigger) the Process Data watchdog used for Digital I/O after a buffer was completely and successfully written. Interrupt and watchdog trigger generation are configurable. The SyncManager Status register reflects the current buffer state.

For debugging purposes it is also possible to trigger Distributed Clock Latch events upon successful buffer accesses (for some ESCs).

55.3.12.4 Single byte buffer length / watchdog trigger for digital output PDI

If a SyncManager is configured for a length of 1 byte (or even 0), the buffer mechanism is disabled, i.e., read/write accesses to the configured address will pass the SyncManager without interference. The additional buffers 1 and 2 are not used in buffered mode, and alternation of write/read accesses is not necessary for mailbox mode. Consistency is not an issue for a single byte buffer. Nevertheless, watchdog triggering is still possible if the buffer length is 1 byte (interrupt generation as well).

NOTE

For some ESCs in Mailbox mode, watchdog and interrupt generation are depending on the alternation of write and read accesses, although the write/read accesses itself are executed without interference. I.e., Buffered mode should be used for single byte buffers for watchdog generation.

Watchdog trigger generation with single byte SyncManagers is used for Digital Outputs, because the outputs are only driven with output data if the Process Data watchdog is triggered. One SyncManager has to be configured for each byte of the Digital Output register (0x0F00:0x0F03) which is used for outputs. The SyncManagers have to be configured like this:

- Buffered Mode (otherwise the process data watchdog will not be wound up with some ESCs upon the second and following writes, because the Digital I/O PDI does not read the addresses)
- Length of 1 byte
- EtherCAT write / PDI read
- Watchdog Trigger enabled

NOTE

A SyncManager with length 0 behaves like a disabled SyncManager. It does not interfere accesses nor generate interrupt or watchdog trigger signals

55.3.12.5 Repeating mailbox communication

Acknowledge bits in the SyncManager Activation register (offset 0x06[1]) and the PDI Control register (offset 0x07[1]) are used in mailbox mode for retransmissions of buffers from a slave to the master. If a mailbox read frame gets lost/broken on the way back to the master, the master can toggle the Repeat Request bit. The slave polls this bit or receives an interrupt (SyncManager activation register changed, register 0x0220[4]) and writes the last buffer again to the SyncManager. Then the PDI toggles the Repeat Acknowledge bit in the PDI Control register. The master will read out this bit and read the buffer content. Communication resumes afterwards. This mechanism is shown in Figure 28 for a mailbox write service. The Mailbox confirmation is lost on its way from the slave to the master and has to be repeated again.

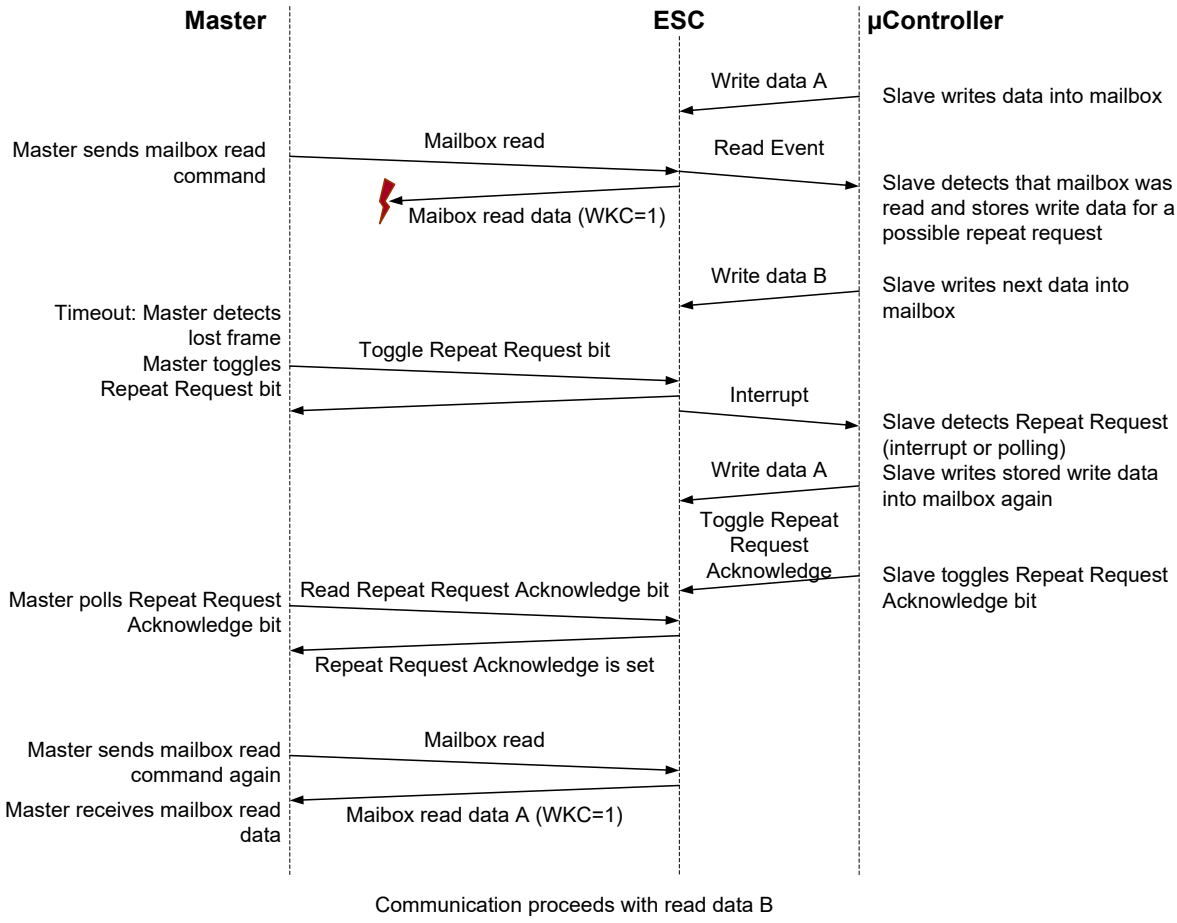

Figure 387. Handling of a repeat request with read mailbox

55.3.12.6 SyncManager deactivation by the PDI

A SyncManager can be deactivated by the PDI to inform the master of local problems (typically used in buffered mode only). The master can detect SyncManager deactivation by checking the Working Counter, which is not incremented if a deactivated SyncManager buffer is accessed. If a SyncManager is deactivated by the PDI (PDI Control register 0x7[0]=1), the state of the SyncManager is reset, interrupts are cleared and the SyncManager has to be written first after re-activation. The entire SyncManager buffer area is read/write protected while the SyncManager is deactivated by the PDI.

55.3.13 SII EEPROM

EtherCAT Subordinate Controllers use a mandatory NVRAM (typically a serial EEPROM with I2C interface) to store EtherCAT Slave Information (ESI). EEPROM sizes from 1 Kbit up to 4 Mbit are supported, depending on the ESC.

The EtherCAT IP Core supports omitting the serial I2C EEPROM if a µController with read/write access to an NVRAM (e.g., the one which contains the µController's program and data, or the FPGA configuration EPPROM) is used to emulate the EEPROM transactions.

The EEPROM structure is shown in the below figure. The ESI uses word addressing.

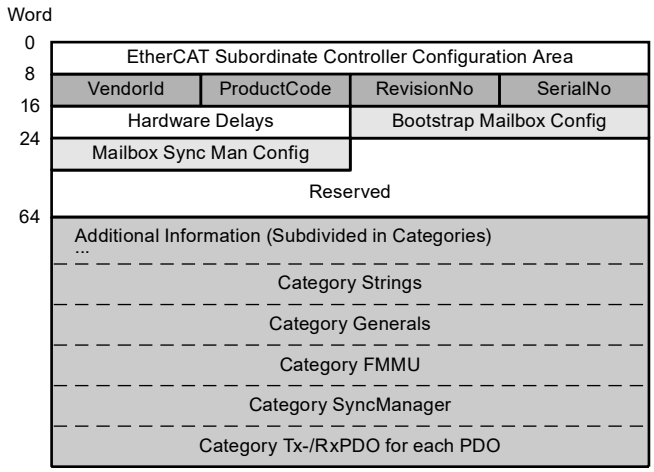

Figure 388. SII EEPROM layout

55.3.13.1 SII EEPROM Content

The ESC Configuration Area (EEPROM word addresses 0 to 7) is automatically read by the ESC after power-on or reset. It contains the PDI configuration, DC settings, and the Configured Station Alias.

The consistency of the ESC Configuration data is secured with a checksum.

The EtherCAT master can invoke reloading the EEPROM content. In this case the Configured Station Alias register 0x0012:0x0013 and ESC Configuration register bits 0x0141[1,4,5,6,7] (enhanced link detection) are not transferred into the registers, they are only transferred at the initial EEPROM loading after power-on or reset.

The ESC Configuration Area is shown in the below table.

Table 801. ESC Configuration Area

Word Address	Parameter	Description	Register Address
0x0	PDI Control/ ESC Configuration	Initialization value for PDI Control register (EEPROM ADR 0x0000[9] is also mapped to register 0x0110[2])	0x0140:0x0141
0x1	PDI Configuration	Initialization value for PDI Configuration register	0x0150:0x0151
0x2	Pulse Length of SYNC Signals	Initialization value for Pulse Length of SYNC Signals register	0x0982:0x0983

Table continues on the next page...

Table 801. ESC Configuration Area (continued)

0x3	Extended PDI Configuration	Initialization value for extended PDI Configuration register	0x0152:0x0153
0x4	Configured Station Alias	Initialization value for Configured Station Alias Address register	0x0012:0x0013
0x5	Reserved	Reserved, shall be zero	-
0x6	Reserved	Reserved, shall be zero	-
0x7	Checksum	Low byte contains remainder of division of word 0 to word 6 as unsigned number divided by the polynomial x8+x2+x+1(initial value 0xFF). NOTE: For debugging purposes it is possible to disable the checksum validation with a checksum value of 0x88A4. Never use this for production!	-

NOTE: Reserved words or reserved bits of the ESC Configuration Area should be filled with 0.

An excerpt of the SII EEPROM content following the ESC Configuration area is shown in below table.

Table 802. SII EEPROM Content Excerp

Word Address	Parameter
0x0	PDI Control
0x1	PDI Configuration

55.3.13.2 SII EEPROM logical interface

The SII EEPROM interface of the eCAT is either controlled by EtherCAT or by the PDI. Initially, EtherCAT has EEPROM interface access, but it can transfer access to the PDI.

Table 803. SII EEPROM interface register overview

Register Address	Description
0x0500	EEPROM Configuration
0x0501	EEPROM PDI Access State
0x0502:0x0503	EEPROM Control/Status
0x0504:0x0507	EEPROM Address
0x0508:0x050F	EEPROM Data

The EEPROM interface supports three commands: write to one EEPROM address (1 Word), read from EEPROM (2 or 4 Words, depending on eCAT), or reload eCAT configuration from EEPROM.

55.3.13.2.1 SII EEPROM errors

The ESC retries reading the EEPROM after power-on or reset once if an error has occurred (missing acknowledge, wrong checksum). If reading the ESC Configuration Area fails twice, the Error Device Information bit is set, and the PDI Operational bit in the ESC DL Status register (0x0110[0]) remains clear and the EEPROM_Loaded signal (if available) remains inactive. The process memory is not accessible until the ESC Configuration Area is loaded successfully.

All registers initialized by the ESC Configuration Area keep their values in case of an error. This is also true for the Error Device Information bit as well as the PDI Operational bit. Only if the EEPROM was loaded/reloaded successfully, the registers take over

the new values (except for Configured Station Alias register 0x0012:0x0013 and ESC Configuration register bits 0x0141[1,4,5,6,7] – enhanced link detection).

The SII EEPROM interface has these error status bits in register EEPROM Control/Status (0x0502:0x0503):

Table 804. SII EEPROM interface errors

Bit	Name	Description
11	Checksum Error	ECAT Configuration Area checksum is wrong (after device initialization or EEPROM reload). Registers initialized with EEPROM values keep their value. Reason: CRC error Solution: Check CRC
12	Error Device Information	ECAT Configuration not loaded Reasons: Checksum error, acknowledge error, EEPROM missing Solution: Check other error bits
13	Error Acknowledge/ Command	Missing Acknowledge or invalid command Reason: a) Missing acknowledge from EEPROM chip (see below). EEPROM chip is busy performing operations internally or EEPROM chip is not available. b) Invalid command issued Solution: a) Retry access. EEPROM device does not acknowledge if it is internally busy. b) Use valid commands
14	Error Write Enable	Write without Write Enable (ECAT control only): Reason: ECAT issued a write command without Write Enable bit set (0x0502[0]) Solution: Set Write Enable bit in the same frame as the write command

55.3.13.2.1.1 Missing acknowledge

Missing acknowledges from the EEPROM chip are a common issue, especially if a fast PDI uses the EEPROM interface. E.g., a write access to the EEPROM with missing acknowledge may look like this:

1. ECAT/PDI issue write command (first command)
2. ESC is busy transferring the write data to the EEPROM chip.
3. ESC is not busy anymore. EEPROM chip is internally busy transferring data from input buffer to storage area.
4. ECAT/PDI issue a second command.
5. ESC is busy transferring the write data to the EEPROM chip. EEPROM chip does not acknowledge any access until internal transfer has finished (may take up to several ms).
6. ESC is not busy anymore. Error Acknowledge/Command bit is set. (ESC has to re-issue the second command after EEPROM chip is finished and the command is acknowledged).
7. EEPROM chip finishes internal transfer.
8. ESC re-issues the second command, the command is acknowledged and executed successful.

This is also possible for a read access, because some EEPROM chips require an idle period between any two accesses. During this idle period, they do not acknowledge any access.

55.3.13.2.2 SII EEPROM interface assignment to ECAT/PDI

The EtherCAT master controls the EEPROM interface (default) if EEPROM configuration register 0x0500[0]=0 and EEPROM PDI Access register 0x0501[0]=0, otherwise PDI controls the EEPROM interface. These access rights should be checked by both sides before using the EEPROM Interface.

A typical EEPROM interface control hand-over is as follows:

1. ECAT assigns EEPROM interface to PDI by writing 0x0500[0]=1
2. If PDI wishes to access EEPROM, it takes over EEPROM control by writing 0x0501[0]=1.
3. PDI issues EEPROM commands.
4. After PDI has finished EEPROM commands, PDI releases EEPROM control by writing 0x0501[0]=0.
5. ECAT may take back the EEPROM interface by writing 0x0500[0]=0
6. ECAT checks EEPROM control by reading 0x0501
7. ECAT issues EEPROM commands.

If the PDI does not release EEPROM control (e.g. because of a software failure), ECAT can force releasing the access:

1. ECAT writes 0x02 to register 0x0500 (as the result, 0x0501[0] is cleared)
2. ECAT writes 0x00 to register 0x0500
3. ECAT has control over EEPROM interface

55.3.13.2.3 Read/write/reload example

The following steps have to be performed for an SII EEPROM read or write access:

1. Check if the Busy bit of the EEPROM Status register is cleared (0x0502[15]=0) and the EEPROM interface is not busy, otherwise wait until the EEPROM interface is not busy anymore.
2. Check if the Error bits of the EEPROM Status register are cleared. If not, write “000” to the command register (register 0x0502 bits [10:8]).
3. Write EEPROM word address to EEPROM Address register.
4. Write command only: put write data into EEPROM Data register (1 word/2 byte only).
5. Issue command by writing to Control register.
    a. For a read command, write 001 into Command Register 0x0502[10:8].
    b. For a write command, write 1 into Write Enable bit 0x0502[0] and 010 into Command Register 0x0502[10:8]. Both bits have to be written in one frame. The Write enable bit realizes a write protection mechanism. It is valid for subsequent EEPROM commands issued in the same frame and self-clearing afterwards. The Write enable bit needs not to be written from PDI if it controls the EEPROM interface.
    c. For a reload command, write 100 into Command Register 0x0502[10:8].
6. The command is executed after the EOF if the EtherCAT frame had no errors. With PDI control, the command is executed immediately.
7. Wait until the Busy bit of the EEPROM Status register is cleared.
8. Check the Error bits of the EEPROM Status register. The Error bits are cleared by clearing the command register. Retry command (back to step 5) if EEPROM acknowledge was missing. If necessary, wait some time before retrying to allow slow EEPROMs to store the data internally.
9. a) For a Read command: Read data is available in EEPROM Data registers (2 or 4 Words, depending on eCAT – check register 0x0502[6]).

b) For a Reload command: ESC configuration is reloaded into appropriate registers.

NOTE: The Command register bits are self-clearing. Manually clearing the command register will also clear the status information.

55.3.13.3 SII EEPROM electrical interface (I2C)

The SII EEPROM Interface is intended to be a point-to-point interface between the ESC and the I²C EEPROM. If other I²C masters are required to access the I²C bus, the ESC must be held in reset state (e.g. for in-circuit-programming of the EEPROM), otherwise access collisions are possible.

The SII EEPROM interface has the following signals1:

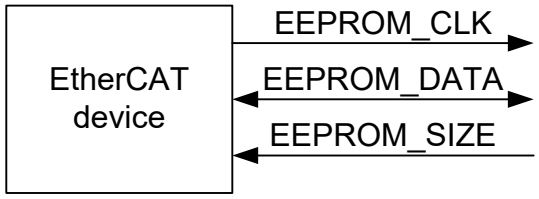

Figure 389. I²C EEPROM signals

Table 805. I²C EEPROM signals

Signal	Direction	Description
EEPROM_CLK	OUT	I²C clock
EEPROM_DATA	BIDIR	I²C data
EEPROM_SIZE	IN	EEPROM size configuration

Both EEPROM_CLK and EEPROM_DATA must have a pull-up resistor (4.7 kΩ recommended for ESCs), either integrated into the ESC or connected externally.

55.3.13.3.1 Addressing

EtherCAT and ESCs use word addressing when accessing the EEPROM, although the I²C interface actually uses byte addressing. The lowest address bit A[0] is added internally by the EEPROM interface controller of the ESCs. I.e., the EEPROM address register (0x0504:0x0507) reflects the physical EEPROM address bits A[18:1] (higher address bits are reserved/are zero).

SII EEPROM word 0 is typically located at I²C address 0, i.e., the I²C device address has to be set to

0. Some ESCs support an offset in the I²C base address.

55.3.13.3.2 EEPROM size

Depending on the EEPROM size, one out of two EEPROM algorithms has to be selected with the EEPROM_SIZE configuration signal. Smaller EEPROMs need only one address byte, larger ones need two address bytes:

Table 806. EEPROM size

EEPROM Size	Address Bytes	Max. I²C Address Bits	EEPROM_SIZE signal
1 Kbit – 16 Kbit	1	11	0
32 Kbit – 4 Mbit	2	19	1

55.3.13.3.3 I²C access protocol

Each EEPROM access begins with a Start condition and ends with a Stop condition. Data is transferred byte-wise, and each byte is acknowledged by the recipient.

The Start condition is a falling edge on EEPROM_DATA while EEPROM_CLK is high, the Stop condition is a rising edge on EEPROM_DATA while EEPROM_CLK is high. In all other cases, EEPROM_DATA has to remain stable while EEPROM_CLK is high, as this indicates valid data. A byte transfer is acknowledged in an additional bit, which is driven low by the recipient of the byte transfer if it acknowledges the byte.

NOTE: If the EEPROM does not acknowledge an access (Ack bit=high), it might be busy internally. Especially if the EERPOM interface is handled by a µController via the PDI, this situation may come up, because many µControllers can write to the EEPROM interface much faster than many EEPROMs can transfer the data from their input registers into their NVRAM.

The first byte of an I²C access is the Control Byte (Bit 7/MSB is transferred first):

Table 807. I²C control byte

Bit	Description
0	Read/Write access: 0: Write 1: Read
[3:1]	Chip Select Bits/Highest Address Bits
[7:4]	Control Code: 1010

Depending on the access, either read data will follow or additional address bytes and write data. This is described in the following chapters.

The EEPROM has an internal byte pointer, which is incremented automatically after each data byte transfer.

55.3.14 Watchdogs

The ESCs support up to two internal watchdogs (WD), a Process Data watchdog used for monitoring process data accesses, and a PDI watchdog monitoring PDI activity. The timeout for both watchdogs can be configured individually, but they share a single Watchdog Divider (WD_DIV, register 0x0400:0x0401). The watchdog timeout is calculated from the Watchdog Divider settings multiplied with the Watchdog Time settings for PDI (WD_PDI, register 0x0410:0x0411) or Process Data (WD_PD, register 0x0420:0x0421). Base time unit is 40 ns. The Watchdog timeout jitters, the jitter depends on the Watchdog Divider settings. i.e., selecting smaller Watchdog Divider settings results in smaller jitter.

The following equations are used for a quick estimation of the watchdog timeout (they are not exact in terms of nanoseconds):

$t_{WD\_Div} = (W_{D\_DIV} + 2) * 40ns$

$t_{WD\_PDI} = [t_{WD\_Div} * W_{D\_PDI} ; t_{WD\_Div} * W_{D\_PDI} + t_{WD\_Div}]$

$t_{WD\_PD} = [t_{WD\_Div} * W_{D\_PD} ; t_{WD\_Div} * W_{D\_PD} + t_{WD\_Div}]$

55.3.14.1 Process data watchdog

The Process Data watchdog is rewound (triggered) by a write access to a SyncManager buffer area if the SyncManager is configured to generate a watchdog trigger signal (SyncManager Control register 0x0804[6] for SyncManager 0, etc.). The watchdog trigger signal is generated after the buffer was completely and successfully written (similar to the Interrupt Write of a SyncManager). The Process Data watchdog can be disabled by setting the Process Data Watchdog Time to 0. A timeout of the Process Data watchdog has these consequences:

- Watchdog Status register for Process Data (0x0440[0]) reflects the watchdog status.
- The Digital I/O PDI takes back digital output data, either by not driving the signals anymore or by driving them low (ESC and configuration dependent).
- The Watchdog Counter Process Data (0x0442) is incremented.

55.3.14.2 PDI watchdog

The PDI watchdog is rewound (triggered) by any correct read or write access by the PDI. The PDI watchdog can be disabled by setting the PDI Watchdog Time to 0. A timeout of the PDI watchdog has these consequences:

- ESC DL Status register (0x0110[1]) reflects the watchdog status. This can be mapped to the ECAT Interrupt to inform the master.
- The Watchdog Counter PDI (0x0443) is incremented.

NOTE

The Digital I/O PDI only triggers the PDI watchdog upon input events

55.3.15 EtherCAT state machine

The EtherCAT State machine (ESM) is responsible for the coordination of master and slave applications at start up and during operation. State changes are typically initiated by requests of the master. They are acknowledged by the local application after the associated operations have been executed. Unsolicited state changes of the local application are also possible.

Simple devices without a µController can be configured to use EtherCAT State Machine emulation. These devices simply accept and acknowledge any state change automatically.

There are four states an EtherCAT slave shall support, plus one optional state:

- Init (state after Reset)
- Pre-Operational
- Safe-Operational
- Operational
- Bootstrap (optional)

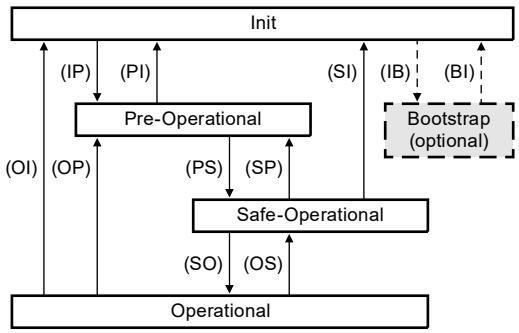

Figure 390. EtherCAT state machine

Each state defines required services. Before a state change is confirmed by the slave all services required for the requested state have to be provided or stopped respectively

55.3.16 LED Signals (Indicators)

55.3.16.1 RUN LED

The AL status is displayed with the RUN LED (green). The RUN output of an ESC is controlled by the AL status register (0x0130) and supports the following states, which are automatically translated into blink codes:

Table 808. RUN LED state indication

RUN LED	Description
Off	The device is in state INIT
Blinking (slow)	The device is in state PRE-OPERATIONAL
Single Flash	The device is in state SAFE-OPERATIONAL
On	The device is in state OPERATIONAL
Flickering (fast)	The device is in state BOOTSTRAP or loading the SII EEPROM*

- Some ESCs support RUN LED flickering while the SII EEPROM is loaded.

55.3.16.1.1 RUN LED override

Some ESCs support optional RUN LED outputs by overriding the state indication of the RUN LED. The output can be set by master or local application. This can be used e.g. for locating a specific slave by forcing the RUN LED to indicate a triple flash (Device Identification).

The RUN LED override is disabled automatically by a following ESM state change.

Table 809. Registers for RUN LED control

Register Address	Name	Description
0x0130	AL Status register	After a state change, the RUN LED indicates the current ESM state.
0x0138	RUN LED Override	Direct control of the RUN LED from ECAT and/or PDI

55.3.16.2 ERR LED

The ERR LED indicates local errors and application errors. It is either connected to the application controller or to the eCAT (optional eCAT feature). If it is connected to the eCAT, some errors are automatically indicated by the eCAT, other error states are detected by the application controller and indicated by writing to the ERR LED Override register 0x0139.

The following ERR LED states can be automatically generated by an eCAT, without interaction of an application controller. The support of individual error states is eCAT specific.

Table 57:

Table 810. Automatic eCAT ERR LED state indication

ERR LED	Description	Examples
Off	No error	
Flickering (fast)	SII EEPROM loading error	no SII EEPROM device, SII CRC error
Blinking (slow)	Invalid hardware configuration	ESC pin sharing violation

Table continues on the next page...

Table 810. Automatic eCAT ERR LED state indication (continued)

Single Flash	AL Status register Error Indication bit 0x0130[4] is set while device emulation is disabled	Local application controller sets Error Indication bit. NOTE: E.g., if the µController makes a state change with Error Indication bit 0x0130[4] set after a Process Data Watchdog Timeout, it has to manually set the ERR LED to Double Flash again (otherwise the ESC would generate a Single Flash due to the Error Indication bit automatically).
Double Flash	Process Data Watchdog timeout (edge detected) while device is OPERATIONAL	master is disconnected/not sending process data any more
On	PDI Watchdog timeout (edge detected) or Build-In self-test error	local application controller failure or self-test failure

NOTE: Do not confuse the application ERR LED with the port receive error LEDs (PERR(x)) supported by some eCATs.

55.3.16.2.1 ERR LED override

If the ESC supports the ERR LED, the local application (and the master) is able to control the ERR LED via the ERR LED override register.

The ERR LED override is disabled automatically if an error is detected by the ESC which is associated with an ERR LED blink code.

Table 811. Registers for ERR LED control

Register Address	Name	Description
0x0139	ERR LED Override	Direct control of the ERR LED from ECAT and/or PDI

55.3.16.3 STATE LED and STATE_RUN LED signal

The STATE LED is a bicolor-LED combining RUN and ERR LED. Since the RUN LED part of the STATE LED must be turned off while the ERR LED part is active, the RUN and ERR LED signals cannot be simply combined to drive the bicolor LED. Some ESCs support a STATE_RUN signal, which is turned off while ERR LED is on, so STATE_RUN and ERR signals can be used to drive the bicolor STATE LED. Otherwise the logical combination “RUN and not(ERR)” has to be used to control the RUN LED part of the STATE LED.

55.3.16.4 LINKACT LED

The Link/Activity state of each port is displayed with the LINKACT LED (green).

Table 812. LINKACT LED states

LINKACT LED	Description
Off	No link
Blinking	Link and activity
On	Link without activity

It is highly recommended to use the LINKACT LED signals of the eCATs for driving visible LEDs, instead of the Link/Activity LED signals of the PHY, because the ESC signals reflect the actual link/activity state of the device – not only the state of the PHYs –, and the ESC signals adhere to the ETG.1300 EtherCAT Indicator and Labeling Specification.

The LINKACT LED indicates the link status after evaluation of the Enhanced link detection plus MI link detection and configuration, it corresponds with the ESC DL Status register (0x0110[15,13,11,9] – Communication established.

55.3.16.5 Port Error LED (PERR)

Some eCATs support port receive error indicators PERR(x), which display physical layer RX errors. The PERR(x) LEDs are not part of the ETG.1300 EtherCAT Indicator and Labeling Specification. They are only intended for testing and debugging. The PERR(x) LEDs flash once if a physical layer RX error occurs.

55.3.17 Distributed Clocks (DC)

The Distributed Clocks (DC) unit of EtherCAT Subordinate Controllers supports the following features:

- Clock synchronization between the slaves (and the master)
- Generation of synchronous output signals (SyncSignals)
- Precise time stamping of input events (LatchSignals)
- Generation of synchronous interrupts
- Synchronous Digital Output updates
- Synchronous Digital Input sampling

55.3.17.1 Clocks synchronization

DC clock synchronization enables all EtherCAT devices (master and slaves) to share the same EtherCAT System Time. The EtherCAT devices can be synchronized to each other, and consequently, the local applications are synchronized as well.

For system synchronization all slaves are synchronized to one Reference Clock. Typically, the first ESC with Distributed Clocks capability after the master within one segment holds the reference time (System Time). This System Time is used as the reference clock to synchronize the DC slave clocks of other devices and of the master. The propagation delays, local clock sources drift, and local clock offsets are taken into account for the clock synchronization.

The ESCs can generate SyncSignals for local applications to be synchronized to the EtherCAT System Time. SyncSignals can be used directly (e.g., as interrupts) or for Digital Output updating/Digital Input sampling. Additionally, LatchSignals can be time stamped with respect to the EtherCAT System Time.

Definition of the System Time:

- Beginning on January, 1st 2000 at 0:00h
- Base unit is 1 ns
- 64 bit value (enough for more than 500 years)
- Lower 32 bits span over 4.2 seconds (typically enough for communication and time stamping). Some ESCs only have 32 bit DCs, which are compatible with 64 bit DCs.

Definition of the Reference Clock:

One EtherCAT device will be used as a Reference Clock. Typically, the Reference Clock is the first ESC with DC capability between master and all the slaves to be synchronized (DC slaves). The Reference Clock might be adjusted to a global reference clock, e.g. to an IEEE 1588 grandmaster clock. The reference clock provides the System Time.

Each DC slave holds a copy of the Reference Clock, which is calculated from the local clock and the local offset. The Reference Clock has a local clock, too.

Definition of the Master Clock:

The Reference Clock is typically initialized by the EtherCAT master using the master clock to deliver the System Time according to the System Time definition. The EtherCAT master clock is typically bound to a global clock reference (RTC or the master PC, IEEE1588, GPS, etc.), which is either directly available to the master or indirectly by an EtherCAT slave providing access to the reference.

Propagation Delay:

The propagation delay between Reference Clock and slave clock has to be taken into account when the System Time is distributed to the slaves.

Offset:

The offset between local clock and Reference Clock has two reasons: the propagation delay from the ESC holding the Reference Clock to the device with the slave clock, and initial differences of the local times resulting from different times at which the ESCs have been powered up. This offset is compensated locally in each slave. The ESC holding the Reference Clock derives the System Time from its local time by adding a local offset. This offset represents the difference between local time (started at power-up) and master time (starting on January, 1st 2000 at 0:00h).

Drift:

Since Reference Clock and DC slaves are typically not sourced by the same clock source (e.g., a quartz), their clock sources are subject to small deviations of the clock periods. The result is that one clock is running slightly faster than the other one, their local clocks are drifting apart.

55.3.17.1.1 ESC classification regarding DC support

Three classes of ESCs are distinguished regarding Distributed Clocks support:

- Slaves supporting only propagation delay measurement: Mandatory for ESCs with 3 or more ports. Local clock and receive time stamps are supported.
- Slaves without Distributed Clocks support: Slaves with max. 2 ports do not have to support DC features. Processing/ forwarding delay of such slaves is treated like a wire delay by the surrounding DC capable slaves.

55.3.17.2 Propagation delay measurement

Since each slave introduces a small processing/forwarding delay in each direction (within the device and also in the PHY), as well as the cable between the ESCs has a delay, the propagation delay between Reference Clock and the respective slave clock has to be considered for the synchronization of the slave clocks.

1. For measuring the propagation delay, the master sends a broadcast write to register DC Receive Time Port 0 (at least the first byte).
2. Each slave device stores the time of its local clock when the first bit of the Ethernet preamble of the frame was received, separately for each port (Receive Time Port 0-3 registers).
3. The master reads all time stamps and calculates the delay times with respect to the topology. The delay time between Reference Clock and an individual slave is written to the slave's System Time Delay register (0x0928:0x092B).

The receive time registers are used to sample the receive time of a specific frame (a broadcast write to Receive Time Port 0 register).

The clocks must not be synchronized for the delay measurement, only local clock values are used. Since the local clocks of the slaves are not synchronized, there is no relation between the Receive Times of different slaves. So the propagation delay calculation has to be based on receive time differences between the ports of a slave.

Devices with two ports do not need to support Distributed Clocks at all, their delay is treated as an additional "wire delay" between the surrounding DC-capable slaves. Devices with more than 2 ports have to support at least propagation delay measurements (DC Receive Times).

Some eCATs use the broadcast write to Receive Time Port 0 register as an indicator to latch the receive times of the next frame at all ports other than port 0 (if port 0 is open). Thus, another frame which is still traveling around the ring might trigger the measurement, and the receive times do no correlate. For these eCATs, the ring has to be empty before the broadcast write is issued.

Table 813. Registers for propagation delay measurement

Register Address	Name	Description
0x0900:0x0903	Receive Time Port 0	Local time when receiving frame on Port 0
0x0904:0x0907	Receive Time Port 1	Local time when receiving frame on Port 1
0x0908:0x09B	Reserved	Reserved
0x090C:0x090F	Reserved	Reserved
0x0918:0x091F	Receive Time ECAT Processing Unit	Local time when receiving frame at the ECAT Processing Unit
0x0936	Receive Time Latch Mode	ET1200: Receive time latching in forwarding or reverse mode

55.3.17.2.1 Propagation delay measurement in reverse mode

For redundancy operation, it is necessary to perform propagation delay measurements either in forwarding mode (master connected to port 0), or in reverse mode (master connected to port 1). For ET1200, care has to be taken because the measurement principle is slightly different for these two ESC types: DC Receive Time Latch Mode register 0x0936 has to be used. As ET1100 and IP Core do not require register 0x0936, the following rules can be used for propagation delay measurement in a mixed ET1200/ET1100/IP Core environment (ESC20 does not support propagation delay measurement in reverse mode).

- In forwarding mode, the master should write 0x00 to register 0x0936 of all slaves, and perform the delay measurement afterwards.
- In reverse mode, the master should write 0x01 to register 0x0936 of all slaves, and perform the delay measurement afterwards.

55.3.17.2.2 Propagation delay measurement example

The propagation delay between the local device and the Reference Clock device is calculated for the network example shown in the below figure. The example assumes that slave A is the Reference Clock. The loops of slave D and F are closed internally. The wire delays are assumed to be symmetrical, and the processing and forwarding delays are assumed to be identical for all ESCs.

Parameters used for propagation delay calculation are listed in the below table.

Table 814. Parameters for propagation delay calculation

Parameter	Description
t_{Px}	Processing delay of slave x (through EtherCAT Processing Unit, x=A-F)
t_{Fx}	Forwarding delay of slave x (alongside EtherCAT Processing Unit, x=A-F)
t_{xy}	Propagation delay from slave x to slave y (x/y=A-F)
t_{Wxy}	Wire propagation delay between slaves x and y (assumed to be symmetrical in both directions, x/y=A-F)
t_{x0}, t_{x1}, t_{x2}	Receive Time Port 0/1/2 values of slave x (time when first preamble bit is detected, x=A-F), measured with a write access to DC Receive Time 0 register.
t_P	Processing delay (through EtherCAT Processing Unit) if all slaves are identical

Table continues on the next page...

Table 814. Parameters for propagation delay calculation (continued)

t_F	Forwarding delay (alongside EtherCAT Processing Unit) if all slaves are identical
t_{Diff}	Difference between Processing delay and forwarding delay tDiff = tP – tF if all slaves are identical. ESC specific information, part of the ESI.
t_{Ref_x}	Propagation delay from Reference Clock (slave A) to slave x

- **Propagation delay between Slave C and D**

  The propagation delays between slave C and D (t_{CD} and t_{DC}) consist of a processing delay and the wire delay:

  $t_{CD} = t_{PC} + t_{WCD}$ $t_{DC} = t_{PD} + t_{WCD}$

  Assuming that the processing delays of slave C and D are identical ($t_P = t_{PC} = t_{PD}$): $t_{CD} = t_{DC} = t_P + t_{WCD}$

  The two Receive Times of slave C have the following relation: $t_{C1} = t_{C0} + t_{CD} + t_{DC}$

  So the propagation delays between slave C and D are $t_{CD} = t_{DC} = (t_{C1} - t_{C0}) / 2$

- **Propagation delay between Slave B and C**

  The propagation delays between slave B and C (t_{BC} and t_{CB}) are calculated as follows: $t_{BC} = t_{PB} + t_{WBC}$

  $t_{CB} = t_{FC} + t_{WBC}$

  Assuming that the processing delays of slaves B, C and D are identical ($t_P = t_{PB} = t_{PC} = t_{PD}$), and the difference between forwarding and processing delay of slave C is $t_{Diff} = t_{PC} - t_{FC}$:

  $t_{BC} = t_P + t_{WBC}$

  $t_{CB} = t_{BC} - t_{Diff}$

  The Receive Times (port 0 and 1) of slave B have the following relation: $t_{B1} = t_{B0} + t_{BC} + t_{CD} + t_{DC} + t_{CB}$

  So the propagation delay between slave B and C is $2*t_{BC} - t_{Diff} = (t_{B1} - t_{B0}) - (t_{C1} - t_{C0})$

  $t_{BC} = ((t_{B1} - t_{B0}) - (t_{C1} - t_{C0}) + t_{Diff}) / 2$

  And for the other direction:

  $t_{CB} = ((t_{B1} - t_{B0}) - (t_{C1} - t_{C0}) - t_{Diff}) / 2$

- **Propagation delays between slave E and F**

  The propagation delays between slave E and F are calculated like the delays between slave C and D: $t_{EF} = t_{PE} + t_{WEF}$

  $t_{FE} = t_{PF} + t_{WEF}$

  Assuming that the processing delays of slave E and F are identical ($t_P = t_{PE} = t_{PF}$): $t_{EF} = t_{FE} = (t_{E1} - t_{E0}) / 2$

- **Propagation delay between Slave B and E**

  The propagation delays between slave B and E (t_{BE} and t_{EB}) are calculated as follows: $t_{BE} = t_{FB} + t_{WBE}$

  $t_{EB} = t_{FE} + t_{WBE}$

  Assuming that the processing delays of slaves B to F are identical ($t_P = t_{Px}$), and the difference between forwarding and processing delay of these slaves is $t_{Diff} = t_{Px} - t_{Fx}$:

  $t_{BE} = t_{EB} = t_P - t_{Diff} + t_{WBE}$

  The Receive Times Port 1 and 2 of slave B have the following relation: $t_{B2} = t_{B1} + t_{BE} + t_{EF} + t_{FE} + t_{EB}$

  So the propagation delay between slave B and E is $2*t_{BE} = (t_{B2} - t_{B1}) - t_{EF} - t_{FE}$

  $t_{BE} = t_{EB} = ((t_{B2} - t_{B1}) - (t_{E1} - t_{E0})) / 2$

- **Propagation delay between slave A and B**

The propagation delays between slave A and B are calculated as follows: $t_{AB} = t_{PA} + t_{WAB}$

$t_{BA} = t_{FB} + t_{WAB}$

Assuming that the processing delays of all slaves are identical (tP = tPx), and the difference between forwarding and processing delay of these slaves is tDiff = tPx - tFx :

$t_{AB} = t_{P} + t_{WAB}$

$t_{BA} = t_{AB} - t_{Diff}$

The Receive Times of slave A have the following relation: $t_{A1} = t_{A0} + t_{AB} + (t_{B1} - t_{B0}) + (t_{B2} - t_{B1}) + t_{BA}$

So the propagation delay between slave A and B is $t_{AB} = ((t_{A1} - t_{A0}) - (t_{B2} - t_{B0}) + t_{Diff}) / 2$

And for the other direction:

$t_{BA} = ((t_{A1} - t_{A0}) - (t_{B2} - t_{B0}) - t_{Diff}) / 2$

- **Summary of Propagation Delay Calculation between Slaves**

  $t_{AB} = ((t_{A1} - t_{A0}) - (t_{B2} - t_{B0}) + t_{Diff}) / 2$ $t_{BA} = ((t_{A1} - t_{A0}) - (t_{B2} - t_{B0}) - t_{Diff}) / 2$ $t_{BC} = ((t_{B1} - t_{B0}) - (t_{C1} - t_{C0}) + t_{Diff}) / 2$ $t_{CB} = ((t_{B1} - t_{B0}) - (t_{C1} - t_{C0}) - t_{Diff}) / 2$ $t_{CD} = t_{DC} = (t_{C1} - t_{C0}) / 2$

  $t_{EF} = t_{FE} = (t_{E1} - t_{E0}) / 2$

  $t_{BE} = t_{EB} = ((t_{B2} - t_{B1}) - (t_{E1} - t_{E0})) / 2$

- **Propagation Delays between Reference Clock and Slave Clocks**

  The System Time Delay register of each slave clock takes the propagation delay from the Reference Clock to the slave. This delay is calculated like this:

  $t_{Ref\_B} = t_{AB}$

  $t_{Ref\_C} = t_{AB} + t_{BC}$

  $t_{Ref\_D} = t_{AB} + t_{BC} + t_{CD}$

  $t_{Ref\_E} = t_{AB} + t_{BC} + t_{CD} + t_{DC} + t_{CB} + t_{BE}$

  $t_{Ref\_F} = t_{AB} + t_{BC} + t_{CD} + t_{DC} + t_{CB} + t_{BE} + t_{EF}$

55.3.17.3 Offset compensation

The local time of each device is a free-running clock which typically will not have the same time as the Reference Clock. To achieve the same absolute System Time in all devices, the offset between the Reference Clock and every slave device's clock is calculated by the master. The offset time is written to register System Time Offset to adjust the local time for every individual device. Small offset errors are eliminated by the drift compensation after some time, but this time might become extremely high for large offset errors – especially for 64 bit DCs.

Each DC slave calculates its local copy of the System time using its local time and the local offset value:

$t_{Local\ copy\ of\ System\ Time} = t_{Local\ time} + t_{Offset}$

This time is used for SyncSignal generation and time stamping of LatchSignals. It is also provided to the PDI for use by µControllers.

The System Time of the Reference Clock is bound to the master clock by calculating the difference and compensating it using the System Time Offset of the Reference Clock.

Registers used for Offset Compensation are listed in below table.

Table 815. Registers for offset compensation

Register Address	Name	Description

Table continues on the next page...

Table 815. Registers for offset compensation (continued)

0x0910:0x0917	System Time	Local copy of System Time (read from PDI)
0x0918:0x091F	Receive Time ECAT Processing Unit	Local Time (tLocal time)
0x0920:0x0927	System Time Offset	Difference between local time and System Time (tOffset)

55.3.17.4 Resetting the Time Control Loop

Before starting drift compensation, the internal filters of the Time Control Loop must be reset. Their current status is typically unknown, and they can have negative impact on the settling time. The filters are reset by writing the Speed Counter Start value to the Speed Counter Start register (0x0930:0x0931). Writing the current value of the register again is sufficient to reset the filters.

Registers used for resetting the Time Control Loop filters are listed in below table.

Table 816. Registers for Resetting the Time Control Loop

Register Address	Name	Description
0x0930:0x0931	Speed Counter Start	Bandwidth for adjustment of local copy of System Time Writing a value resets the internal filters.

55.3.17.5 Drift compensation

After the delay time between the Reference Clock and the slave clocks has been measured, and the offset between both clocks has been compensated, the natural drift of every local clock (emerging from quartz variations between the Reference Clock's quartz and the local quartz) is compensated by the time control loop which is integrated into each ESC.

For drift compensation, the master distributes the System Time from the Reference Clock to all slave clocks periodically. The ARMW or FRMW commands can be used for this purpose. The time control loop of each slave takes the lower 32 bit of the System Time received from the Reference Clock and compares it to its local copy of the System Time. For this difference, the propagation delay has to be taken into account:

Δt = (tLocal time + tOffset – tPropagation delay) – tReceived System Time

If Δt is positive, the local time is running faster than the System time, and has to be slowed down. If Δt is negative, the local time is running slower than the System time, and has to speed up. The time control loop adjusts the speed of the local clock.

For a fast compensation of the static deviations of the clock speeds, the master should initially send many ARMW/FRMW commands (e.g. 15,000) for drift compensation in separate frames after initialization of the propagation delays and offsets. The control loops compensate the static deviations and the distributed clocks are synchronized. Afterwards, the drift compensation frames are sent periodically for compensation of dynamic clock drifts.

NOTE: The System Time Offset allows fast compensation of differences between local copy of the system time and the System Time, the drift compensation is very slow. Thus, shortly before drift compensation is started, the offset should be roughly compensated using the System Time Offset register. Otherwise settling time might become very high.

NOTE: Δt must not exceed 230 ns (~ 1 second), otherwise stability is not guaranteed. For fast settling times, Δt should be as low as possible.

55.3.17.6 Reference between DC registers/functions and clocks

Table 817. Reference between DC registers/functions and clocks

Register Address	Name	Referring to clock

Table continues on the next page...

Table 817. Reference between DC registers/functions and clocks (continued)

0x0900:0x090F	Receive Time Port n	Local Time ($t_{Local\ time}$)
0x0918:0x091F	Receive Time ECAT Processing Unit	Local Time ($t_{Local\ time}$)
0x0910:0x0917	System Time	Local copy of System Time ($t_{Local\ time} + t_{Offset}$)
0x0990:0y0997	SYNC0 Start Time	Local copy of System Time ($t_{Local\ time} + t_{Offset}$)
0x0998:0x099F	NEXT SYNC1 Pulse	Local copy of System Time ($t_{Local\ time} + t_{Offset}$)
0x09B0:0x09B7	Latch0 Time Positive Edge	Local copy of System Time ($t_{Local\ time} + t_{Offset}$)
0x09B8:0x09BF	Latch0 Time Negative Edge	Local copy of System Time ($t_{Local\ time} + t_{Offset}$)
0x09C0:0x09C7	Latch1 Time Positive Edge	Local copy of System Time ($t_{Local\ time} + t_{Offset}$)
0x09C8:0x09CF	Latch1 Time Negative Edge	Local copy of System Time ($t_{Local\ time} + t_{Offset}$)
0x09F0:0x09F3	EtherCAT Buffer Change Event Time	Local Time ($t_{Local\ time}$)
0x09F8:0x09FB	PDI Buffer Start Event Time	Local Time ($t_{Local\ time}$)
0x09FC:0x09FF	PDI Buffer Change Event Time	Local Time ($t_{Local\ time}$)

55.3.17.7 When is synchronization established?

There are two possibilities to detect if DC synchronization of a slave is established:

- Read System Time Difference (0x92C:0x092F):

If the difference is below an application specific threshold, DC has locked.

Advantage: Can be read using a single BRD command for the entire network: if the upper N bits are zero, synchronization is established.

Recommended if an EtherCAT slave is the reference clock. If the master is the reference clock, the threshold has to be increased to accomplish for the master jitter, which could make this solution unusable.

- Read Speed Counter Difference (0x0932:0x0933):

If the value is stable (within an application-specific range), DC has locked. Disadvantage: Loss of lock is recognized late.

55.3.17.8 Clock synchronization initialization example

The initialization procedure of clock synchronization including propagation delay measurement, offset compensation, filter reset, and drift compensation is shown in the following. After initialization, all DC slaves are synchronized with the Reference Clock.

1. Master reads the DL Status register of all slaves and calculates the network topology.
2. Master sends a broadcast write to Receive Time Port 0 register (at least first byte). All slaves latch the local time of the first preamble bit of this frame at all ports and at the ECAT Processing Unit. Some ESCs need the EtherCAT network to be free of frames before the broadcast write is sent.
3. Master waits until the broadcast write frame has returned.
4. Master reads all Receive Time Port 0-3 registers (depending on the topology and the Receive Time ECAT Processing Unit register (0x0918:0x091F) which contains the upper 32 bits of the receive times.

5. Master calculates individual propagation delays and writes them to System Time Delay registers of the slaves. Possible overruns of the 32 bit Receive Times have to be checked and taken into account.
6. Master sets System Time Offset register of the Reference Clock so that the Reference Clock is bound to the master time. The offset for the Reference Clock is master time minus Receive Time ECAT Processing Unit (local time) of the Reference Clock.
7. Master calculates System Time offsets for all DC slaves and writes them to the System Time Offset registers. The offset of each slave is Receive Time ECAT Processing Unit from Reference Clock minus Receive Time ECAT Processing Unit from each DC slave.
8. Master resets all slaves' Time Control Loop filters by writing to the Speed Counter Start register (0x0930:0x0931).
9. For static drift compensation, the master sends many separate ARMW or FRMW drift compensation frames (e.g., 15,000 frames) to distribute the System Time of the Reference Clock to all DC slaves.
10. For dynamic drift compensation, the master sends ARMW or FRMW commands periodically to distribute the System Time of the Reverence Clock to all DC slaves. The rate of the drift compensation commands depends on the acceptable maximum deviation.

55.3.17.9 SyncSignals and LatchSignals

ESCs with Distributed Clocks support generation of SyncSignals and time stamping of LatchSignals. The SyncSignals can be used internally for

- Interrupt generation (mapping to AL Event Request register 0x0220:0x0223 and PDI IRQ)
- PDI Digital Output Update events
- PDI Digital Input Latch events

The SyncSignals can also be directly mapped to output signals (SYNC[1:0]) for use by external devices, e.g., as interrupt signals (less jitter than PDI IRQ, no interrupt source decoding).

The Latch Event unit supports time stamping of up to two LatchSignals (LATCH[1:0], rising and falling edge separately), and time stamping of SyncManager events for debugging purposes.

55.3.17.9.1 Interface

The Distributed Clocks unit has the following external signals (depending on the ESC and the ESC configuration):

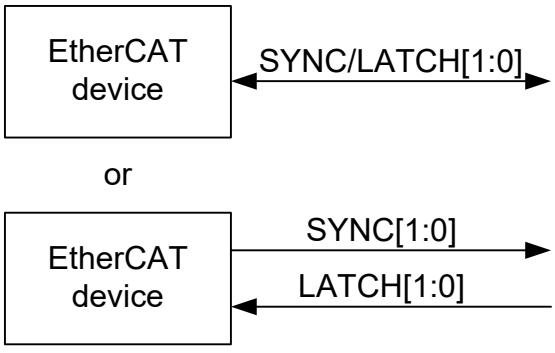

Figure 391. Distributed clocks signals

Table 818. Distributed clocks signals

Signal	Direction	Description
SYNC/LATCH[1:0]	IN/OUT	Combined SyncSignals / LatchSignals

Table continues on the next page...

Table 818. Distributed clocks signals (continued)

Signal	Direction	Description
SYNC[1:0]	OUT	SyncSignals (also named SYNC0/ SYNC1)
LATCH[1:0]	IN	LatchSignals (also named LATCH0/ LATCH1)

Not all of these signals might be available depending on the ESC and its hardware configuration.

55.3.17.9.2 Configuration

The mapping of Distributed Clocks SyncSignals and LatchSignals to the external SYNC/LATCH[1:0] signals is controlled by the setting of the Sync/Latch PDI Configuration register 0x0151. The SYNC[1:0] driver characteristics are also selected in this register. The SyncSignals are internally available for interrupt generation and Digital I/O synchronization regardless of the Sync/Latch PDI Configuration. The mapping of SyncSignals to the AL Event Request register is also controlled by the Sync/Latch PDI Configuration register 0x0151.

The length of a SyncSignal pulse is defined in the DC Pulse Length of SYNC Signals register (0x0982:0x0983). A value of 0 selects acknowledged modes.

Some ESCs support power saving options (partly disabling DC units) controlled by two bits of the ESC Configuration register (0x0141[3:2]), others have individual configuration options for each SyncSignal/LatchSignal.

The Sync/Latch signals are not driven (high-impedance) by some ESCs until the SII EEPROM is successfully loaded. Take care of proper SyncSignal usage while the EEPROM is not loaded (e.g. pull-down/pull-up resistors).

55.3.17.9.3 SyncSignal generation

The DC Cyclic Unit / Sync Unit supports the generation of a base SyncSignal SYNC0 and a dependent SyncSignal SYNC1. The SyncSignals can both be used internally and externally of the ESC. SyncSignals can be generated at a specific System Time. Four operation modes are supported: cyclic generation, single shot, cyclic acknowledge, and single shot acknowledge mode. The acknowledged modes are typically used for interrupt generation. The interrupts have to be acknowledged by a µController.

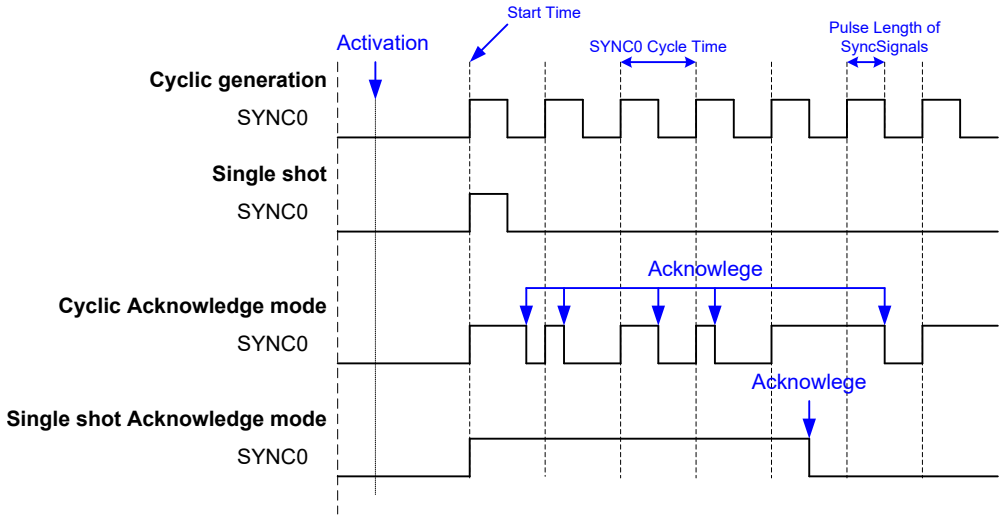

Figure 392. SyncSignal Generation modes

The SyncSignal operation mode is selected by the configuration of the Pulse Length and the SYNC0 Cycle Time, according to the following table:

Table 819. SyncSignal Generation mode selection

Pulse Length of SYNC Signals (0x0982:0x0983)	SYNC0 Cycle Time (0x09A0:0x09A3)	
	> 0	= 0
> 0	Cyclic Generation	Single Shot
= 0	Cyclic Acknowledge	Single Shot Acknowledge

The cycle time of the SYNC0 signal is configured in the SYNC0 Cycle Time register (0x09A0:0x09A3), the start time is set in the Start Time Cyclic Operation register (0x0990:0x0997). After the Sync Unit is activated and the output of the SYNC0/1 signals is enabled (DC Activation register 0x0981), the Sync Unit waits until the start time is reached and generates the first SYNC0 pulse.

Some ESCs support additional activation options like auto-activation when the Start Time is written, or 64 bit extension if only 32 bit of the Start Time is written. Other options are to detect invalid Start Times and provide debug output of SyncSignals.

Internally, the SyncSignals are generated with an update rate of 100 MHz (10 ns update cycle). The jitter of the internal SyncSignal generation in comparison to the local copy of the System Time is 12 ns.

The registers used for SyncSignal Generation are shown in below table.

Table 820. Registers for SyncSignal generation

Register Address	Name	Description
0x0141[3:2]	ESC Configuration	Enable/Disable DC Units (power saving)
0x0151	Sync/Latch PDI Configuration	Configuration of SYNC/LATCH[1:0] pins
0x0980[0]	Cyclic Unit Control	Assignment of cyclic function to EtherCAT or PDI
0x0981	Activation	Activation of cyclic function and SYNC pins
0x0982:0x0983	Pulse Length of SYNC signals	Length of SYNC impulse length
0x0984	Activation Status	Activation status of SYNC0/SYNC1
0x098E	SYNC0 Status	Status of SYNC0 signal
0x098F	SYNC1 Status	Status of SYNC1 signal
0x0990:0y0997	SYNC0 Start Time	Start System time of cyclic operation
0x0998:0x099F	NEXT SYNC1 Pulse	System Time of next Sync1 Pulse
0x09A0:0x09A3	SYNC0 Cycle Time	Cycle Time of SYNC0
0x09A4:0x09A7	SYNC1 Cycle Time	Cycle Time of SYNC1

Some of these registers are set via SII EEPROM/IP Core configuration, or they are not available in specific ESCs.

55.3.17.9.3.1 Cyclic generation

In Cyclic Generation mode, the Sync unit generates isochronous SyncSignals after the Start Time. The generation ends if the Cyclic Unit is deactivated or SYNC0/1 generation is deactivated. The Cycle times are determined by the SYNC0/1 Cycle Time registers. The Pulse Length of the SYNC signals has to be greater than 0. If the Pulse Length is greater than the Cycle Time, the SyncSignal will always be activated after the Start Time.

55.3.17.9.3.2 Single Shot mode

In Single Shot mode (SYNC0 Cycle Time set to 0), only one SyncSignal pulse is generated after the Start Time is reached. Another pulse can only be generated by deactivating the Cyclic Unit (0x0981[0]=0), reprogramming the Start Time, and reactivation of the Cyclic Unit.

55.3.17.9.3.3 Cyclic Acknowledge mode

The Cyclic Acknowledge mode is typically used for generation of isochronous interrupts. The acknowledged modes are selected by setting the Pulse Length of SYNC Signals to 0 (0x0982:0x0983). Each SyncSignal pulse remains active until it is acknowledged – typically by a µController – by reading the appropriate SYNC0 or SYNC1 Status register (0x098E, 0x098F). The first pulse is generated after the Start Time is reached, following pulses are generated when the next regular SYNC0/1 event would occur.

55.3.17.9.3.4 Single Shot Acknowledge mode

In Single Shot Acknowledge mode (both Pulse Length of SYNC Signals and SYNC0 Cycle Time are 0), only one pulse is generated when the Start Time is reached. The pulse remains active until it is acknowledged by reading the appropriate SYNC0/1 Status registers. Another pulse can only be generated by deactivating the Cyclic Unit (0x0981[0]=0), reprogramming the Start Time, and reactivation of the Cyclic Unit.

55.3.17.9.3.5 SYNC1 generation

The second SyncSignal (SYNC1) depends on SYNC0, it can be generated with a predefined delay after SYNC0 pulses. The delay is configured in the SYNC1 Cycle Time register (0x09A4:0x09A7).

If the SYNC1 Cycle Time is larger than the SYNC0 Cycle Time, it will be generated as follows: when the Start Time Cyclic Operation is reached, a SYNC0 pulse is generated. The SYNC1 pulse is generated after the SYNC0 pulse with a delay of SYNC1 Cycle Time. The next SYNC1 pulse is generated when the next SYNC0 pulse was generated, plus the SYNC1 Cycle Time.

Some example configurations are shown in the following figure:

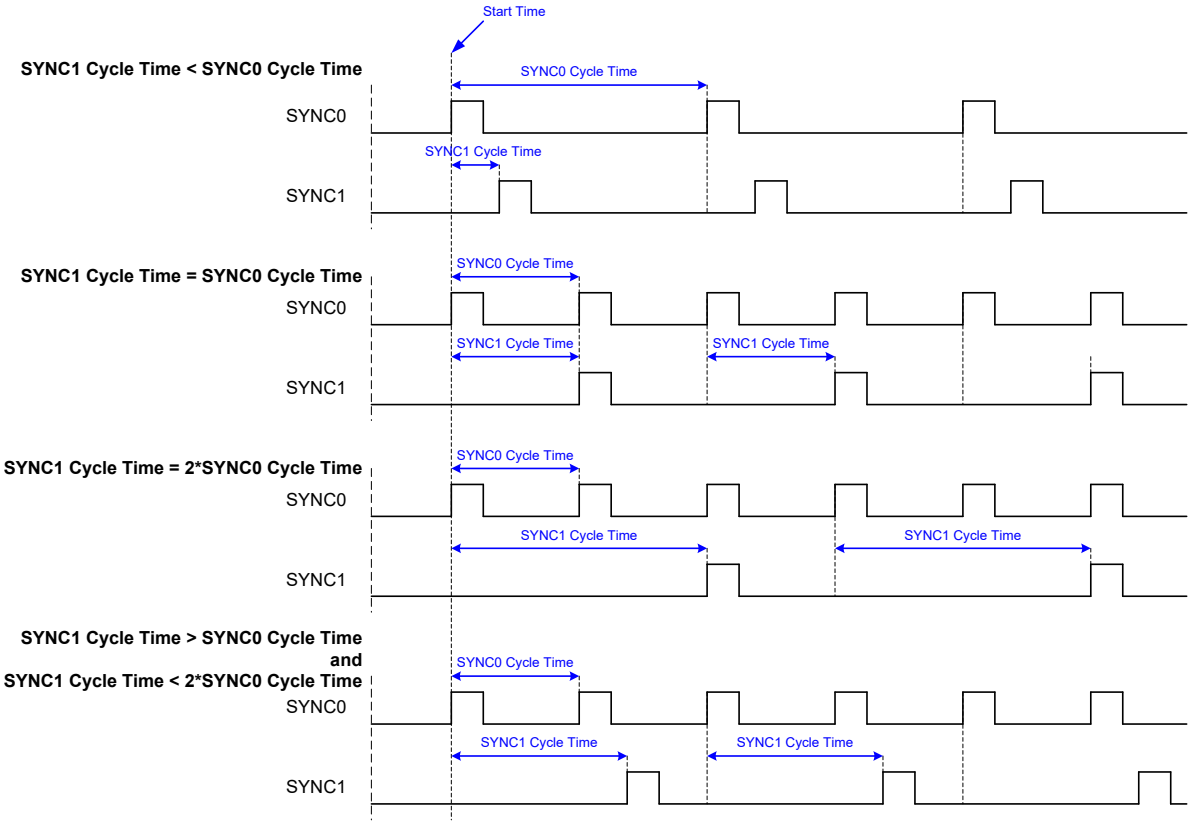

Figure 393. SYNC0/1 cycle time examples

NOTE: If The SYNC1 Cycle Time is 0, SYNC1 reflects SYNC0.

55.3.17.9.3.6 SyncSignal initialization example

The SyncSignal generation is initialized with the following procedure:

1. Enable DC SYNC Out Unit in ESC Configuration register (0x0141[2]=1; specific ESCs only)
2. Set SYNC/Latch PDI Configuration register (0x0151, initialized by SII EEPROM) to SYNC0/1 output with appropriate driver settings.
3. Set Pulse Length register (0x0982:0x0983, initialized by EEPROM) to pulse length of SYNC signals. Select a value > 0 ns for cyclic repetition of the SyncSignals
4. Assign Sync Unit to ECAT or PDI (0x0980, part of ESI)
5. Set cycle time of SYNC0 signal (0x09A0:0x09A3) and for SYNC1 signal (0x09A4:0x09A7)
6. Set Start Time of Cyclic Operation (0x0990:0x0997) to a time later than the time the cyclic generation will be activated (end of activation frame; e.g., read the System Time and add the time for writing Start Time and Activation). For 32 bit DCs, the SyncSignal generation will start at worst after a turn-over of the System Time (~ 4 s), but with 64 bit DCs, SyncSignal generation may start in hundreds of years.
7. Activate Cyclic Operation (0x0981[0]=1) to start cyclic generation of SyncSignals and activate SYNC0/1 generation (0x0981[2:1]=0x3). The Sync Unit waits until the Start Time of Cyclic Operation is reached for the generation of the first SYNC0 pulse.

Register Start Time of Cyclic Operation and register Next SYNC1 pulse can be read to get the time of the next output event. In the acknowledged modes, the Sync0/1 Status registers (0x098E:0x098F) give the status of the SyncSignals. The SyncSignals are acknowledged by reading the SYNC0/1 Status registers.

55.3.17.9.4 LatchSignals

The DC Latch Unit enables time stamping of LatchSignal events for two external signals, LATCH0 and LATCH1. Both rising edge and falling edge time stamps are recorded. Additionally, time stamping of SyncManager events is possible with some ESCs.

LatchSignals are sampled with a sample rate of 100 MHz, the corresponding time stamp has an internal jitter of 11 ns.

The state of the LatchSignals can be read from the Latch Status registers (0x09AE:0x09AF) – if supported by the ESC.

The DC Latch Unit supports two modes: single event or continuous mode, configured in the Latch0/1 Control registers (0x09A8:0x09A8).

The registers used for LatchSignal event time stamping are shown in below table.

Table 821. Registers for latch input events

Register Address	Name	Description
0x0141[3:2]	ESC Configuration	Enable/Disable DC Units (power saving)
0x0151	Sync/Latch PDI Configuration	Configuration of SYNC/LATCH[1:0] pins
0x0980[5:4]	Cyclic Unit Control	Assignment of cyclic function to EtherCAT or PDI
0x09A8	Latch0 Control	Latch unit configuration for Latch0
0x09A9	Latch1 Control	Latch unit configuration for Latch1
0x09AE	Latch0 Status	Latch status of Latch0
0x09AF	Latch1 Status	Latch status Latch1
0x09B0:0x09B7	Latch0 Time Positive Edge	System time at positive edge Latch0
0x09B8:0x09BF	Latch0 Time Negative Edge	System time at negative edge Latch0
0x09C0:0x09C7	Latch1 Time Positive Edge	System time at positive edge Latch1
0x09C8:0x09CF	Latch1 Time Negative Edge	System time at negative edge Latch1
0x09F0:0x09F3	EtherCAT Buffer Change Event Time	Local time at beginning of frame causing ECAT SyncManager buffer change event
0x09F8:0x09FB	PDI Buffer Start Event Time	Local time at PDI SyncManager buffer start event
0x09FC:0x09FF	PDI Buffer Change Event Time	Local time at PDI SyncManager buffer change event

Some of these registers are set via SII EEPROM/IP Core configuration, or they are not available in specific ESCs.

55.3.17.9.4.1 Single Event Mode

In single event mode, only the timestamps of the first rising and the first falling edge of the LatchSignals are recorded. The Latch Status registers (0x09AE:0x09AF) contain information about the events which already have occurred. The Latch Time registers (0x09B0 to 0x09CF) contain the time stamps.

Each event is acknowledged by reading the corresponding Latch Time register. After reading the Latch Time register, the Latch unit is waiting for the next event. Latch events are mapped to the AL Event Request register in single event mode.

55.3.17.9.4.2 Continuous Mode

In continuous mode, each event is stored in the Latch Time registers. At reading, the time stamp of the last event is read. The Latch Status registers (0x09AE:0x09AF) do not reflect the latch event states in continuous mode.

55.3.17.9.4.3 SyncManager Event

Some ESCs support debugging of SyncManager interactions with time stamps for buffer events. The last event can be read out at the SyncManager Event Time registers (0x09F0:0x09FF), if the SyncManager is configured appropriately.

55.3.17.9.4.4 ECAT or PDI Control

The SyncSignal unit and the two LatchSignal units of the Distributed Clocks entity can be assigned independently by the master to be controlled either by ECAT or a local µController (PDI) using the Cyclic Unit Control register 0x0980. With PDI control, a µController can e.g. set up cyclic interrupts for itself.

55.3.17.9.5 System time PDI controlled

Sometimes Distributed Clocks of different EtherCAT networks have to be synchronized. One solution is master-master communication, the other one is based on a physical device which is present in both EtherCAT networks. One of the networks contains the DC Reference Clock (DC source), the other one – DC destination – is synchronized to the Reference Clock in the DC source network.

Some ESCs support such a synchronization by a different functionality of the System Time register (0x0910:0x0913). In normal operation mode, a write access initiated by the EtherCAT master to the System Time register triggers the synchronization: the written value is compared to the local copy of the System Time, and the difference is fed into the control loop. If the System Time is PDI controlled, the PDI writes the System Time register, and the written value is compared to the DC Latch0 Time Positive Edge register (0x09B0:0x09B3). This feature makes the accuracy of the synchronization independent of the µController/PDI response times.

The following figures illustrate how the System Time is transferred from the DC source to the DC destination. ESC 1 and ESC 2 are located in different EtherCAT networks. The EtherCAT network of ESC 1 contains the Reference Clock, the network of ESC 2 will become synchronized to this Reference Clock. ESC 2 is the “reference clock” of its EtherCAT network. There are two options for synchronization, which has to be performed on a regular basis.

The first option is to let the µController generate a trigger pulse for ESC 1 and 2. The time of the rising edge is stored in the Latch0 Time Positive Edge register both in ESC 1 and 2. Afterwards, the µController reads this time from ESC 1 and writes it into the System Time register of ESC 2. The difference of the Latch0 times is used to feed the control loop

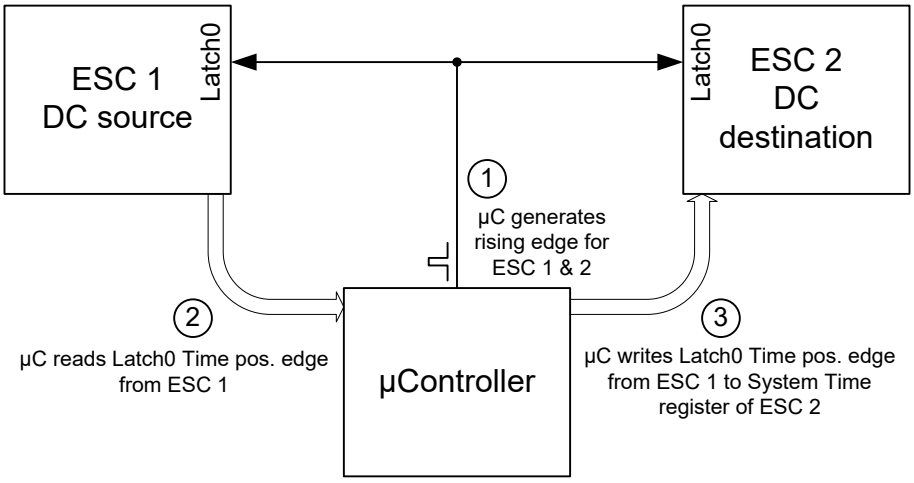

Figure 394. System time PDI controlled with three steps

The second option uses a SyncSignal output of ESC 1 to trigger Latch0 at ESC 2 and an interrupt at the µController. Upon receiving an interrupt, the µController writes the time of the SyncSignal pulse to the System Time register of ESC 2. The µController has to calculate the time of the SyncSignal based upon Start Time Cyclic Operation and SYNC Cycle Time configuration of ESC 1 from interrupt to interrupt. The advantage of the second solution is less communication, the disadvantages are more calculation overhead and error detection/troubleshooting.

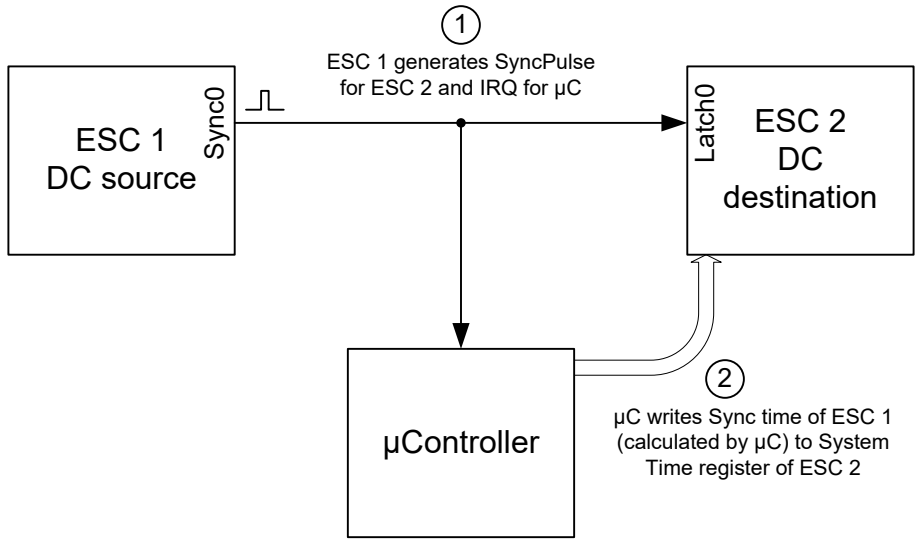

Figure 395. System time PDI controlled with two steps

55.3.17.9.6 Offset compensation

The local time of each device is a free-running clock which typically will not have the same time as the Reference Clock. To achieve the same absolute System Time in all devices, the offset between the Reference Clock and every slave device's clock is calculated by the master. The offset time is written to register System Time Offset to adjust the local time for every individual device. Small offset errors are eliminated by the drift compensation after some time, but this time might become extremely high for large offset errors – especially for 64 bit DCs.

Each DC slave calculates its local copy of the System time using its local time and the local offset value:

$t_{Local\ copy\ of\ System\ Time} = t_{Local\ time} + t_{Offset}$

This time is used for SyncSignal generation and time stamping of LatchSignals. It is also provided to the PDI for use by µControllers.

The System Time of the Reference Clock is bound to the master clock by calculating the difference and compensating it using the System Time Offset of the Reference Clock.

Registers used for Offset Compensation are listed in below table.

Table 822. Registers for offset compensation

Register Address	Name	Description
0x0910:0x0917	System Time	Local copy of System Time (read from PDI)
0x0918:0x091F	Receive Time ECAT Processing Unit	Local Time (tLocal time)
0x0920:0x0927	System Time Offset	Difference between local time and System Time (tOffset)

55.3.18 PDI selection and configuration

55.3.18.1 PDI selection and configuration

Typically, the PDI selection and configuration is part of the eCAT Configuration Area of the SII EEPROM. Some eCATs (e.g. IP Core) have the PDI selected and configured at power-on time. In this case, the eCAT Configuration Area should reflect the actual settings, although they are not evaluated by the eCAT itself. For the other eCATs, the PDI becomes active after the SII EEPROM is successfully loaded. All PDI pins are inactive (high impedance) until then (as well as the DC Sync/Latch signals). Some eCATs and PDIs provide an EEPROM_Loaded signal, which indicates that the EEPROM is successfully loaded and the PDI can be used. Attach a pull-down resistor to the EEPROM_Loaded pin, because it is also not driven (high impedance) until the EEPROM is successfully loaded. The PDI of an IP Core is active after reset is released, which enables e.g. EEPROM emulation by a µController. Take care of Digital Output signals and DC SyncSignals while the EEPROM is not loaded to achieve proper output behavior.

55.3.18.2 General purpose I/O

Some eCATs support general purpose inputs, outputs, or both. General Purpose I/O is much different from Digital I/O, because of missing consistency and security features, and no bit-write support.

55.3.18.2.1 General purpose inputs

The general purpose inputs are directly mapped into the General Purpose Input registers. Consistency of the general purpose inputs is not provided.

55.3.18.2.2 General purpose output

The general purpose output signals reflect the values of the General Purpose Output register without watchdog protection. The General Purpose Output register can be written both by ECAT and PDI. The general purpose outputs are intended e.g. for application specific LED outputs. General purpose outputs are updated at the end of an EtherCAT frame or at the end of a PDI access. Consistency of the general purpose outputs is not provided, and they are also not watchdog-secured. Additionally, they do not support bit-wise modification with FMMUs.

55.3.19 Clocking

Table 823. Primary core clocks

Clocks	Description
CLK25	period: 40ns Core clock (25MHz)
CLK50	period: 20ns phase shift: 0ns Clock reference: CLK25 Core clock(50MHz) for RMII only. Phase shift is rising edge to rising edge.
CLK100	period: 10ns phase shift: 0ns Clock reference: CLK25 Core clock(100MHz).Phase shift is rising edge to rising edge.
MII_RX_CLK0-1	period: 40ns

Table continues on the next page...

Table 823. Primary core clocks (continued)

Clocks	Description
	MII receive reference clock (25 MHz). IEEE802.3 requirement. Each clock is asynchronous to any other clock.
MII_TX_CLK0-1	Input clock. Transmit clock port 0 for automatic TX Shift configuration. Set to 0 for manual TX Shift configuration.
PDI_OPB_CLK	period: 40ns/N phase shift: 0ns Clock reference: CLK25 OPB bus clock. Multiple of 25 MHz (N=1, 2, 3, etc.). Phase shift is rising edge to rising edge.

55.3.20 Reset

This sections describes the reset signals of the block.

Table 824. Primary core reset

Signal	Clock Reference	Description
nRESET	none	Asynchronous reset input
EtherCAT_IPCore_inst/ nRESET_CHAIN[1]	CLK25	Internal reset, asynchronously asserted, synchronously deasserted.
PDI_EMULATION	CLK25	Disable internal register 0x0120 if PDI emulation is enabled. Write value is directly routed to 0x0130.

55.3.21 Interrupts

ESCs support two types of interrupts: AL Event Requests targeted at a µController, and ECAT event requests targeted at the EtherCAT master. Additionally, the Distributed Clocks SyncSignals can be used as interrupts for a µController as well.

The following table lists the module interrupts.

Table 825. Interrupt signals

Condition	Interrupt Signal Name	Direction	Description
OPB	PDI_OPB_IRQ	O	Interrupt

55.3.21.1 AL event request (PDI interrupt)

AL Event Requests can be signaled to a µController using the PDI Interrupt Request signal (IRQ/SPI_IRQ, etc.). For IRQ generation, the AL Event Request register (0x0220:0x0223) is combined with the AL Event Mask register (0x0204:0x0207) using a logical AND operation, then all resulting bits are combined (logical OR) into one interrupt signal. The output driver characteristics of the IRQ signal are configurable using the SYNC/LATCH PDI configuration register (0x0151). The AL Event Mask register allows for selecting the interrupts which are relevant for the µController and handled by the application.

The DC SyncSignals can be used for interrupt generation in two ways:

- The DC SYNC signals are mapped into the AL Event Request Register (configured with SYNC/LATCH PDI Configuration register 0x0151.3/7). In this case, all interrupts from the ESC to the µController are combined into one IRQ signal, and the Distributed Clocks LATCH0/1 inputs can still be used. The IRQ signal has a jitter of ~40 ns.
- The DC SyncSignals are directly connected to µController interrupt inputs. The µController can react on DC SyncSignal interrupts faster (without reading AL Request register), but it needs more interrupt inputs. The jitter of the SyncSignals is ~12 ns. The DC Latch functions are only available for one Latch input or not at all (if both DC SYNC outputs are used).

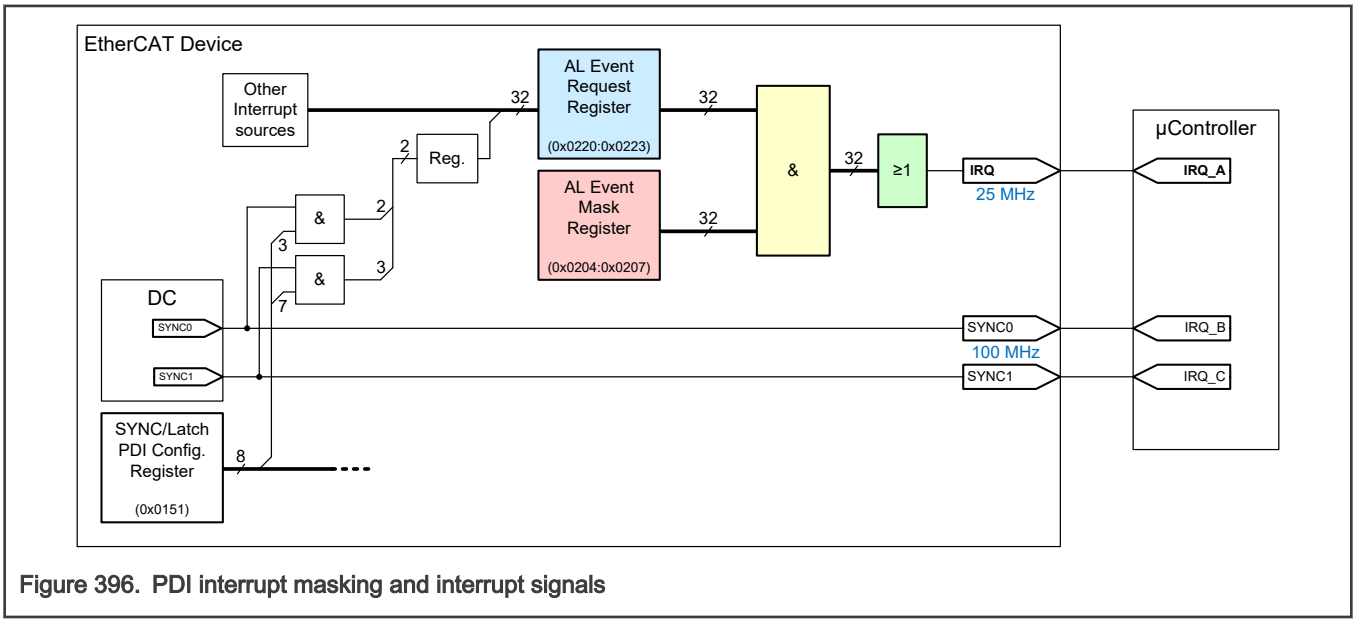

Figure 396. PDI interrupt masking and interrupt signals

Table 826. Registers for AL event request configuration

Name	Description
PDI Configuration (0x0150)	IRQ driver characteristics, depending on PDI
SYNC/LATCH PDI Configuration (0x0151)	Mapping DC SyncSignals to Interrupts
AL Event Mask (0x0204:0x0207)	Mask register
AL Event Request (0x0220:0x0223)	Pending Interrupts
SyncManager Control (0x0804 + N*8)	Mapping SyncManager Interrupts

55.3.21.2 ECAT event request (ECAT Interrupt)

ECAT event requests are used to inform the EtherCAT master of slave events. ECAT events make use of the IRQ field inside EtherCAT datagrams. The ECAT Event Request register (0x0210:0x0211) is combined with the ECAT Event Mask register (0x0200:0x0201) using a logical AND operation. The resulting interrupt bits are combined with the incoming ECAT IRQ field using a logical OR operation, and written into the outgoing ECAT IRQ field. The ECAT Event Mask register allows for selecting the interrupts which are relevant for the EtherCAT master and handled by the master application. NOTE: The master cannot distinguish which slave (or even more than one) was the origin of an interrupt.

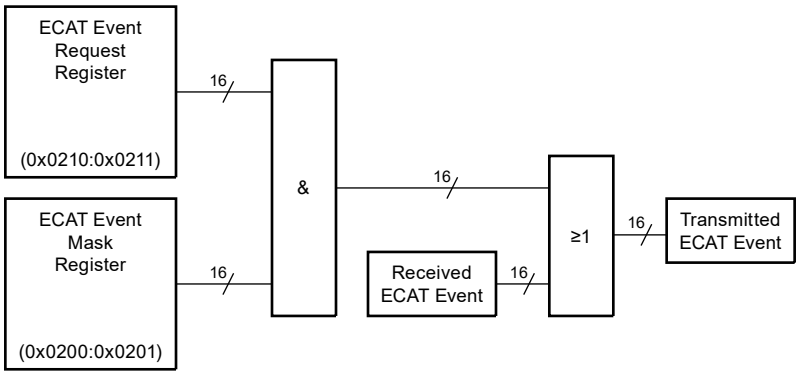

Figure 397. ECAT interrupt masking

Table 827. Registers for ECAT request configuration

Name (Register Address)	Description
ECAT Event Mask (0x0200:0x0201)	Mask Register
ECAT Event Request (0x0210:0x0211)	Pending Interrupts
SyncManager control (0x0804 + N*8)	Mapping SyncManager Interrupts

55.4 External signals

This sections deals with the external signals of the block.

55.4.1 Signal descriptions

Table 828. Signals

Signal			Description
ECAT_RX_CLK_0	RX clk	Input	Rx clk for ESC port0
ECAT_RX_DV_0	RX data valid signal	Input	RX data valid for port0
ECAT_RX_ER_0	RX data error signal	Input	RX data error for port0
ECAT_RX_DATA0_0	RX data 0	Input	RX data 0 for port0
ECAT_RX_DATA1_0	RX data 1	Input	RX data 1 for port0
ECAT_RX_DATA2_0	RX data 2	Input	RX data 2 for port0
ECAT_RX_DATA3_0	RX data 3	Input	RX data 3 for port0

Table 828. Signals (continued)

Signal			Description
SYSTEMTIME_OUT[63:0]	SystemTime out signal	Output	SystemTime out signal
PDI_OPB_IRQ	OPB interrupt	Output	EtherCAT System interrupt

55.5 Initialization

55.5.1 Power-on sequence

Table 829. EtherCAT power-on sequence

No.	Step	Result
1	Power-On	Voltages reach proper levels ASICs only: Power-on values are sampled
3	PLL locks	Clocks are generated properly
4	Release RESET	EtherCAT operation begins. Process memory is not accessible until the SII EEPROM is loaded, as well as any function depending on ESC Configuration data. IP Core: PDI is operational; others: PDI is not operational until EEPROM is loaded.
5	Links are established	EtherCAT communication begins, master can access ESC registers
6	Loading EtherCAT EEPROM	Only upon successful EEPROM loading: • ESC Configuration registers initialized • Register bit 0x0110[0] turns to 1 • Process Data RAM becomes accessible • Some PDIs: EEPROM_Loaded signal is driven high • SC is in Init state Steps 5 and 6 are executed in parallel
7	Example: Master proceeds to Operational state	EtherCAT proceeds to Operational state

NOTE

The PDI signals are not driven until the ESC EEPROM is loaded successfully, especially the EEPROM_Loaded signal is not driven and needs a pull-down resistor if it is used.

55.6 Memory map and registers

This section describes the module memory map and registers.

55.6.1 ETHERCAT register descriptions

55.6.1.1 ETHERCAT memory map

55.6.1.2 Type (TYPE)

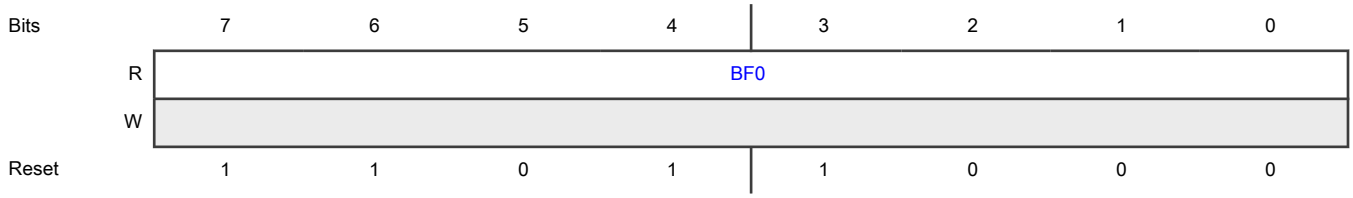
Offset

Register	Offset
TYPE	0h

Function

Provides information on type

Diagram



Fields

Field	Function
7-0 BF0	Type of EtherCAT controller Bit field access for ECAT: r/- Bit field access for PDI: r/-

55.6.1.3 Revision (REVISION)

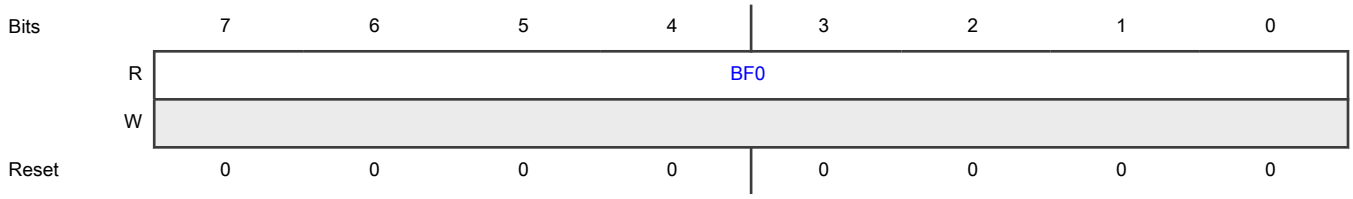
Offset

Register	Offset
REVISION	1h

Function

Provides information on revision

Diagram



Fields

Field	Function
7-0 BF0	Revision of EtherCAT controller. IP Core: major version X (version X.Y.Z) Bit field access for ECAT: r/- Bit field access for PDI: r/-

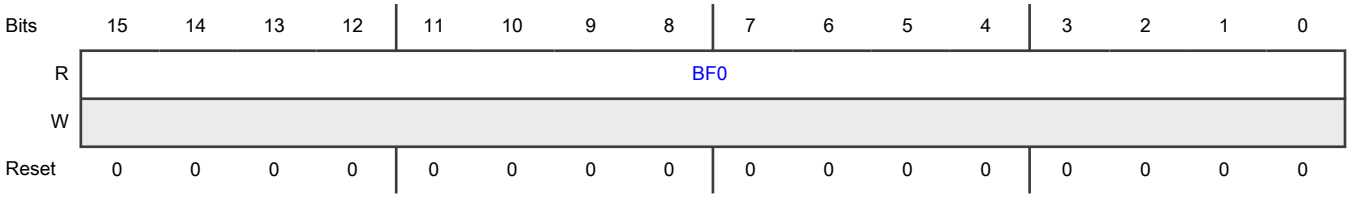
55.6.1.4 Build (BUILD)

Offset

Register	Offset
BUILD	2h

Function
Provides information on build

Diagram



Fields

Field	Function
15-0 BF0	Build of EtherCAT controller EtherCAT IP Core (version X.Y.Z): [3:0] maintenance version Z [7:4] minor version Y [15:8] patch level/ development build: ----0x00: Original release ----0x01-0x0F: Patch level of original release ----0x10-0xFF: Development build Bit field access for ECAT: r/- Bit field access for PDI: r/-

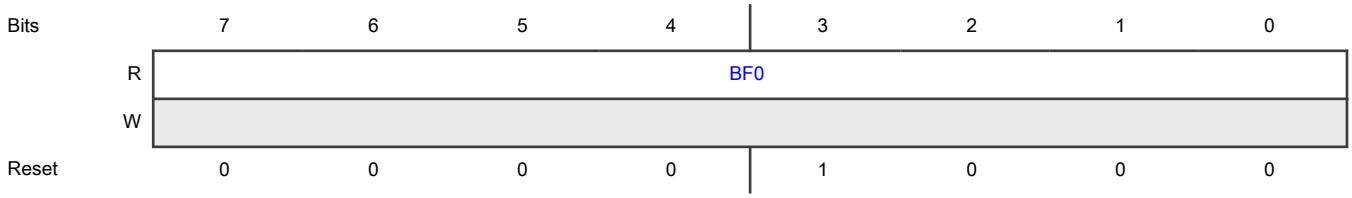
55.6.1.5 FMMUs supported (FMMUS_SUPPORTED)

Offset

Register	Offset
FMMUS_SUPPORTED	4h

Function
Specifies number of FMMU channels supported

Diagram



Fields

Field	Function
7-0	Number of supported FMMU channels (or entities)
BF0	Bit field access for ECAT: r/- Bit field access for PDI: r/- Reset value for bit depends on the configuration.

55.6.1.6 SyncManagers supported (SYNCMANAGERS_SUPPORTED)

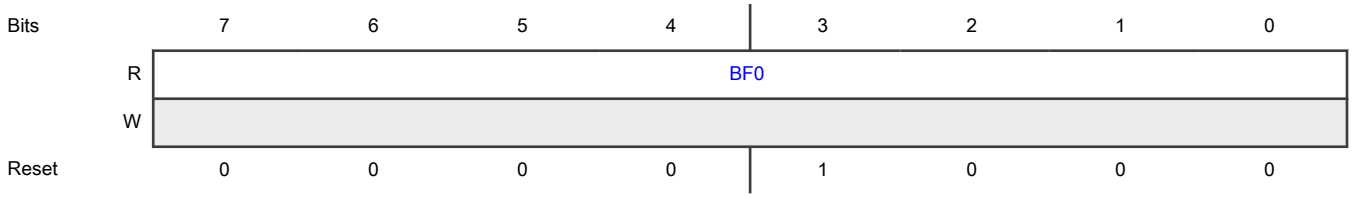
Offset

Register	Offset
SYNCMANAGERS_SUPPORTED	5h

Function

Specifies number of SyncManager channels supported

Diagram



Fields

Field	Function
7-0	Number of supported SyncManager channels (or entities)
BF0	Bit field access for ECAT: r/- Bit field access for PDI: r/- Reset value for bit depends on the configuration.

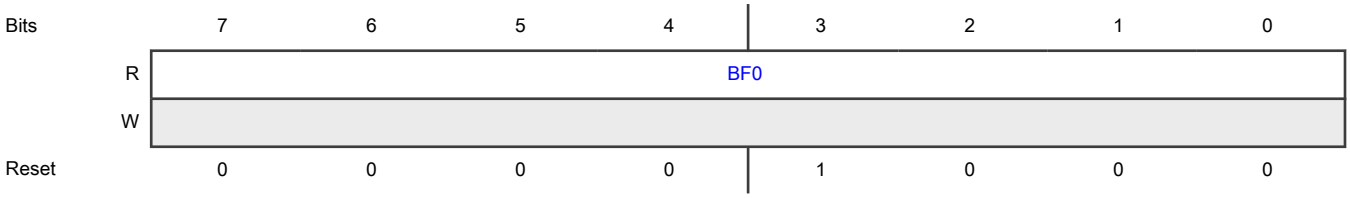
55.6.1.7 RAM Size (RAM_SIZE)

Offset

Register	Offset
RAM_SIZE	6h

Function
Specifies process data RAM size

Diagram



Fields

Field	Function
7-0 BF0	Process Data RAM size supported in KByte Bit field access for ECAT: r/- Bit field access for PDI: r/- Reset value for bit depends on the configuration.

55.6.1.8 Port configuration (PORT_DESCRIPTOR)

Offset

Register	Offset
PORT_DESCRIPTOR	7h

Function

- 00: Not implemented
- 01: Not configured (SII EEPROM)
- 10: Reserved
- 11: MII / RMII

55.6.1.31 AL Control (AL_CONTROL)

Offset

Register	Offset
AL_CONTROL	120h

Function

NOTE

AL Control register behaves like a mailbox if Device Emulation is off (0x0141[0]=0): The PDI has to read/write* the AL Control register after ECAT has written it. Otherwise ECAT cannot write again to the AL Control register. After Reset, AL Control register can be written by ECAT. (Regarding mailbox functionality, both low and high byte of the AL Control register trigger read/write functions, e.g., reading 0x0121 is sufficient to make this register writable again).

55.6.1.32 AL Control (AL_CONTROL_PDI)

Offset

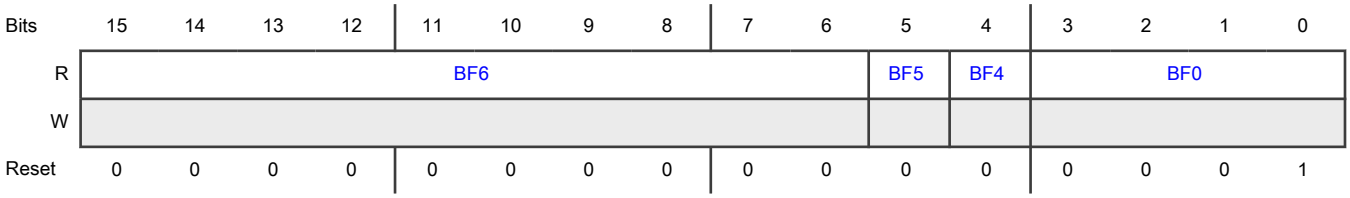
Register	Offset
AL_CONTROL_PDI	120h

Function

NOTE

AL Control register behaves like a mailbox if Device Emulation is off (0x0141[0]=0): The PDI has to read/write* the AL Control register after ECAT has written it. Otherwise ECAT cannot write again to the AL Control register. After Reset, AL Control register can be written by ECAT. (Regarding mailbox functionality, both low and high byte of the AL Control register trigger read/write functions, e.g., reading 0x0121 is sufficient to make this register writable again).

Diagram



Fields

Field	Function
15-6 BF6	Reserved, write 0 Bit field access for ECAT: r/(w) Bit field access for PDI: r/-
5 BF5	Device Identification: Bit field access for ECAT: r/(w) Bit field access for PDI: r/- 0b - No request 1b - Device Identification request

55.6.1.52 RX Error Counter (RX_ERROR_COUNTER_PORT0_PDI - RX_ERROR_COUNTER_PORT1_PDI)

Offset

Register	Offset
RX_ERROR_COUNTER_PORT0_PDI	300h
RX_ERROR_COUNTER_PORT1_PDI	302h

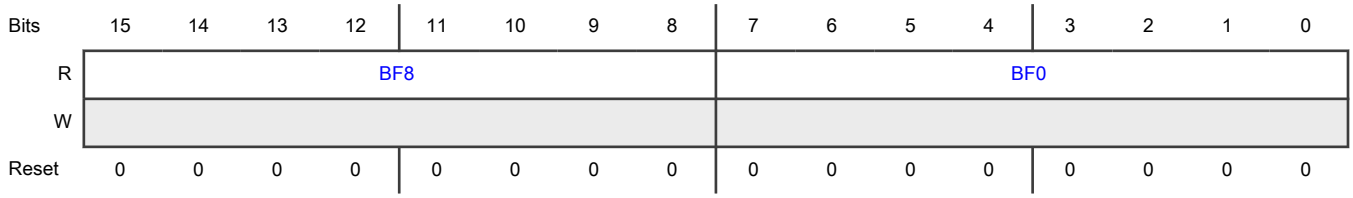
Function

Errors are only counted if the corresponding port is enabled.

NOTE

Error Counters 0x0300-0x030B are cleared if one of the implemented RX Error counters 0x0300-0x030B is written (preferably 0x0300). Write value is ignored (write 0). Errors are only counted if the loop of the port is open.

Diagram



Fields

Field	Function
15-8 BF8	RX Error counter of Port y (counting is stopped when 0xFF is reached). Bit field access for ECAT: r/ w(clr). Bit field access for PDI: r/-
7-0 BF0	Invalid frame counter of Port y (counting is stopped when 0xFF is reached). Bit field access for ECAT: r/ w(clr). Bit field access for PDI: r/-

55.6.1.53 Forwarded RX Error Counter (FORWARDED_RX_ERROR_COUNTER_PORT0 - FORWARDED_RX_ERROR_COUNTER_PORT1)

Offset

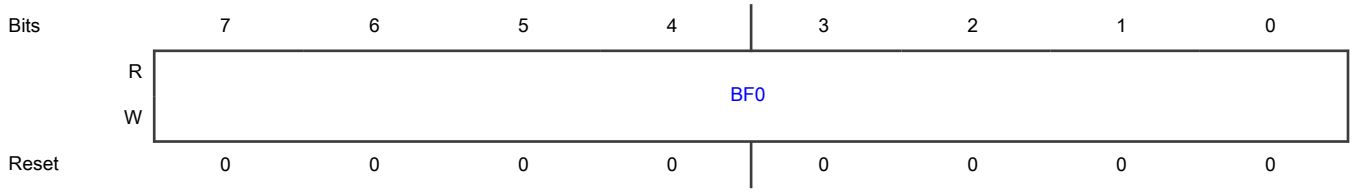
Register	Offset
FORWARDED_RX_ERROR_COUNTER_PORT0	308h
FORWARDED_RX_ERROR_COUNTER_PORT1	309h

Function

NOTE

Error Counters 0x0300-0x030B are cleared if one of the implemented RX Error counters 0x0300-0x030B is written (preferably 0x0300). Write value is ignored (write 0). Errors are only counted if the loop of the port is open.

Diagram



Fields

Field	Function

0 BF0	ECAT write enable2 This bit is always 1 if PDI has EEPROM control. Bit field access for ECAT: r/(w) Bit field access for PDI: r/- 0b - Write requests are disabled 1b - Write requests are enabled

55.6.1.79 EEPROM Address (EEPROM_ADDRESS)

Offset

Register	Offset
EEPROM_ADDRESS	504h

Function

EtherCAT controls the SII EEPROM interface if EEPROM configuration register 0x0500[0]=0 and EEPROM PDI Access register 0x0501[0]=0,otherwise PDI controls the EEPROM interface. In EEPROM emulation mode, the PDI executes pending EEPROM commands. The PDI has access to some registers while the EEPROM Interface is busy.

NOTE

r/(w): write access depends upon the assignment of the EEPROM interface (ECAT/PDI). Write access is blocked if EEPROM interface is busy (0x0502[15]=1).

Diagram

55.6.1.121 Register System Time (SYSTEM_TIME)

Offset

Register	Offset
SYSTEM_TIME	910h

Function

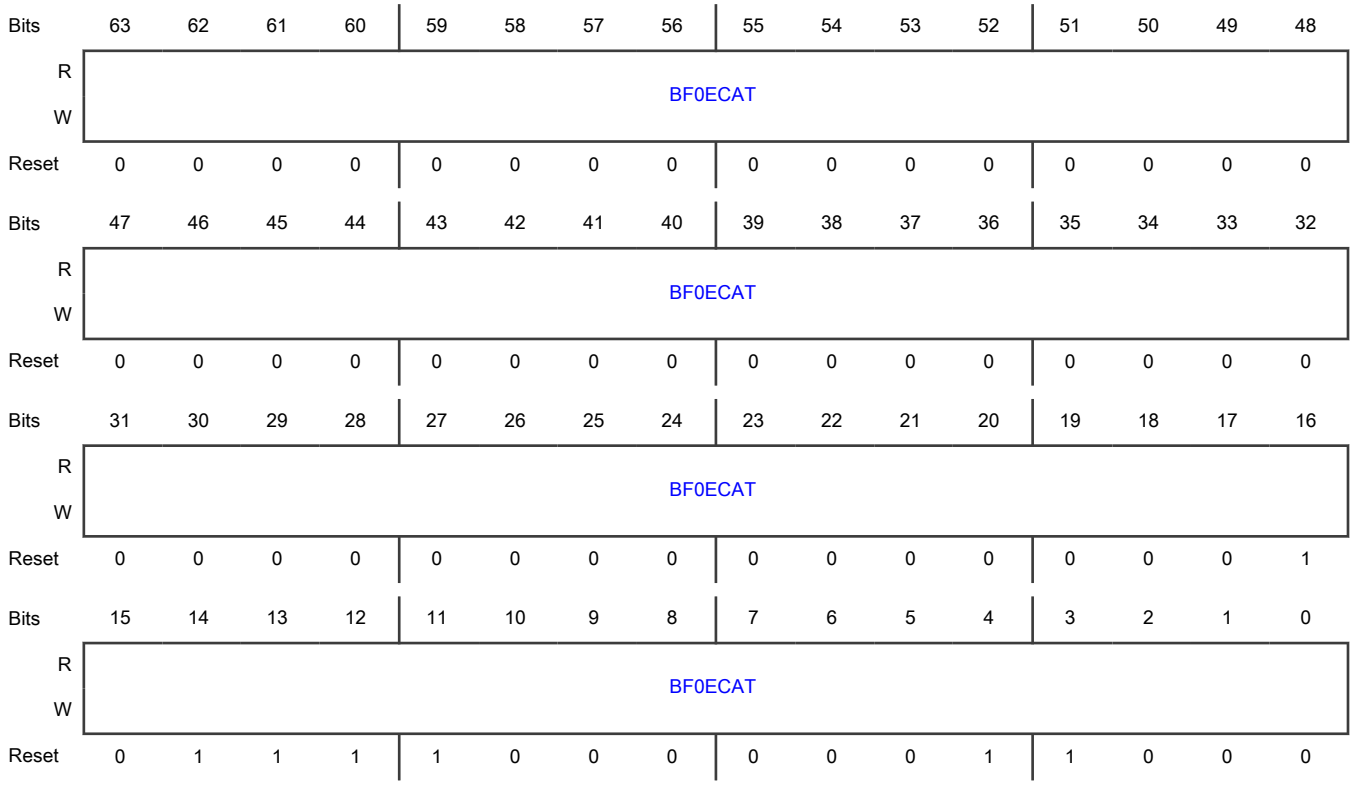
Time Loop Control unit is usually assigned to ECAT. Write access to Time Loop Control registers by PDI (and not ECAT) is only possible with explicit IP Core configuration.

NOTE

Write access to this register depends upon ESC configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI-controlled)

.

Diagram



Fields

Field	Function
63-0 BF0ECAT	ECAT read access Local copy of the System Time when the frame passed the reference clock (i.e., including System Time Delay). Time latched at beginning of the frame (Ethernet SOF delimiter) Bit field access for ECAT: r Bit field access for PDI: nil

55.6.1.122 Register System Time (SYSTEM_TIME_PDI)

Offset

Register	Offset
SYSTEM_TIME_PDI	910h

Function

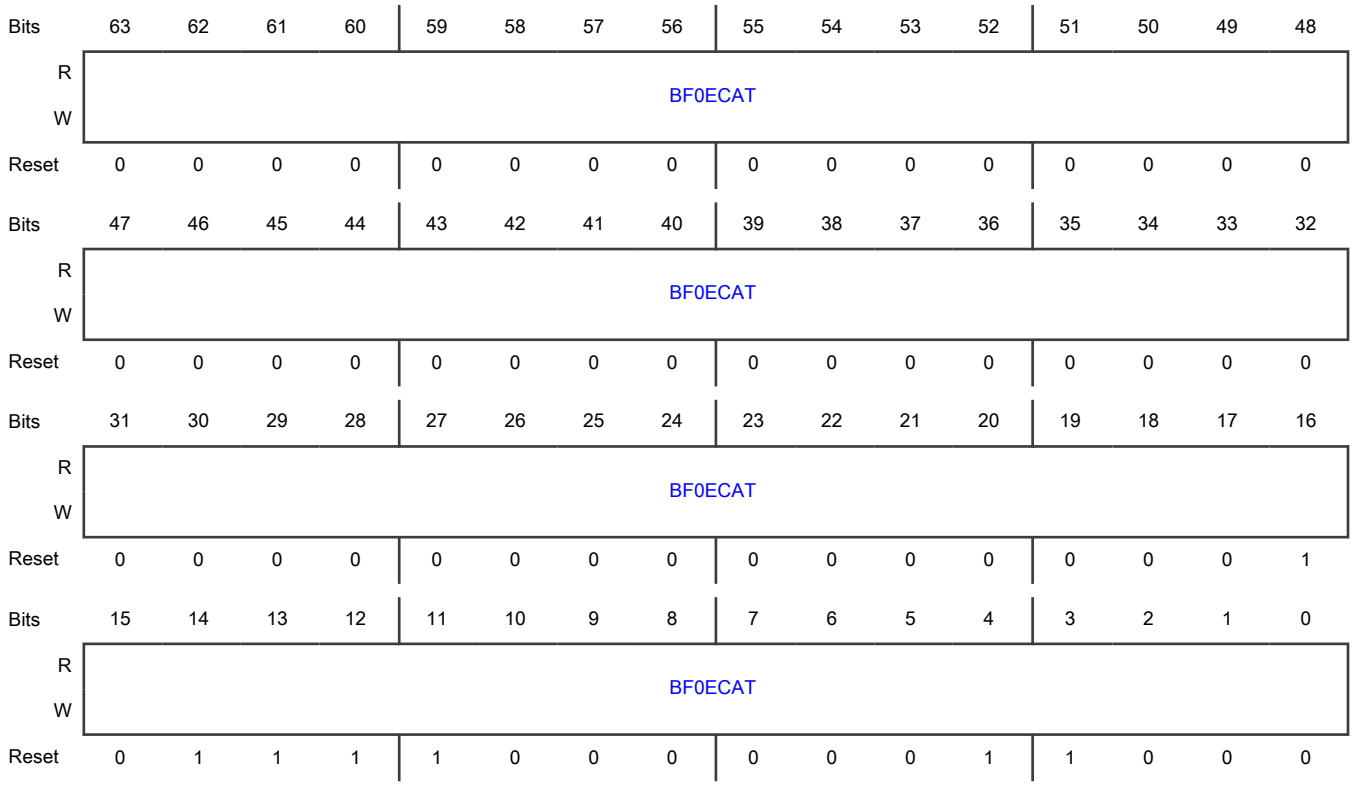
Time Loop Control unit is usually assigned to ECAT. Write access to Time Loop Control registers by PDI (and not ECAT) is only possible with explicit IP Core configuration.

NOTE

Write access to this register depends upon ESC configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI-controlled)

.

Diagram



Fields

Field	Function
63-0 BF0ECAT	PDI read access Local copy of the System Time. Time latched when reading first byte (0x0910) Bit field access for PDI: r Bit field access for ECAT: nil

55.6.1.123 Distributed Clocks Register Receive Time ECAT Processing Unit (RECEIVE_TIME_ECAT_PROCESSING_UNIT)

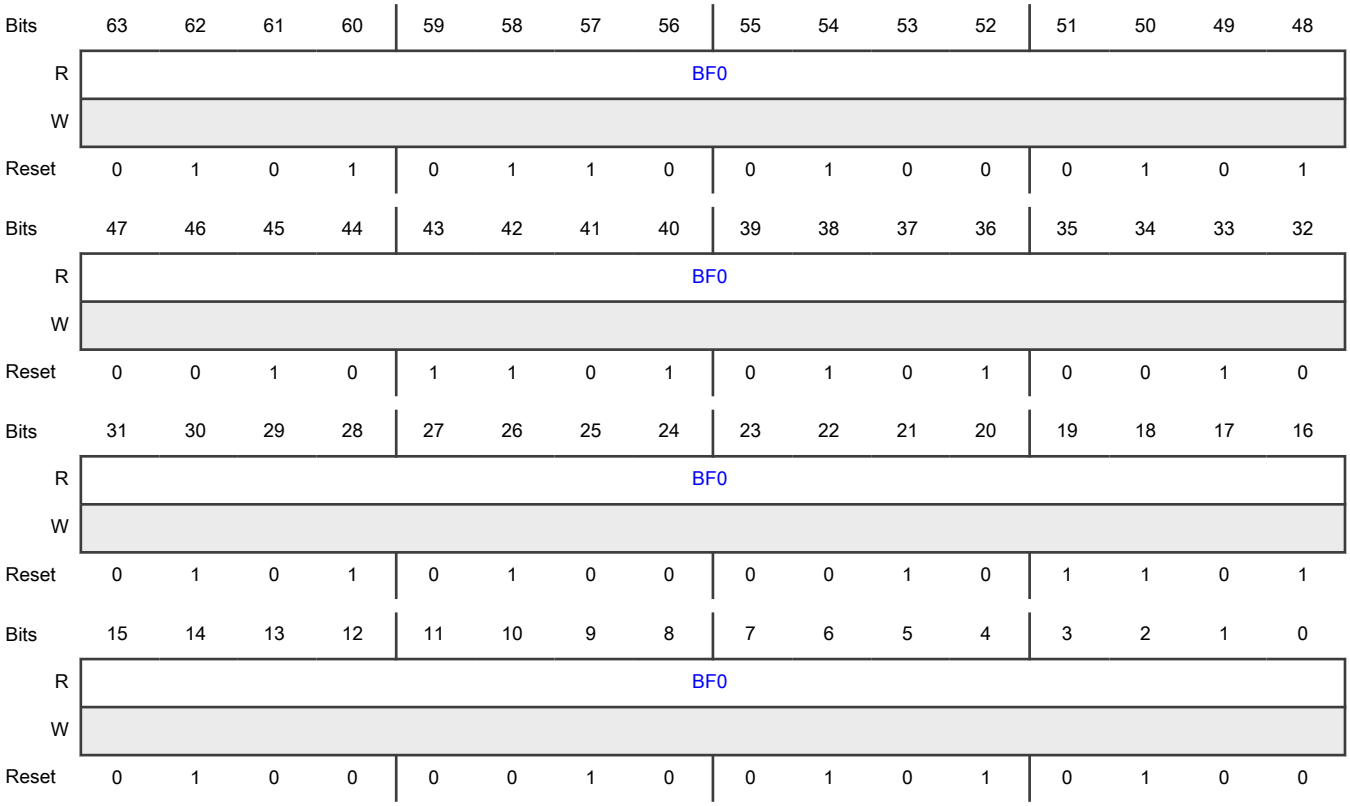
Offset

Register	Offset
RECEIVE_TIME_ECAT_PROCESSING_UNIT	918h

Function

Register Receive Time ECAT Processing Unit

Diagram



Fields

Field	Function
63-0 BF0	Local time at the beginning of a frame (start first bit of preamble) received at the ECAT Processing Unit containing a write access to register 0x0900 NOTE: E.g., if port 0 is open, this register reflects the Receive Time Port 0 as a 64 Bit value. Any valid EtherCAT write access to register 0x0900 triggers latching, not only BWR/FPWR commands as with register 0x0900. Bit field access for ECAT: r/- Bit field access for PDI: r/-

55.6.1.124 Register System Time Offset (SYSTEM_TIME_OFFSET)

Offset

Register	Offset
SYSTEM_TIME_OFFSET	920h

Function

NOTE

Write access to this register depends upon eCAT configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI-controlled). Reset internal system time difference filter and speed counter filter by writing Speed Counter Start (0x0930:0x0931) after changing this value.

Diagram

55.6.1.125 Register System Time Delay (SYSTEM_TIME_DELAY)

Offset

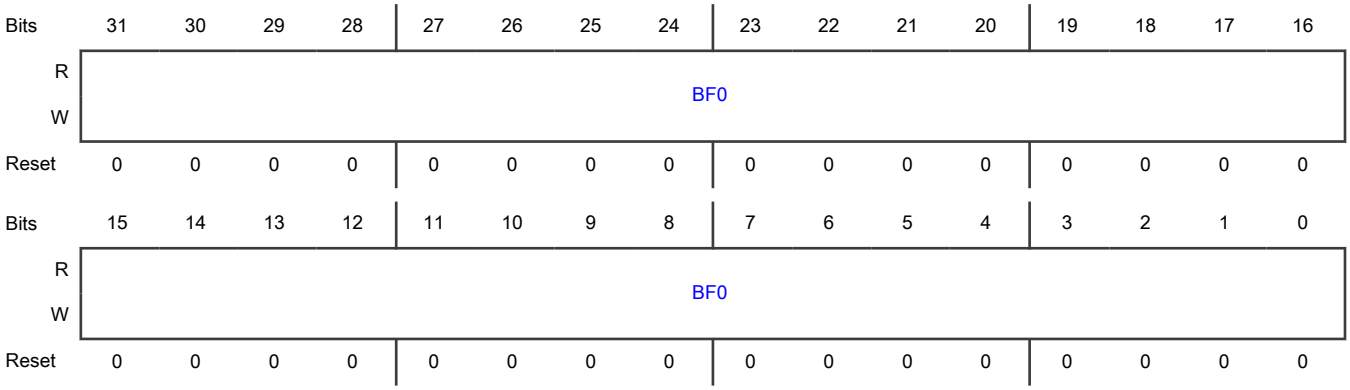
Register	Offset
SYSTEM_TIME_DELAY	928h

Function

NOTE

Write access to this register depends upon eCAT configuration (typically ECAT, PDI only with explicit eCAT configuration: System Time PDI-controlled). Reset internal system time difference filter and speed counter filter by.writing Speed Counter Start (0x0930:0x0931) after changing this value

Diagram



Fields

Field	Function
31-0 BF0	Delay between Reference Clock and the eCAT Bit field access for ECAT: r/(w) Bit field access for PDI: r/(w)

55.6.1.126 Register System Time Difference (SYSTEM_TIME_DIFFERENCE)

Offset

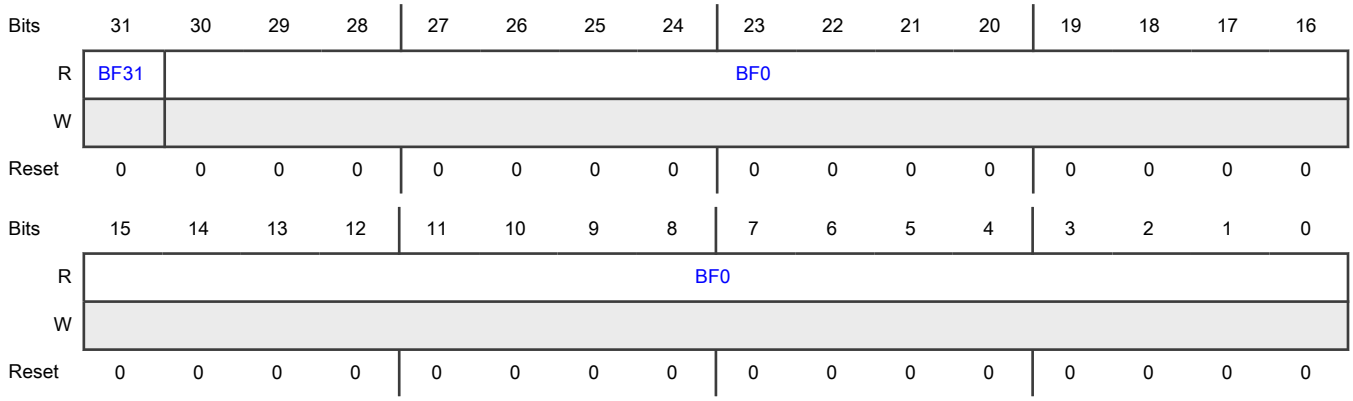
Register	Offset
SYSTEM_TIME_DIFFERENCE	92Ch

Function

NOTE

Register bits [31:8] are internally latched (ECAT/PDI independently) when bits [7:0] are read, which guarantees reading a consistent value.

Diagram



Fields

Field	Function
31 BF31	Bit field access for ECAT: r/- Bit field access for PDI: r/- 0b - Local copy of System Time less than received System Time 1b - Local copy of System Time greater than or equal to received System Time
30-0 BF0	Mean difference between local copy of system Time and received System Time values *Difference = Received System Time – local copy of System Time* Bit field access for ECAT: r/- Bit field access for PDI: r/-

55.6.1.127 Register Speed Counter Start (SPEED_COUNTER_START)

Offset

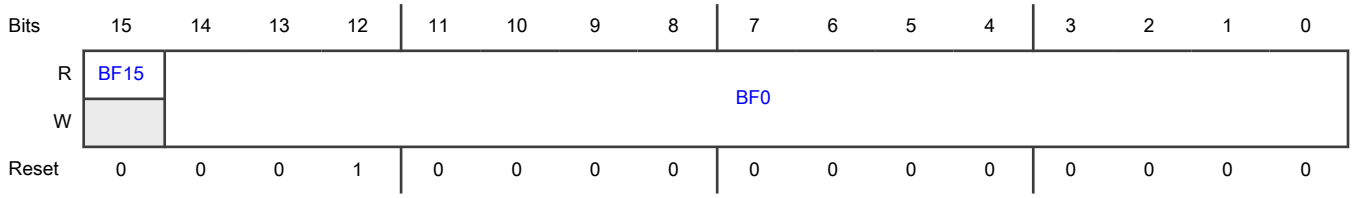
Register	Offset
SPEED_COUNTER_START	930h

Function

NOTE

Write access to this register depends upon eCAT configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI-controlled).

Diagram



Fields

Field	Function
15 BF15	Reserved, write 0 Bit field access for ECAT: r/- Bit field access for PDI: r/-
14-0 BF0	Bandwidth for adjustment of local copy of system Time (larger values → smaller bandwidth and smoother adjustment) A write access resets System Time Difference (0x092C:0x092F) and Speed Counter Diff (0x0932:0x0933). Valid values: 0x0080 to 0x3FFF Bit field access for ECAT: r/(w) Bit field access for PDI: r/(w)

55.6.1.128 Register Speed Counter Diff (SPEED_COUNTER_DIFF)

Offset

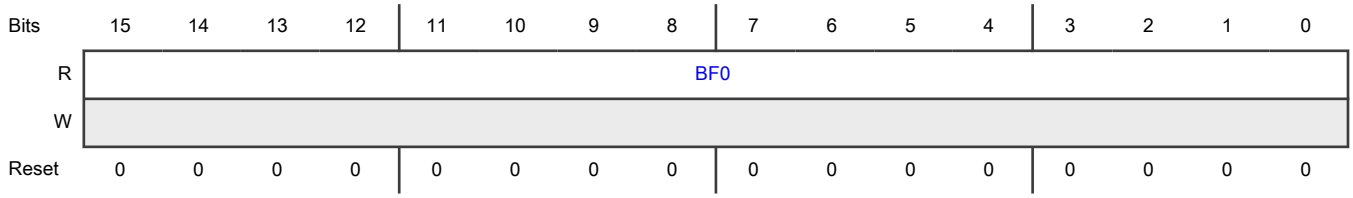
Register	Offset
SPEED_COUNTER_DIFF	932h

Function

NOTE

Calculate the clock deviation after System Time Difference has settled at a low value as follows: A / (B * C), where A = Speed Counter Diff, B = 5(Speed Counter Start + Speed Counter Diff + 2) and C = Speed Counter Start - Speed Counter Diff + 2

Diagram



Fields

Field	Function

7 BF7	SyncSignal debug pulse (Vasily bit): This bit is self-clearing, always read 0. All pulses are generated at the same time, the cycle time is ignored. The configured pulse length is used. Bit field access for ECAT: r/(w) Bit field access for PDI: r/(w) 0b - Deactivated 1b - Immediately generate one ping only on SYNC0-1 according to 0x0981[2:1] for debugging.
6 BF6	Near future configuration (approx.): Bit field access for ECAT: r/(w) Bit field access for PDI: r/(w) 0b - 1/2 DC width future (2^31ns or 2^63ns) 1b - ~2.1 sec. future (2^31ns)
5 BF5	Start Time plausibility check: Bit field access for ECAT: r/(w) Bit field access for PDI: r/(w) 0b - Disabled. SyncSignal generation if Start Time is reached. 1b - Immediate SyncSignal generation if Start Time is outside near future (see 0x0981[6])
4 BF4	Extension of Start Time Cyclic Operation (0x0990:0x0993): Bit field access for ECAT: r/(w) Bit field access for PDI: r/(w) 0b - No extension 1b - Extend 32 bit written Start Time to 64 bit
3 BF3	Auto-activation by writing Start Time Cyclic Operation (0x0990:0x0997): Bit field access for ECAT: r/(w) Bit field access for PDI: r/(w) 0b - Disabled 1b - Auto-activation enabled. 0x0981[0] is set automatically after Start Time is written

55.6.1.138 Register Start Time Cyclic Operation (UNIT_START_TIME_CYCLIC_OPERATION)

Offset

Register	Offset
UNIT_START_TIME_CYCLIC_OPERATION	990h

Function

NOTE

Register bits [63:8] are internally latched (ECAT/PDI independently) when bits [7:0] are read, which guarantees reading a consistent value. Write to this register depends upon setting of 0x0980[0]. Write value is taken over when 0x0981[0] has a transition to 1. Auto-activation (0x0981[3]=1): 0x0981[0] is set automatically after this register is written. Extension of Start Time (0x0981[4]=1): upper 32 bits are automatically extended after writing this register if only lower 32 bits are written within one frame.

56.2 Overview

USB controller provides high-performance USB functionality that conforms to the *Universal Serial Bus Specification*, Rev. 2.0.

NOTE

The document uses the term "OTG" throughout. USB core hardware does not support the automatic OTG function by hardware. It is a dual-role (Host and Device mode) core, which you can implement in software with the hardware assist.

The USB controller consists of two independent USB controller cores: two On-The-Go (OTG) controller cores. Each controller core supports UTMI interfaces according to its feature. See Features for more details. Both the controller cores are single-port cores. For the OTG cores, there is only one port. The port can be used as either a downstream or an upstream port.

56.2.1 Block diagram

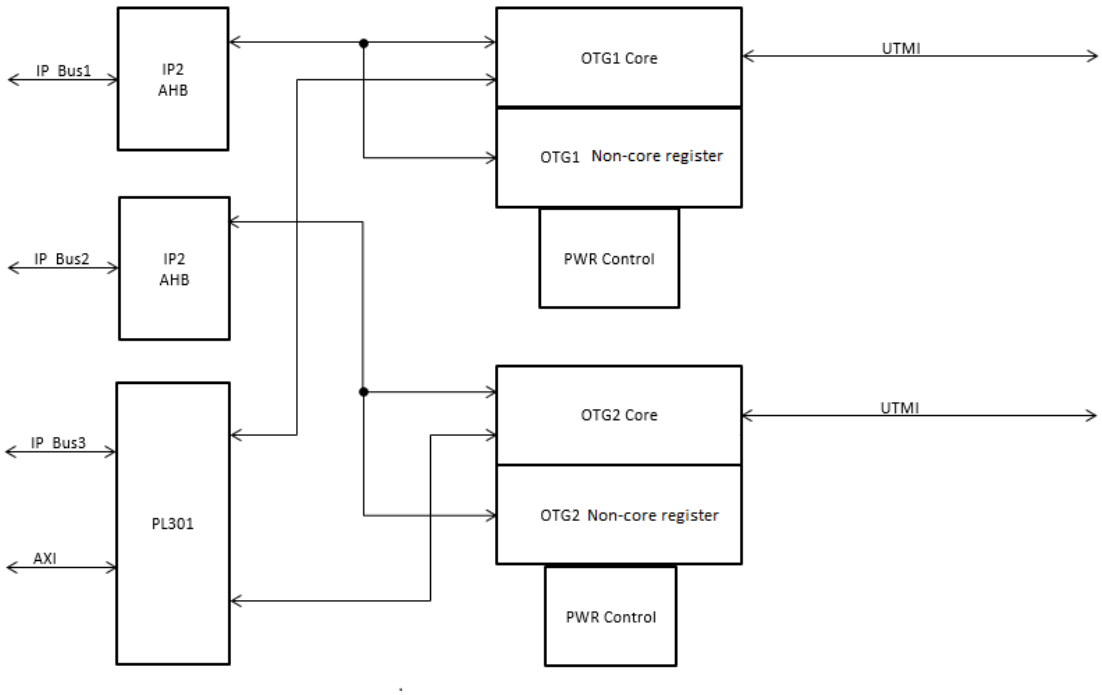

Figure 398. USB block diagram

56.2.2 Features

There are two USB 2.0 controller cores in this chip:

- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.
- Controller Core 1 is also named 'OTG2 Core'; its connected port is named 'OTG2 port'.
- Supports USB 2.0 Controller Core 0
  - High-speed/full-speed/low-speed (HS/FS/LS) OTG core
  - HS/FS/LS UTMI compliant interface
  - HS, FS, and LS operation in Host mode (with UTMI transceiver)
  - HS and FS operation in Peripheral mode (with UTMI transceiver)
  - OTG signaling, session request protocol, and host negotiation protocol
  - 8 bidirectional endpoints
  - Support charger detection
- USB 2.0 Controller Core 1
  - HS/FS/LS OTG core
  - HS/FS/LS UTMI compliant interface
  - HS, FS, and LS operation in Host mode (with UTMI transceiver)
  - HS and FS operation in Peripheral mode (with UTMI transceiver)

  - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
  - 8 bidirectional endpoints
- Low-Power mode with local and remote wake-up capability
- Embedded DMA controller in each core

56.3 Functional description

These sections describe the functionality of the various building blocks of USB.

56.3.1 Submodule sections

56.3.1.1 USB 2.0 controller core 0

USB 2.0 Controller 0 is an instantiation of an EHCI-compatible core that supports HS, FS, and LS operation.

In Host mode, this controller core supports HS, FS, and LS operation. In Device mode, it supports HS and FS operation.

56.3.1.1.1 Host mode

The controller supports direct connection of an HS, FS, or LS device with on-chip UTMI transceiver. The system does not have a separate transaction translator block. The DMA and protocol engine blocks include the transaction translator function, which is normally associated with an USB 2.0 HS hub to support connection to FS and LS devices.

56.3.1.1.2 Peripheral (device) mode

- 8 bidirectional endpoints
- HS or FS operation
- Support of HNP and SRP
- Remote wake-up capability

56.3.1.2 USB 2.0 controller core 1

USB 2.0 Controller Core 1 is an instantiation of EHCI-compatible core which supports HS/FS/LS operation USB 2.0 Controller Core 1 is identical as Core 0.

In Host mode, this controller core supports HS, FS, and LS operation. In Device mode, it supports HS and FS operation.

56.3.2 Operation sections

56.3.2.1 Host operational model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (a general term for system software). A separate section discusses each significant operational feature of the EHCI HC. Each section presents the operational model requirements for the host controller hardware. You can also find recommended system software operational models presented for features where appropriate.

56.3.2.1.1 Host controller initialization

After initial power-on or HCReset (hardware or through HCReset field in USB Command (USBCMD), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.

Table 831. Default values of operational register space

Operational register	Default value (after reset)
USB Command (USBCMD)	0008_0000h (0008_0B00h, if *Asynchronous Schedule Park Capability is 1*)
USB Status (USBSTS)	0000_1000h
Interrupt Enable (USBINTR)	0000_0000h
USB Frame Index (FRINDEX)	0000_0000h
Frame List Base Address (PERIODICLISTBASE)	Undefined
Next Asynch. Address (ASYNCLISTADDR)	Undefined
Configure Flag (CONFIGFLAG)	0000_0000h
Port Status & Control (PORTSC1)	0000_2000h (write 1 to w/*PPC*); 0000_3000h (write 0 to w/*PPC*)

To initialize the host controller, perform the following steps:

- Write the appropriate value to Interrupt Enable (USBINTR) to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to Frame List Base Address (PERIODICLISTBASE). If no work items are in the periodic schedule, all elements of the periodic frame list should have their T-Bits set to one.
- Write USB Command (USBCMD) to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting USBCMD[RS].

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled ports, but the schedules have not enabled. To communicate with devices through the asynchronous schedule, you must write Next Asynch. Address (ASYNCLISTADDR) with the address of a control or bulk queue head. Then enable the asynchronous schedule by writing 1 to USBCMD[ASE] in USBCMD. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing 1 to USBCMD[PSE] in USBCMD.

NOTE

It is possible to turn on the schedules before resetting the first port (and enabling).

When writing USBCMD, system software must ensure preserving the appropriate fields, depending on the intended operation.

56.3.2.1.2 Port routing and control

The EHCI specification defines that a USB 2.0 host controller (HC) consists of one HS host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion HCs. Companion host controllers (CHCs) may be implementations of either Universal or Open host controller specifications. Use this configuration to deliver the required full USB 2.0-defined port capability; for example, LS, FS, and HS capability for every port.

NOTE

The USB controllers neither require nor support companion controllers to support FS and LS device. USB controllers support FA and LS devices by emulating HS hub functionality. Therefore, there is no port routing present in the controller. See Embedded transaction translator function for more information.

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and CHCs within an USB 2.0 HC.

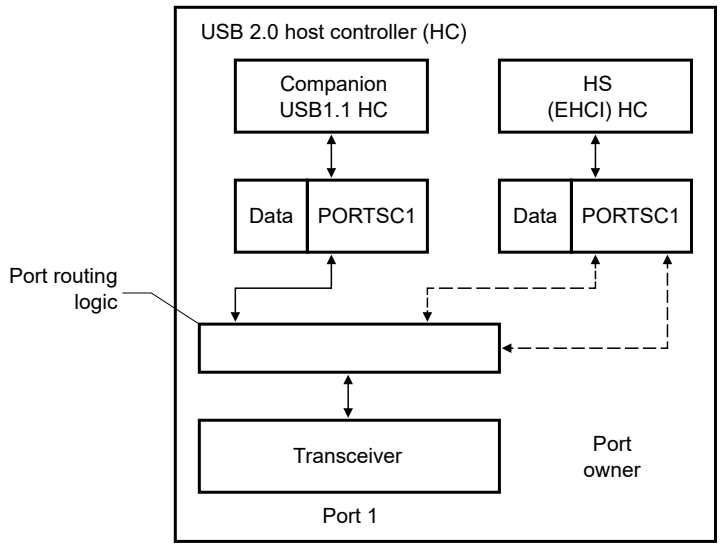

Figure 399. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port. Each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each CHC has only the port control and status registers to operate. Either the EHCI HC or one companion HC controls each transceiver. Routing logic lies among the transceiver, the port status and control registers.[6]

You can control the port routing logic from signals originating in the EHCI HC. The EHCI HC has a global routing policy control field and per-port ownership control fields. CONFIGFLAG[CF] is the global routing policy control. At power on or reset, the default routing policy follows the companion controllers (if they exist). If the system does not include a driver for the EHCI HC and the HC includes companion controllers, then the ports still work in FS and LS mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the CHCs' port registers do not see a connect indication from the transceiver. Similarly, when a CHC owns a port, the EHCI controller's port registers do not see a connect indication from the transceiver. The following sections describe the details on the rules for the port routing logic. If the implementation includes companion controllers, implement the USB 2.0 HC as a multi-function PCI device. The CHCs' function numbers must be less than the EHCI HC function number. The EHCI HC must be a larger function number with respect to the CHCs associated with this EHCI HC. If a PCI device implementation contains only an EHCI controller (that is, no companion controllers or other PCI functions), then the EHCI HC must function as 0, in accordance with the PCI Specification. HCSPARAMS[N_CC] in Host Controller Structural Parameters (HCSPARAMS) indicates whether the controller implementation includes CHCs. When HCSPARAMS[N_CC] has a non-zero value, there exists CHCs. If HCSPARAMS[N_CC] has a 0 value, then the HC implementation does not include CHCs. While exposing the HC root ports to attachment of FS or LS devices, the ports always fail the HS chirp during reset without enabling the ports. System software can notify the user of the illegal condition. This type of implementation requires connection of an USB 2.0 hub to a root port to provide FS and LS device connectivity.

System software uses information in the HC capability registers to determine routing of the ports to the CHCs. See HCSPARAMS for more information.

56.3.2.1.2.1 Port routing control through EHCI CONFIGFLAG[CF]

The USB 2.0 host controller has either a single CHC or an EHCI HC for each port. Two mechanisms in the EHCI HC control the port routing logic: a host controller global flag and per-port control. Use Configured Flag (CF) to globally set the policy of the routing logic. Each port register has a Port Owner control which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever CF transitions from 0 to 1 (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to 0). While CF is 1, the EHCI Driver controls individual ports' routing through Port Owner control. Likewise, whenever CF transitions from 1 to 0 (as a result of Aux

[6] It is not recommended to implement the routing logic in the 480 MHz clock domain of the transceiver.

power application, HCRESET, or software writing 0 to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is 0.

The *view* of the port depends on the current owner. A Universal or Open CHC will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI HCs are not visible to CHCs.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC's CONFIGFLAG[CF].

Table 832. Default port routing depending on EHCI HC CONFIGFLAG[CF]

HS CF	Default port ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports. The system supports only FS and LS devices in the system. The exact port assignments are implementation dependent. The ports behave only as FS and LS ports in this configuration
1B	EHCI HC	The EHCI HC has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is EHCI HC. The EHCI HC has access to the additional port status and control bits defined in this specification (see Port Status & Control (PORTSC1)). The EHCI HC can temporarily release control of the port to a companion HC by changing the *PortOwner* in PORTSC1 to 1.

56.3.2.1.2.2 Port routing control through portOwner and disconnect event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation. The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.
- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The

EHCI USB_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

56.3.2.1.2.3 Example port routing state machine

The following figure illustrates an example of how to manage the port ownership. The following sections describe the entry conditions to each state.

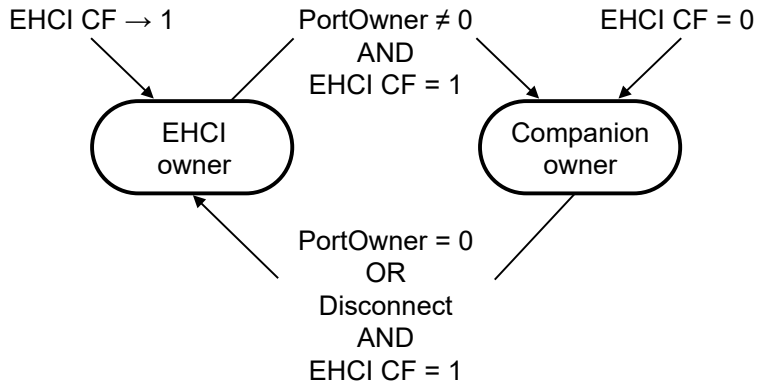

Figure 400. Port owner handoff state machine

56.3.2.1.2.3.1 EHCI HC owner

Entry to this state occurs when one of the following events occur:

- When EHCI HC's CONFIGFLAG[CF] in CONFIGFLAG transitions from 0 to 1. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When a companion HC owns the port and there is no connection of the device with the port. There is notification of the disconnect to the EHCI port routing control logic, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to 0. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes 0 to PortOwner in PORTSC1. This allows you to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

56.3.2.1.2.3.2 Companion HC owner

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

56.3.2.1.2.4 Port power

The Port Power Control (PPC) bit in the USB_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see HCSPARAMS register). When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

Table 833. Port Power Enable Control Rules

CF	CHC[1] (PP)	EHC[2] (PP)	Owner	PPE[3]	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).

2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

56.3.2.1.2.5 Port reporting over-current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB_PORTSC1 register has an over-current status and over-current change bit. The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to Table 834 for summary behavior for over-current detection when the host controller is halted (suspended from a device component point of view).

56.3.2.1.3 Suspend/resume-host operational model

The EHCI HC provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub. Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB_PORTSC1 registers.

Selective suspend is a feature supported by every USB_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the Arm platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

56.3.2.1.3.1 Port suspend/resume

System software places individual ports into suspend mode by writing one into the appropriate USB_PORTSC1 Suspend bit. You must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is 1) and the EHCI is the port owner (PortOwner bit is 0).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see USB_nPORTSC1). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 µsec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB_USBSTS register is zero), before terminating a resume by writing zero to a port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB_USBSTS register.

Table 834. Behavior During Wake-up Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, the USB_ PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]

Table continues on the next page...

Table 834. Behavior During Wake-up Events (continued)

Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

56.3.2.1.4 Schedule traversal rules

The host controller executes transactions for devices using a simple, shared-memory schedule. The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB_PERIODICLISTBASE register (see USB_nPERIODICLISTBASE) DEVICEADDR. The USB_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host data structures. In each micro-frame, if the periodic schedule is enabled (see Periodic scheduling threshold) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB_PERIODICLISTBASE and the USB_FRINDEX registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.

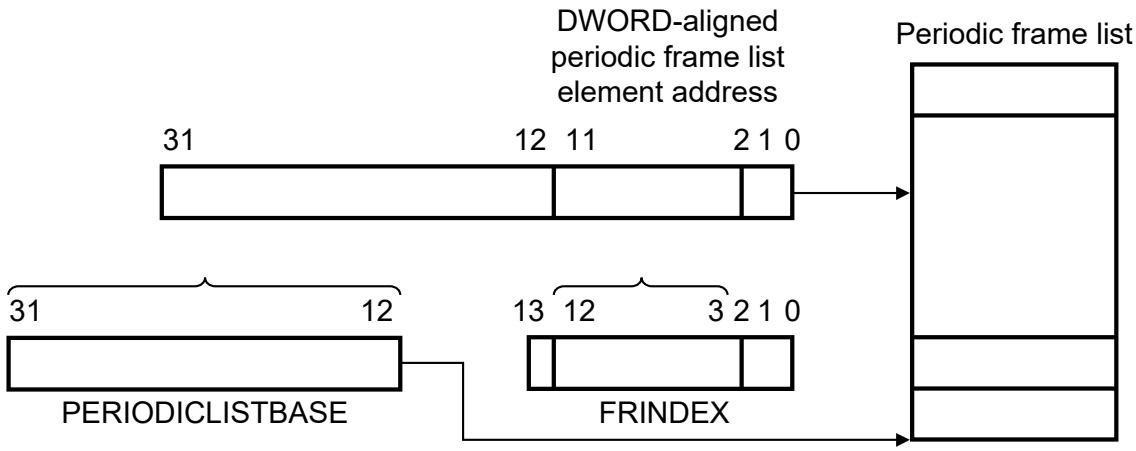

Figure 401. Derivation of Pointer into Frame List Array

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register USB_ASYNCLISTADDR to access the asynchronous schedule, see the figure below.

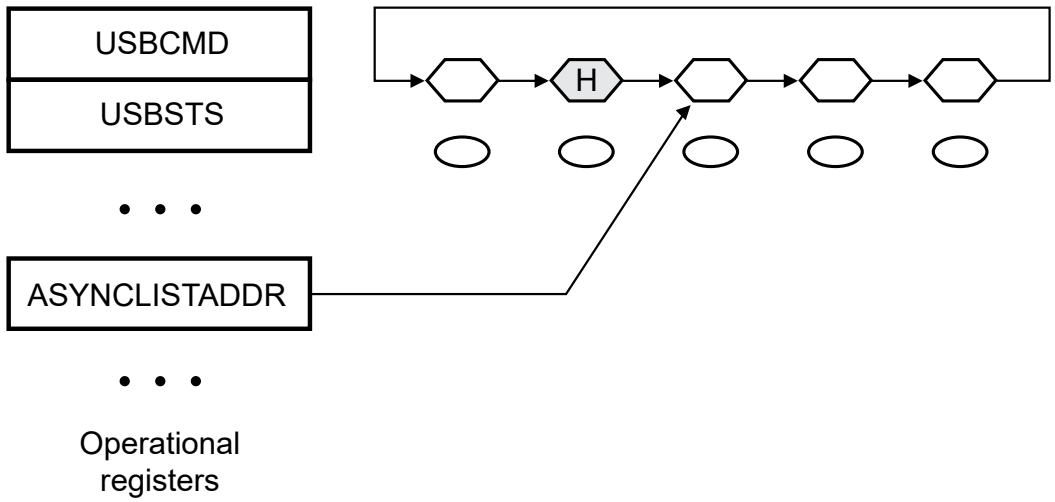

Figure 402. General Format of Asynchronous Schedule List

The USB_ASYNCLISTADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the USB_ASYNCLISTADDR register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See Asynchronous schedule for complete operational details.

56.3.2.1.4.1 Example - preserving micro-frame integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries. For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

56.3.2.1.4.1.1 Transaction fit - a best-fit approximation algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction. This curve is the 80 % bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves is illustrated in Figure 403. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80 % and the Last Start plots is bandwidth reclamation area. In this algorithm, the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ($f(x)$) between the 80 % and Last Start curves. The function $f(x)$ adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

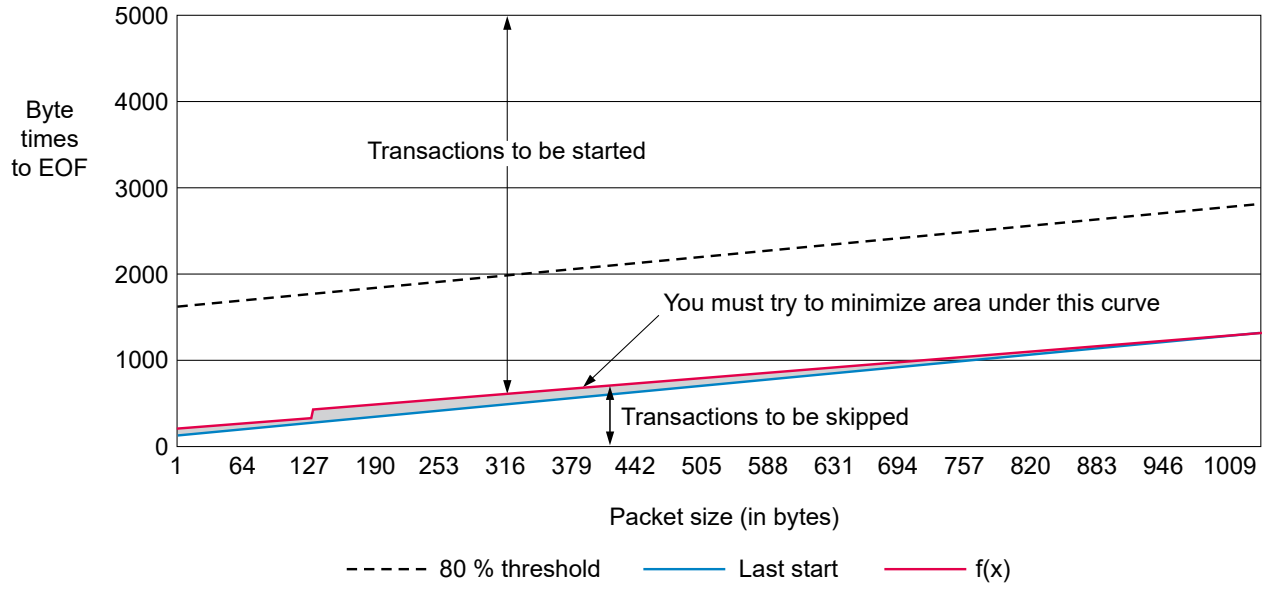

Figure 403. Best Fit Approximation

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 835. Example Worse-case Transaction Timing Components

Component	Bit time	Byte Time	Explanation
Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, EOP, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, EOP, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includes sync, token, EOP, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, EOP, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, EOP, and so on.
		144	Total

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in Figure 403 was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```
Algorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
     Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
     Rvalue = FALSE
End If
Return rvalue
End
```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the *f*(*x*) plot was getting close to the LastStart line.

56.3.2.1.5 Periodic schedule frame boundaries vs bus frame boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned. Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

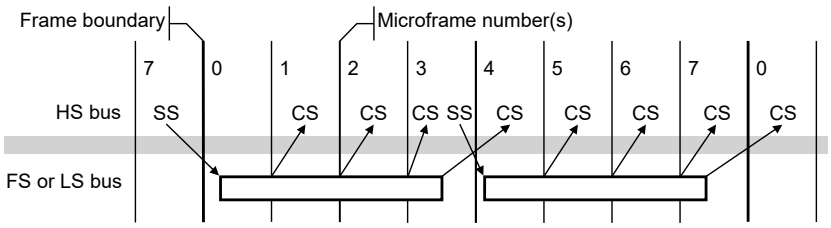

Figure 404. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB_FRINDEX) documented in FRINDEX and initially illustrated in Schedule traversal rules. Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

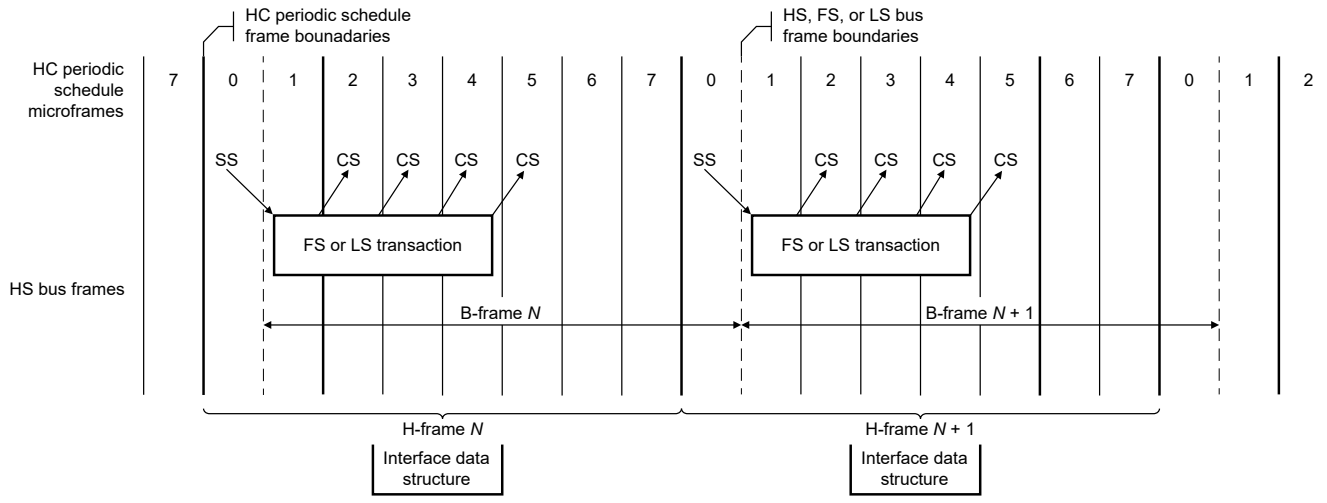

Figure 405. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in FRINDEX, the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. FRINDEX provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

Table 836. Operation of FRINDEX and SOFV (SOF Value Register)

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]
N	N	111b	N+1	N	000b
N+1	N	000b	N+1	N+1	001b
N+1	N+1	001b	N+1	N+1	010b
N+1	N+1	010b	N+1	N+1	011b
N+1	N+1	011b	N+1	N+1	100b
N+1	N+1	100b	N+1	N+1	101b
N+1	N+1	101b	N+1	N+1	110b
N+1	N+1	110b	N+1	N+1	111b

NOTE

Where [F] = [13:3]; [μF] = [2:0]

56.3.2.1.6 Periodic schedule

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB_USBCMD register. If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB_PERIODICLISTBASE register to traverse the periodic schedule.

The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero.

The Periodic Schedule Status bit in the USB_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic schedule has made the desired transition.

Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions.

The following figure illustrates isochronous transfers (using Isochronous transaction descriptors (iTDs) and Split-transaction isochronous transfer descriptors(siTDs)) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

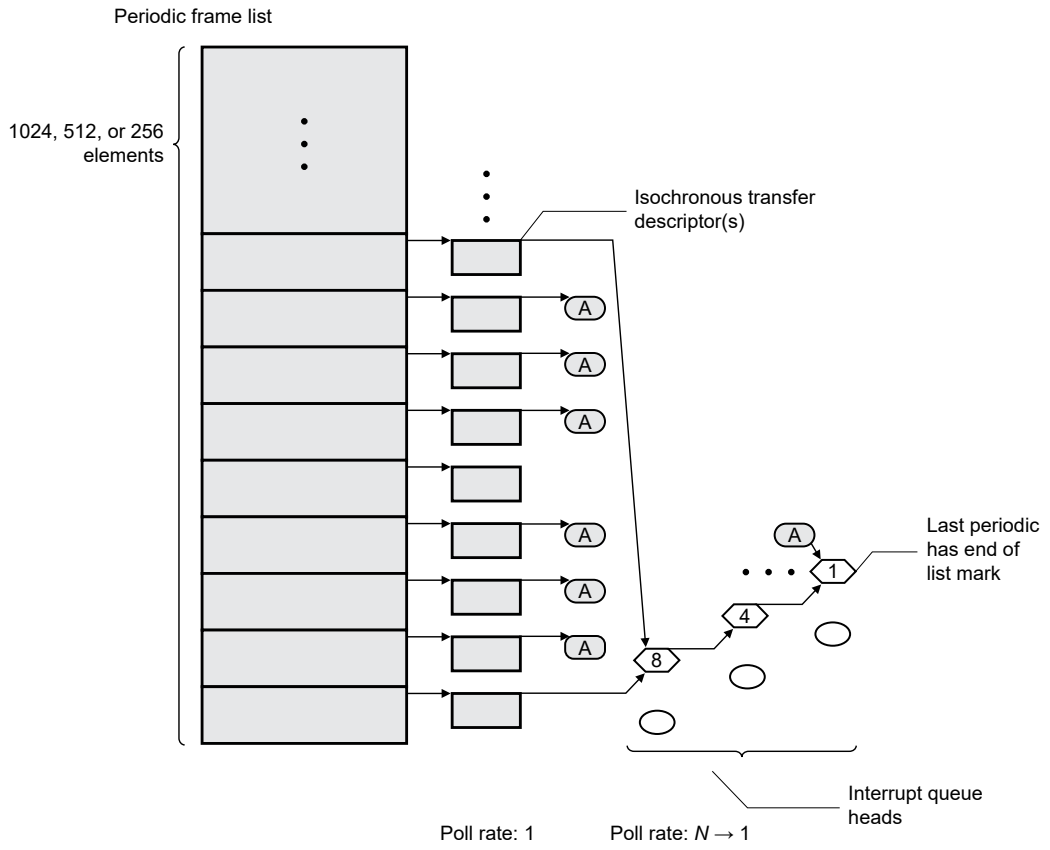

Figure 406. Example Periodic Schedule

56.3.2.1.7 Managing isochronous transfers using iTDs

The structure of an iTD is presented in Isochronous (high-speed) transfer descriptor (iTD). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

56.3.2.1.7.1 Host controller operational model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Therefore, each transaction descriptor corresponds to one micro-frame. Each iTD can span 8 micro-frames worth of transactions. When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array. If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Size. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set the USBINT bit in the USB_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

56.3.2.1.7.2 Software operational model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

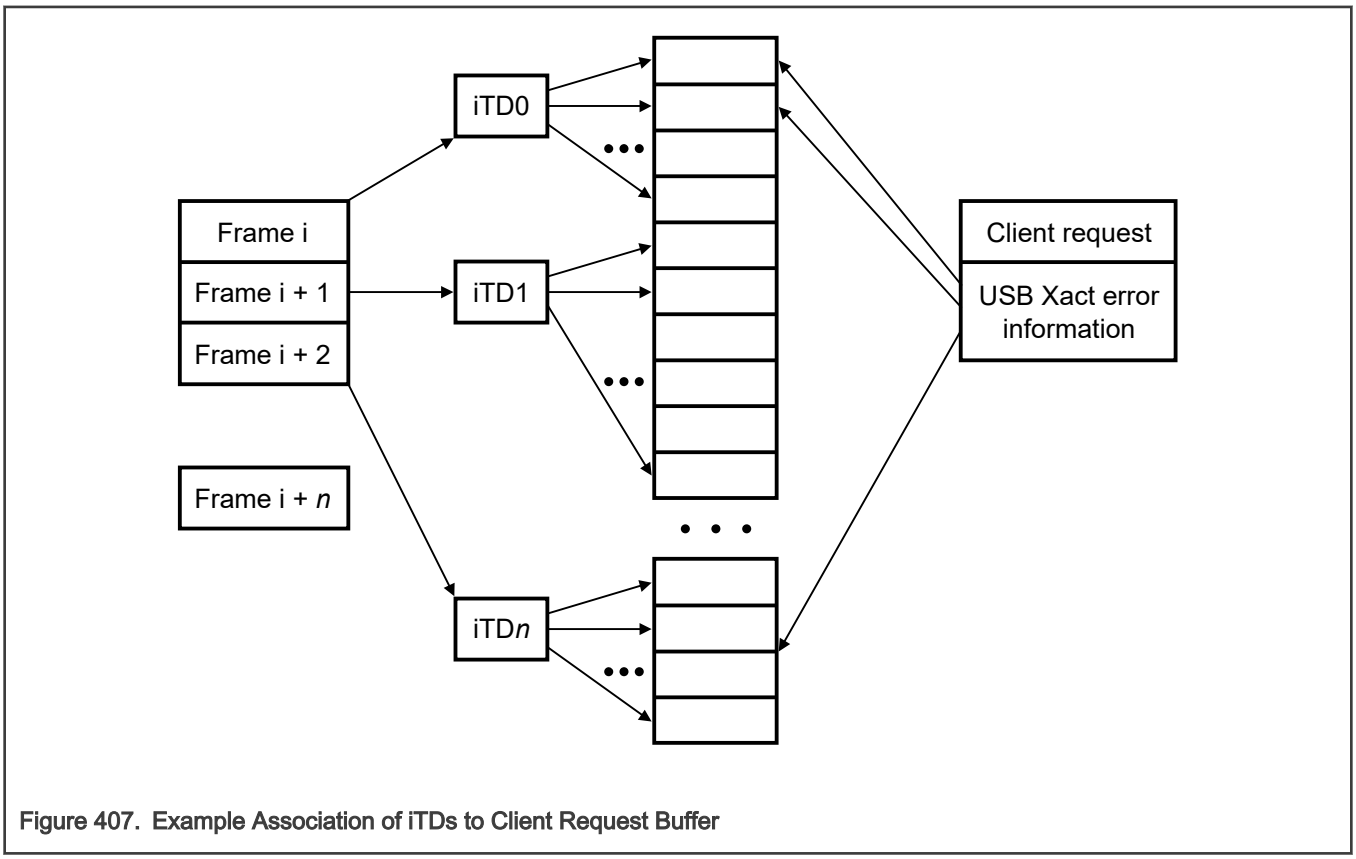

Figure 407. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

56.3.2.1.7.2.1 Periodic scheduling threshold

The Isochronous Scheduling Threshold field in the USB_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures. It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB_FRINDEX register (plus the constant 1 uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

56.3.2.1.8 Asynchronous schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register. If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB_ASYNCLISTADDR register. The default value of the USB_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB_USBCMD and the Asynchronous Schedule Status bit in the USB_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see Empty asynchronous schedule detection)
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 402. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

56.3.2.1.8.1 Adding queue heads to asynchronous schedule

This is a software requirement section. There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB_ASYNCLISTADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid Queue element transfer descriptors (qTDs) and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadCurrent is a pointer to a queue head that is
          -- already in the active list
          -- pQHeadNew is a pointer to the queue head to be added
          --
          -- This algorithm links a new queue head into an existing
          -- list
          --
          pQueueHeadNew.HorizontalPointer  =  pQueueHeadCurrent.HorizontalPointer
          pQueueHeadCurrent.HorizontalPointer =  physicalAddressOf(pQueueHeadNew)
End InsertQueueHead
```

56.3.2.1.8.2 Removing queue heads from asynchronous schedule

This is a software requirement section. There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list. Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadPrevious is a pointer to a queue head that
          -- references the queue head to remove
          -- pQHeadToUnlink is a pointer to the queue head to be
          -- removed
          -- pQheadNext is a pointer to a queue head still in the
          -- schedule. Software provides this pointer with the
          -- following strict rules:
          --          if the host software is one queue head, then
          --          pQHeadNext must be the same as
          --          QueueheadToUnlink.HorizontalPointer. If the host
          --          software is unlinking a consecutive series of
          --          queue heads, QHeadNext must be set by software to
          --          the  queue head remaining in the schedule.
          --
          -- This algorithm unlinks a queue head from a circular list
          --
          pQueueHeadPrevious.HorizontalPointer =  pQueueHeadToUnlink.HorizontalPointer
                              pQueueHeadToUnlink.HorizontalPointer = pQHeadNext
End UnlinkQueueHead
```

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

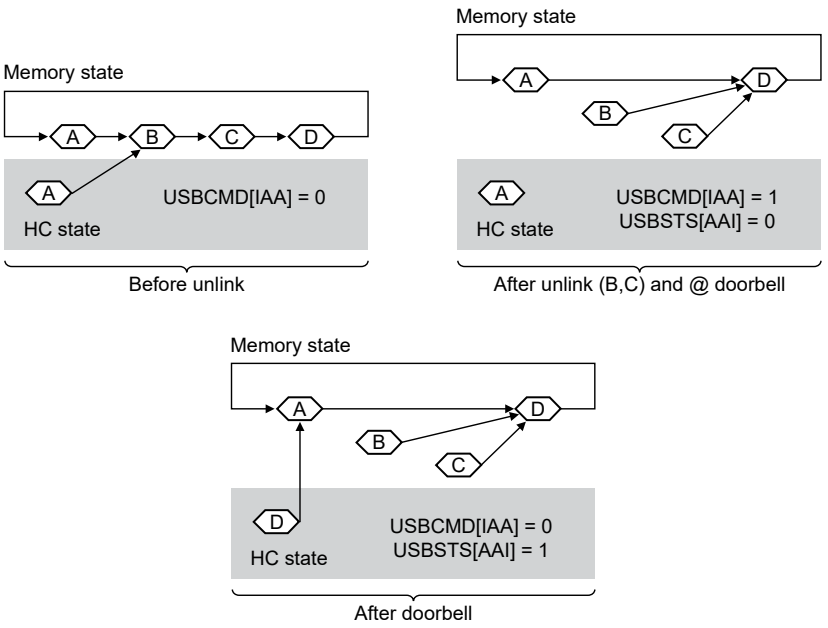

Figure 408. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB_USBSTS register, before using the doorbell handshake again.

56.3.2.1.8.3 Empty asynchronous schedule detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty. The queue head data structure (see Queue head) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see Asynchronous schedule traversal: *Start event*).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

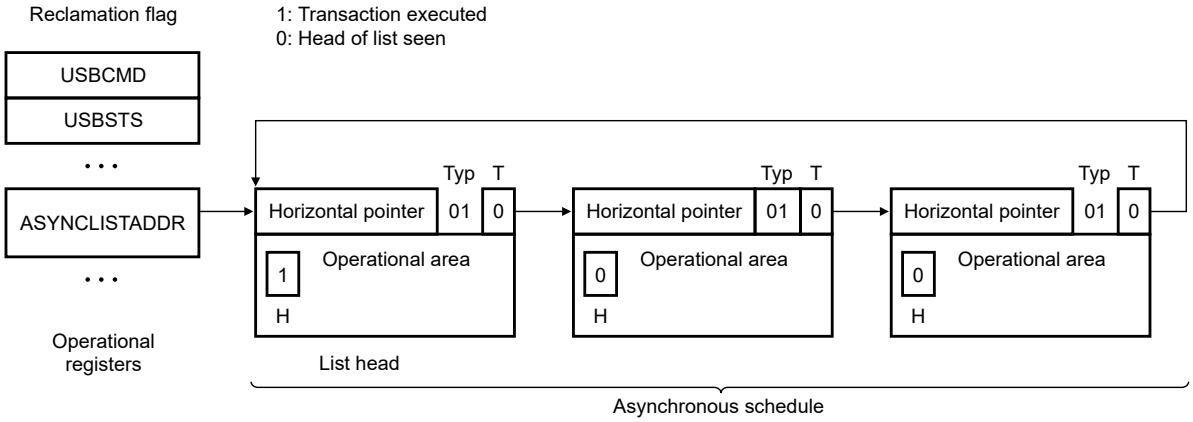

Figure 409. Asynchronous Schedule List w/Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

56.3.2.1.8.4 Restarting asynchronous schedule before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame. It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

56.3.2.1.8.4.1 Example method for restarting asynchronous Schedule traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting*?

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10 µsec. The value is derived based on the analysis in Example derivation for *AsyncSchedSleepTime*. The traversal algorithm is simple:

- Traverse the Asynchronous schedule until either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

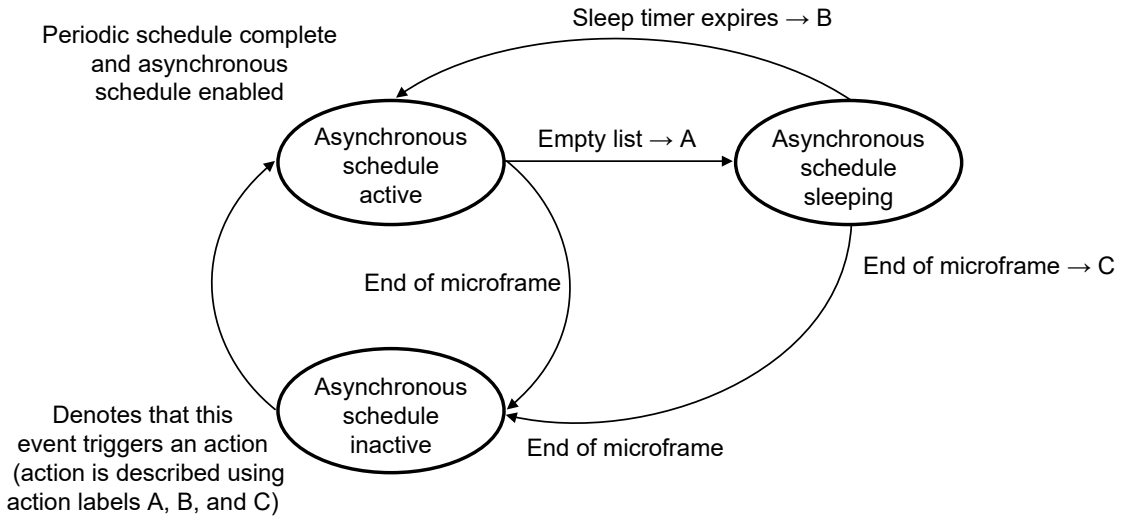

Figure 410. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in the figure above are defined in the following table.

Table 837. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.
B	When the *AsynchronousTraversalSleepTimer* expires, the host controller sets the Reclamation bit in the USBSTS register to one, and moves the Nak Counter reload state machine to WaitForListHead (see Nak count reload control).
C	The host controller cancels the sleep timer (*AsynchronousTraversalSleepTimer*).

56.3.2.1.8.4.2 Async sched not active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

56.3.2.1.8.4.3 Async sched active

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the *AsynchronousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

56.3.2.1.8.4.4 Async sched sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

56.3.2.1.8.4.5 Example derivation for AsyncSchedSleepTime

The derivation is based on analysis of what work the host controller could be doing next. It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

Table 838. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10 µs provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10 µs sleep period would allow the host controller to get the NAK results on the first complete-split.

56.3.2.1.8.5 Asynchronous schedule traversal: *Start event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame. In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in Restarting asynchronous schedule before EOF . Asynchronous schedule *Start Event*s are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see Restarting asynchronous schedule before EOF).

56.3.2.1.8.6 Reclamation status bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see Empty asynchronous schedule detection) depends on the proper management of the *Reclamation* bit in the USB_USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see Fetch queue head).

The host controller is required to set the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented in Asynchronous schedule traversal: *Start event*, occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see Execute transaction). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

56.3.2.1.9 Operational model for Nak counter

This section describes the operational model for the *NakCnt* field defined in a queue head. See Queue head initialization for more information. Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in the table below. The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the NakCnt field adjustment rules.

Table 839. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement *NakCnt*	N/A (protocol error)
OUT	decrement *NakCnt*	No Action[1] Start
Split	decrement *NakCnt*	N/A (protocol error)
Complete Split	No Action	Decrement *NakCnt*

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in Nak count reload control .

NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all NakCnt's go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see Empty asynchronous schedule detection).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see Asynchronous schedule traversal: *Start event*. Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

56.3.2.1.9.1 Nak count reload control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see Execute transaction). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see Queue head) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see Asynchronous schedule traversal: *Start event* for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see Figure 409).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction (see the figure below). The host controller does not perform the nak counter reload operation if the RL field (see Queue head) is set to zero.

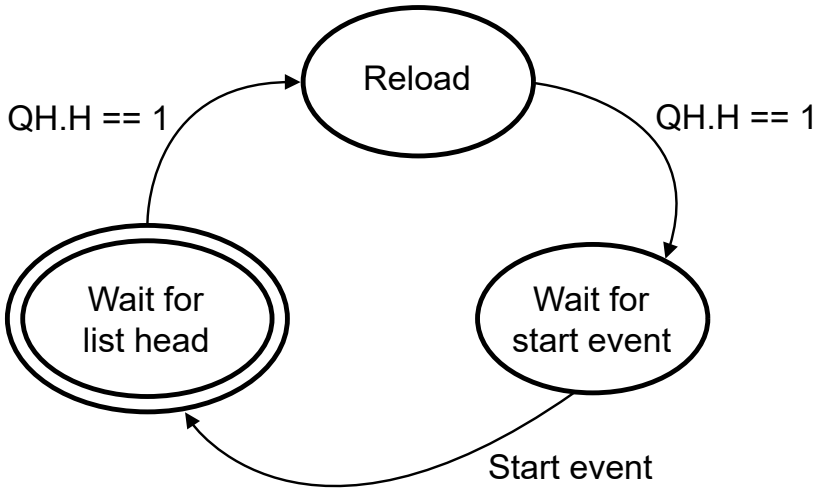

Figure 411. Example HC State Machine for Controlling Nak Counter Reloads

56.3.2.1.9.1.1 Wait for list head

This is the initial state. The state machine enters this state from Wait for Start Event when a start event as defined in Asynchronous schedule traversal: *Start event* occurs. The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule. This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

56.3.2.1.9.1.2 Do reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

56.3.2.1.9.1.3 Wait for start event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

56.3.2.1.10 Managing control/bulk/interrupt transfers through queue heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in Table 891). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.

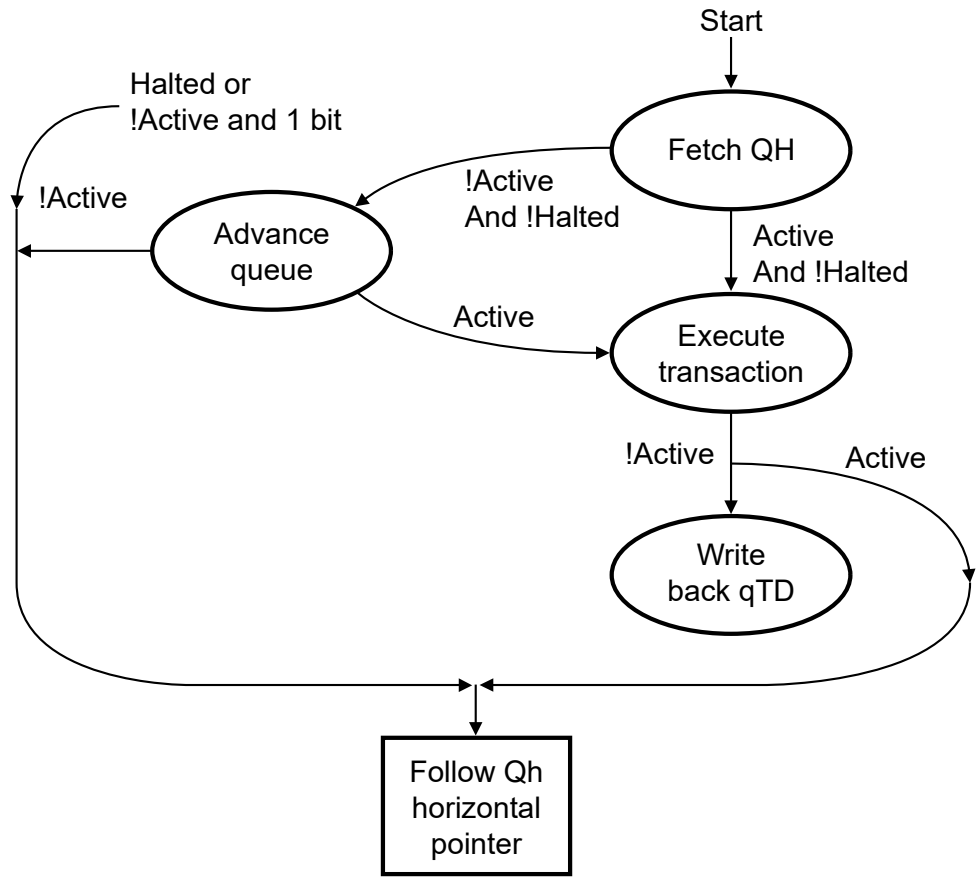

Figure 412. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see Execute transaction) describes the basic requirements for all endpoints. Split transactions for asynchronous transfers and Split transaction interrupt describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

56.3.2.1.10.1 Fetch queue head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register. Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in Queue head.

While in this state, the host controller performs operations to implement empty schedule detection (see Empty asynchronous schedule detection) and Nak Counter reloads (see Operational model for Nak counter). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in Empty asynchronous schedule detection). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in Operational model for Nak counter.

This state is complete when the queue head has been read on-chip.

56.3.2.1.10.2 Advance queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control* (*dtc*) bit (see Table 893).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

56.3.2.1.10.3 Execute transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are

other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see Split transactions for asynchronous transfers and Split transaction interrupt .

56.3.2.1.10.3.1 Interrupt transfer pre-condition criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it. For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

56.3.2.1.10.3.2 Asynchronous transfer pre-operations and pre-condition criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state (Operational model for Nak counter). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

56.3.2.1.10.3.3 Transfer type independent pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see Transaction fit - a best-fit approximation algorithm for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,[4] or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction (see Transaction fit - a best-fit approximation algorithm), for example method for implementing the frame boundary test).

> **NOTE**
>
> For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is

advanced to the next appropriate value (for example, advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See Buffer pointer list use for data streaming with qTDs .

NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in Transaction error .

The following events cause the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to 0. When this occurs, the *Halted* bit is set to 1 and *Active* is set to 0. This results in the hardware not advancing the queue and the pipe halts. You must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to 1 and the *Active* bit is set to 0. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is 0 after the transaction completes.
  - For a 0-length transaction, it was 0 before the transaction was started. When this condition occurs, the *Active* bit is set to 0.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to 0 and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to Split transactions for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

56.3.2.1.10.3.4 Halting a queue head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt). The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB_n_USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset,* and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB_n_USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

56.3.2.1.10.3.5 Asynchronous schedule park mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule. This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Execute transaction apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB_n_HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB_n_USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB_n_USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB_n_USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in Execute transaction . It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asynchronous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 840. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/ Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction.[1,2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	DATA[0,1] w/ short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction.[2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't' care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. [2]
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

56.3.2.1.10.4 Write back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero. The source data for the write-back is the transfer results area of the queue head overlay area (see Table 840). The host controller uses the *Current qTD Pointer* field as the target address for the qTD. The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

56.3.2.1.10.5 Follow queue head horizontal pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or
- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

56.3.2.1.10.6 Buffer pointer list use for data streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*. This means: if the buffer spans more than one physical page, it must obey the following rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 KB. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 KB buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

The following figure illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

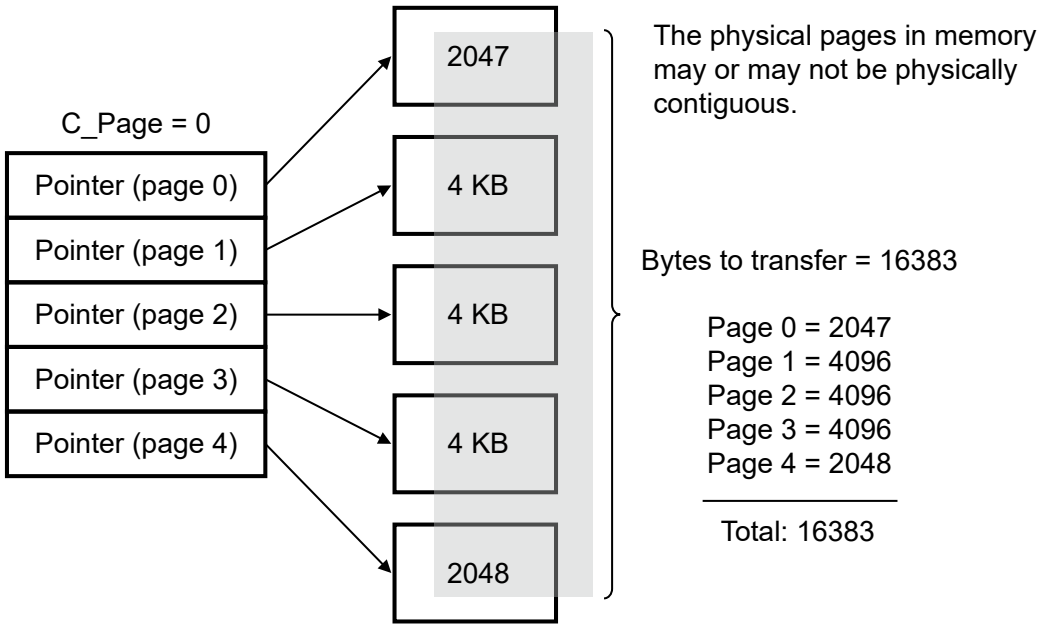

Figure 413. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C_Page*) when necessary. The three conditions for how the host controller handles *C_Page*:

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.
- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

NOTE

The only valid adjustment the host controller may make to *C_Page* is to increment by one.

56.3.2.1.10.7 Adding interrupt queue heads to the periodic schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate. System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame with-in 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

Table 841. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on *S-Mask* = 01h	A queue head for the *bInterval* of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the *S-Mask* field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on *S-Mask* = 02h	Another example of a queue head with a *bInterval* of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the *S-Mask* is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

56.3.2.1.10.8 Managing transfer complete interrupts from queue heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete* (*IOC*) bit set to one, or whenever a transfer (qTD) completes with a short packet. If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

56.3.2.1.11 Ping control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints. Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 842. Ping Control State Transition Table

Event			
Current	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr [1]	Do Ping
Do Ping	PING	Stall	N/C [2] Do
OUT	OUT	Nak	Do Ping

Table continues on the next page...

Table 842. Ping Control State Transition Table (continued)

Do OUT	OUT	Nyet	Do Ping
Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr[1]	Do Ping
Do OUT	OUT	Stall	N/C [2]

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

Table 843. Ping State bit Encoding

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

56.3.2.1.12 Split transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs. This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol. Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see Split transaction isochronous transfer descriptor (siTD)). Control, Bulk and Interrupt are managed using the queuing data structures (see Queue head). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

56.3.2.1.12.1 Split transactions for asynchronous transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head. All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type* (*C*) bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software

to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

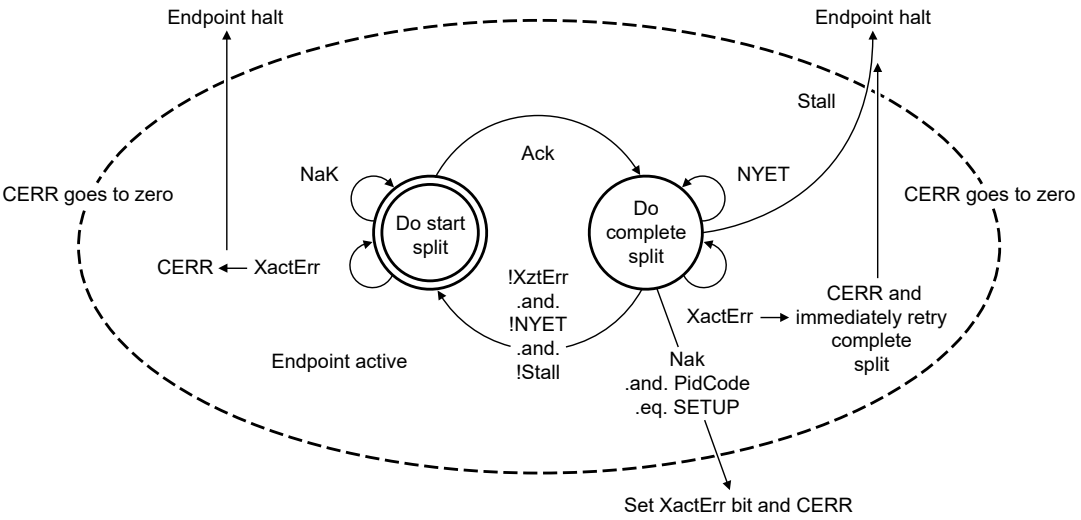

Figure 414. Host Controller Asynchronous Schedule Split-Transaction State Machine

56.3.2.1.12.1.1 Asynchronous - do start split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

56.3.2.1.12.1.2 Asynchronous - do complete split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A

method to accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Managing control/bulk/interrupt transfers through queue heads).

56.3.2.1.12.2 Split transaction interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule. Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in Managing control/bulk/interrupt transfers through queue heads, but only occurs on the completion of a split transaction.

56.3.2.1.12.2.1 Split transaction scheduling mechanisms for interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field. The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and ^{C}X labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

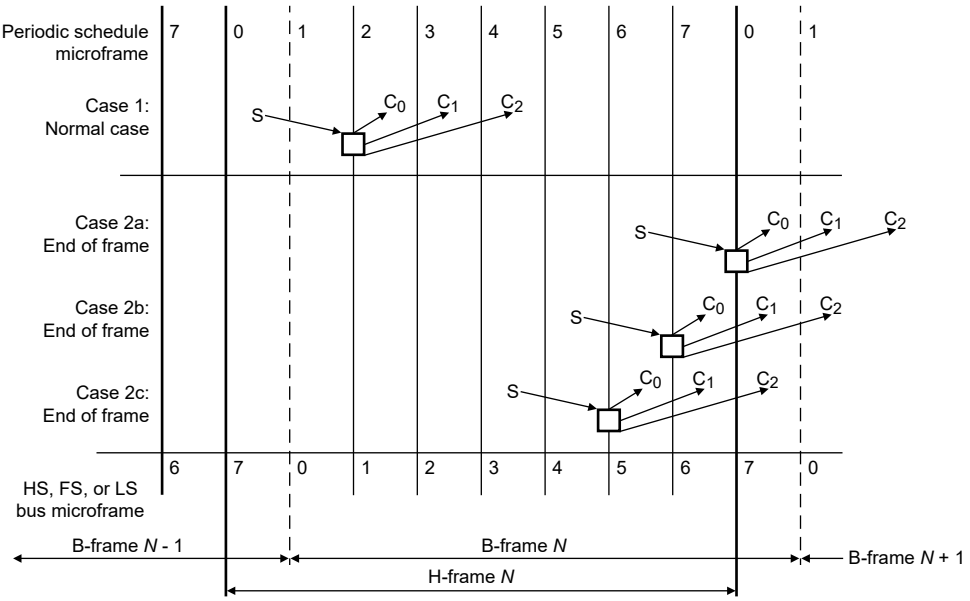

Figure 415. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

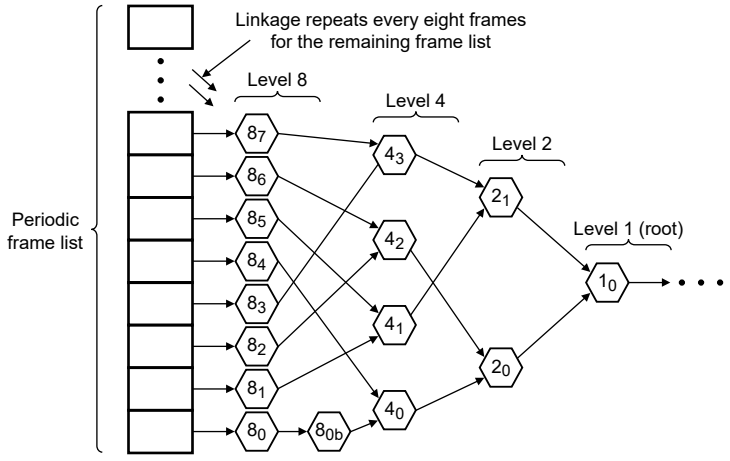

Figure 416. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads

that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to 8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Host controller operational model for FSTNs defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see Table 889). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 415, case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 415, case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

56.3.2.1.12.2.2 Host controller operational model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c). An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see siTD back link pointer).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.
- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See Execute transaction and Tracking split transaction progress for interrupt transfers for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See Periodic isochronous - do complete split for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.
- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

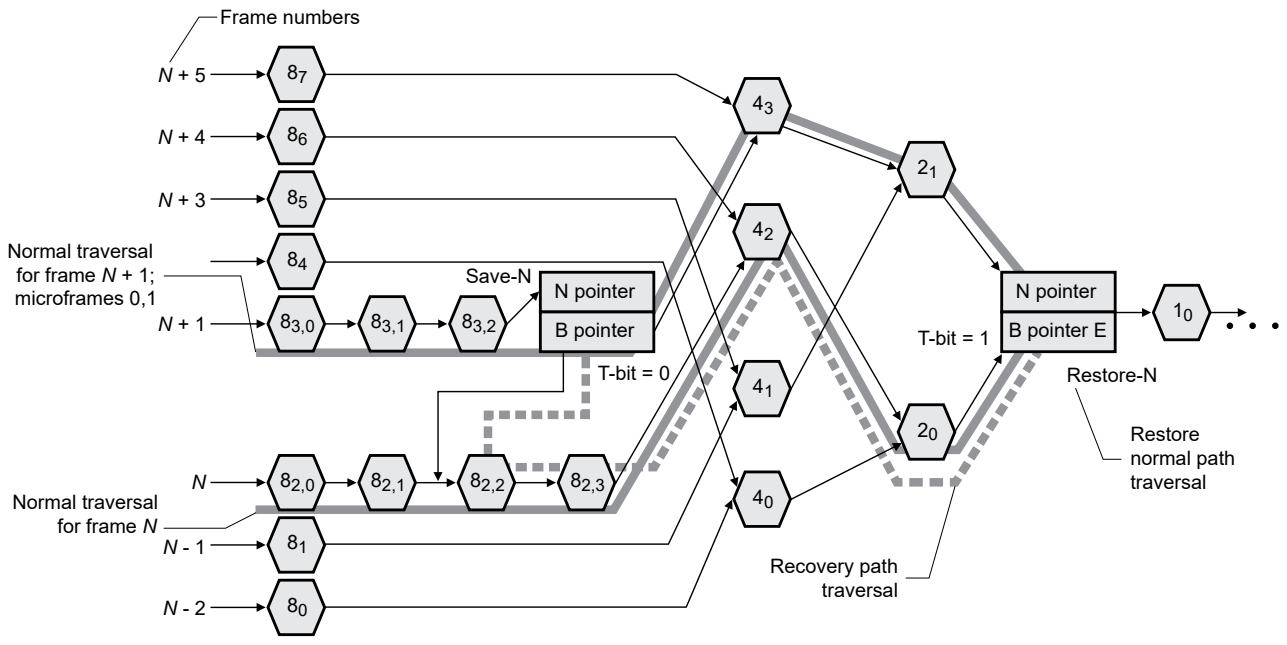

Figure 417. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition

of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 4_3, 2_1, Restore-N, 1_0 …}. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 …}.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 …}.

56.3.2.1.12.2.3 Software operational model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse. When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer and T-bit* equal to zero.
    - *Back Path Link Pointer.Typ* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer*'s *T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

56.3.2.1.12.2.4 Tracking split transaction progress for interrupt transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost. For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline. When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted, and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog-*mask bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.
- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

56.3.2.1.12.2.5 Split transaction execution state machine for interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.* As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence. Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit* is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is, *cMicroFrameBit* = (1 shifted-left(*FRINDEX*[2:0])). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start - or complete-split transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at Do_Start and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to Do_Complete. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the Do_Complete state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the Do_Complete state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

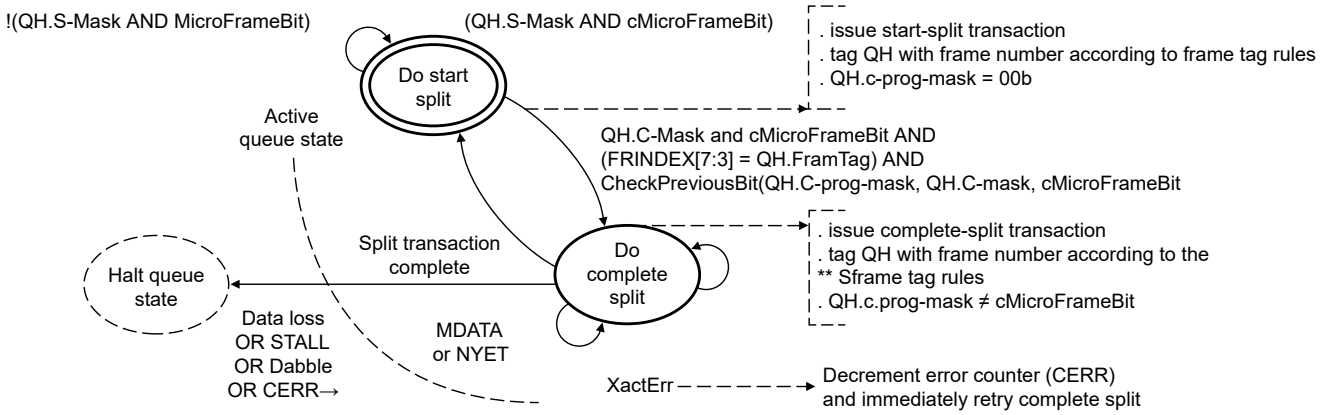

Figure 418. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section Periodic isochronous - do complete split for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX*[7:3]. An equal indicates a match.

- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask)then
                              If not(previousBit bitAND QH.C-prog-mask) then
                    rvalue = FALSE;
          End if
End If
-- If the C-prog-mask already has a one in this bit position,
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
 rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section Periodic isochronous - do start split). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros, then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one, and the *CErr* field is decremented.

- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.
- Transaction Error (XactErr). Timeout, data CRC failure, and so on. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero). If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section Managing control/bulk/interrupt transfers through queue heads).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section Managing control/bulk/interrupt transfers through queue heads).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.
- ERR. There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- STALL. The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

Table 844. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame. Host controller should continue walking the schedule.
A not(C)	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	Progress bit check failed. These mean a complete-split has been missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted.

Table continues on the next page...

Table 844. Interrupt IN/OUT Do Complete Split State Execution Criteria (continued)

		If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CERR*. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A not(B) C	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	*QH.FrameTag* test failed. This means that exactly one or more *H-Frames* have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CERR*. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CERR*. In either case, set the *Missed Micro-frame* bit in the status field to a one. Note: When executing in the context of a *Recovery Path* mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the normal processing mode. Regardless, the host controller must not execute a start-split in the context of an executing in a *Recovery Path* mode.

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see Figure 415).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c (Figure 415).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases (Figure 415).

56.3.2.1.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation. This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI HC provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

56.3.2.1.12.3 Split transaction isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions. This data structure uses the scheduling model of isochronous TDs (iTD, Section Isochronous (high-speed) transfer descriptor (iTD)) (see Section Managing isochronous transfers using iTDs for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

56.3.2.1.12.3.1 Split transaction scheduling mechanisms for isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur. The requirements described in Section Split transaction scheduling mechanisms for interrupt apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^{S}X and ^{C}X labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

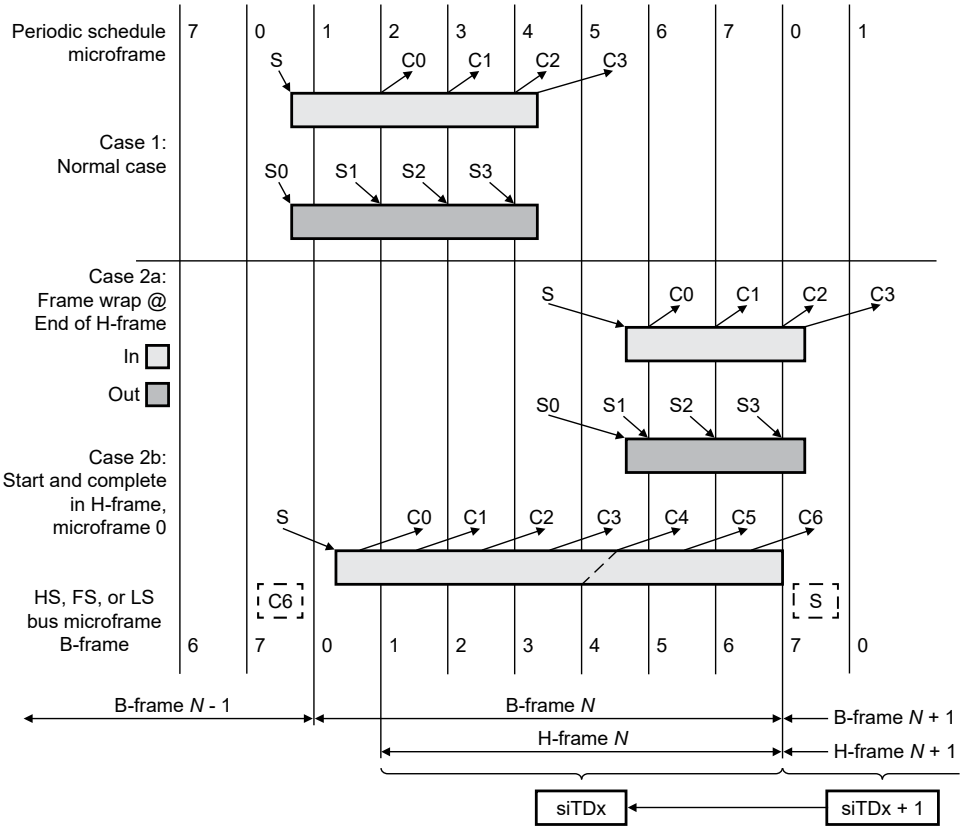

Figure 419. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1*: The entire split transaction is completely bounded by an *H-Frame.* For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.
- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame,* micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list.(For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 bytes maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see Figure 420). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Section Split transaction execution state machine for interrupt.

- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 419, case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by USB_n_FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 419, case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Complete Split, and the current micro-frame as indicated by *USB_n_FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.
- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

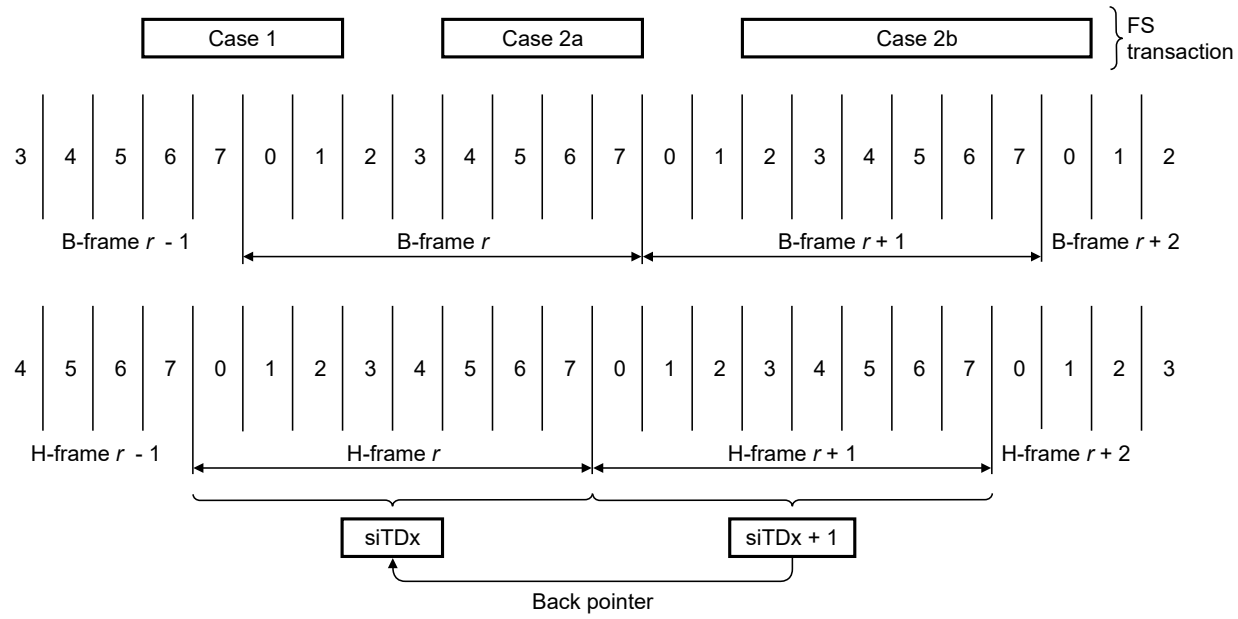

Figure 420. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.

- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction $siTD_X$ is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of $H\text{-}Frame_{Y+1}$, or micro-frame 0 of $H\text{-}Frame_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from $H\text{-}Frame_{Y+2}$is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described is Section Periodic isochronous - do complete split .

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame* N and the last complete-split would need to occur in micro-frame 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

56.3.2.1.12.3.2 Tracking split transaction progress for isochronous transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts, and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position* (*TP*) and *Transaction Count* (*T-count*). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section Periodic isochronous - do start split for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the

micro-frame (USB_n_FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section Asynchronous - do complete split for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and gives the remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

56.3.2.1.12.3.3 Split transaction execution state machine for isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section Tracking split transaction progress for interrupt transfers , plus the variable *cMicroFrameBit* defined in Section Split transaction execution state machine for interrupt to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

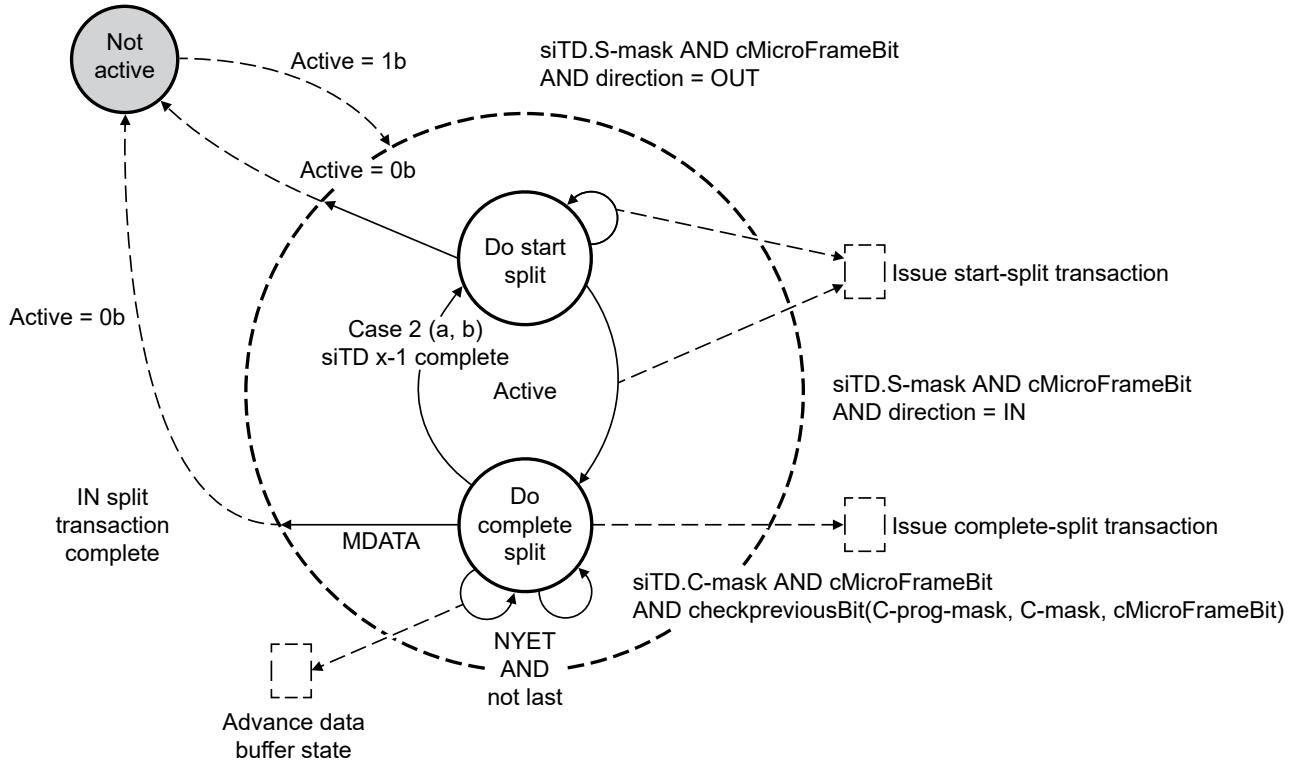

Figure 421. Split Transaction State Machine for Isochronous

56.3.2.1.12.3.4 Periodic isochronous - do start split

Isochronous split transaction OUTs use only this state. An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 420) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

Table 845. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

.

Table 846. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when *T-count* starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when *T-count* starts at greater than 2.
MID	!=1	MID	*TP* stays at MID while *T-count* is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in Table 846.

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count*, and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip, start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section Split transaction for isochronous - processing examples.

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit*() algorithm defined in Periodic isochronous - do complete split can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

56.3.2.1.12.3.5 Periodic isochronous - do complete split

This state is only used by a split-transaction isochronous IN endpoint. This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section Periodic isochronous - do start split). The sequence in which this test is applied depends on the current value of USB_n_FRINDEX[2:0]. If USB_n_FRINDEX[2:0] is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
          Boolean rvalue = TRUE;
          previousBit = cMicroFrameBit rotate-right(1)
          -- Bit-wise anding previousBit with C-mask indicates whether there was an intent
          -- to send a complete split in the previous micro-frame. So, if the
          -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
          -- happened.
          if previousBit bitAND siTD.C-mask then
                    if not (previousBit bitAND siTD.C-prog-mask) then
                              rvalue = FALSE
                    End if
          End if
          Return rvalue
End Algorithm
```

If Test A is true and USB_n_FRINDEX[2:0] is zero or one, then this is a case 2a or 2b scheduling boundary (see Figure 419). See Section Periodic isochronous - do start split for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer,*
- Adjust *siTD.Current Offset* by the number of bytes received,
- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, and so on. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section Periodic isochronous - do complete split . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.
- MDATA (and Last). See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-mask*s incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

56.3.2.1.12.3.6 Complete-split for scheduling boundary cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 419) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 847. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer P (page select) Current Offset	All bits in the status field	C-prog-mask

Table continues on the next page...

Table 847. Summary siTD Split Transaction State (continued)

TP (transaction position) T-count (transaction count)		

NOTE

TP and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero, or
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, then the host controller must use the transaction state from $siTD_{X-1}$.

In order to access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_X$.*Back Pointer*.

The host controller must save the entire state from $siTD_X$ while processing $siTD_{X-1}$. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 847) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s *Active* bit is a one, then the host controller returns to the context of $siTD_X$, and follows its next pointer to the next schedule item. No updates to $siTD_X$ are necessary.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If $siTD_{X-1}$*'s Active* bit is a zero, (because it was zero when the host controller first visited $siTD_{X-1}$ via $siTD_X$*'s* back pointer, it transitioned to zero as a result of a detected error, or the results of $siTD_{X-1}$*'s* complete-split transaction transitioned it to zero), then the host controller returns to the context of $siTD_X$ and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and $siTD_X$.*S-mask*[0] is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_X$, then follows $siTD_X$.*Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_X$.*Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its *Active* bit set to zero when the host controller returns to the context of $siTD_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

56.3.2.1.12.3.7 Split transaction for isochronous - processing examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines. The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see Figure 412).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 848. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDX		Micro-Frames								Initial SplitXState
#	Masks	0	1	2	3	4	5	6	7	
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, software ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that $siTD_{X+1}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+1}$ and fetches $siTD_X$. It executes the complete split transaction using the transaction state of $siTD_X$. If the $siTD_X$ split transaction is complete, siTD's *Active* bit is set to zero, and results written back to $siTD_X$. The host controller retains the fact that $siTD_X$ is retired and transitions the *SplitXState* in the $siTD_{X+1}$ to Do Start Split. At this point, the host controller is prepared to execute the start-split for $siTD_{X+1}$ when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section Periodic isochronous - do complete split), that is, before all the scheduled complete-splits have been executed, the host controller will transition $siTD_X$.*SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, $siTD_{X+1}$ does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame X+2,* micro-frame 0, the host controller detects that $siTD_{X+2}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of $siTD_{X+2}$, and traverses its next pointer without any state change updates to $siTD_{X+2}$. S

During *H-Frame X+2*, micro-frame 1, the host controller detects $siTD_{X+2}$'s *S-mask[0]* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of $siTD_{X+2}$ and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for $siTD_{X+2}$ when it reaches micro-frame 4.

56.3.2.1.13 Host controller pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports. When the schedules are enabled, the EHCI HC will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create Arm platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the Arm platform, based on recent history usage. In the more aggressive power saving modes, the Arm platform can disable its caches. Current PC architectures assume that bus-controller accesses to main memory must be cache-coherent. So, when bus controllers are busy touching memory, the Arm platform power management software can detect this activity over time and inhibit the transition of the Arm platform into its lowest power savings mode. USB controllers are bus controllers and the frequency at which they access their memory-based schedules keeps the Arm platform power management software from placing the Arm platform into its lowest power savings state.

USB Host controllers do not access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend will not work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the Arm platform power management to get the Arm platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the Arm platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the Arm platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

56.3.2.1.14 Port test modes - host operational model

EHCI HCs must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SE0_NAK as described in the USB Specification Revision 2.0. The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB_n_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB_n_PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI HC implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCReset* to a one.

56.3.2.1.15 Interrupts-host operational model

The EHCI HC hardware provides interrupt capability based on a number of sources. There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, and so on), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section Host system error details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, Arm platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to reads the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register from a one to a zero.

56.3.2.1.15.1 Transfer/transaction based interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

56.3.2.1.15.1.1 Transaction error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully. The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set, and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 849. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1[1]
Timeout	-1	XactErr set to a one.	1[1]
Bad PID[2]	-1	XactErr set to a one.	1[1]
Babble	N/A	Section Serial bus babble	1
Buffer Error	N/A	Section Data buffer error	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see Halting a queue head .
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

56.3.2.1.15.1.2 Serial bus babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*. When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see Halting a queue head). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB_n_USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or the opposite way). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk, or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

56.3.2.1.15.1.3 Data buffer error

This event indicates that an overrun of incoming data or an underrun of outgoing data has occurred for this transaction. This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD, or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

56.3.2.1.15.1.4 USB interrupt (Interrupt on completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB_n_USBSTS register to be set to a one. In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB_n_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB_n_USBSTS register is also set to a one.

56.3.2.1.15.1.5 Short packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk, or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB_n_USBSTS register is set to a one. If the *USB Interrupt Enable* bit is set in the USB_n_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

56.3.2.1.15.2 Host controller event interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section Interrupt on async advance).

56.3.2.1.15.2.1 Port change events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one. If the *Port Change Interrupt Enable* bit in the USB_n_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

56.3.2.1.15.2.2 Frame list rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs. If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, and so on. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

56.3.2.1.15.2.3 Interrupt on async advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register. If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupton Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section Removing queue heads from asynchronous schedule .

56.3.2.1.15.2.4 Host system error

The host controller is a bus controller and any interaction between the host controller and the system may experience errors. The type of host error may be catastrophic to the host controller (such as a Controller Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

Table 850. Summary Behavior of EHCI HC on host system errors

Cycle Type	Controller Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a *Host System Error*, Software must reset the host controller through *HCReset* in the USB.USBCMD register before re-initializing and restarting the host controller.

56.3.2.2 EHCI deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com. Device operation and On-The-Go operation is not specified in the EHCI and therefore the implementation supported in this core is proprietary. The Host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in Host mode without the need for a companion controller.
- Device operation - In Host mode, the device operational registers are generally disabled and thus device mode is mostly transparent when in Host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

56.3.2.2.1 Embedded transaction translator function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator. Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

56.3.2.2.1.1 Capability registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

56.3.2.2.1.2 Operational registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the PORTSC1 register.

56.3.2.2.1.3 Discovery-EHCI deviation

In a standard EHCI controller design, the EHCI HC driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation. The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result, and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI HC driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

Table 851. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from an HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from an HS hub or directly attached. When the FS/LS device is downstream from an HS hub, then port-level control is done using the Hub Class through

Table continues on the next page...

Table 851. Summary of EHCI (continued)

	the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from an HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (that is, Split target hub)]	FS and LS device can be either downstream from an HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (that is, Split target hub is the root hub)]

56.3.2.2.1.4 Data structures

The same data structures used for FS/LS transactions though an HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator. Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
   - Hub Address = 0
   - Transactions to direct attached device/hub.
     - QH.EPS = Port Speed
   - Transactions to a device downstream from direct attached FS hub.
     - QH.EPS = Downstream Device Speed

     NOTE

     When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

     Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.
2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
   - All FS ISO transactions:
     - Hub Address = 0
     - siTD.EPS = 00 (full speed)
       - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

56.3.2.2.1.5 Operational model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller, there is no physical bus between EHCI HC driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume that the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

56.3.2.2.1.5.1 Micro-frame pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI HC driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer cannot babble through the SOF (start of B-frame 0.)

56.3.2.2.1.5.2 Split state machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator. Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 852. Summary of the Conditions of Handshakes[1]

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

56.3.2.2.1.5.3 Asynchronous transaction scheduling and buffer management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- Transaction tracking for 2 data pipes.

56.3.2.2.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

56.3.2.2.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

56.3.2.2.1.5.4 Periodic transaction scheduling and buffer management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Abort of pending start-splits

  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames
- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

56.3.2.2.1.5.4.1 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames

56.3.2.2.1.5.4.2 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

56.3.2.2.1.5.5 Multiple transaction translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the HCSPARAMS register.

56.3.2.2.2 Device operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

56.3.2.2.2.1 USBMODE

EHCI HC driver cannot start EHCI host operations until there is USB Device Mode (USBMODE) configuration for host operation. This is because the dual-role controller is not initially in either a host or device mode.

56.3.2.2.2.2 Non-zero fields the register file

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in Device mode. Adhere to the following:

- Write operations to all EHCI reserved fields (some of which are device fields) by writing 0 to the operation registers. You must adhere to this EHCI requirement of the device controller driver (DCD).
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields). This is because Host mode does not define fields that are exclusive to device.

56.3.2.2.2.3 SOF interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for Host mode. EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See USB_nUSBSTS and USB_nUSBINTR registers.

56.3.2.2.3 Embedded design interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

56.3.2.2.3.1 Frame adjust register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 MHz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 MHz transceiver clock for 16-bit physical interfaces.

56.3.2.2.4 Miscellaneous variations from EHCI

56.3.2.2.4.1 Programmable physical interface behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the USB_nPORTSC1 register providing a capability that is not defined by EHCI.

56.3.2.2.4.2 Discovery

56.3.2.2.4.2.1 Port reset

The port connect methods specified by EHCI require setting the port reset bit in the USB_nPORTSC1 register for a duration of 10 ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.
- Software shall write a '0' to reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI HC driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

56.3.2.2.4.2.2 Port speed detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host

controller supports direct attach of non High-Speed devices. Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

56.3.2.2.4.3 Port test mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

56.3.2.3 Device operational model

The function of the device operation is to transfer a request in the memory image to and from the USB. Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the DCD point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

56.3.2.3.1 Device controller initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs. Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

  NOTE

  Transitioning from Host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
  - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

    NOTE

    All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

  - For information on device queue heads, refer to section Device data structures.
- Configure USB.ENDPOINTLISTADDR Pointer.
  - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
  - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
  - For a list of available interrupts refer to the USB_nUSBINTR and the USB_nUSBSTS register tables.
- Set Run/Stop bit to Run Mode.
  - After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

56.3.2.3.2 Port state and control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'. After receiving a reset on the bus, the port will enter the *defaultFS or defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0. The following state diagram depicts the state of a USB 2.0 device.

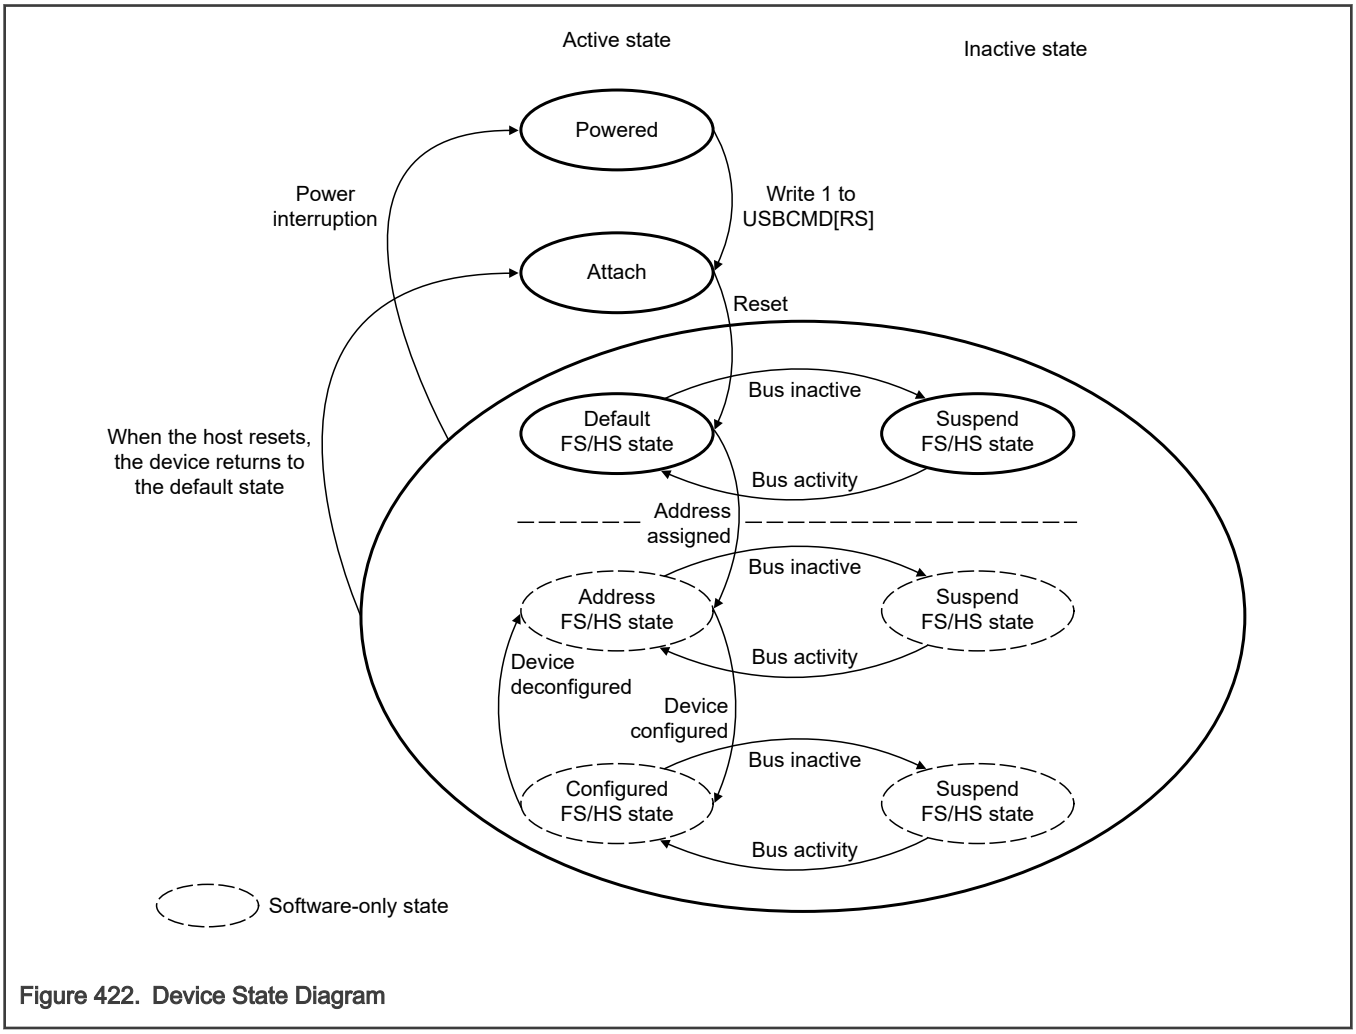

Figure 422. Device State Diagram

States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

Table 853. Device Controller State Information Bits

Bit	Register
DCSuspend	USBSTS

Table continues on the next page...

Table 853. Device Controller State Information Bits (continued)

USB Reset Received	USBSTS
Port Change Detect	USBSTS
High-Speed Port	PORTSC1

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB_UOG_ENDPTCTRLx registers and initializing the associated queue heads.

56.3.2.3.2.1 Bus reset

A bus reset is used by the host to initialize downstream devices. When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled, and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the USB_nENDPTSTAT register and writing the same value back to the USB_nENDPTSTAT register.

Clear all the endpoint complete status bits by reading the USB_nPTCOMPLETE register and writing the same value back to the USB_nENDPTCOMPLETE register.

Cancel all primed status by waiting until all bits in the USB_nENDPTPRIME are 0 and then writing 0xFFFFFFFF to USB_nENDPTFLUSH.

Read the reset bit in the USB_nPORTSC1 register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the USB_nPORTSC1 to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device.

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

56.3.2.3.2.2 Suspend/resume

The details of suspend and resume are explained in these sections.

56.3.2.3.2.2.1 Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wake-up. The ability of a device to signal remote wake-up is optional. If the USB device is capable of remote wake-up signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wake-up signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the USB_nPORTSC1 is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

56.3.2.3.2.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port. Resume signaling is sent upstream by writing a '1' to the Resume bit in the USB_nPORTSC1 while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

56.3.2.3.3 Managing endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device. The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk, interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

56.3.2.3.3.1 Endpoint initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB_UOG_ENDPTCTRLx register. Each 32-bit USB_UOG_ENDPTCTRLx is split into an upper and lower half. The lower half of USB_UOG_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB_UOG_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

Table 854. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

56.3.2.3.3.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB_UOG_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB_UOG_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the USB_UOG_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

Table 855. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL

Table continues on the next page...

Table 855. Device Controller Stall Response Matrix (continued)

IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

56.3.2.3.3.3 Data toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe. For more information on data toggle, refer to the USB 2.0 specification.

56.3.2.3.3.3.1 Data toggle reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB_UOG_ENDPTCTRLx register. This should only be necessary when configuring/ initializing an endpoint or returning from a STALL condition.

56.3.2.3.3.3.2 Data toggle inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

56.3.2.3.3.3.3 Priming transmit endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH). After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB_UOG_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section.

56.3.2.3.3.3.4 Priming receive endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller, the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

56.3.2.3.4 Operational model For packet transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification. At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that cannot be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

56.3.2.3.4.1 Interrupt/bulk endpoint operational model

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

N = INT(Number Of Bytes/Max. Packet Length) + 1

With Zero Length Termination (ZLT) = 1

N = MAXINT(Number Of Bytes/Max. Packet Length)

Table 856. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	

Table continues on the next page...

Table 856. Variable Length Transfer Protocol Example (ZLT = 0) (continued)

512	256	3	256	256	0
512	512	2	512	0	

Table 857. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit, and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

56.3.2.3.4.1.1 Interrupt/bulk endpoint bus response matrix

The table below shows the response matrix for Interrupt/Bulk Endpoint Bus.

Table 858. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A

Table continues on the next page...

Table 858. Interrupt/Bulk Endpoint Bus Response Matrix (continued)

In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

56.3.2.3.4.2 Control endpoint operation model

This section details the setup phase, data phase, status phase, and the control endpoint bus response matrix.

56.3.2.3.4.2.1 Setup phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted be an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in USB_nUSBMODE. (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting UBS_nENDSETUPSTAT to determine that a setup packet was received on a particular pipe:
  1. Write 1 to clear corresponding bit UBS_nENDSETUPSTAT.
  2. Write 1 to Setup Tripwire (SUTW) in USB_nUSBCMD register.
  3. Duplicate contents of dQH.SetupBuffer into local software byte array.
  4. Read Setup TripWire (SUTW) in USB_nUSBCMD register. (if set - continue; if cleared - goto 2)
  5. Write 0 to clear Setup Tripwire (SUTW) in USB nUSBCMD register.
  6. Process setup packet using local software byte array copy and execute status/handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

56.3.2.3.4.2.2 Data phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the USB_nENDPTPRIME register is zero and the associated bit in the USB_nENDPTSTAT register is a one. If a prime fails, that is, the USB_nENDPTPRIME bit goes to zero and the USB_nENDPTSTAT bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (USB_nENDPTSTAT) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

56.3.2.3.4.2.3 Status phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase. The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

56.3.2.3.4.2.4 Control endpoint bus response matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

Table 859. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

56.3.2.3.4.3 Isochronous endpoint operational model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes. Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame, it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT

    NOTE

    For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.
- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received**
    - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:

- Packet received is > maximum packet length. [*Buffer Error* bit is set]
- Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]

— Fulfillment Error [*Transaction Error* bit is set]

- # Packets Occurred > 0 AND # Packets Occurred < MULT

— CRC Error [*Transaction Error* bit is set]

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

56.3.2.3.4.3.1 Isochronous pipe synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB_UOG_FRINDEX register) can be used as a marker. To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB_UOG_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

NOTE

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

56.3.2.3.4.3.2 Isochronous endpoint bus response matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

Table 860. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

   NULL Packet = Zero Length Packet

56.3.2.3.5 Managing queue heads

The following figure shows the End Point Queue Head.

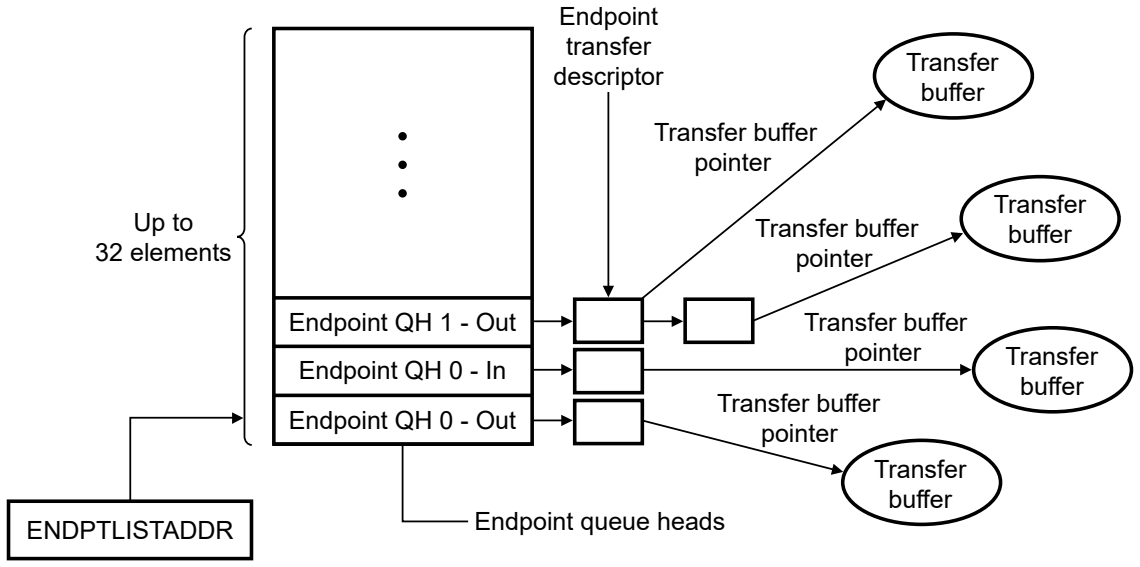

Figure 423. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 423. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section Software link pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational model For packet transfers, the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

56.3.2.3.5.1 Queue head initialization

One device queue head must be initialized for each active endpoint. To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1, 2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate bit field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

56.3.2.3.5.2 Operational model for setup transfers

As discussed in section Control endpoint operation model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
- After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section Flushing/de-priming an endpoint.
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

56.3.2.3.6 Managing transfers with transfer descriptors

These sections detail how to build, execute, and complete transfers with transfer descriptors.

56.3.2.3.6.1 Software link pointers

It is necessary for the DCD software to maintain head and tail pointers for the linked list of dTDs for each respective queue head. This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

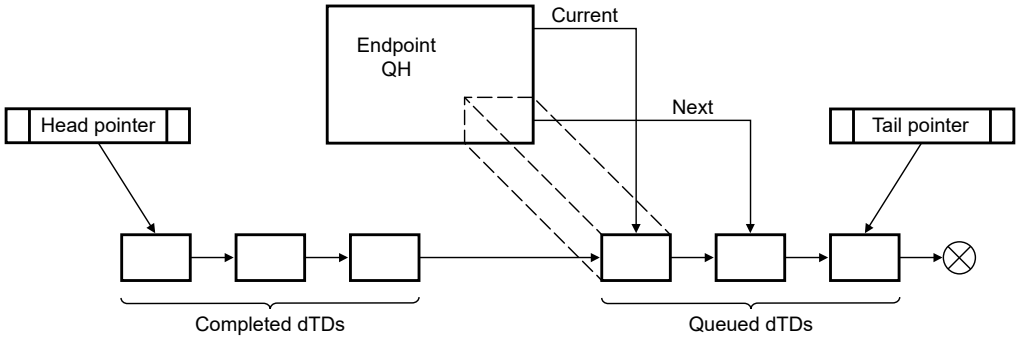

Figure 424. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

56.3.2.3.6.2 Building a transfer descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer. Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

56.3.2.3.6.3 Executing a transfer descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
    1. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
    2. Clear active & halt bit in dQH (in case set from a previous error).
    3. Prime endpoint by writing 1 to correct bit position in ENDPTPRIME. Software should check that the dTD/dQH content in external memory is updated before setting the bit in ENDPTPRIME register.
- Case 2: Link list is not empty
    1. Add dTD to end of linked list.
    2. Read correct prime bit in ENDPTPRIME - if 1 DONE.
    3. Set ATDTW bit in USBCMD register to 1.
    4. Read correct status bit in ENDPTSTAT. (store in tmp. variable for later)
    5. Read ATDTW bit in USBCMD register.
        - If 0 goto 3.
        - If 1 continue to 6.
    6. Write ATDTW bit in USBCMD register to 0.
    7. If status bit read in (3) is 1 DONE.
    8. If status bit read in (3) is 0, then Goto Case 1: Step 1.

56.3.2.3.6.4 Transfer completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0

- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device error matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according to the USB variable length packet protocol.

56.3.2.3.6.5 Flushing/de-priming an endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer. There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in ENDPTFLUSH.
2. Wait until all bits in ENDPTFLUSH are '0'.
   - Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read ENDPTSTAT register to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
   - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using ENDPTFLUSH register. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

56.3.2.3.6.6 Device error matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 861. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

Table 862. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.

Table continues on the next page...

Table 862. Error Descriptions (continued)

Error	Description
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

56.3.2.3.7 Servicing interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

56.3.2.3.7.1 High-frequency interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these are listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 863. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 423 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt[1] - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 423 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

56.3.2.3.7.2 Low-frequency interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 864. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

56.3.2.3.7.3 Error interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrupt events.

Table 865. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

56.3.3 Modes

The USB has two main modes of operation: Normal mode and Low-Power mode. Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

56.3.3.1 Normal mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

NOTE

Each controller supports only the interface type listed below. Selecting a different interface type in the PORTSC_PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port
  - This port supports on-chip UTMI transceiver only.
- OTG2 port
  - This port supports on-chip UTMI transceiver only.

56.3.3.2 Low-power mode

Each USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. Host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in Suspend mode by software.

Either the local Arm platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see Power control.

56.3.3.2.1 Power control

The USB controller supports suspend and wake-up functionality. The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the Arm platform from core sleep mode by generating an interrupt.

56.3.3.2.1.1 Entering low power suspend mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB_USBCMD, and wait until the AS and PS bits in USB_USBSTS become "0."
2. Set the "SUSPEND" bit in USB_PORTSC1
3. Set VBUSVALID_TO_SESSVALID in USBPHYx_USB1_VBUS_DETECT
4. Set the "PHCD" bit in USB_PORTSC1
5. Set all PWD bits in USBPHYx_PWD
6. Set CLKGATE in USBPHYx_CTRL

NOTE

Step 4,5,6 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB_USBSTS)
2. Set VBUSVALID_TO_SESSVALID in USBPHYx_USB1_VBUS_DETECT
3. Set the "PHCD" bit on USB_PORTSC1
4. Set all PWD bits in USBPHYx_PWD
5. Set CLKGATE in USBPHYx_CTRL

NOTE

Step 3,4,5 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

56.3.3.2.1.2 Wake-up events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

The core monitors a number of wake-up conditions, depending on whether it is on Host or Device mode. Upon detection of a wake-up condition, an interrupt will be generated to Arm platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the Arm platform clocks if they were stopped during the suspend.

56.3.3.2.1.2.1 Host mode events

The host controller wakes up on the following events:

- Remote Wake-Up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core during the detection of a J-K transition on DM/DP line.

- Wake-Up On Overcurrent

While enabling Wake-Up On Overcurrent (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core during the detection of an overcurrent.

- Wake-Up On Disconnect

While enabling Wake-Up On Disconnect (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core during the detection of a disconnection event (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

While enabling a Wake-Up On Connect (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core during the detection of the connection event (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, see USB_nPORTSC1.

56.3.4 Interrupts

56.3.4.1 USB core interrupts

Each USB core uses one dedicated vector in the Interrupt Table. In the Interrupt section, you can find the vector numbers for each core.

USB cores control all interrupt sources except wake-up interrupts. Refer to USB_nUSBINTR for details.

56.3.4.2 USB wake-up interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt. These interrupts are generated by the Power Control blocks which run on the 32 kHz standby clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 kHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the Arm platform clock. The software should wait for at least three 32 kHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

56.3.5 Clocking

The following table describes the clock sources for USB. Please see the clock control chapter for clock setting, configuration, and gating information.

Table 866. USB Clocks

Clock	Description
ipg_ahb_clk	AHB bus clock
ipg_clk_s	Peripheral access clock
ipg_clk_s_pl301	PL301 peripheral clock

56.4 External signals

The following table describes the external signals of USB. See the chip-specific information to know the external signals supported by your chip.

Table 867. USB External Signals

Signal	Description
OTGn_DN	DN OTG Signal
OTGn_DP	DP OTG Signal
OTGn_ID	ID signal
OTGn_OC	OTG External input for VBUS overcurrent detection
OTGn_PWR	To control PMIC to supply VBUS voltage

Table continues on the next page...

Table 867. USB External Signals (continued)

Signal	Description
USB2_VBUS	USB 5 V signal
USB2_TXRTUNE	Transmitter resistor tune pin

56.5 Initialization

This section provides the information required to initialize the USB controller properly. For more details on how to enable and disable, see Host controller initialization and Device controller initialization.

56.6 Application information

This section describes the detailed application knowledge for OTG1 and OTG2 ports.

56.6.1 Register interface

There are three categories of configuration, control, and status registers: identification, capability, and operational registers.

NOTE

USB control registers support only DWORD (32-bit) access.

- Use the identification registers that contain the complete set of the hardware configuration parameters to declare the peripheral interface presence.
- Static, read-only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

Complementary nature of host and device control show up by EHCI registers listed alongside device registers.

The following table describes the Interface register sets.

Table 868. Interface register sets

Offset	Register Set	Explanation
000h-07Ch	Identification registers	Use the identification registers that include a table of the hardware configuration parameters to declare the peripheral interface presence.
100h-124h	Capability registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. Use these values as parameters to the host or DCD.
080h-0FCh 140h-1FCh	Operational registers	System software uses operational registers to control and monitor the operational state of the host/device controller.

56.6.1.1 Configuration, control, and status register set

The following table describes the Device/Host capability registers.

NOTE

Depending on implementation, "*x*" can have the following values: UOG1, UOG2.

Table 869. Device/Host Capability Registers

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_*x*_ID	Identification Register	O	O
004h	4	USB_*x*_HWGENERAL	General Hardware Parameters	O	O
008h	4	USB_*x*_HWHOST	Host Hardware Parameters	X	O
00Ch	4	USB_*x*_HWDEVICE	Device Hardware Parameters	O	X
010h	4	USB_*x*_HWTXBUF	TX Buffer Hardware Parameters	O	O
014h	4	USB_*x*_HWRXBUF	RX Buffer Hardware Parameters	O	O
018-07Fh		-	Reserved		
080h	4	USB_*x*_GPTIMER0LD	General Purpose Timer #0 Load Register	O	O
084h	4	USB_*x*_GPTIMER0CTRL	General Purpose Timer #0 Control Register	O	O
088h	4	USB_*x*_GPTIMER1LD	General Purpose Timer #1 Load Register	O	O
08Ch	4	USB_*x*_GPTIMER1CTRL	General Purpose Timer #1 Control Register	O	O
090h	4	USB_*x*_SBUSCFG	System Bus Interface Configuration Register	O	O
094-09Fh		-	Reserved		
100h	1	USB_*x*_CAPLENGTH	Capability Register Length	O	O
101h		-	Reserved		
102h	2	USB_*x*_HCIVERSION	Host Controller Interface Version Number	X	O
104h	4	USB_*x*_HCSPARAMS	Host Controller Structural Parameters	X	O
108h	4	USB_*x*_HCCPARAMS	Host Controller Capability Parameters	X	O
10C-11Fh		-	Reserved		
120h	2	USB_*x*_DCIVERSION	Device Controller Interface Version Number	O	X
122h	2	-	Reserved		
124h	4	USB_*x*_DCCPARAMS	Device Controller Capability Parameters	O	X
128-13Fh		-	Reserved		
140h	4	USB_*x*_USBCMD	USB Command Register	O	O

Table continues on the next page...

Table 869. Device/Host Capability Registers (continued)

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
144h	4	USB_*x*_USBSTS	USB Status Register	O	O
148h	4	USB_*x*_USBINTR	USB Interrupt Enable Register	O	O
14Ch	4	USB_*x*_FRINDEX	USB Frame Index	O	O
150h	4	-	Reserved		
154h	4	USB_*x*_PERIODICLISTBASE	Frame List Base Address	X	O
		USB_*x*_DEVICEADDR	USB Device Address	O	X
158h	4	USB_*x*_ASYNCLISTADDR	Next Asynchronous List Address	X	O
	4	USB_*x*_ENDPOINTLISTADDR	Address at Endpoint list in memory	O	X
15Ch	4	-	Reserved		
160h	4	USB_*x*_BURSTSIZE	Programmable Burst Size	O	O
164h	4	USB_*x*_TXFILLTUNING	Host Transmit Pre-Buffer Packet Tuning	X	O
168h	4	-	Reserved		
170h	4	-	Reserved		
178h	4	USB_*x*_ENDPTNAK	Endpoint NAK register	O	X
17Ch	4	USB_*x*_ENDPTNAKEN	Endpoint NAK Enable register	O	X
180h	4	USB_*x*_CONFIGFLAG	Configured Flag Register	X	O
184h	4	USB_*x*_PORTSC1	Port Status/Control Register 1	O	O

Table 869. Device/Host Capability Registers (continued)

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
1B8h	4	USB_*x*_ENDPTSTATUS	Endpoint Status	O	X
1BCh	4	USB_*x*_ENDPTCOMPLETE	Endpoint Complete	O	X
1C0 1C4 ... 1DCh	64	USB_*x*_ENDPTCTRL0 USB_*x*_ENDPTCTRL1 .... USB_*x*_ENDPTCTRL7	Endpoint Control Register 0-7	O	X

NOTE

"O" means the register is available in host/device operation mode.

"X" means the register is reserved in host/device operation mode.

56.6.1.2 Identification registers

Identification registers are used to declare the target interface presence and include a table of the hardware configuration parameters.

56.6.1.3 OTG operations

56.6.1.3.1 Register bits

Register interface has behavior descriptions for Device mode and Host mode. However, for OTG operations, it is necessary to perform tasks independent of the Controller mode.

NOTE

The only way to transit the controller mode out of host or device mode is with the controller reset bit. Therefore, it is also necessary for the OTG tasks to be performed independent of a controller reset as well as independent of the controller mode.

The following figure shows the controller mode.

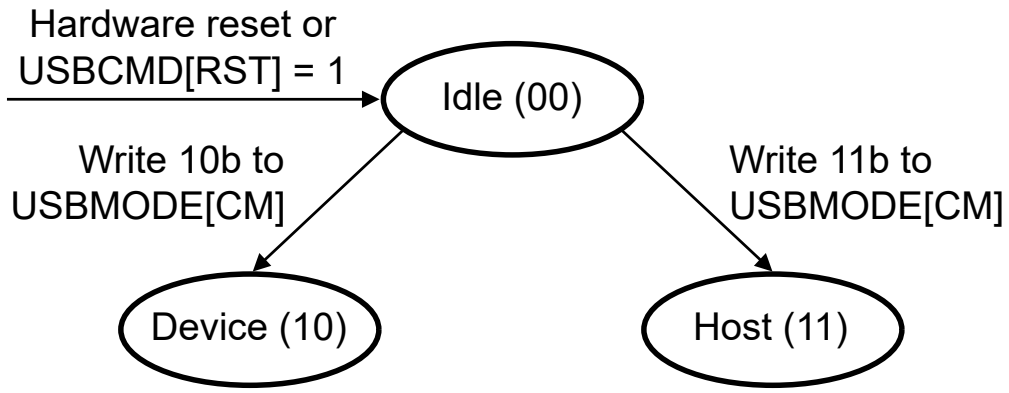

Figure 425. Controller Mode

To this end, listed below are the register bits that are used for OTG operations, which are independent of the controller mode and are also not affected by a write to the reset bit in the USBCMD register:

All Identification Registers

All Device/Host Capability Registers

OTGSC: All bits

PORTSC1:

- Physical Interface Select
- Physical Interface Serial Select
- Physical Interface Data Width
- Physical Interface Low Power
- Physical Interface Wake Signals
- Port Indicators
- Port Power

56.6.2 Host data structures

This section defines the interface data structures used to communicate control, status, and data between Host Controller Driver (HCD) (software) and the Enhanced Host Controller (hardware). The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) transfers for the host controller. The asynchronous list is the root for all the bulk and control transfers. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI HC spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

56.6.2.1 Periodic frame list

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the PERIODICLISTBASE address register and the FRINDEX register. The periodic schedule is based on an array of pointers called the Periodic Frame List. The PERIODICLISTBASE address register is combined with the FRINDEX register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding (1 msec) window of work over time.

The following figure shows the organization of periodic schedule.

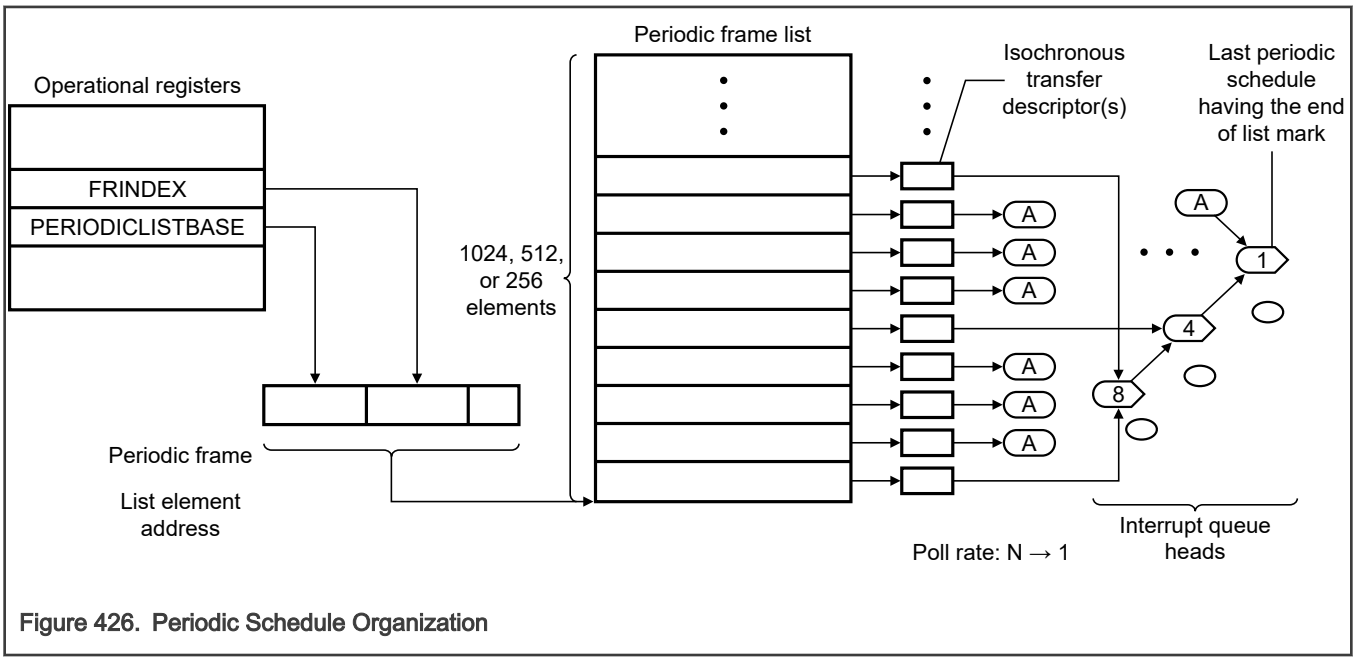

Figure 426. Periodic Schedule Organization

Split transaction Interrupt, Bulk, and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 8, 16, 32, 64, 128, 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the Frame list element pointer.

Table 870. Format of Frame List Element Pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Frame List Link Pointer																											0		Typ			03-00 H

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

Table 871. Typ Field Value Definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.
