43.8.2.2 TRDC Register (TRDC_CR)

Offset

Register	Offset
TRDC_CR	0h

Function

This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	LK1	0										0			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	GVLDR	GVLDB	0						0				HRL			GVLDM
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Fields

Field	Function
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0b - The CR can be written by any secure privileged write. 1b - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MRCs are disabled. 1b - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MBCs are disabled. 1b - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC’s hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC DACs are disabled. 1b - TRDC DACs are enabled.

43.8.2.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

Offset

Register	Offset
TRDC_HWCFG0	F0h

Function

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus masters along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: f TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	1	1	0	0	0	0	1	0	0	0	0

Fields

Field	Function
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus masters This read-only field defines the number of bus masters.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

43.8.2.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

Offset

Register	Offset
TRDC_HWCFG1	F4h

Function

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus master.

43.8.2.5 TRDC Hardware Configuration Register 2 (TRDC_HWCFG2)

Offset

Register	Offset
TRDC_HWCFG2	F8h

Function

This register contains information on the TRDC's hardware configuration. It provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus master. The HWCFG2 register is associated with bus masters [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Function
31-0 PIDPn	Process identifier present Process identifier present from bus master n, where n = [31-0]. This field provides a bitmap to signal that bus master (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus master n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus master n sources a process identifier register.

43.8.2.6 TRDC Hardware Configuration Register 3 (TRDC_HWCFG3)

Offset

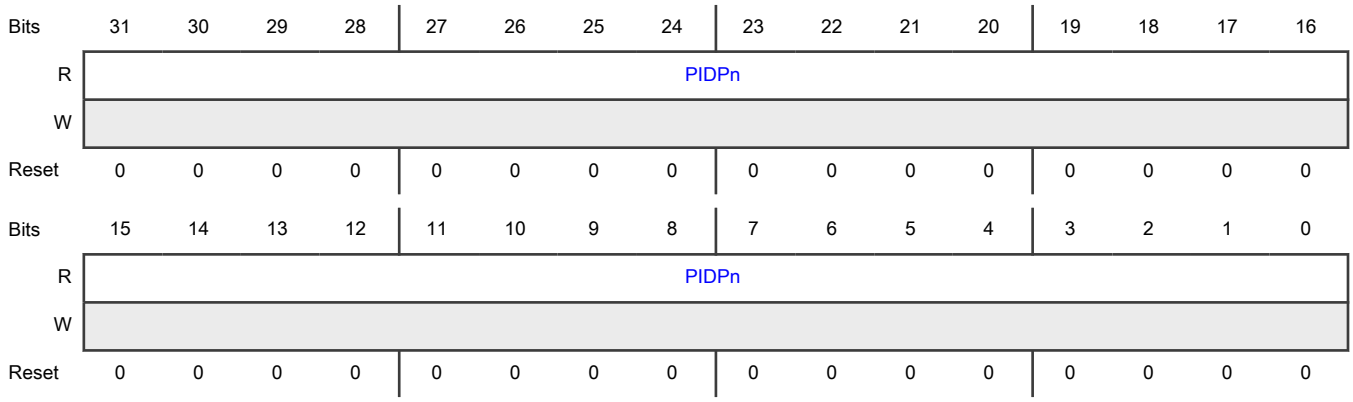
Register	Offset
TRDC_HWCFG3	FCh

Function

This register contains information on the TRDC's hardware configuration. Specifically, it provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus master. The HWCFG3 register is associated with bus masters [63-32], while the HWCFG2 register covers bus masters [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 PIDPn	Process identifier present Process identifier present from bus master n, where n = [63-32]. This field provides a bitmap to signal that bus master n (where n is defined as 32 + bit number) sources a process identifier register to the TRDC_DAC logic. Process identifier present from bus master n, where n = [31-0]. This field provides a bitmap to signal that bus master (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus master n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus master n sources a process identifier register.

43.8.2.7 Domain Assignment Configuration Register (DACFG0 - DACFG5)

Offset

Register	Offset
DACFG0	100h
DACFG1	101h
DACFG2	102h
DACFG3	103h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
DACFG4	104h
DACFG5	105h

Function

This register defines the number of implemented domain assignment registers for bus master m, where m+1 can specify from 1 to 64 bus masters. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus master. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a master doesn't exist but it is in the same 32-bit group as DACFG for an existing master. For example, when there are only 2 DACFG0-1 registers for 2 master, and masters for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus masters have one or more domain assignment registers, while non-processor masters have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	7	6	5	4	3	2	1	0

Register reset values

Register	Reset value
DACFG0	02h
DACFG1	03h
DACFG2–DACFG4	81h
DACFG5	07h

Fields

Field	Function
7 NCM	Non-CPU Master This read-only field signals that bus master m is a non-CPU master. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus master. 0b - Bus master is a processor. 1b - Bus master is a non-processor.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6-4 —	Reserved
3-0 NMDAR	Number of master domain assignment registers for bus master m This read-only field specifies the number of registers associated with the master domain assignment register for a given bus master. The value is limited to the range [0-8], where zero indicates a non-existent bus master and non-zero values indicate the number of implemented registers associated with this MDAm.

43.8.2.8 TRDC IDAU Control Register (TRDC_IDAU_CR)

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

Function

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

43.8.2.9 TRDC FLW Control (TRDC_FLW_CTL)

Offset

Register	Offset
TRDC_FLW_CTL	1E0h

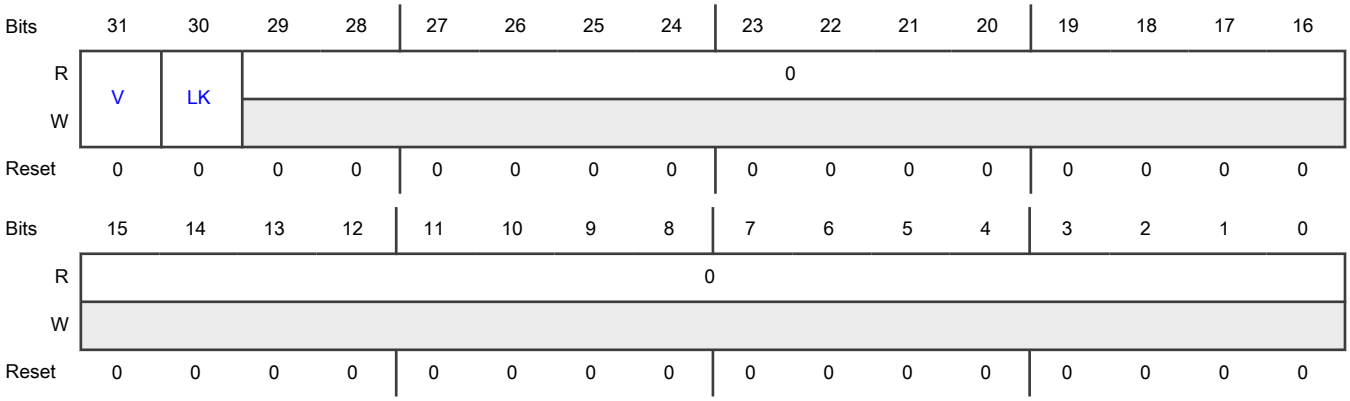
Function

This register provides control of the FLW = Flash Logical Window operation.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31 V	Valid bit 0b - FLW function is disabled. 1b - FLW function is enabled.
30 LK	Lock bit 0b - FLW registers may be modified. 1b - FLW registers are locked until the next reset.
29-0 —	Reserved

43.8.2.10 TRDC FLW Physical Base (TRDC_FLW_PBASE)

Offset

Register	Offset
TRDC_FLW_PBASE	1E4h

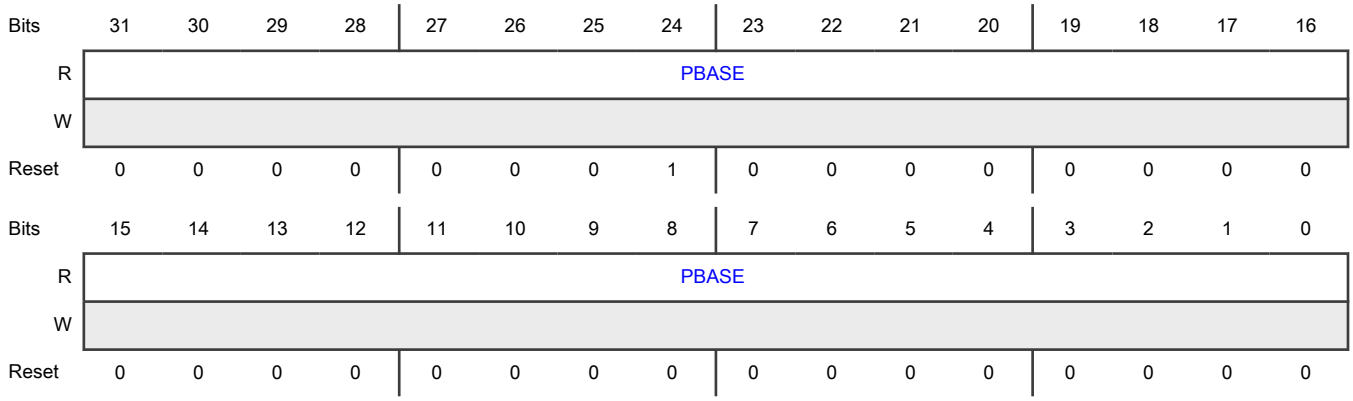
Function

This read-only register gives the physical base address of the Flash Logical Window.

This register exists for this device but has not effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 PBASE	Physical base address Physical address of the base of the FLW (mod 32KBytes).

43.8.2.11 TRDC FLW Array Base (TRDC_FLW_ABASE)

Offset

Register	Offset
TRDC_FLW_ABASE	1E8h

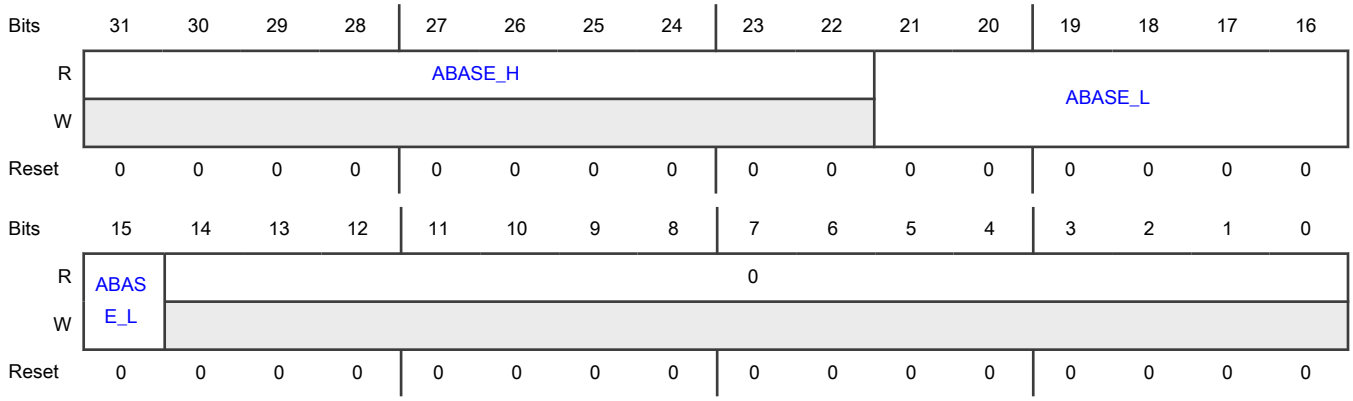
Function

This register gives the flash array base address of the Flash Logical Window.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Diagram



Fields

Field	Function
31-22 ABASE_H	Array base address high Flash array address upper bits of the base of the FLW (mod 32KBytes).
21-15 ABASE_L	Array base address low Flash array address lower bits of the base of the FLW (mod 32KBytes).
14-0 —	Reserved

43.8.2.12 TRDC FLW Block Count (TRDC_FLW_BCNT)

Offset

Register	Offset
TRDC_FLW_BCNT	1ECh

Function

This register gives the size of the Flash Logic Window in 32KByte blocks.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Fields

Field	Function
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

43.8.2.14 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Function

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Function
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

43.8.2.15 MBC Domain Error Word0 Register (MBC0_DERR_W0 - MBC1_DERR_W0)

Offset

Register	Offset
MBC0_DERR_W0	400h
MBC1_DERR_W0	410h

Function

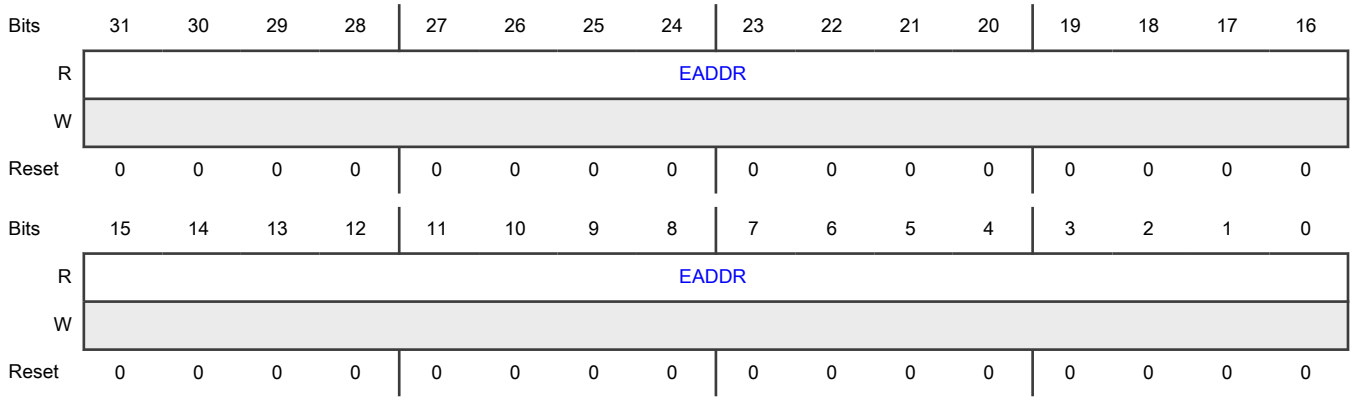
This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 EADDR	Error address This is the unaliased virtual address of the access that generated the access violation.

43.8.2.16 MBC Domain Error Word1 Register (MBC0_DERR_W1 - MBC1_DERR_W1)

Offset

Register	Offset
MBC0_DERR_W1	404h
MBC1_DERR_W1	414h

Function

This read-only register array provides the attributes of an access violation detected by Memory Block Checker (MBC). These registers are organized as a word array, which is indexed by the violating submodule instance number. Refer to register Domain Error Location(DERRLOCd), Domain Error Word0 Register(DERR_W0_i), and Domain error capture management for more information.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Fields

Field	Function
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00b - No access violation has been detected. 01b - No access violation has been detected. 10b - A single access violation has been detected. 11b - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the MBC slave that has the violation. 000b - mbcxslv0 001b - mbcxslv1 010b - mbcxslv2 011b - mbcxslv3
23-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0b - Read access 1b - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000b - Secure user mode, instruction fetch access. 001b - Secure user mode, data access. 010b - Secure privileged mode, instruction fetch access. 011b - Secure privileged mode, data access. 100b - Nonsecure user mode, instruction fetch access. 101b - Nonsecure user mode, data access. 110b - Nonsecure privileged mode, instruction fetch access. 111b - Nonsecure privileged mode, data access.
7-4 —	Reserved
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

43.8.2.17 MBC Domain Error Word3 Register (MBC0_DERR_W3 - MBC1_DERR_W3)

Offset

Register	Offset
MBC0_DERR_W3	40Ch
MBC1_DERR_W3	41Ch

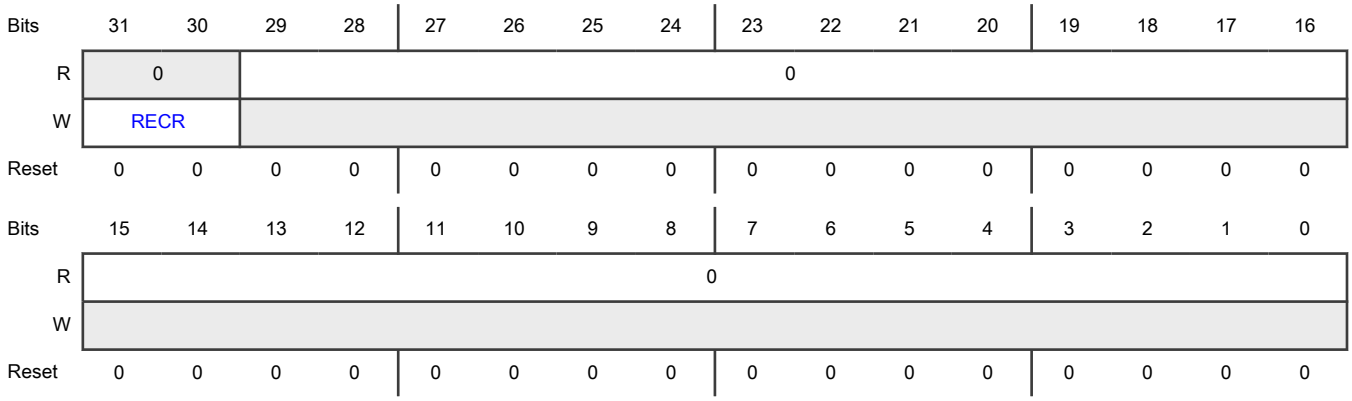
Function

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Diagram



Fields

Field	Function
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

MDA_W6_5_DFMT0	8B8h

Function

The MDA_Wr_m registers provide a 2-dimensional data structure for assigning bus masters to domains. The number of implemented registers is defined by DACFGm[NMDAR]. This per-master domain assignment is then repeated for each bus master (MDAm). Thus, m specifies the master number and r refers to the specific MDA register for a given bus master.

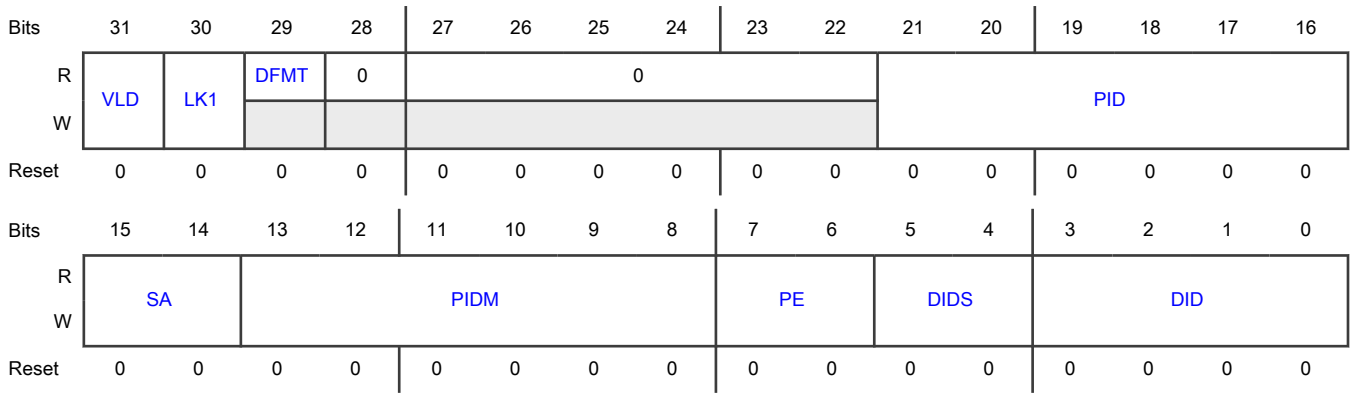
Each Wr within the MDAm structure is a word-sized definition; there are two formats supported, one for processor cores and another for non-processors. Processor masters typically support one or more Wr domain definitions, while non-processor masters support a single Wr. Processor masters Domain Assignment register names use a _DFMT0 suffix. Non-processor masters Domain Assignment register names use a _DFMT1 suffix.

The DAC submodule is responsible for the generation of domain identifiers for every transaction from every bus master. If there is a single Wr for a given master, then the specified domain identifier is used directly. If there are multiple Wr values for a given master, then the DAC evaluates the conditional terms to determine a “hit”. For all Wr hits, their corresponding domain identifiers are simply logically summed together (boolean OR). Use cases are typically expected to *hit in a single Wr* for a processor master. Special care is needed if *none* of the conditional terms hit in any Wr evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

Each MDA_Wr_m register has one of two programming models depending on the state of the domain format field, DFMT. The model described in this section is for DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in Master Domain Assignment (MDA_Wr_m_DFMT1) register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Diagram



Fields

Field	Function
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by CR[GVLDM] = 1. If CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid. 1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROZ 0b - Processor-core domain assignment 1b - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 PID	Process Identifier This field specifies that the process identifier is to be combined with the PIDM field and included in the domain hit determination. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.
15-14 SA	Secure attribute This field defines the secure/nonsecure attribute for processor cores.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The bus master's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the master attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00b - Force the bus attribute for this master to secure. 01b - Force the bus attribute for this master to nonsecure. 10b - Use the bus master's secure/nonsecure attribute directly. 11b - Use the bus master's secure/nonsecure attribute directly.
13-8 PIDM	Process Identifier Mask This field provides a masking capability so that multiple process identifiers can be included as part of the domain hit determination. If a bit in the PIDM is set, then the corresponding bit of the PID is ignored in the comparison. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.
7-6 PE	Process identifier enable Controls the optional inclusion of the PID, qualified by PIDM, into the domain hit evaluation. It provides the ability to include inclusive or exclusive sets of masked PID values. 00b - No process identifier is included in the domain hit evaluation. 01b - No process identifier is included in the domain hit evaluation. 10b - PE = 2. The process identifier is included in the domain hit evaluation as defined by the expression: `partial_domain_hit = (PE == 2) && ((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))` 11b - PE = 3. The process identifier is included in the domain hit evaluation as defined by the expression: `partial_domain_hit = (PE == 3) && ~((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))`
5-4 DIDS	DID Select This field selects the source of the domain identifier. 00b - Use MDAm[3:0] as the domain identifier. 01b - Use the input DID as the domain identifier. 10b - Use MDAm[3:2] concatenated with the low-order 2 bits of the input DID (DID_in[1:0]) as the domain identifier. 11b - Reserved for future use.
3-0	Domain identifier

Table continues on the next page...

Table continued from the previous page...

Field	Function
DID	This 4-bit field is the domain ID attribute that is sent on the accesses from the bus master connected to the DAC when DIDS=00b. DID[3:2] is used when DIDS=10b

43.8.2.22 DAC Master Domain Assignment Register (MDA_W0_2_DFMT1 - MDA_W0_4_DFMT1)

Offset

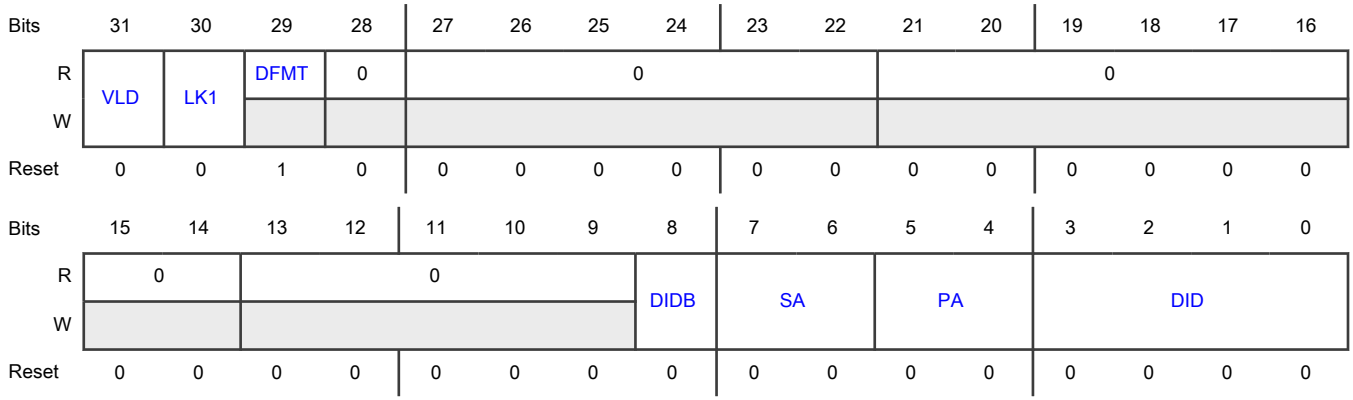
Register	Offset
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h
MDA_W0_4_DFMT1	880h

Function

This register is identical to Master Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus masters.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Diagram



Fields

Field	Function
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by CR[GVLDM] = 1. If CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0b - Processor-core domain assignment 1b - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus master. This capability allows non-processor bus masters, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset.

DAC	DID Input

43.8.2.23 MBC Global Configuration Register (MBC0_MEM0_GLBCFG - MBC1_MEM3_GLBCFG)

Offset

For m = 0 to 1; r = 0 to 3:

Register	Offset
MBCm_MEMr_GLBCFG	1_0000h + (m × 2000h) + (r × 4h)

Function

These MBC global configuration read-only registers contain information on the MBC's hardware configuration. Specifically, it defines the number of memory blocks and the size of each block in each MBC mem (r).

Table continues on the next page...

Table continued from the previous page...

Field	Function
DID_SELn	Destination domain bitmap select. 0b - No effect. 1b - Selects NSE bits for this domain.
15-12 —	Reserved
11-8 MEM_SEL	Memory Select Destination memory bitmap select. • Bit [11] - MBC MEM 3 • Bit [10] - MBC MEM 2 • Bit [9] - MBC MEM 1 • Bit [8] - MBC MEM 0
7-6 —	Reserved
5-2 WNDX	Word index into the block NSE bitmap. It selects the BLK_NSE_Wn register, where WNDX determines the value of n.
1 —	Reserved
0 AI	Auto Increment 0b - No effect. 1b - Add 1 to the WNDX field after the register write.

43.8.2.25 MBC NonSecure Enable Block Set (MBC0_NSE_BLK_SET - MBC1_NSE_BLK_SET)

Offset

Register	Offset
MBC0_NSE_BLK_SET	1_0014h
MBC1_NSE_BLK_SET	1_2014h

Function

A write to this register sets the appropriate NSE Bits for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. If NSE_BLK_INDEX[AI] = 1, then the NSE_BLK_INDEX[WDNX] field is incremented by 1 (modulo-16) after the write is completed. This register reads as zero.

Function

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory slave index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 308. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0
W0	block 7	block 6	block 5	block 4	block 3	block 2	block 1	block 0
W1	block 15	block 14	block 13	block 12	block 11	block 10	block 9	block 8
W2	block 23	block 22	block 21	block 20	block 19	block 18	block 17	block 16
W3	block 31	block 30	block 29	block 28	block 27	block 26	block 25	block 24
W4	block 39	block 38	block 37	block 36	block 35	block 34	block 33	block 32
W5	block 47	block 46	block 45	block 44	block 43	block 42	block 41	block 40

Fields

Field	Function
31 NSE7	NonSecure Enable for block B 0b - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1b - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
30-28 MBACSEL7	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL7 = r and MBC_MEMN_GLBACr[LK] = 1. 000b - select MBC_MEMN_GLBAC0 access control policy for block B 001b - select MBC_MEMN_GLBAC1 access control policy for block B 010b - select MBC_MEMN_GLBAC2 access control policy for block B 011b - select MBC_MEMN_GLBAC3 access control policy for block B 100b - select MBC_MEMN_GLBAC4 access control policy for block B 101b - select MBC_MEMN_GLBAC5 access control policy for block B 110b - select MBC_MEMN_GLBAC6 access control policy for block B 111b - select MBC_MEMN_GLBAC7 access control policy for block B
27 NSE6	NonSecure Enable for block B 0b - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1b - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
26-24 MBACSEL6	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL6 = r and MBC_MEMN_GLBACr[LK] = 1. 000b - select MBC_MEMN_GLBAC0 access control policy for block B 001b - select MBC_MEMN_GLBAC1 access control policy for block B 010b - select MBC_MEMN_GLBAC2 access control policy for block B 011b - select MBC_MEMN_GLBAC3 access control policy for block B

Table continues on the next page...

Function

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory slave index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 309. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64

Table continues on the next page...

Table 309. Block Config Word to Block Number Relationship (continued)

Block NSE Word	BIT31	BIT30-BIT1	BIT0
		. . .	
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

43.8.2.41 MRC Region Descriptor Word 0 (MRC0_DOM0_RGD0_W0 - MRC6_DOM15_RGD15_W0)

Offset

Registers in this array exist only for the following combinations of index values.

Index *m*	Index *d*	Index *r*
0–1	0–15	0–7
2–6	0–15	0–15

Register	Offset
MRCm_DOMd_RGDr_W0	1_4040h + (m × 1000h) + (d × 100h) + (r × 8h)

Function

MRC[m]_DOM[d]_RGD[r]_W[w], where,

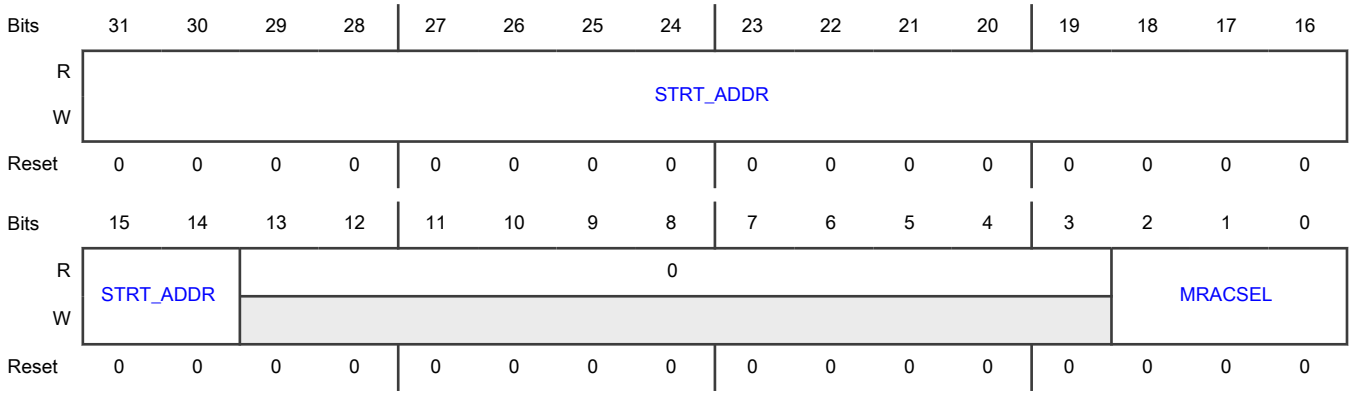
- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_DOM[d]_RGD[r]_W[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 memory region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Diagram



Fields

Field	Function
31-14 STRT_ADDR	Start Address 0-mod-16K physical start address [31:14] of region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.
13-3 —	Reserved
2-0 MRACSEL	Memory Region Access Control Select This field selects the global access control associated with region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1. 000b - Select MRC_GLBAC0 access control policy 001b - Select MRC_GLBAC1 access control policy 010b - Select MRC_GLBAC2 access control policy 011b - Select MRC_GLBAC3 access control policy 100b - Select MRC_GLBAC4 access control policy 101b - Select MRC_GLBAC5 access control policy 110b - Select MRC_GLBAC6 access control policy 111b - Select MRC_GLBAC7 access control policy

43.8.2.42 MRC Region Descriptor Word 1 (MRC0_DOM0_RGD0_W1 - MRC6_DOM15_RGD15_W1)

Offset

Registers in this array exist only for the following combinations of index values.

Index *m*	Index *d*	Index *r*
0–1	0–15	0–7
2–6	0–15	0–15

Register	Offset
MRCm_DOMd_RGDr_W1	1_4044h + (m × 1000h) + (d × 100h) + (r × 8h)

Function

MRC[m]_DOM[d]_RGD[r]_W[w], where,

- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_[d]_rgd[r]_w[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

43.8.2.53 MRC Global Access Control (MRC4_GLBAC1 - MRC4_GLBAC7)

Offset

Register	Offset
MRC4_GLBAC1	1_8024h
MRC4_GLBAC2	1_8028h
MRC4_GLBAC3	1_802Ch
MRC4_GLBAC4	1_8030h
MRC4_GLBAC5	1_8034h
MRC4_GLBAC6	1_8038h
MRC4_GLBAC7	1_803Ch

Function

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, NonsecureUser. The lock bit provides the ability to lock these control access flags, to lock the MRC_BLK_CFG[MRACSEL] field, and to lock the MRC_RGD[STRT_ADDR, END_ADDR, VLD] fields when a locked MRC_GLBAC register is selected.

Diagram

43.8.3.2 TRDC Register (TRDC_CR)

Offset

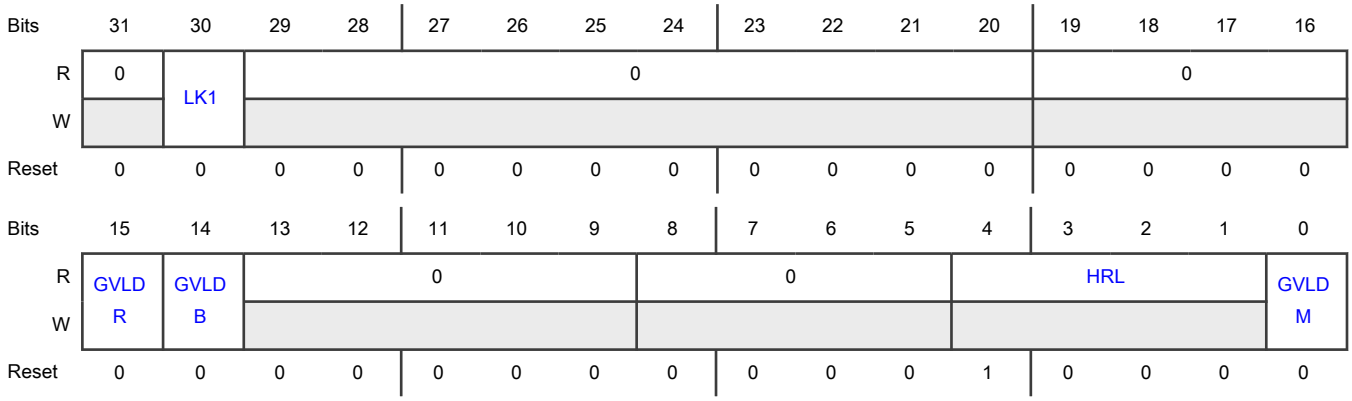
Register	Offset
TRDC_CR	0h

Function

This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0b - The CR can be written by any secure privileged write. 1b - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MRCs are disabled. 1b - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MBCs are disabled. 1b - TRDC MBCs are enabled.
13-9 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC DACs are disabled. 1b - TRDC DACs are enabled.

43.8.3.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

Offset

Register	Offset
TRDC_HWCFG0	F0h

Function

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus masters along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: f TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Reset	0	0	0	0	0	1	0	1	0	0	0	1	0	0	0	0

Fields

Field	Function
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus masters This read-only field defines the number of bus masters.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

43.8.3.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

Offset

Register	Offset
TRDC_HWCFG1	F4h

Function

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus master.

43.8.3.5 TRDC Hardware Configuration Register 2 (TRDC_HWCFG2)

Offset

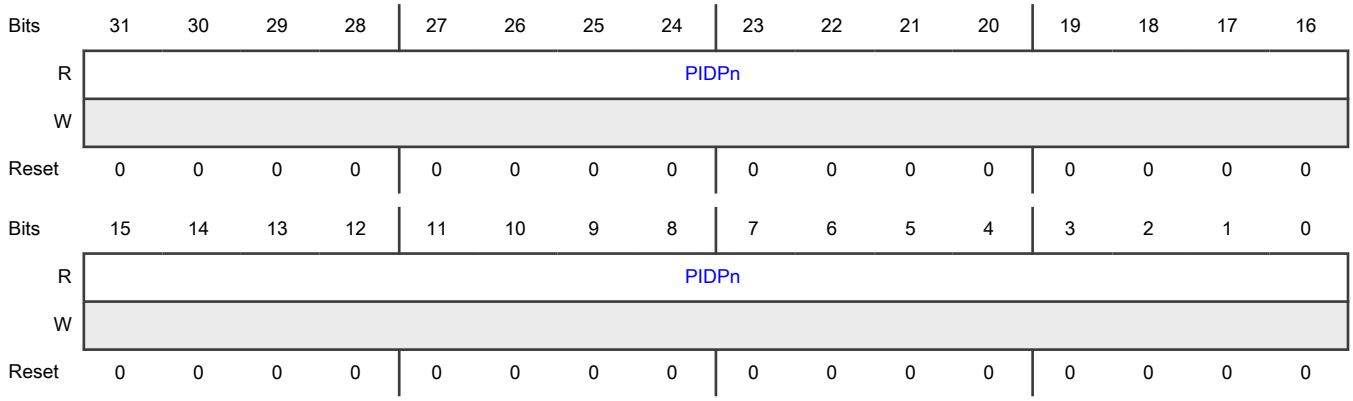
Register	Offset
TRDC_HWCFG2	F8h

Function

This register contains information on the TRDC's hardware configuration. It provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus master. The HWCFG2 register is associated with bus masters [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 PIDPn	Process identifier present Process identifier present from bus master n, where n = [31-0]. This field provides a bitmap to signal that bus master (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus master n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus master n sources a process identifier register.

43.8.3.6 TRDC Hardware Configuration Register 3 (TRDC_HWCFG3)

Offset

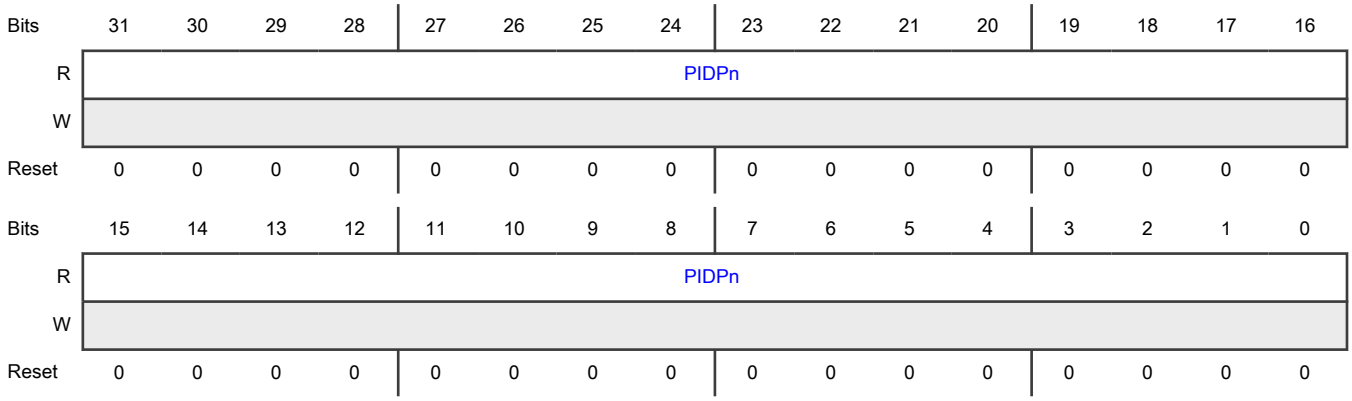
Register	Offset
TRDC_HWCFG3	FCh

Function

This register contains information on the TRDC's hardware configuration. Specifically, it provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus master. The HWCFG3 register is associated with bus masters [63-32], while the HWCFG2 register covers bus masters [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 PIDPn	Process identifier present Process identifier present from bus master n, where n = [63-32]. This field provides a bitmap to signal that bus master n (where n is defined as 32 + bit number) sources a process identifier register to the TRDC_DAC logic. Process identifier present from bus master n, where n = [31-0]. This field provides a bitmap to signal that bus master (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus master n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus master n sources a process identifier register.

43.8.3.7 Domain Assignment Configuration Register (DACFG0 - DACFG4)

Offset

Register	Offset
DACFG0	100h
DACFG1	101h
DACFG2	102h
DACFG3	103h
DACFG4	104h

Function

This register defines the number of implemented domain assignment registers for bus master m, where m+1 can specify from 1 to 64 bus masters. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus master. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a master doesn't exist but it is in the same 32-bit group as DACFG for an existing master. For example, when there are only 2 DACFG0-1 registers for 2 master, and masters for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus masters have one or more domain assignment registers, while non-processor masters have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	1	0	0	0	0	0	0	1

Fields

Field	Function
7 NCM	Non-CPU Master This read-only field signals that bus master m is a non-CPU master. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus master. 0b - Bus master is a processor. 1b - Bus master is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of master domain assignment registers for bus master m This read-only field specifies the number of registers associated with the master domain assignment register for a given bus master. The value is limited to the range [0-8], where zero indicates a non-existent bus master and non-zero values indicate the number of implemented registers associated with this MDAm.

43.8.3.8 TRDC IDAU Control Register (TRDC_IDAU_CR)

Offset

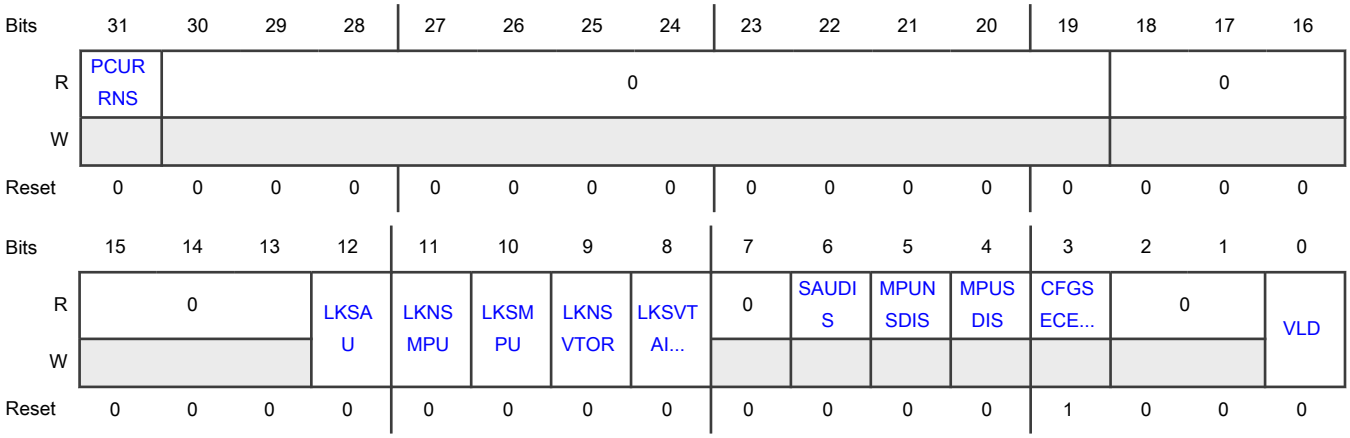
Register	Offset
TRDC_IDAU_CR	1C0h

Function

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31 PCURRNS	Processor current security Current security state of the processor. 0b - Processor is in Secure state 1b - Processor is in Nonsecure state
30-19 —	Reserved
18-16 —	Reserved
15-13 —	Reserved
12 LKSAU	Lock SAU Asserting this bit prevents changes to the processor's Secure SAU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0b - Unlock these registers 1b - Disable writes to the SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers from software or from a debug agent connected to the processor
11 LKNSMPU	Lock Nonsecure MPU Asserting this bit prevents changes to the processor's Nonsecure MPU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0b - Unlock these registers

Table continues on the next page...

43.8.3.9 TRDC FLW Control (TRDC_FLW_CTL)

Offset

Register	Offset
TRDC_FLW_CTL	1E0h

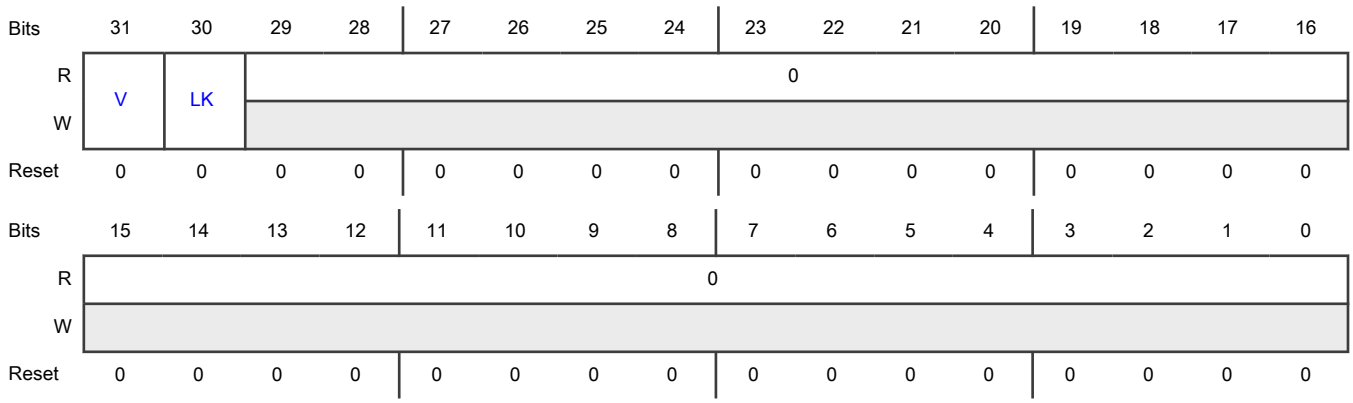
Function

This register provides control of the FLW = Flash Logical Window operation.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31 V	Valid bit 0b - FLW function is disabled. 1b - FLW function is enabled.
30 LK	Lock bit 0b - FLW registers may be modified. 1b - FLW registers are locked until the next reset.
29-0 —	Reserved

43.8.3.10 TRDC FLW Physical Base (TRDC_FLW_PBASE)

Offset

Register	Offset
TRDC_FLW_PBASE	1E4h

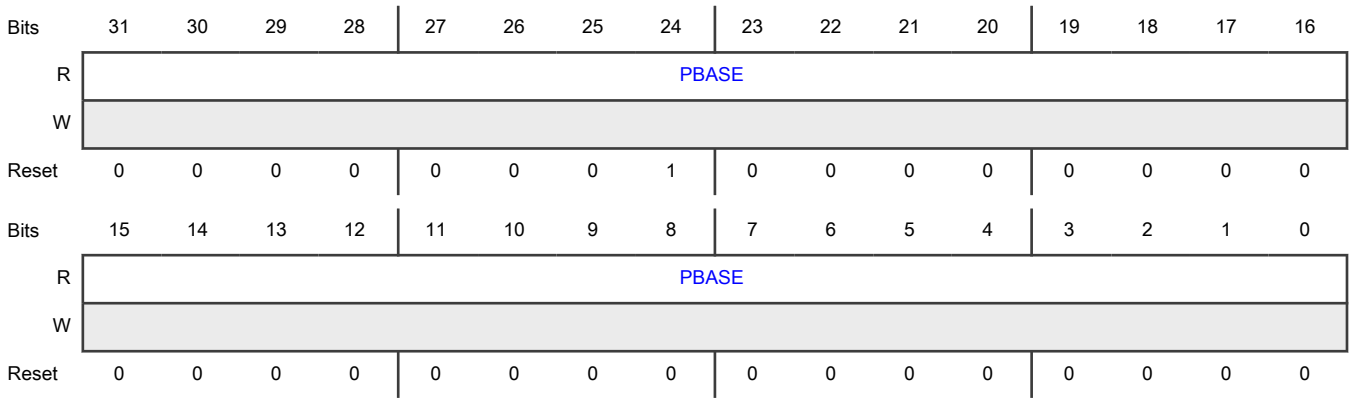
Function

This read-only register gives the physical base address of the Flash Logical Window.

This register exists for this device but has not effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 PBASE	Physical base address Physical address of the base of the FLW (mod 32KBytes).

43.8.3.11 TRDC FLW Array Base (TRDC_FLW_ABASE)

Offset

Register	Offset
TRDC_FLW_ABASE	1E8h

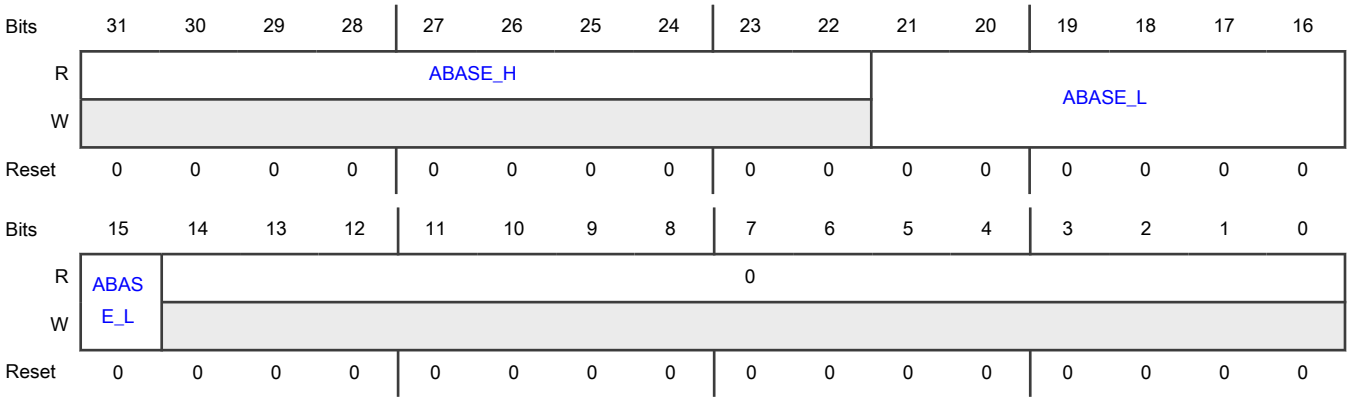
Function

This register gives the flash array base address of the Flash Logical Window.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Diagram



Fields

Field	Function

43.8.3.13 TRDC Fault Domain ID (TRDC_FDID)

Offset

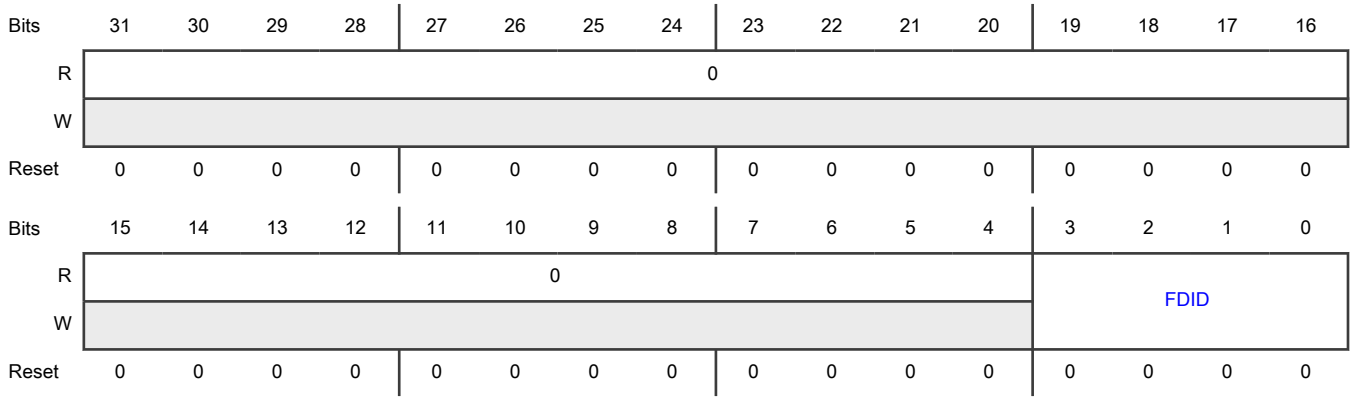
Register	Offset
TRDC_FDID	1FCh

Function

In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

43.8.3.14 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Function

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

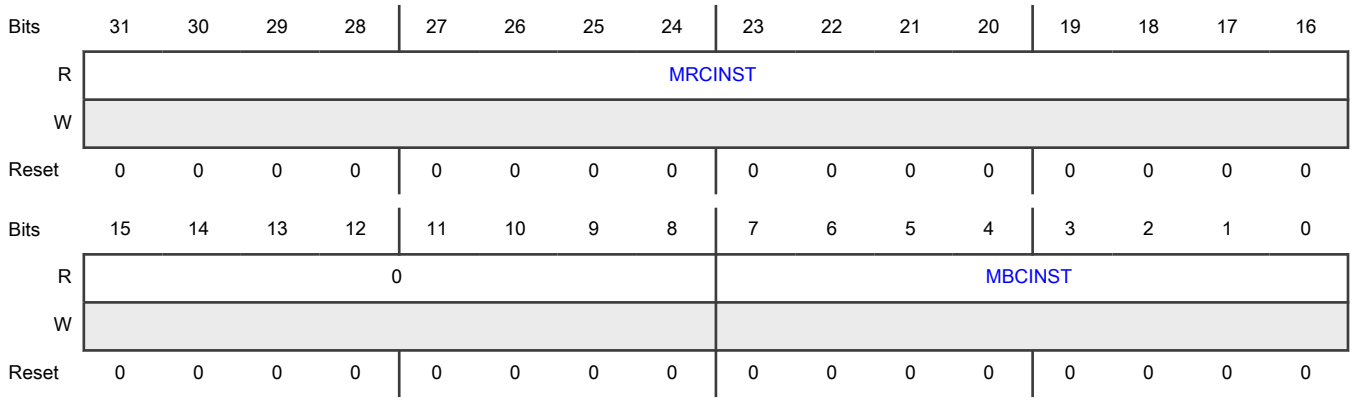
When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of

read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

43.8.3.15 DAC Master Domain Assignment Register (MDA_W0_0_DFMT1 - MDA_W0_4_DFMT1)

Offset

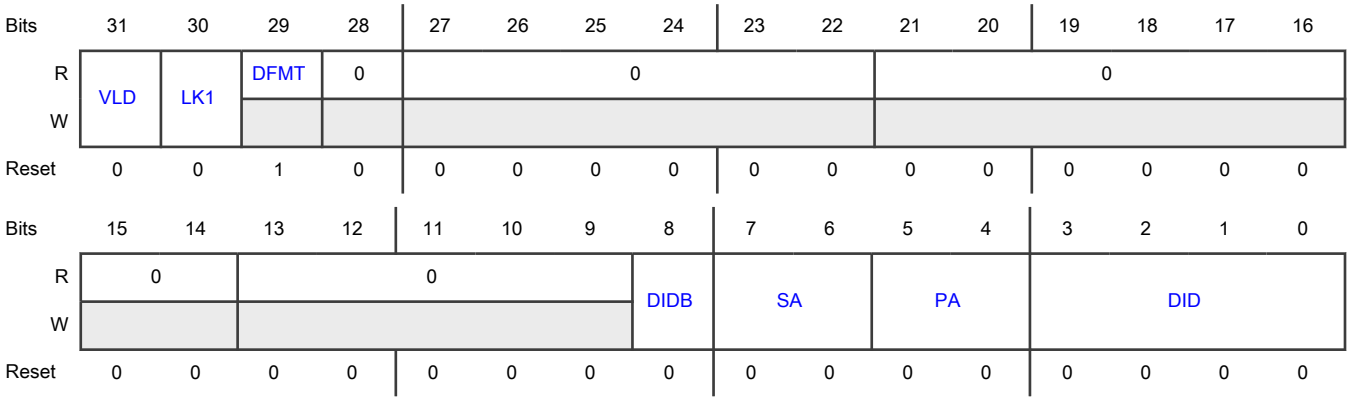
Register	Offset
MDA_W0_0_DFMT1	800h
MDA_W0_1_DFMT1	820h
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h
MDA_W0_4_DFMT1	880h

Function

This register is identical to Master Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus masters.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Diagram



Fields

Field	Function
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by CR[GVLDM] = 1. If CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid. 1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0b - Processor-core domain assignment 1b - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus master. This capability allows non-processor bus masters, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset. **DAC** / **DID Input** 0 / 0 1 / DMA Domain ID 2 / USB Domain ID 0b - Use MDAn[3:0] as the domain identifier.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Use the DID input as the domain identifier.
7-6 SA	Secure attribute This field defines the secure/nonsecure attribute for non-processor cores. **NOTE** The bus master's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the master attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00b - Force the bus attribute for this master to secure. 01b - Force the bus attribute for this master to nonsecure. 10b - Use the bus master's secure/nonsecure attribute directly. 11b - Use the bus master's secure/nonsecure attribute directly.
5-4 PA	Privileged attribute This field defines the privileged/user attribute for non-processor cores. **NOTE** The bus master's input privileged/user attribute is used if PA = 1X, or this VLD = 0. 00b - Force the bus attribute for this master to user. 01b - Force the bus attribute for this master to privileged. 10b - Use the bus master's privileged/user attribute directly. 11b - Use the bus master's privileged/user attribute directly.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus master connected to the DAC when DIDB=0.

1	CM7 Instruction Cache Data Array
2	CM7 Data Cache Tag Array
3	CM7 Data Cache Data Array0
4	CM7 Data Cache Data Array1

44.2 Overview

The Error Injection Module (EIM) is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of internal memories (for example, system RAM, cache RAMs, and peripheral memories). See the chip-specific EIM information to determine which functional safety features are supported by this method.

EIM enables you to induce artificial errors on error-checking mechanisms of a system, such as ECC for RAM read data and parity bits. For each such mechanism that EIM supports on the chip, EIM can inject single-bit and multi-bit inversions on data in the applicable target bus. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

44.2.1 Features

The EIM includes these features:

- Supports 5 error injection channels. See the chip-specific EIM information for channel assignment details.
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

44.2.2 Block diagram

The following diagram shows an example of EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

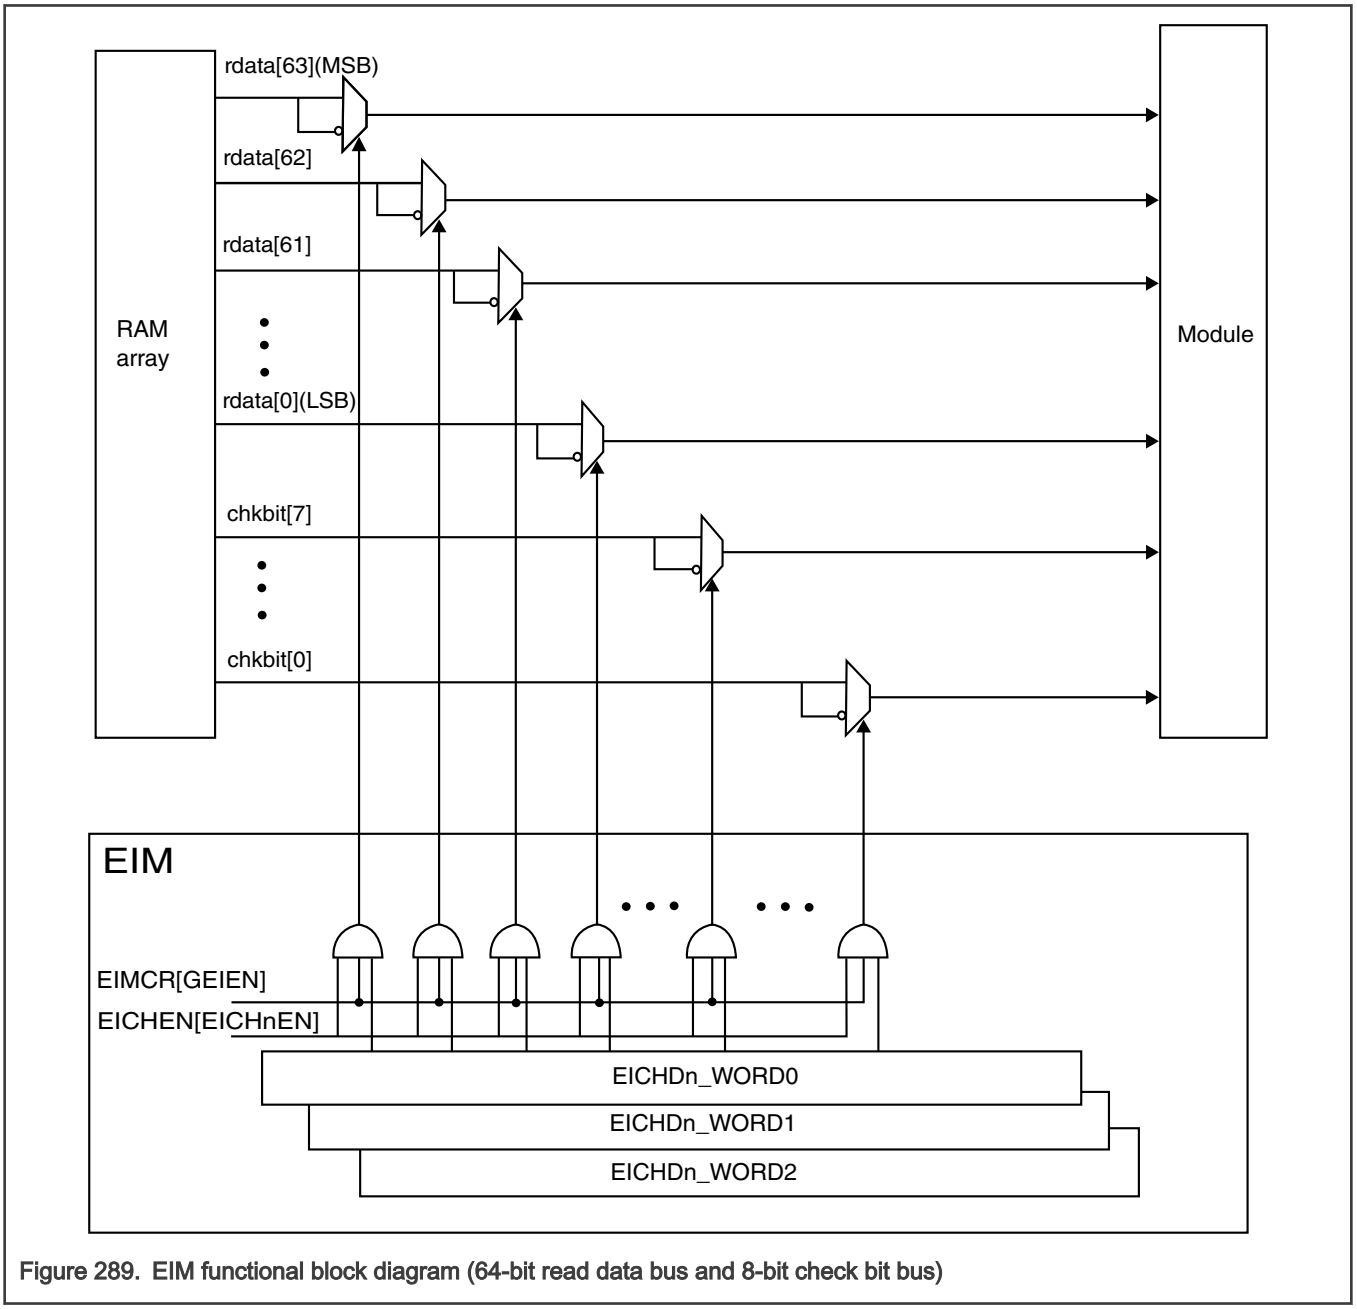

Figure 289. EIM functional block diagram (64-bit read data bus and 8-bit check bit bus)

Several memory elements are implemented within a device, which may not only be the large memory blocks (Flash and SRAM) but also smaller memories like caches, the TCD blocks, and the embedded peripheral memories. Some larger memories may actually be built from multiple memory elements, dependent on their size or function. Each of these memory elements implements its own control logic, the memory controller, that performs the accesses to the actual memory, the memory array. An EIM channel

is associated with a memory controller and provides the capability to alter one or multiple signals in the read access path from the corresponding memory array(s). Only memory controllers controlling a safety related memory may be associated with an EIM channel.

44.3 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.
- Write 1 to EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 5 error injection channels. See the chip-specific EIM information for channel assignment details. Each channel:

- Can be assigned to a single memory array interface by intercepting the assigned memory read data bus and checkbit bus, and injects errors by inverting the value transmitted for selected bits on each bus line.
- Can be assigned to a redundant comparison unit by intercepting the signals being compared, and injecting errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 289 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.

NOTE

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

To enable error injection:

1. Set the EICHD*n*_WORD*m*[CHKBIT_MASK] and EICHD*n*_WORD*m*[B*a*_*b*DATA_MASK] fields for each channel that will be driving an injection.
2. Program the EICHEN register to enable the channels that will be injecting errors.
3. Set the EIMCR[GEIEN] field to globally allow all enabled channels to actively inject errors.

To disable error injection, either disable the EIMCR[GEIEN] field or disable the individual channel enable fields of the EICHEN register.

44.4 Initialization

This module does not require initialization.

44.6 EIM register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 312. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	44	43-32	31-0	—
1	128	127-96	95-64	63-32

44.6.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0)

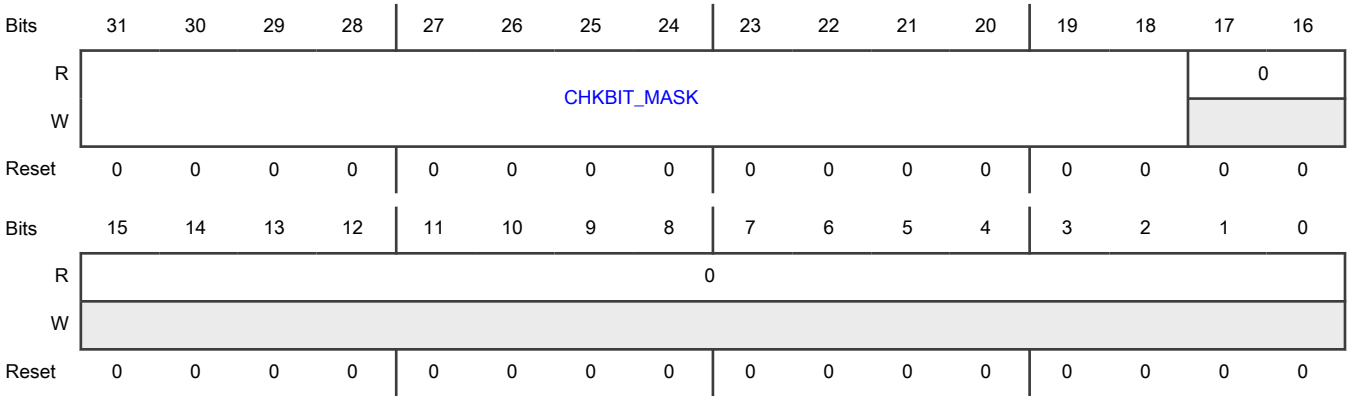
Offset

Register	Offset
EICHD0_WORD0	100h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-18 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[13:0] (14 bits wide), CHKBIT_MASK[13] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.

This device has one instance of the ERM module.

The following table shows the ERM channel assignments and which channel is defined in ERM Configuration Register 0. Unlisted channels are not used.

Table 315. ERM Channel Assignments

Channel	CR0 Bits	Target for Error Report Configuration
0	CR0[31:30]	CM7 Instruction Cache Tag
1	CR0[27:26]	CM7 Instruction Cache Data
2	CR0[23:22]	CM7 Data Cache Tag
3	CR0[19:18]	CM7 Data Cache Data

45.2 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with ECC and parity. The ERM collects error events on memory accesses for memory arrays, such as flash memory, system RAM, or peripheral RAMs. ERM supports various channels for memory sources where each ERM channel is associated with a different memory module. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments. If the memory supports ECC, then ERM syndrome and error address information is captured along with the error event. ERM does not capture syndrome or error address for cache memories or memory with parity instead of ECC.

45.2.1 Features

The ERM includes these features:

- Optional interrupt notification on captured error events
- Support for error event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel
- Recording the count value of the number of corrected error events

45.3 Functional description

45.3.1 Single-bit correction events

When a single-bit correction event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit SR*x*[SBC*n*] to 1.
- Increments the correctable error count value (until the counter reaches its maximum value): CORR_ERR_CNT*n*[COUNT].

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[SBC*n*] to change its value to 0.

To reset the correctable error count value, write all zeros to CORR_ERR_CNT*n*[COUNT].

Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. To enable single-bit correction interrupts for a channel:

1. To enable interrupt notification for single-bit correction events on Memory *n*, set CR*x*[ESCIE*n*] to 1.
2. Subsequently, when a single-bit correction event on Memory *n* is detected, the ERM:
   - Records the event as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[SBC*n*] to change its value to 0.

45.3.2 Non-correctable error events

When a non-correctable ECC error event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit: SR*x*[NCE*n*] to 1.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[NCE*n*] to change its value to 0.

Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. To enable non-correctable error interrupts for a channel:

1. To enable interrupt notifications for non-correctable error events on Memory *n*, set CR*x*[ENCIE*n*] to 1.
2. Subsequently, when a non-correctable error event on Memory *n* is detected, the ERM:
   - Records the event as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[NCE*n*] to change its value to 0.

NOTE

Parity errors can be mapped to non-correctable errors where error attributes like SYNDROME, ADDRESS are not provided.

45.4 Initialization

For each ERM channel supporting memory with ECC, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding SR*x*[SBC*n*] or SR*x*[NCE*n*] field that stores the record of the event.
3. Program the applicable CR*x*[ESCIE*n*] and CR*x*[ENCIE*n*] fields to enable ERM interrupts as desired.

45.5 ERM register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

NOTE

- See the chip-specific ERM information for details on Memory channel mapping.
- To access the channel registers, corresponding memory channel clock must be enabled.

45.5.4 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT3)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h

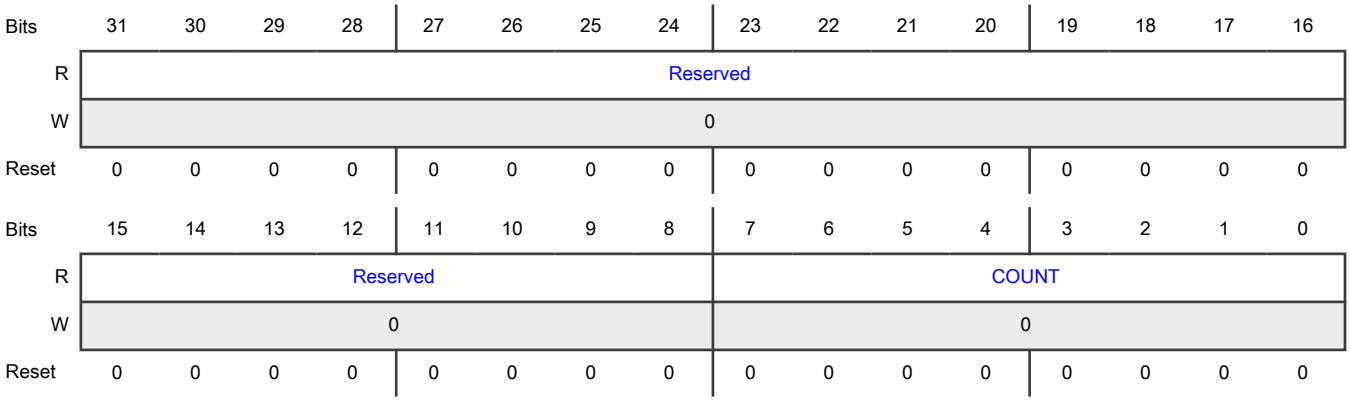
Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory*n*, where*n*denotes the memory channel.

NOTE

Non-correctable errors are considered a serious fault, so the ERM does not provide any mechanism to count non-correctable errors. Only correctable errors are counted.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh.COUNT value will stop when it reaches maximum value FFh and will not wrap even if additional errors occur. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing a non-zero value has no effect.

Chapter 46
Crossbar Switch (AXBS)

46.1 Overview

This section provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

46.1.1 Features

- Symmetric crossbar bus switch implementation
  - Allows concurrent access from different masters to different slaves
  - Slave arbitration attributes configured on a slave-by-slave basis
- Single-clock 32-bit transfer
- Support for burst transfers of 64 bits of data
- Support for low-power park mode
- Master high-priority elevation
- 32-bit AHB crossbar bus switch compatible with ARM's Advanced Microcontroller Bus Architecture (AMBA) Specification v2.0

46.2 Functional description

Information about general operation and arbitration are provided in this section.

46.2.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device does not know whether it owns the slave port it is targeting. The master waits while it does not have control of the slave port it is targeting.

After the master acquires control of the slave port, it controls the port until it relinquishes the port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed-length burst transfer, it retains control of the slave port until that transfer completes.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS*n*[PARK]. This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode to save power, by using CRS*n*[PCTL].

46.2.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

46.2.3 Arbitration

The crossbar switch supports the following arbitration algorithms:

- Round-robin

The arbitration scheme is independently programmable for each slave port.

46.2.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRS*n*). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing access from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port.

Table 316. Methods of how the crossbar switch grants control of a slave port to a master

When	Then the crossbar switch grants control to the requesting master
Both of the following are true: • The current master is not running a transfer. • The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: • The current master is running a fixed-length burst transfer or a locked transfer. • The requesting master's priority level is higher than that of the current master.	At the end of the burst transfer or locked transfer
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: • An IDLE cycle • A non-IDLE cycle to a location other than the current slave port

46.2.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requests the master owns the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is of the ID of the last master.

After a master is granted access to a slave port, a master may perform as many transfers as desired to that port until another master requests the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle, if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume that the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and masters 0, 4, and 5 make simultaneous requests, they are serviced in this order: 4,5, and then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

46.2.3.3 Clocking

This module has no clocking considerations.

46.2.3.4 Interrupts

This module has no interrupts.

46.2.3.5 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

46.3 External signals

This module has no external signals.

46.4 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, the following settings and priorities may be programmed to achieve the maximum system performance:

- During the configuration of the crossbar switch, all other masters must be IDLE.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS*n*[RO].

46.5 Memory map and register definition

Each slave port of the crossbar switch contains configuration registers. Read- and write transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed as read-only to prevent changes to their configuration. After being read-only protected, future writes to them terminate with a data storage error.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular chip, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master and slave assignments for your chip.

All references to the crossbar switch registers are based on the physical port connections.

46.5.1.2 Priority Slave Registers (PRS0 - PRS7)

Offset

Register	Offset
PRS0	0h
PRS1	100h
PRS2	200h
PRS3	300h
PRS4	400h
PRS5	500h
PRS6	600h
PRS7	700h

Function

The priority slave registers(PRS*n*) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit access. After the CRS*n*[RO] bit is set, the PRS*n* register can only be read; attempts to write to it have no effect on PRS*n* and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRS*n* is not updated.

NOTE

Valid values for the M*n* priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains fewer than three masters, only one bit is valid.
- If the chip contains fewer than five masters, only two bits are valid.
- If five or more masters are present, all three bits of the priority field are used.

Chapter 47
Network Interconnect Bus System (NIC-400)

47.1 Overview

This section provides an overview of the NIC-400 (Network Inter-Connect) AXI arbiter IP. The NIC-400 (by Arm Ltd.) is a configurable AXI arbiter between several masters and slaves. The NIC-400 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

This chapter covers in brief the NIC-400 while providing configuration details on the NIC-400 instances used in the chip. For complete details on the NIC-400 design, see the Arm specification, AMBA® Network Interconnect (NIC-400) Technical Reference Manual, version r2p3.

47.1.1 NIC-400 main features

Key features of the NIC-400 module include the following:

- Address space memory mapping.
- Programmer's view, for software-configured parameters, via internal "GPV" ports.
- Support for cross-clock domain synchronization.

It supports Arm CoreLink QoS-400 Network Interconnect Advanced Quality of Service (QoS) to arbitrate and regulate the transactions from various SoC masters.

See the following documentation on Arm website for more details:

- ARM CoreLink QoS-400 Network Interconnect Advanced Quality of Service Supplement to ARM CoreLink NIC-400 Network Interconnect Technical Reference Manual

47.1.2 Modes and operations

The NIC-400 supports a normal functional mode only.

47.2 External signals

There are no external I/O interfaces for NIC-400.

47.3 Module instances

This chip contains two instances of the NIC-400 module: NIC_MAIN and NIC_MEGA.

47.4 Memory map and register definition

For detailed descriptions of these registers, see the Arm document AMBA® Network Interconnect (NIC-400) Technical Reference Manual, version r2p3, and ARM CoreLink QoS-400 Network Interconnect Advanced Quality of Service Supplement to ARM CoreLink NIC-400 Network Interconnect Technical Reference Manual.

47.4.1 NIC_MAIN registers

The NIC_MAIN GPV base address is GPV1_BASE = 0x43900000 (Non-Seure space) or 0x53900000 (Secure space). The following registers are implemented in this NIC:

Table 317. NIC_MAIN registers

Register name	Port name	IP name	Absolute address	Reset value	Notes
fn_mod_ahb	m_a_5	DAP	GPV1_BASE + 0x47000 + 0x028	0	
wr_tidemark	m_a_2	ETR	GPV2_BASE + 0x44000 + 0x040	4	The WFIFO depth is 8.
wr_tidemark	m_a_5	DAP	GPV2_BASE + 0x47000 + 0x040	4	The WFIFO depth is 8.
read_qos	m_a_1	CM7	GPV1_BASE + 0x43000 + 0x100	0	
read_qos	m_a_2	ETR	GPV1_BASE + 0x44000 + 0x100	0	
read_qos	m_a_4	AONMIX	GPV1_BASE + 0x46000 + 0x100	0	
read_qos	m_a_5	DAP	GPV1_BASE + 0x47000 + 0x100	0	
read_qos	m_a_6	eDMA4	GPV1_BASE + 0x48000 + 0x100	0	
read_qos	m_a_7	IEE	GPV1_BASE + 0x49000 + 0x100	0

47.4.3 IB registers

There are no IB registers implemented in this chip.

47.4.4 Address region control registers

There are no registers of this type implemented in this chip.

47.4.5 Peripheral ID registers

The peripheral ID registers are implemented in NIC_MAIN and NIC_MEGA. For more details, see the Arm document AMBA® Network Interconnect (NIC-400) Technical Reference Manual, version r2p3.

Chapter 48
Audio Overview

48.1 Audio Overview

The audio subsystem consists of the following modules: SAI-1, SAI-2, SAI-3, SAI-4, PDM, ASRC, and SPDIF. In addition, the IOMUX must be appropriately configured to get signals in and out of the chip.

Audio Module Overview provides an overview of each of the audio modules, followed by a module-specific section.

48.1.1 Audio Module Overview

SAI*n* are synchronous serial interfaces used to transfer audio data. They can be accessed by both the eDMA and Arm CPUs. Their input/output are connected to the pads through IOMUX.

The PDM Microphone Interface (PDM) is used to receive audio from microphone. It supports 8-channel input with individual enable control for full or partial set of channels.

Asynchronous Sample Rate Converter (ASRC) is used for PCM sample rate conversion from one audio sampling clock domain to another.

The Sony/Philips digital interface (SPDIF) audio module is a stereo transceiver that allows the processor to receive and transmit digital audio over it. The SPDIF receiver section includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency. A recovered clock is provided by the SPDIF receiver section and may be used to drive both internal and external components in the system.

The audio interfaces are summarized as the table below.

Table 319. Audio Interface Summary

Interface	Function	RX Data Line	TX Data Line
SAI-1	External audio	2	2
SAI-2	External audio	1	1
SAI-3	External audio	1	1
SAI-4	External audio	4	4
SPDIF	External audio	1	1
PDM (8 channel)	External microphone		
ASRC	Asynchronous Sample Rate Converter		

SAI-4 is used for multi-channel audio interface, it supports up to 8-channels audio input and 8-channels audio output at 384kHz/32-bit. SAI-1, SAI-2, and SAI-3 is used for stereo audio input and output up to 384KHz/32-bit.

To reduce IO count and keep the flexibilities of supporting multiple RX and TX data lines application, SAI-4 has following options on data pin multiplexing. The multiplexing is done in the IOMUX.

Table 320. SAI-4 TX/RX Data Pin Multiplexing

Options	Number of RX Data Line	Number of TX Data Line
0	1	4
1	2	3

Table continues on the next page...

Table 320. SAI-4 TX/RX Data Pin Multiplexing (continued)

Options	Number of RX Data Line	Number of TX Data Line
2	3	2
3	4	1

Detailed clock multiplexing scheme is shown in the following figure.

Please note that SAI-1 is a standalone SAI module and is not shown in the Audio subsystem clocking diagram below.

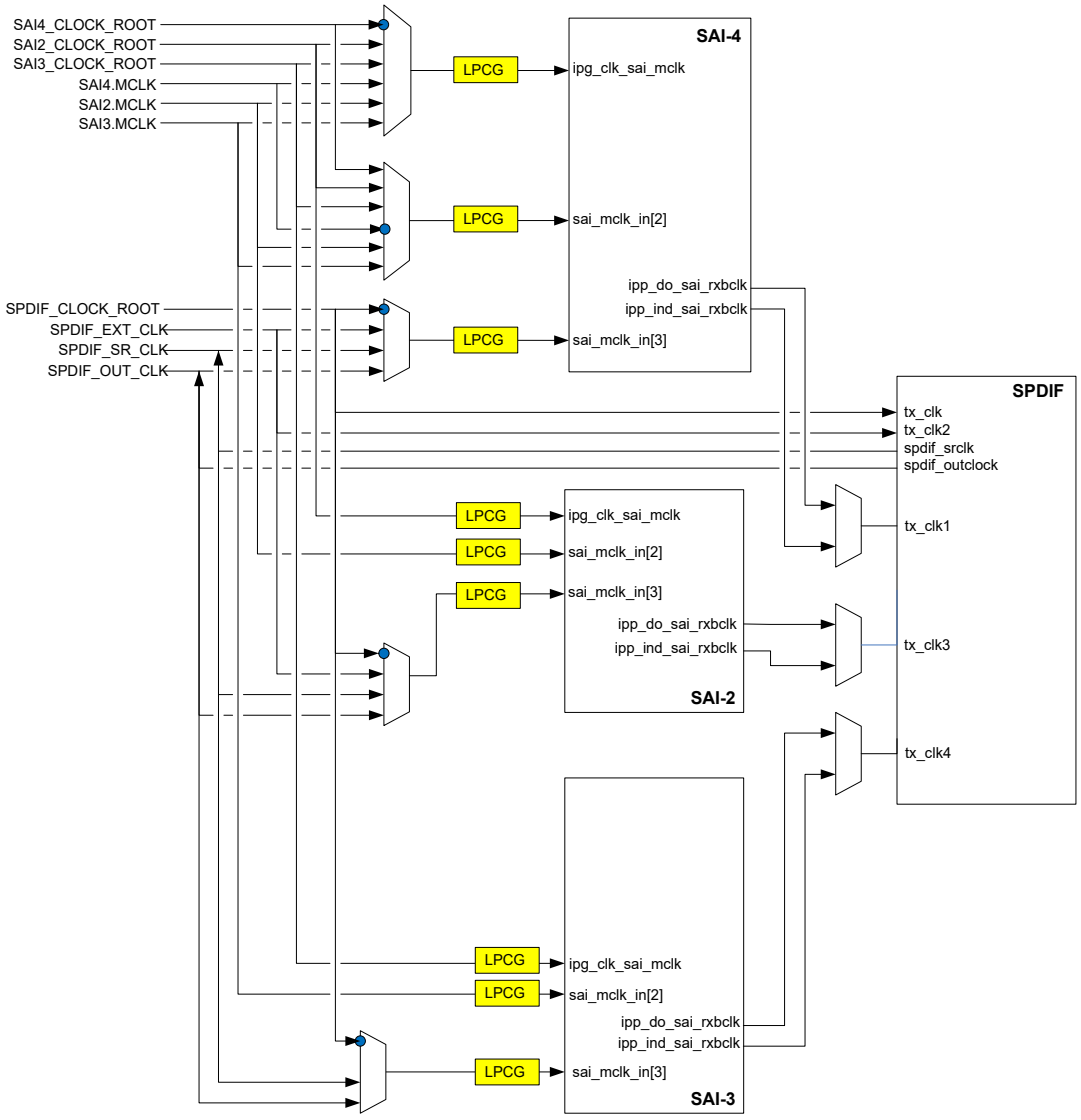

Figure 290. Audio subsystem clocking diagram

NOTE

SPDIF tx_clk1, tx_clk3, and tx_clk4 inputs are selected inside the SAI-4, SAI-2, and SAI-3, respectively.

48.1.2 Synchronous Audio Interface (SAI)

- Transmitter with independent Bit Clock and Frame Sync supporting a maximum of 4 data lines
- Receiver with independent Bit Clock and Frame Sync supporting a maximum of 4 data lines
- Maximum Frame Size of 32 Words
- Word size programmable from 8-bits to 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous FIFO for each Transmit and Receive data line
- Graceful restart after FIFO Error

48.1.3 Sony/Philips Digital Interface (SPDIF)

The Sony/Philips Digital Interface (SPDIF) module is a stereo transceiver that allows the processor to receive and transmit digital audio over it using the IEC60958 standard, consumer format. The chip provides a single SPDIF receiver with one input, and one SPDIF transmitter with one output. The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and features a frequency measurement block that allows the precise measurement of the incoming sampling frequency.

The clock recovered by the SPDIF receiver is provided to drive both internal and external components in the system such as the SPDIF transmitter, SAI ports, as well as external A/Ds or D/As, with clocking control provided via related registers.

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter. The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in two 16-word-deep FIFOs, one FIFO for the left channel, the other FIFO for the right channel. The FIFOs support programmable watermark levels so that FIFO Full service request can be triggered when the combined number of data words stored in both FIFOs is 2, 8, 16 or 32 words. It is recommended to program the watermark level to trigger a FIFO Full service request when 16 word locations are filled. For optimal performance when servicing the FIFO Full service request, the FIFOs should be read alternately, starting with the left channel FIFO. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers, and the data is stored in two 16-word-deep FIFOs, one for the right channel, the other for the left channel. The FIFOs support programmable watermark levels so that FIFO Empty service request can be triggered when the combined number of empty data words locations in both FIFOs is 8, 16, 24 or 32 words. It is recommended to program the watermark level to trigger a FIFO Empty service request when 16 word locations are empty. For optimal performance when servicing the FIFO Empty service request, the FIFOs should be written alternately, starting with the left channel FIFO. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates an SPDIF output bitstream in the biphase mark format (IEC 60958), which consists of audio data, channel status and user bits.

The data handled by the SPDIF module is 24-bit wide. The 24-bit SPDIF data is aligned in the 24 least significant bits of the 32-bit shared peripheral bus data word. The 8 most significant bits of the 32-bit word are ignored by the SPDIF Transmitter when data is being stored in the Transmit FIFOs from the peripheral bus. The 8 most significant bits of the 32-bit word are zeroed by the SPDIF Receiver module when the data is being read from the Receiver FIFOs to the peripheral bus.

Note that 16-bit data is left-aligned in the 24-bit word format of the SPDIF. This means that when receiving 16-bit data, it will be located in the middle two bytes of the 32-bit peripheral bus data word, while the 8 bits of the MSB and the 8 bits of the LSB will be zero. When 16-bit data is to be transmitted, the 32-bit word to be written to the SPDIF Transmit FIFOs should be created as follows: the 16-bit data should be located in the middle two bytes of the 32-bit data word and the 8 bits of the LSB must be set to zero, while the 8 bits of the MSB will be ignored.

48.1.4 PDM Microphone Interface (PDM)

The PDM module receives audio from a microphone. It includes the following features:

- Fixed filtering characteristics for audio application

- Full or partial set of channels operation with individual enable control
- Programmable PDM clock generator
- Programmable decimation rate
- 16-bit signed output result
- Overall stopband attenuation more than 80dB
- Overall passband ripple less than 0.2dB
- CIC filter
- DC remover
- Half Band filter
- FIR filter
- FIFOs with DMA capability
- Hardware Voice Activity Detector (HWVAD)
- 4 lines, 8 channels

NOTE

MQS is not supported in this chip.

This device has one instance of the ASRC module.

The below figure shows the ASRC System Overview for this chip.

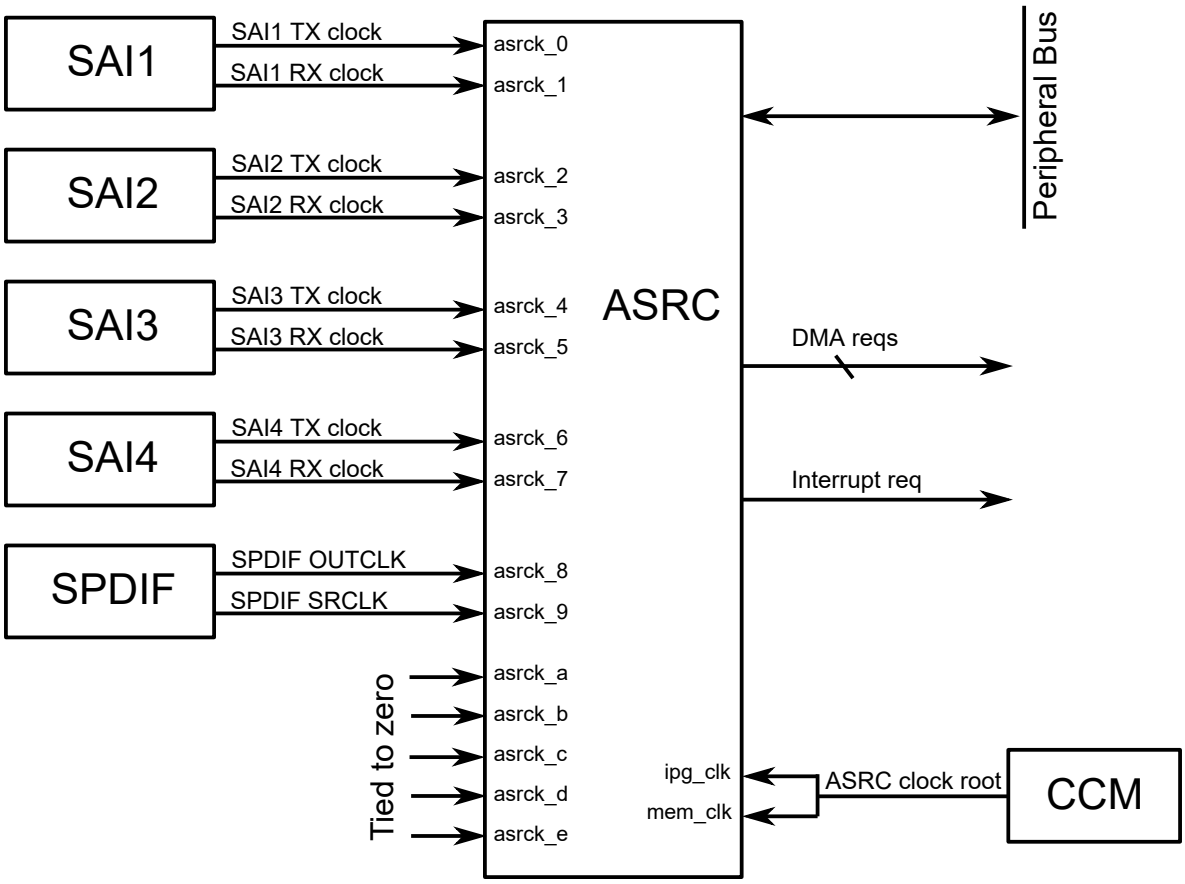

Figure 291. ASRC System Overview

NOTE

Each chip select signal cannot be arbitrarily configured and has its own fixed address range.

49.2 Overview

The Asynchronous Sample Rate Converter (ASRC) converts the sampling rate of a signal associated with an input clock into a signal associated with a different output clock.

The ASRC supports concurrent sample rate conversion of up to 10 channels of about -120 dB THD+N. The ASRC supports up to three sampling rate pairs.

The incoming audio data to this chip may be received from various sources at different sampling rates. The outgoing audio data of this chip may have different sampling rates and it can also be associated with output clocks that are asynchronous to the input clocks.

The ASRC is implemented as a co-processor in hardware, with minimal ARM Platform intervention required.

The ASRC Filter Processor (FP) handles the main signal processing algorithm. It has its own simplified instructions. The FP resources (MIPS,RAM,ROM ALU etc.) are shared among the different conversation pairs.

49.2.1 Block diagram

The following figure is the ASRC block diagram.

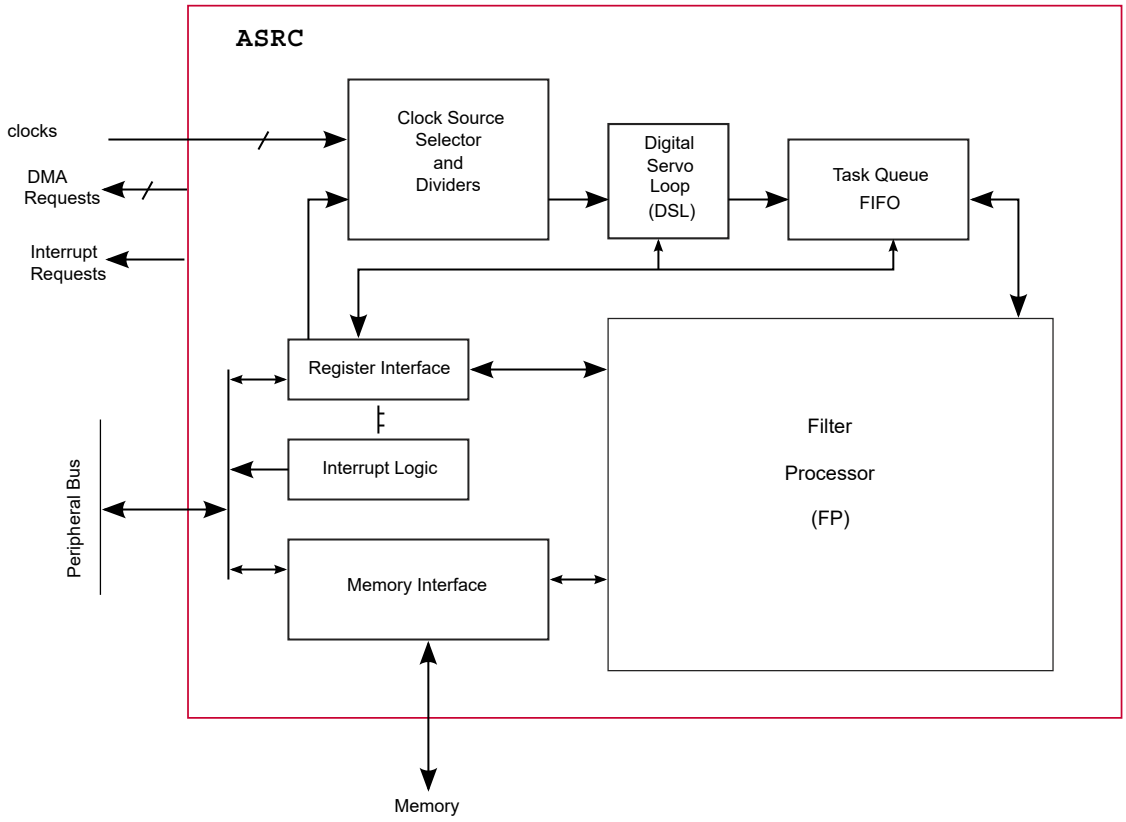

Figure 292. ASRC block diagram

49.2.2 Features

The ASRC features are listed below:

- Any number (0-10) of contiguous channels can be associated to one of the sampling rate pairs
- Support user-programmable threshold for the input/output FIFOs
- Support flexible 8/16/24-bit width of input data, and 16/24-bit width of output data
- Designed for rate conversion between 32 kHz, 44.1 kHz, 48 kHz, 96 kHz, and 192 kHz. The useful signal bandwidth is below 24 kHz
- Other input sampling rates in the range of 8 kHz to 200 kHz is also supported[4]
- Other output sampling rates in the range of 30 kHz to 200 kHz is also supported[4]
  - The limitation is the supported ratio (Fsin/Fsout) range (between 1/24 to 8)
- Automatic accommodation to slow variations in the incoming and outgoing sampling rates.
- Linear phase
- Tolerant to sample clock jitter

[4] The ASRC designed input and output sampling rate are between 44.1 kHz, 32 kHz, 48 kHz, 96 kHz, and 192 kHz. Useful signal bandwidth is below 24 kHz.

- Designed for real-time streaming audio usage. The output sampling clock must be always physically available in the system.

Clock/Data Connections

- The sampling rate clocks are directly connected to the ASRC block. The ratio estimation of the input clocks with output clocks are done in ASRC hardware when both input/output sampling clocks are physically available.
- When both the input sampling clock and the output sampling clock are physically available, the rate conversion can work by configuring the physical clocks.
- When the input sampling clock is not physically available, the rate conversion can still work by setting ideal-ratio values into ASRC interface registers.
- The clock signals come from the following blocks:
  - SAI, receiving bit clock and transmitting bit clock
  - SPDIF, receiving bit clock and transmitting bit clock
  - other audio peripherals etc.
- The Digital Servo Loop (DSL) is a digital PLL for tracking the relationship between input/output sampling clocks. It is shared among all pairs in a first-come-first-serve form
- The exchange of audio data is done by the processor accessing ASRC block through registers defined on shared peripheral bus

49.3 Functional description

This section provides a complete functional description of the block.

49.3.1 Operating modes

The ASRC supports modes described in the following sections:

- Data transfer schemes
- Word alignment supported

49.3.1.1 Data transfer schemes

49.3.1.1.1 Data input modes

The input mode for each of the three channel sets may be set independently. Three modes of supplying data to the ASRC input FIFOs are available:

- Polling
- Interrupt
- DMA

In all input-data transfer schemes, the ASRC fetches data from each enabled FIFO and processes the data sample-by-sample after each rising edge of the associated input sampling clock until the FIFO level reaches a threshold.

After the threshold is reached, the ASRC requests data. The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples.

The threshold can be defined by interface registers ASRMCRx, x = A, B or C.

If the ASRC attempts to fetch data from an empty FIFO, an error is generated and the ASRSTR[AOLE] bit is set. If the ASRC overload interrupt is enabled (ASRIER[AOLIE] bit is set), an interrupt is generated.

When writing data to an input FIFO, you must ensure that it is in a predefined sequence. For example, when writing to an input FIFO, the sequence should be: channel_0, channel_1, channel_2,..., channel_n, channel_0, channel_1, channel_2, etc. Here

channel_n stands for the data intended for the n^{th} channel. The hardware re-allocates each data to its corresponding channel FIFO. The channel being re-allocated is shown by ASRCCR[ACIx], x=A,B or C.

49.3.1.1.1.1 Data input polling mode

Polling mode is the default mode following power-on or individual reset, and is selected by clearing the associated channel set A, B, or C data-input interrupt enable bit (ASRIER[ADIEx], where x=A, B or C). In this mode, data-input interrupts are disabled. When the FIFO level is below the threshold, the associated status bit (ASRSTR[AIDEx], where x=A, B, or C) is set. To clear the status bit, the FIFO must be written with enough data to raise the level above the threshold.

49.3.1.1.1.2 Data input interrupt mode

The ASRC input FIFOs can also be serviced by interrupts. To enable interrupts, the corresponding data-input interrupt enable bits (ASRIER[ADIEx], where x=A, B, or C) should be set. An interrupt is automatically generated any time the input FIFO level is below the threshold. The interrupt is cleared when enough data is written to the FIFO to raise the level above the threshold.

49.3.1.1.1.3 Data input DMA mode

The ASRC input FIFOs can also be filled using DMA. In this mode, the data-input interrupt-enable bits (ASRIER[ADIEx], where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

49.3.1.1.2 Data output modes

The output mode for each of the 3 channel sets (A, B, and C) may be set independently.

Three modes of retrieving data from the ASRC output FIFOs are available:

- Polling
- Interrupt
- DMA

In all output-data transfer schemes, the ASRC places a processed sample into the associated output FIFO. After a threshold is reached, the ASRC requests that data be transferred out of the FIFO.

The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples. The threshold can be defined by interface registers ASRMCRx, x = A, B or C.

If the ASRC attempts to place data into a FIFO that is already full, an error is generated and the ASRSTR[AOLE] bit is set. If the ASRC overload interrupt is enabled (ASRIER[AOLIE] bit is set), an interrupt is generated.

Each output FIFO is organized in the same channel order in which the associated input FIFO was written.

Three transfer modes are supported by Interface Block.

49.3.1.1.2.1 Data output polling mode

The ASRC output FIFOs can be serviced by polling. In this mode, ensure the associated output-data interrupt enable bit (ASRIER[ADOEx], where x=A, B, or C) is cleared. In this mode, all output-data interrupts are disabled. Any time the output FIFO exceeds the threshold the associated status bit (ASRSTR[AODFx], where x=A, B, or C) is set. To clear the status bit, enough data must be read from the associated output FIFO to lower the level below the threshold.

49.3.1.1.2.2 Data output interrupt mode

The ASRC output FIFOs may also be serviced using interrupts. To enable this mode, the corresponding output-data interrupt-enable bits (ASRIER[ADOEx], where x=A, B, or C) should be set. Any time the output FIFO level exceeds the threshold, an interrupt is automatically generated. The interrupt is cleared when enough data is read from the FIFO to lower the level below the threshold.

49.3.1.1.2.3 Data output DMA mode

The ASRC output FIFOs can also be read using DMA. In this mode, the output-data interrupt-enable bits (ASRIER[ADOEx], where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

49.3.1.2 Word alignment supported

49.3.1.2.1 Input data alignment modes

The position and length of input data word to the input data FIFOs ASRDIA, ASRDIB, ASRDIC are programmable. The control bits are defined in ASRMCR1x {x=A, B, or C}. It supports the following modes:

Table 322. Input data alignment

Format	Bit number

49.3.1.2.2 Output data alignment modes

The position and length of output data word from the output data FIFOs ASRDOA, ASRDOB, ASRDOC are programmable. The control bits are defined in ASRMCR1x {x=A, B, or C}. It supports the following modes:

Table 323. Output data alignment

49.3.2 Algorithm description

49.3.2.1 Signal processing flow

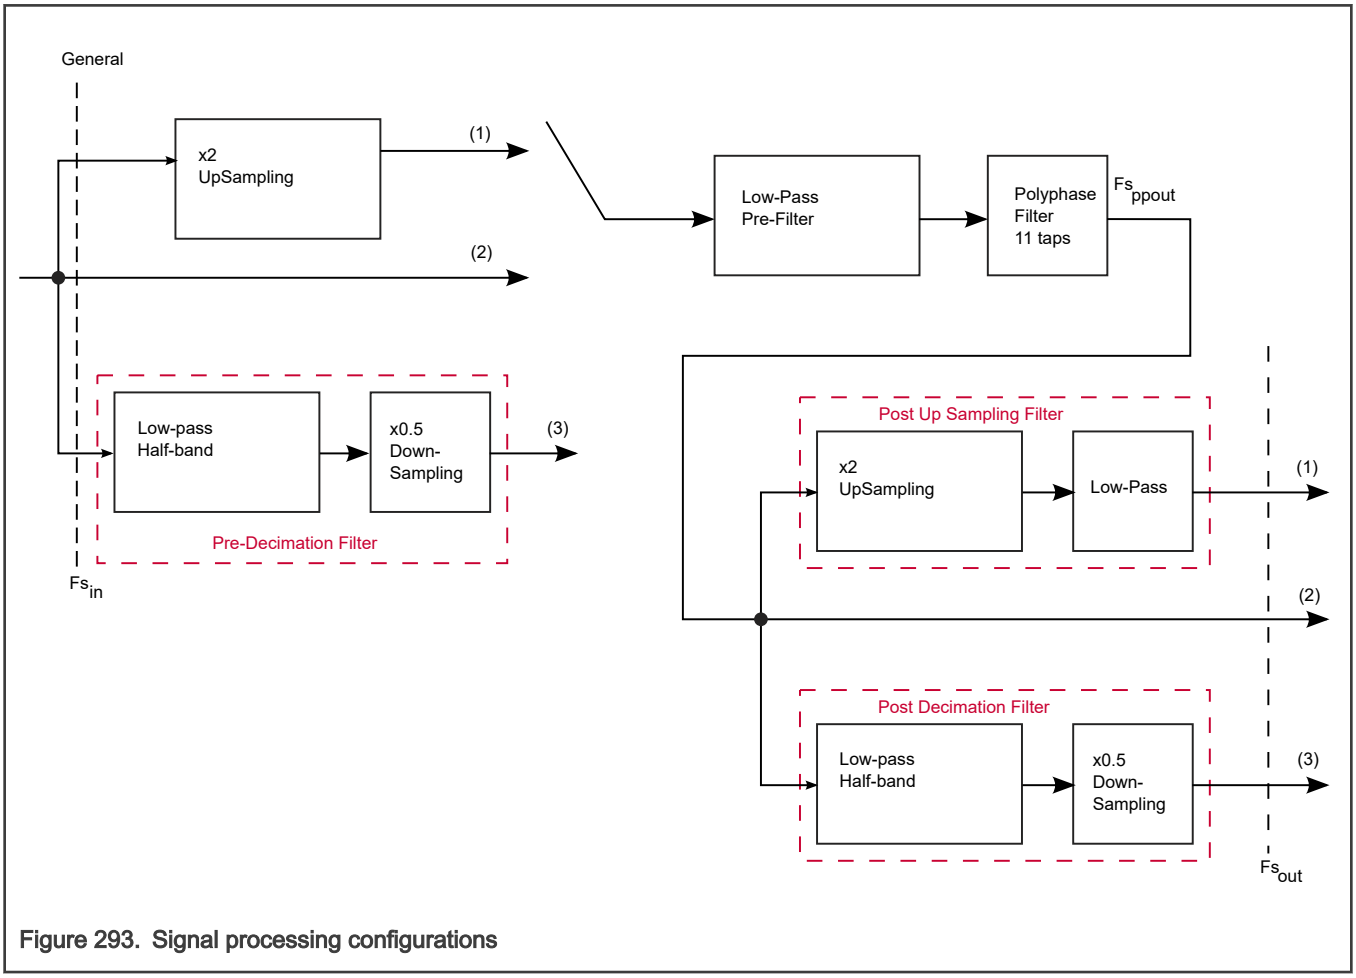

Figure 293. Signal processing configurations

The figure above shows the possible configurations of the ASRC. Each configuration consists of 2 to 4 stages.

- x2 up-sampling rate expander (zero insertion only) (input branch 1), direct connection (input branch 2), or low-pass pre decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (input branch 3),
- low-pass pre-filter, the low-pass bandwidth is at most 0.25 x Fs, where Fs is the sampling rate of the input signal to this low-pass pre-filter,
- polyphase filter,
- x2 post upsampling filter (consisting of a x2 up-sampling rate expander (zero insertion only) with low-pass half-band FIR filter) (output branch 1), direct connection (output branch 2), or low-pass post decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (output branch 3).

By flowing through different processing branches and different setups of the pre-filter, this ASRC scheme can be used to handle different rate conversion requirements.

Table 324. ASRC rate conversion configurations

Configuration	Max signal bandwidth before polyphase filter	Signal sampling rate of polyphase filter output
a: Input Branch 1 + Output Branch 1	$BW_{in} = Fs_{in}/2$	$Fs_{ppout} = Fs_{out}/2$
b: Input Branch 1 + Output Branch 2	$BW_{in} = Fs_{in}/2$	$Fs_{ppout} = Fs_{out}$
c: Input Branch 1 + Output Branch 3	$BW_{in} = Fs_{in}/2$	$Fs_{ppout} = 2Fs_{out}$
d: Input Branch 2 + Output Branch 1	$BW_{in} = Fs_{in}/4$	$Fs_{ppout} = Fs_{out}/2$
e: Input Branch 2 + Output Branch 2	$BW_{in} = Fs_{in}/4$	$Fs_{ppout} = Fs_{out}$
f: Input Branch 2 + Output Branch 3	$BW_{in} = Fs_{in}/4$	$Fs_{ppout} = 2Fs_{out}$
g: Input Branch 3 + Output Branch 1	$BW_{in} = Fs_{in}/8$	$Fs_{ppout} = Fs_{out}/2$
h: Input Branch 3 + Output Branch 2	$BW_{in} = Fs_{in}/8$	$Fs_{ppout} = Fs_{out}$
i: Input Branch 3 + Output Branch 3	$BW_{in} = Fs_{in}/8$	$Fs_{ppout} = 2Fs_{out}$

Table 325 lists some typical settings for typical sample rate conversation pairs to achieve less MIPS. ASRC can be set to automatically fill these settings depending on input/output sample rate or users can configure the fields manually to achieve better filter bandwidth performance.

	88.2	NA	{2,2}	{2,2}	{1,2}	{1,2}	{1,2}	{1,2}	{1,1}	{1,1}	{1,1}	{1,1}	{1,1}
	96	NA	{2,2}	{2,2}	{1,2}	{1,2}	{1,2}	{1,2}	{1,1}	{1,1}	{1,1}	{1,1}	{1,1}
	128	NA	NA	{2,2}	{2,2}	{1,2}	{1,2}	{1,2}	{1,1}	{1,1}	{1,1}	{1,1}	{1,1}
	192	NA	NA	NA	{2,2}	{2,2}	{2,2}	{2,2}	{2,1}	{2,1}	{2,1}	{2,1}	{2,1}

NOTE

In the {Pre_Proc, Post_Proc} pair, the meaning of the values are:

Pre_Proc:

- 0 --- Pre-processing Branch 1 as shown in Figure 293
- 1 --- Pre-processing Branch 2 as shown in Figure 293
- 2 --- Pre-processing Branch 3 as shown in Figure 293, decimation-by-2

Post_Proc:

- 0 --- Post-processing Branch 1 as shown in Figure 293
- 1 --- Post-processing Branch 2 as shown in Figure 293
- 2 --- Post-processing Branch 3 as shown in Figure 293

The latencies of the different option can be roughly calculated as follows:

- For PreProc = 0, PostProc = 1 : min latency = constant_A / input-sample-rate + constant_B / output-sample-rate
- For PreProc = 0, PostProc = 0 : min latency = constant_A / input-sample-rate + constant_C / output-sample-rate
- For PreProc = 1, PostProc = 1 : min latency = constant_D / input-sample-rate + constant_B / output-sample-rate

The constants above (e.g., constant_A means the Constant for Preproc = 0, constant_B means the Constant for Postproc = 1, ...) are only influenced by the PreProc/PostProc and (input/output) sampling rate to which they are connected. Input latencies have no relationship with the output latencies, but both elements add together to form the total latencies.

For a rough estimation, the constants can be set as:

- Constant for Preproc = 0: 39
- Constant for Preproc = 1: 78.5
- Constant for Preproc = 2: 235
- Constant for Postproc = 0: 42.5
- Constant for Postproc = 1: 8.5

- Constant for Postproc = 2: 172

The max latency can be derived from this value by using the following formula (where 32 means the input/output FIFO depth that initiates data transfer):

- max latency = min latency + 32 / input-sample-rate + 32 / output-sample-rate

49.3.2.2 Operation of the filter

49.3.2.2.1 Support of physical clocks

This design supports physical sampling clocks. The clocks can be provided by:

- Sony/Phillips digital interface (SPDIF)
- Serial Audio Interface (SAI)
- Core master clock derivative as ASRCK1

NOTE

Your specific device may not support all of the clock sources. See the chip-specific section for this module, at the beginning of this chapter.

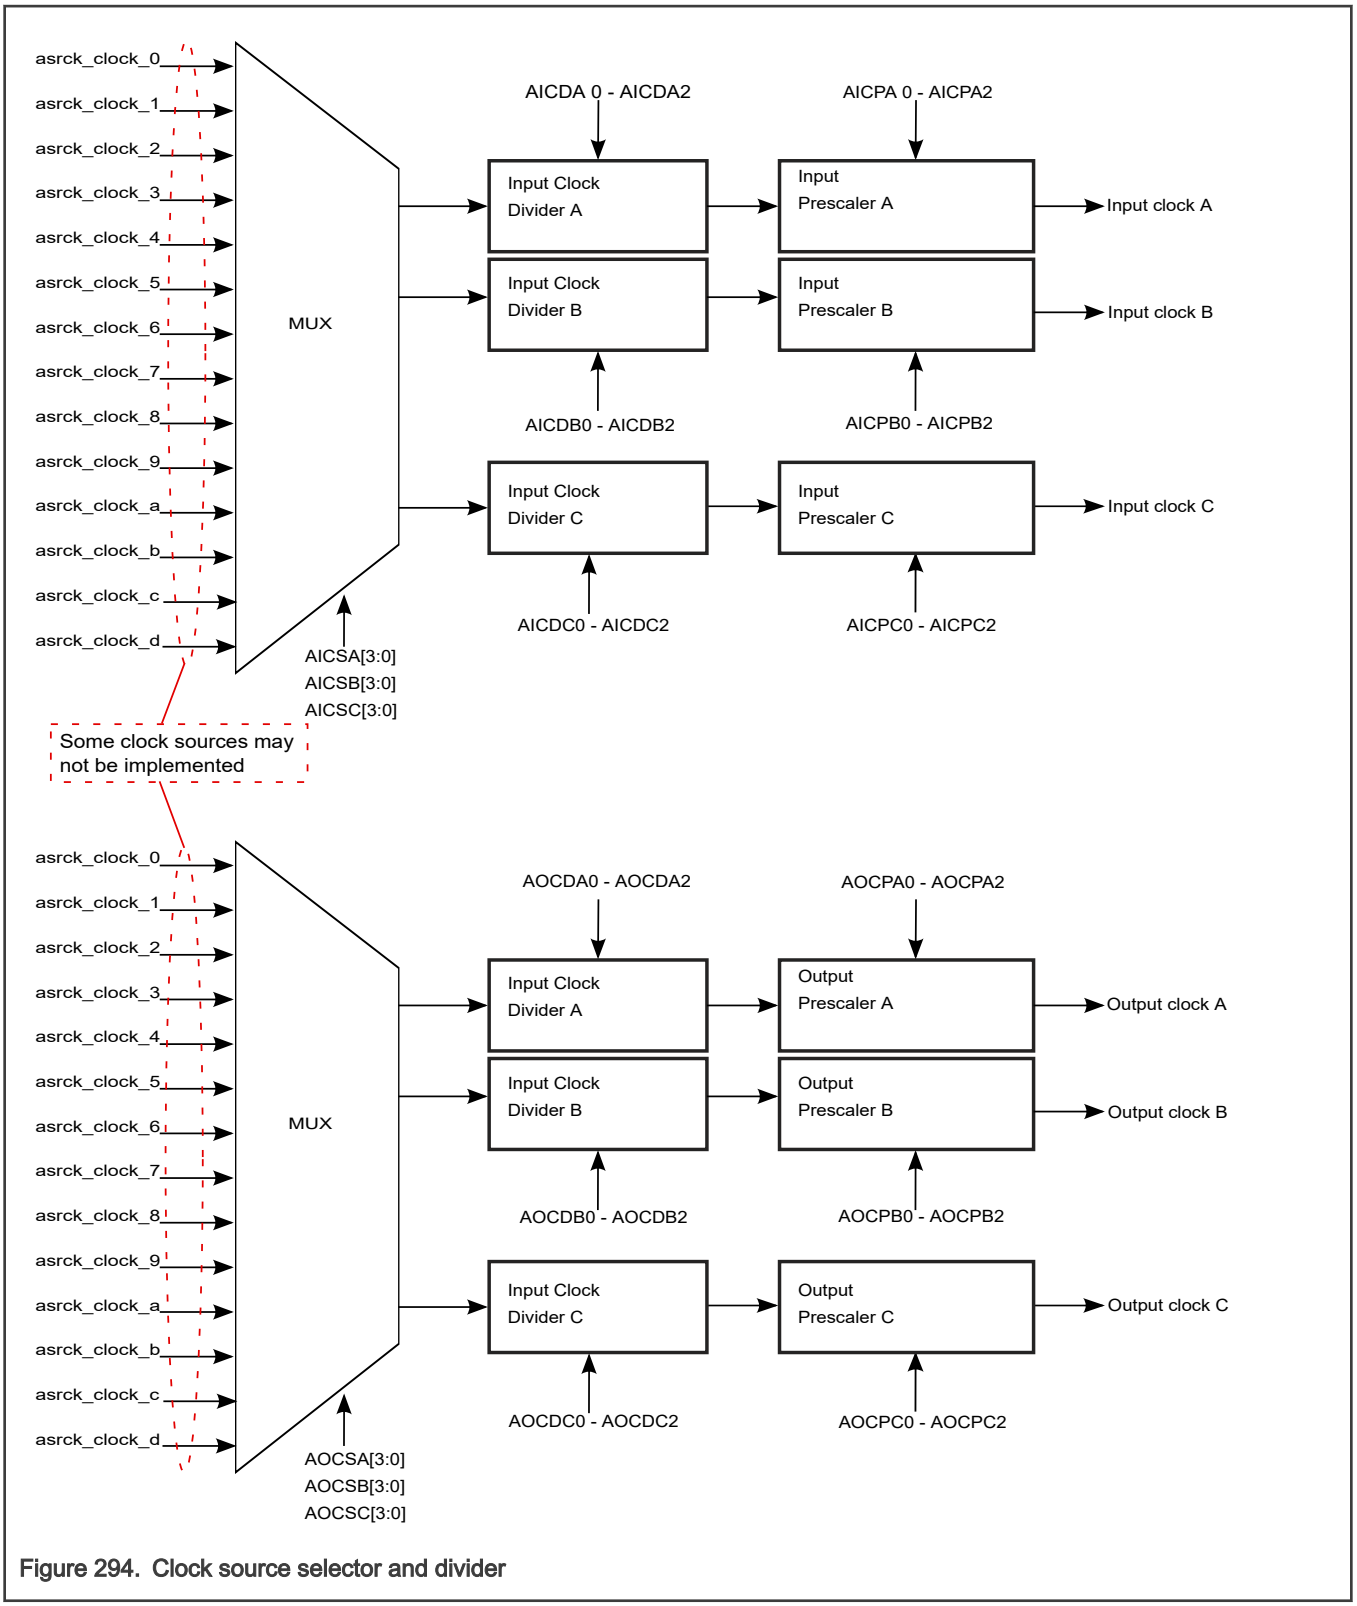

Figure 294. Clock source selector and divider

Software can set the ASRC Clock Source Register (ASRCSR) and the Clock Divider Register to select the desired clock source and divide it to the needed sample rate clock for use by the ASRC.

The following is the description of the Clock Source Selector and Divider figure above (x refers to A, B or C):

- If the input clock is available, Pair x divider and prescaler depends on the input clock and input sample rate, which can be calculated by:
  - Input Clock x = (Input Sample Rate x) * AICDx * (2^(AICPx))
  - Where the Input Sample Clock Source x is determined by ASRCSR[AICSx]
- If the output clock is available, Pair x divider and prescaler depends on the output clock and output sample rate, which can be calculated by:
  - Output Clock x = (Output Sample Rate x) * AOCDx * (2^(AOCPx))
  - Where the Output Sample Clock Source x is determined by ASRCSR[AOCSx]

NOTE

The clocks have the following restriction: If the prescaler is set to 1, the clock divider can only be set to 1 and the clock source must have a 50% duty cycle.

NOTE

For normal setup procedure for the ASRC block, see section Application information.

49.3.3 Clocks

The table below describes the clock sources for ASRC. Please see clock control block for clock setting, configuration and gating information.

Table 326. ASRC clocks

Clock name	Description
asrck_clock_d	ASRC module clock
ipg_clk	Peripheral clock
mem_clk	Peripheral access clock

49.3.4 Interrupts

ASRC has several interrupts events.

The priorities are shown in the following table.

Table 327. Interrupt priorities/vector

Priority	Offset	Description
lowest	0x0	ASRC Pair A input data needed
	0x2	ASRC Pair B input data needed
	0x4	ASRC Pair C input data needed
	0x6	ASRC Pair A output data ready
	0x8	ASRC Pair B output data ready
	0xA	ASRC Pair C output data ready
highest	0xC	ASRC Overload

49.3.5 DMA requests

ASRC has six DMA requests. They are directly connected to the lowest six status bits in the ASRSTR register. For some ARM platforms, the six status bits are directly connected to the DMA peripheral as DMA event signals.

Table 328. DMA requests

Type	Description
0	ASRC Pair A input data needed
1	ASRC Pair B input data needed
2	ASRC Pair C input data needed
3	ASRC Pair A output data ready
4	ASRC Pair B output data ready
5	ASRC Pair C output data ready

49.4 External signals

The ASRC does not have external signals pinned out.

The following table shows the bit definitions that are used by the ASRCSR register to control the sources of the input and output clocks of the ASRC.

NOTE

Your specific device may not support all of the clock sources. See the chip-specific section for this module, at the beginning of this chapter.

Table 329. ASRC bit clock definitions

Bit Clk Name	Definition	Description
bit clock 0	SAI1_TX_BCLK	SAI1 Transmitter serial bit clock
bit clock 1	SAI1_RX_BCLK	SAI1 Receiver serial bit clock
bit clock 2	SAI2_TX_BCLK	SAI2 Transmitter serial bit clock
bit clock 3	SAI2_RX_BCLK	SAI2 Receiver serial bit clock
bit clock 4	SAI3_TX_BCLK	SAI3 Transmitter serial bit clock
bit clock 5	SAI3_RX_BCLK	SAI3 Receiver serial bit clock
bit clock 6	SAI4_TX_BCLK	SAI4 Transmitter serial bit clock
bit clock 7	SAI4_RX_BCLK	SAI4 Receiver serial bit clock
bit clock 8	SPDIF_TX_BCLK	SPDIF Transmitter serial bit clock
bit clock 9	SPDIF_RX_BCLK	SPDIF Receiver serial bit clock

Table continues on the next page...

Table 329. ASRC bit clock definitions (continued)

Bit Clk Name	Definition	Description
bit clock A	SAI2_CLK_ROOT	SAI2 Clock Root
bit clock B	SAI3_CLK_ROOT	SAI3 Clock Root
bit clock C	SAI4_CLK_ROOT	SAI4 Clock Root
bit clock D	MIC_CLK_ROOT	MIC Clock Root
bit clock E	MQS_CLK_ROOT	MQS Clock Root

49.5 Application information

The following outlines an **example** setup procedure for the ASRC block:

1. Configure and enable the ASRC clock source. See this device's clocking chapter for more information
2. Disable the ASRC (write 0x00000000 to ASRCTR)
3. Enable the peripheral that is connected to the ASRC. See this device's clocking chapter and the ASRC chip specific section for more information
4. Configure the following:
    a. Enable ASRC function(ASRCTR[ASRCEN]=1)
    b. Enable Use of Ideal Ratio for Pair A (ASRCTR[IDRA]=1)
    c. Enable Use of Ratio for Pair A (ASRCTR[URSA]=1)
    d. Assign 2 channels to Pair A (ASRCNCR[ANCA]=2)
    e. Configure Post-Processing Configuration and Pre-Processing Configuration for Conversion Pair A. See Signal processing flow
    f. Set ASRC Clock Divider 1 (ASRCDR1) and ASRC Clock Divider 2 (ASRCDR2. See Support of physical clocks for more information
    g. Set the Input Clock Source A (ASRCSR[AICSA]) and Output Clock Source A (ASRCSR[AOCSA]) both to Bit Clock n

    NOTE

    Select one of the bit clocks supported by your specific device. See the chip-specific section for this module, at the beginning of this chapter.

    h. Set the Ideal Ratio for Pair A. The ratio depends on input sample rate and output sample rate. See the ASRC Ideal Ratio for Pair A-High Part (ASRIDRHA) and ASRC Ideal Ratio for Pair A -Low Part (ASRIDRLA) register descriptions. If the input sample rate is equal to the output sample rate, Ideal Ratio is 1:
        - Ideal Ratio for Pair A-High Part (ASRIDRHA = 0x4)
        - Ideal Ratio for Pair A-Low Part (ASRIDRLA = 0x0)
5. For Pair A - Set input threshold to 32 and output threshold to 8 (ASRMCRA[INFIFO_THRESHOLDA], ASRMCRA[OUTFIFO_THRESHOLDA])
6. Zeroize Pair A buffers(ASRMCRA[ZEROBUFA]=1)
7. Do not bypass polyA filter (ASRMCRA[BYPASSPOLYA]=0)
8. Set Pair A data width (ASRMCR1A[IWD]) and data alignment(ASRMCR1A[IMSB] and ASRC_ASRMCR1A[OMSB]) depends on the audio data format

9. Disable interrupt handler (ASRIER = 0x00000000)
10. After configuration is done, enable the ASRC pair(ASRCTR[ASREA]=1)
11. Poll until the initialization is done (ASRCFG and ASRCFG[INIRQA]) == 0)
12. Feed Input Data (ASRDIA)
13. Get Output Data (ASRDOA)
14. Disable ASRC (ASRCTR[ASRCEN] = 0)

49.6 ASRC memory map/register definition

49.6.1 ASRC register descriptions

All useful registers are listed in the memory map below. The access of undefined registers behaves as normal registers.

All the interface registers are LSB aligned except the input FIFOs and the output FIFOs, and each register has only 24 effective bits.

The input FIFO and output FIFO word alignment can be defined using ASRMCR1{A,B,C} registers in 32-bit interface system.

49.6.1.1 ASRC memory map

ASRC base address: 429A_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	ASRC Control (ASRCTR)	32	RW	0000_0000h
4h	ASRC Interrupt Enable (ASRIER)	32	RW	0000_0000h
Ch	ASRC Channel Number Configuration (ASRCNCR)	32	RW	0000_0000h
10h	ASRC Filter Configuration Status (ASRCFG)	32	RW	0000_0000h
14h	ASRC Clock Source (ASRCSR)	32	RW	0000_0000h

B4h	ASRC FIFO Status for Pair C (ASRFSTC)	32	R	0000_0000h
C0h - C8h	ASRC Misc Control 1 for Pair X (ASRMCR1A - ASRMCR1C)	32	RW	0000_0000h

49.6.1.2 ASRC Control (ASRCTR)

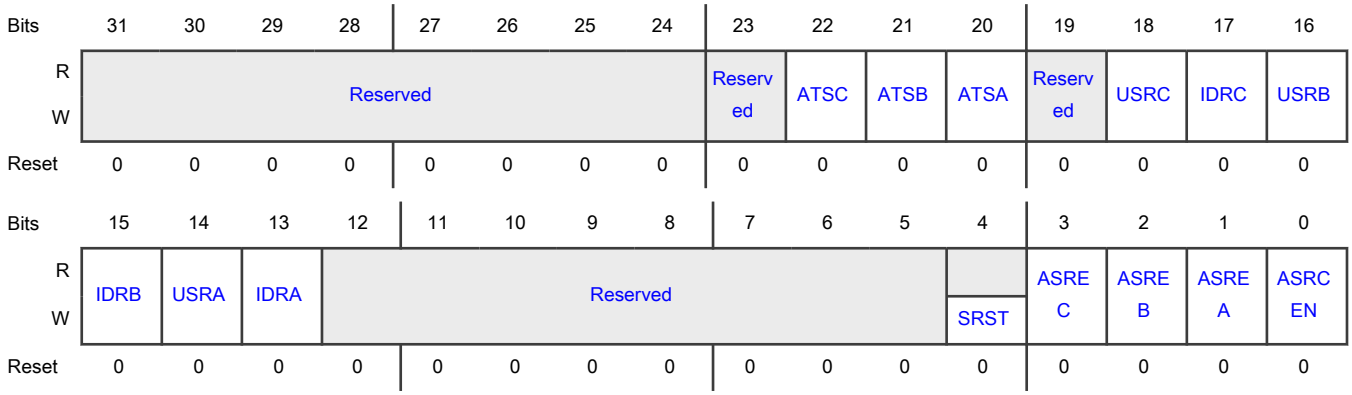
Offset

Register	Offset
ASRCTR	0h

Function

Controls the ASRC operations.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 —	Should be written as zero for compatibility.
22 ATSC	ASRC Pair C Automatic Selection For Processing Options When this bit is 1, pair C automatically updates its pre-processing and post-processing options (ASRCFG[PREMODC], ASRCFG[POSTMODC] see ASRC Filter Configuration Status Register for Pair C) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see ASRC 76 kHz Period in terms of ASRC processing clock and ASRC 56 kHz Period in terms of ASRC processing clock). When this bit is 0, the user is responsible for choosing the proper processing options for pair C. This bit should be disabled when {USRC, IDRC}={1,1}. 0b - Pair C does not automatically update its pre-processing and post-processing options 1b - Pair C automatically updates its pre-processing and post-processing options
21 ATSB	ASRC Pair B Automatic Selection For Processing Options When this bit is 1, pair B automatically updates its pre-processing and post-processing options (ASRCFG[PREMODB], ASRCFG[POSTMODB] see ASRC Filter Configuration Status Register for Pair B) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see ASRC 76 kHz Period in terms of ASRC processing clock and ASRC 56 kHz Period in terms of ASRC processing clock). When this bit is 0, the user is responsible for choosing the proper processing options for pair B. This bit should be disabled when {USRB, IDRB}={1,1}. 0b - Pair B does not automatically update its pre-processing and post-processing options 1b - Pair B automatically updates its pre-processing and post-processing options
20	ASRC Pair A Automatic Selection For Processing Options

Table continues on the next page...

Table continued from the previous page...

Field	Function
ATSA	When this bit is 1, pair A automatically updates its pre-processing and post-processing options (ASRCFG[PREMODA], ASRCFG[POSTMODA] see ASRC Filter Configuration Status Register for Pair A) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see ASRC 76 kHz Period in terms of ASRC processing clock and ASRC 56 kHz Period in terms of ASRC processing clock). When this bit is 0, the user is responsible for choosing the proper processing options for pair A. This bit should be disabled when {USRA, IDRA}={1,1}. 0b - Pair A does not automatically update its pre-processing and post-processing options 1b - Pair A automatically updates its pre-processing and post-processing options
19 —	Should be written as zero for compatibility.
18 USRC	Use Ratio for Pair C Use ratio as the input to ASRC. This bit is used in conjunction with IDRC control bit. 0b - Do not use ratio as the input to ASRC for pair C 1b - Use ratio as the input to ASRC for pair C
17 IDRC	Use Ideal Ratio for Pair C When USRC=0, this bit has no usage. When USRC=1 and IDRC=0, ASRC internal measured ratio is used. When USRC=1 and IDRC=1, the idea ratio from the interface register ASRIDRHC, ASRIDRLC is used. It is suggested to manually set ASRCFG[POSTMODC], ASRCFG[PREMODC] according to Pre-processing, post-processing options in this case. 0b - ASRC internal measured ratio is used 1b - Ideal ratio from the interface register ASRIDRHC, ASRIDRLC is used
16 USRB	Use Ratio for Pair B Use ratio as the input to ASRC. This bit is used in conjunction with IDRB control bit. 0b - Do not use ratio as the input to ASRC for pair B 1b - Use ratio as the input to ASRC for pair B
15 IDRB	Use Ideal Ratio for Pair B When USRB=0, this bit has no usage. When USRB=1 and IDRB=0, ASRC internal measured ratio is used. When USRB=1 and IDRB=1, the idea ratio from the interface register ASRIDRHB, ASRIDRLB is used. It is suggested to manually set ASRCFG[POSTMODB], ASRCFG[PREMODB] according to Pre-processing, post-processing options in this case. 0b - ASRC internal measured ratio is used

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ideal ratio from the interface register ASRIDRHB, ASRIDRLB is used
14 USRA	Use Ratio for Pair A Use ratio as the input to ASRC. This bit is used in conjunction with IDRA control bit. 0b - Do not use ratio as the input to ASRC for pair A 1b - Use ratio as the input to ASRC for pair A
13 IDRA	Use Ideal Ratio for Pair A When USRA=0, this bit has no usage. When USRA=1 and IDRA=0, ASRC internal measured ratio is used. When USRA=1 and IDRA=1, the ideal ratio from the interface register ASRIDRHA, ASRIDRLA is used. It is suggested to manually set ASRCFG[POSTMODA], ASRCFG[PREMODA] according to Pre-processing, post-processing options in this case. 0b - ASRC internal measured ratio is used 1b - Ideal ratio from the interface register ASRIDRHA, ASRIDRLA is used
12-5 —	Should be written as zero for compatibility.
4 SRST	Software Reset This bit is self-clear bit. Once it has been written as 1, it generates a software reset signal inside ASRC. After 9 cycles of the ASRC processing clock, this reset process stops, and this bit is cleared automatically. 0b - ASRC Software reset cleared 1b - ASRC Software reset generated. NOTE: This is a self-clear bit
3 ASREC	ASRC Enable C Enable the operation of the conversion C of ASRC. 0b - Disabled 1b - Enabled
2 ASREB	ASRC Enable B Enables the operation of the conversion B of ASRC. 0b - Disabled 1b - Enabled
1 ASREA	ASRC Enable A Enables the operation of the conversion A of ASRC. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

49.6.1.4 ASRC Channel Number Configuration (ASRCNCR)

Offset

Register	Offset
ASRCNCR	Ch

Function

Sets the number of channels used by each ASRC conversion pair.

There are 10 channels available for distribution among 3 conversion pairs, they are ordered as 0,1,...,9. The bottom [0, ANCA-1] channels are used for pair A, the top [10-ANCC, 9] channels are used for pair C, and the [ANCA, ANCA+ANCB-1] channels are allocated for pair B. In case that ANCA=0, then the [0, ANCB-1] channels are assigned for pair B.

49.6.1.7 ASRC Clock Divider 1 (ASRCDR1)

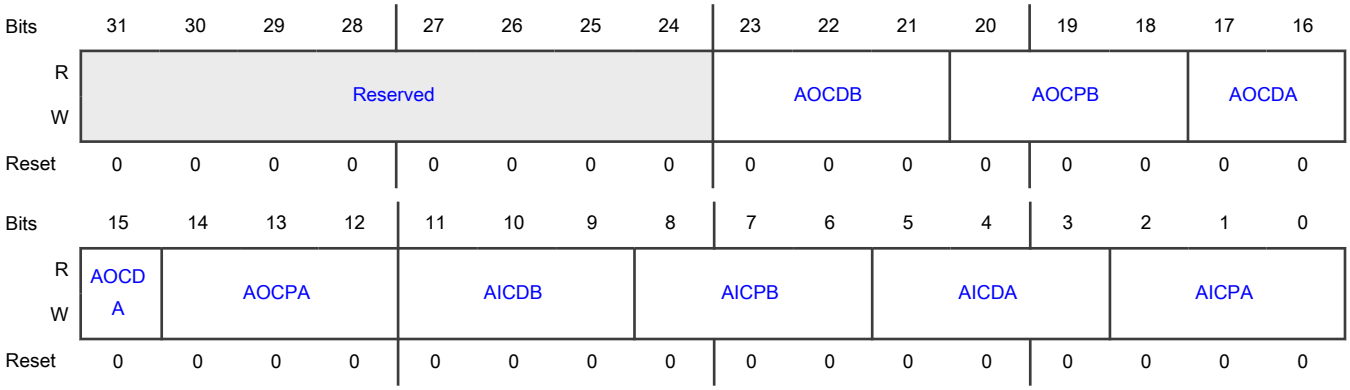
Offset

Register	Offset
ASRCDR1	18h

Function

Controls the division factors of the ASRC input and output clock sources.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-21 AOCDB	Output Clock Divider B Specifies the divide ratio of the output clock divider B. The divide ratio may range from 1 to 8 (AOCDB[2:0] = 000 to 111).
20-18 AOCPB	Output Clock Prescaler B Specifies the prescaling factor of the output prescaler B. The prescaling ratio may be any power of 2 from 1 to 128.

Table continues on the next page...

Table continued from the previous page...

Field	Function
17-15 AOCDA	Output Clock Divider A Specifies the divide ratio of the output clock divider A. The divide ratio may range from 1 to 8 (AOCDA[2:0] = 000 to 111).
14-12 AOCPA	Output Clock Prescaler A Specifies the prescaling factor of the output prescaler A. The prescaling ratio may be any power of 2 from 1 to 128.
11-9 AICDB	Input Clock Divider B Specifies the divide ratio of the input clock divider B. The divide ratio may range from 1 to 8 (AICDB[2:0] = 000 to 111).
8-6 AICPB	Input Clock Prescaler B Specifies the prescaling factor of the input prescaler B. The prescaling ratio may be any power of 2 from 1 to 128.
5-3 AICDA	Input Clock Divider A Specifies the divide ratio of the input clock divider A. The divide ratio may range from 1 to 8 (AICDA[2:0] = 000 to 111).
2-0 AICPA	Input Clock Prescaler A Specifies the prescaling factor of the input prescaler A. The prescaling ratio may be any power of 2 from 1 to 128.

49.6.1.8 ASRC Clock Divider 2 (ASRCDR2)

Offset

Register	Offset
ASRCDR2	1Ch

Function

Controls the division factors of the ASRC input and output clock sources.

Diagram

Field	Function
31-24 —	Reserved
23-12 —	Should be written as zero for compatibility.
11-9 AOCDC	Output Clock Divider C Specifies the divide ratio of the output clock divider C. The divide ratio may range from 1 to 8 (AOCDC[2:0] = 000 to 111).
8-6 AOCPC	Output Clock Prescaler C Specifies the prescaling factor of the output prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.
5-3 AICDC	Input Clock Divider C Specifies the divide ratio of the input clock divider C. The divide ratio may range from 1 to 8 (AICDC[2:0] = 000 to 111).
2-0 AICPC	Input Clock Prescaler C Specifies the prescaling factor of the input prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.

49.6.1.9 ASRC Status (ASRSTR)

Offset

Register	Offset
ASRSTR	20h

Function

Used by the processor core to examine the status of the ASRC block and clear the overload interrupt request and AOLE flag bit. Read of the status register returns the current state of ASRC.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-22 —	Should be written as zero for compatibility.
21 DSLCNT	Digital Servo Loop (DSL) Counter Input to FIFO Ready When set, this bit indicates that new DSL counter information is stored in the internal ASRC FIFO. When clear, this bit indicates that new DSL counter information is in the process of storage into the internal ASRC FIFO. When ASRIER[AFPWE]=1, the rising edge of this signal proposes an interrupt request. Writing any value with this bit set clears the interrupt request proposed by the rising edge of this bit. 0b - New DSL counter information is in the process of storage into the internal ASRC FIFO 1b - New DSL counter information is stored in the internal ASRC FIFO
20 ATQOL	Task Queue FIFO overload When set, this bit indicates that task queue FIFO logic is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - Task queue FIFO logic is not overloaded 1b - Task queue FIFO logic is overloaded
19	Pair C Output Task Overload

Table continues on the next page...

Table continued from the previous page...

Field	Function
AOOLC	When set, this bit indicates that pair C output task is overloaded. This may help to check the reason why overload interrupt happens.> The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - Pair C output task is not overloaded 1b - Pair C output task is overloaded
18 AOOLB	Pair B Output Task Overload When set, this bit indicates that pair B output task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - Pair B output task is not overloaded 1b - Pair B output task is overloaded
17 AOOLA	Pair A Output Task Overload When set, this bit indicates that pair A output task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - Pair A output task is not overloaded 1b - Pair A output task is overloaded
16 AIOLC	Pair C Input Task Overload When set, this bit indicates that pair C input task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - Pair C input task is not overloaded 1b - Pair C input task is overloaded
15 AIOLB	Pair B Input Task Overload When set, this bit indicates that pair B input task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - Pair B input task is not overloaded 1b - Pair B input task is overloaded
14 AIOLA	Pair A Input Task Overload When set, this bit indicates that pair A input task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRSTR[AOLE] as 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Pair A input task is not overloaded 1b - Pair A input task is overloaded
13 AODOC	Output Data Buffer C has Overflowed When set, this bit indicates that output data buffer C has overflowed. When clear, this bit indicates that output data buffer C has not overflowed The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - No Overflow in Output data buffer C 1b - Overflow in Output data buffer C
12 AODOB	Output Data Buffer B has Overflowed When set, this bit indicates that output data buffer B has overflowed. When clear, this bit indicates that output data buffer B has not overflowed The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - No Overflow in Output data buffer B 1b - Overflow in Output data buffer B
11 AODOA	Output Data Buffer A has Overflowed When set, this bit indicates that output data buffer A has overflowed. When clear, this bit indicates that output data buffer A has not overflowed. The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - No Overflow in Output data buffer A 1b - Overflow in Output data buffer A
10 AIDUC	Input Data Buffer C has Underflowed When set, this bit indicates that input data buffer C has underflowed. When clear, this bit indicates that input data buffer C has not underflowed. The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - No Underflow in Input data buffer C 1b - Underflow in Input data buffer C
9 AIDUB	Input Data Buffer B has Underflowed When set, this bit indicates that input data buffer B has underflowed. When clear, this bit indicates that input data buffer B has not underflowed. The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - No Underflow in Input data buffer B 1b - Underflow in Input data buffer B
8	Input Data Buffer A has Underflowed

Table continues on the next page...

Table continued from the previous page...

Field	Function
AIDUA	When set, this bit indicates that input data buffer A has underflowed. When clear, this bit indicates that input data buffer A has not underflowed. The bit is cleared when writing ASRSTR[AOLE] as 1. 0b - No Underflow in Input data buffer A 1b - Underflow in Input data buffer A
7 FPWT	FP is in Wait States This bit is for debug only. When set, this bit indicates that ASRC is in wait states. When clear, this bit indicates that ASRC is not in wait states. 0b - ASRC is not in wait state 1b - ASRC is in wait state
6 AOLE	Overload Error Flag When set, this bit indicates that the task rate is too high for the ASRC to handle. The reasons for overload may be: • too high input clock frequency, • too high output clock frequency, • incorrect selection of the pre-filter, • low ASRC processing clock, • too many channels, • underrun, • or any combination of the reasons above. Since the ASRC uses the same hardware resources to perform various tasks, the real reason for the overload is not straight forward, and it should be carefully analyzed by the programmer. If ASRIER[AOLIE]=1, an interrupt is proposed when this bit is set. Write any value with this bit set as one into the status register clears this bit and the interrupt request proposed by this bit. 0b - No overload 1b - Task rate is too high
5 AODFC	Number of data in Output Data Buffer C is Greater than Threshold When set, this bit indicates that number of data already existing in ASRDOC is greater than threshold and the processor can read data from ASRDOC. A DMA request is always generated when the AODFC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0b - The threshold has not yet been met and no data output C interrupt is generated 1b - When AODFC is set, the ASRC generates data output C interrupt request to the processor if ASRIER[ADOEC] = 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 AODFB	Number of data in Output Data Buffer B is Greater than Threshold When set, this bit indicates that number of data already existing in ASRDOB is greater than threshold and the processor can read data from ASRDOB. A DMA request is always generated when the AODFB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0b - The threshold has not yet been met and no data output B interrupt is generated 1b - When AODFB is set, the ASRC generates data output B interrupt request to the processor if ASRIER[ADOEB] = 1
3 AODFA	Number of Data in Output Data Buffer A is Greater than Threshold When set, this bit indicates that number of data already existing in ASRDOA is greater than threshold and the processor can read data from ASRDOA. A DMA request is always generated when the AODFA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0b - The threshold has not yet been met and no data output A interrupt is generated 1b - When AODFA is set, the ASRC generates data output A interrupt request to the processor if ASRIER[ADOEA] = 1
2 AIDEC	Number of Data in Input Data Buffer C is Less than Threshold When set, this bit indicates that the number of data still available in ASRDIC is less than the threshold and the processor can write data to ASRDIC. A DMA request is always generated when the AIDEC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0b - The threshold has been met and no data input C interrupt is generated 1b - When AIDEC is set, the ASRC generates data input C interrupt request to the processor if ASRIER[AIDEC] = 1
1 AIDEB	Number of Data in Input Data Buffer B is Less than Threshold When set, this bit indicates that number of data still available in ASRDIB is less than threshold and the processor can write data to ASRDIB. A DMA request is always generated when the AIDEB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0b - The threshold has been met and no data input B interrupt is generated 1b - When AIDEB is set, the ASRC generates data input B interrupt request to the processor if ASRIER[AIDEB] = 1
0 AIDEA	Number of Data in Input Data Buffer A is Less than Threshold When set, this bit indicates that number of data still available in ASRDIA is less than the threshold and the processor can write data to ASRDIA. A DMA request is always generated when the AIDEA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event. 0b - The threshold has been met and no data input A interrupt is generated 1b - When AIDEA is set, the ASRC generates data input A interrupt request to the processor if ASRIER[AIDEA] = 1

49.6.1.10 ASRC Parameter x (ASRPM1 - ASRPM5)

Offset

Register	Offset
ASRPM1	40h
ASRPM2	44h
ASRPM3	48h
ASRPM4	4Ch
ASRPM5	50h

Function

Parameter registers determine the performance of ASRC.

The parameter registers must be initialized by software before ASRC is enabled. Recommended values are given in the table below:

Table 330. ASRC Parameter Registers (ASRPM1~ASRPM5)

Register	Offset	Access	Reset Value	Recommend Value
ASRPM1	0x40	R/W	0x00_0000	0x7fffff
ASRPM2	0x44	R/W	0x00_0000	0x255555
ASRPM3	0x48	R/W	0x00_0000	0xff7280
ASRPM4	0x4C	R/W	0x00_0000	0xff7280
ASRPM5	0x50	R/W	0x00_0000	0xff7280

ASRIDRLC	94h

Function

The ideal ratio registers (ASRIDRHC, ASRIDRLC) hold the ratio value IDRATIOC. IDRATIOC = Fs_{inC}/Fs_{outC} = Ts_{outC}/Ts_{inC} is a 32-bit fixed point value with 26 fractional bits. This value is only useful when ASRCTR[USRC, IDRC]=2'b11.

49.6.1.21 ASRC 76 kHz Period (ASR76K)

Offset

Register	Offset
ASR76K	98h

Function

Holds the period of the 76 kHz sampling clock in terms of the ASRC processing clock with frequency Fs_{ASRC}. ASR76K = Fs_{ASRC}/Fs_{76k}. Reset value is 0x0A47 which assumes that Fs_{ASRC}=200 MHz. This register is used to help the ASRC internal logic to decide the pre-processing and the post-processing options automatically (see ASRC Control Register and ASRC Filter Configuration Status Register). In a system when Fs_{ASRC} = 133 MHz, the value should be assigned explicitly as 0x06D6 in user application code.

50.2 Overview

MICFIL delivers audio from microphones to the processor in several applications, such as mobile telephones. As current digital audio systems use a multi-bit audio signal (also known as multi-bit PCM) to represent the signal, this module implements the required digital interface (a series of filters) to transform a pulse density modulated (PDM) microphone bitstream into a 24-bit PCM signal in the audio band, at a configurable output sampling rate.

The implementation of this digital interface is based on the application of digital signal processing techniques used in hardware. The MICFIL architecture is designed to save gate count and minimize power consumption.

You can implement MICFIL to work in a multi-channel mode. All channels have the same configuration, but you could independently turn on or turn off each input channel.

50.2.1 Block diagram

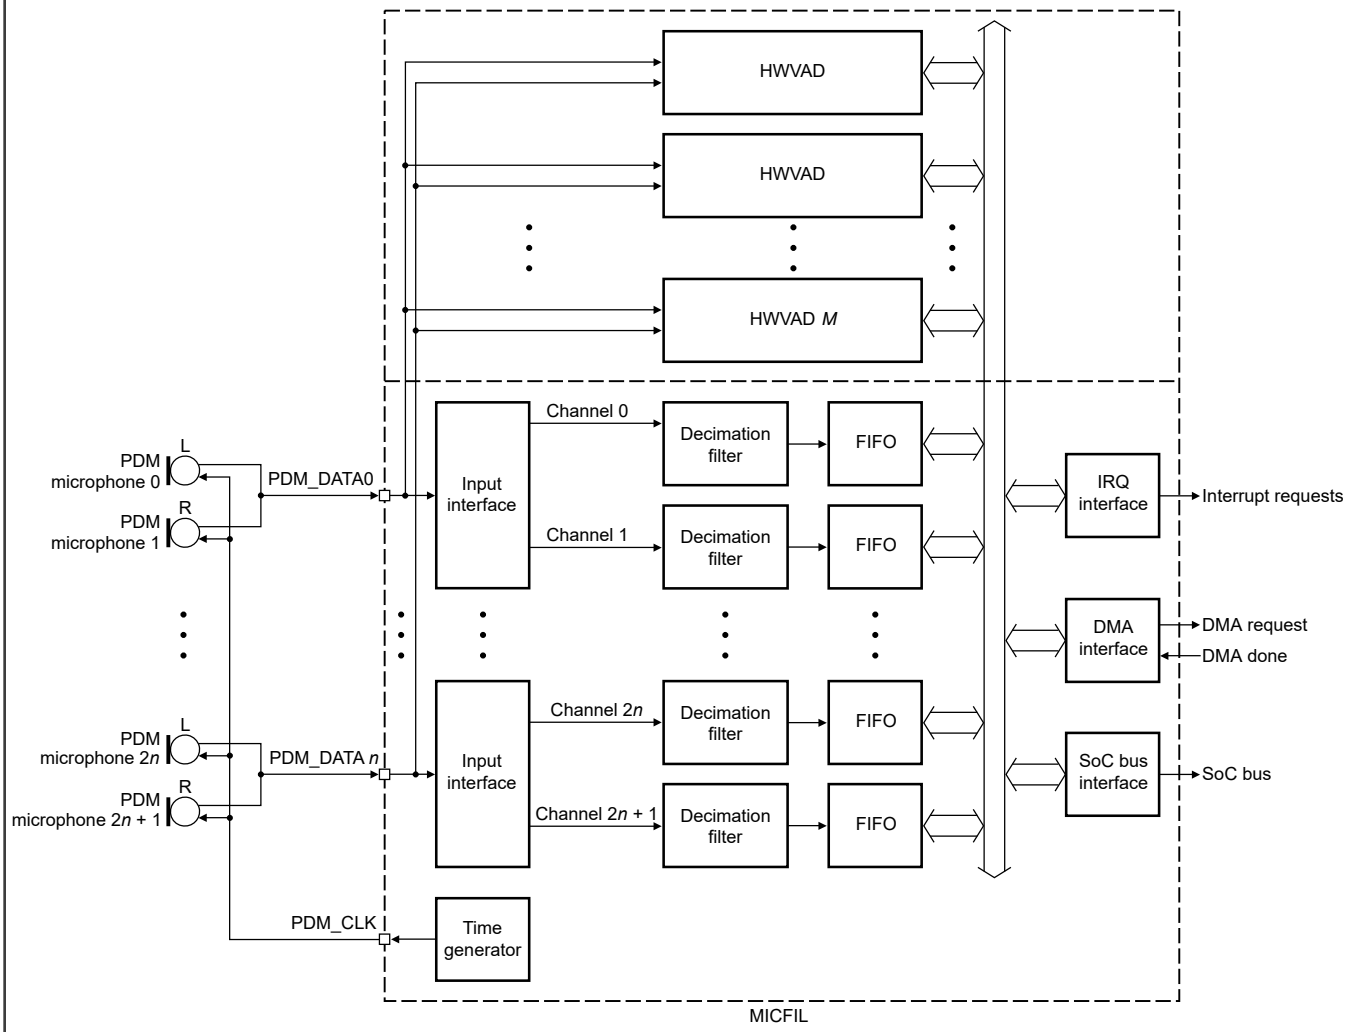

Figure 295. MICFIL block diagram

50.2.2 Features

- Decimation filters:
  - Fixed-point filtering
  - 24-bit PCM audio output
  - Internal clock divider for a programmable PDM clock generation:
  - Full or partial set of channel operations with individual enable controls
  - Programmable decimation rate
  - Programmable DC remover
  - Programmable DC remover at output
  - Range adjustment capability
- FIFOs with interrupt and DMA capability: each FIFO having a length of 8 entries
- HWVAD, equipped with:

— Interrupt capability

— Zero-Crossing Detection (ZCD) option

50.3 Functional description

50.3.1 Time generator

The time generator unit:

- Generates the PDM_CLK to microphones. This clock is the same and is active for all the PDM microphones, which means, it is not possible to turn off the PDM_CLK only for one single microphone.
- Delivers the PDM_CLK to all microphones that must operate at the same clock frequency. Each input interface receives a time multiplexed PDM bitstream from two PDM microphones and it separates audio information in two channels: left (0) and right (1). Every decimation filter, corresponding to its channel, does this processing.

NOTE

A soft reset affects the time generator unit (see CTRL_1[SRES]). The PDM_CLK starts with a rising edge after a soft reset is issued.

50.3.1.1 Clock divider

The sampling rate of the microphone input depends on the PDM_CLK rate, which you can trim using an internal clock divider, configuring the quality mode (see Quality modes) or trimming the MICFIL's root clock frequency (MICFIL_CLK_ROOT rate).

The internal clock divider frequency. You must configure CTRL_2[CLKDIV] by using Equation 4.

$$\text{CLKDIV} = \frac{\text{MICFIL\_CLK\_ROOT rate}}{8 \times \text{OSR} \times (\text{output rate})}$$

Equation 4. CLKDIV value calculation

After calculating the value of CTRL_2[CLKDIV], you can estimate the generated PDM_CLK rate based on Equation 5, where the "K" factor value depends on the quality mode shown in Table 332 and floor(x) is the function that takes a real number x as input and gives the greatest integer less than or equal to x as output.

$$\text{PDM\_CLK rate} = \frac{\text{MICFIL\_CLK\_ROOT}}{2 \times \text{floor} \times (\text{K} \times \text{CLKDIV})}$$

Equation 5. PDM_CLK rate calculation

Table 332. K factor value

Quality mode	K factor
High Quality	1/2
Medium Quality, Very-Low Quality 0	1
Low Quality, Very-Low Quality 1	2
Very-Low Quality 2	4

50.3.1.1.1 Minimum required CLKDIV

NOTE

This minimum CLKDIV condition is required only if any decimation filter channel is enabled and the clock divider is enabled, otherwise this condition should be ignored.

To work properly the CLKDIV value must have a minimum value according to the quality mode configured (see Quality modes), the number of enabled channels (EC), OSR value and K factor (see I/O timing requirements). When this condition is not met, the LOWFREQF bit is asserted and an error interrupt can be issued (in case ERREN = 1).

The equations to estimate the minimum required CLKDIV value depending on the configured quality mode are shown in Equation 6 (for medium, high and low quality modes) and Equation 7 (for very low quality modes), on these equations floor(x) is the function that takes as input a real number x and gives as output the greatest integer less than or equal to x.

$$\text{floor}(\text{K x CLKDIV}) \geq \text{K x } \frac{10 + 93EC}{8\text{xOSR}}$$

Equation 6. Minimum required CLKDIV value in Medium, High and Low Quality modes

$$\text{floor}(\text{K x CLKDIV}) \geq \text{K x } \frac{10 + 43EC}{8\text{xOSR}}$$

Equation 7. Minimum required CLKDIV value in Very Low Quality modes

50.3.1.2 MICFIL_CLK_ROOT rate and CLKDIV calculation examples

Example 1:

If it is required an output rate = 16 kHz and enables 4 channels (EC=4). A valid configuration is following:

1. Configure High Quality mode and CIC decimation by 32 (CICOSR = 0, then OSR = 16).
2. Check the PDM_CLK rate for High Quality mode in Table 336. PDM_CLK rate = 16 kHz x 8 x OSR = 16 kHz x 8 x 16 = 2.048 MHz.
3. Check the K factor value for High Quality mode in Table 332. K factor is 1/2.
4. Calculate minimum CLKDIV value (see Equation 6): floor(K x CLKDIV) ≥ K x (10 + 93EC)/(8 x OSR) then floor(K x CLKDIV) ≥ 1.4921875. Finally, CLKDIV ≥ 4.
5. Calculate the minimum MICFIL_CLK_ROOT rate:
   - From Equation 4: MICFIL_CLK_ROOT rate = 8 x OSR x CLKDIV x (Output rate)
   - From step 4 result: CLKDIV ≥ 4, then MICFIL_CLK_ROOT rate ≥ 8 x OSR x 4 x 16 kHz.
   - Finally: MICFIL_CLK_ROOT rate ≥ 8.192 MHz
6. Check if selected MICFIL_CLK_ROOT rate and CLKDIV value satisfies the IO timing requirements.
7. Finally, check again if the selected MICFIL_CLK_ROOT rate satisfies Equation 4. If not, adjust CLKDIV or change MICFIL_CLK_ROOT rate accordingly.

Example 2:

If it is required an output rate = 48 kHz and enables 4 channels (EC=4). A valid configuration is following:

1. Configure Medium Quality mode and CIC decimation by 16 (CICOSR = 0, then OSR = 16).
2. Check the PDM_CLK rate for Medium Quality mode in Table 336. PDM_CLK rate = 48 kHz x 4 x OSR = 48 kHz x 4 x 16 = 3.072 MHz.
3. Check the K factor value for Medium Quality mode in Table 332. K factor is 1.
4. Calculate minimum CLKDIV value (see Equation 6): floor(K x CLKDIV) ≥ K x (10 + 93EC)/(8 x OSR) then floor(K x CLKDIV) ≥ 2.984375. Finally, CLKDIV ≥ 3.
5. Calculate the minimum MICFIL_CLK_ROOT rate:
   - From Equation 4: MICFIL_CLK_ROOT rate = 8 x OSR x CLKDIV x (Output rate)
   - From step 4 result: CLKDIV ≥ 3, then MICFIL_CLK_ROOT rate ≥ 8 x OSR x 3 x 48 kHz.
   - Finally: MICFIL_CLK_ROOT rate ≥ 18.432 MHz

- A different value of CLKDIV may be preferable, CLKDIV = 4 results in MICFIL_CLK_ROOT = 24.576 MHz, a standard audio frequency.

6. Check if selected MICFIL_CLK_ROOT rate and CLKDIV value satisfies the IO timing requirements.
7. Finally, check again if the selected MICFIL_CLK_ROOT rate satisfies Equation 4. If not, adjust CLKDIV or change MICFIL_CLK_ROOT rate accordingly.

50.3.1.3 I/O timing requirements

The PDM microphones must meet the setup and hold timing requirements shown in Table 333 and Figure 296. The "K" factor value in Table 333 depends on the quality mode you select based on Table 332.

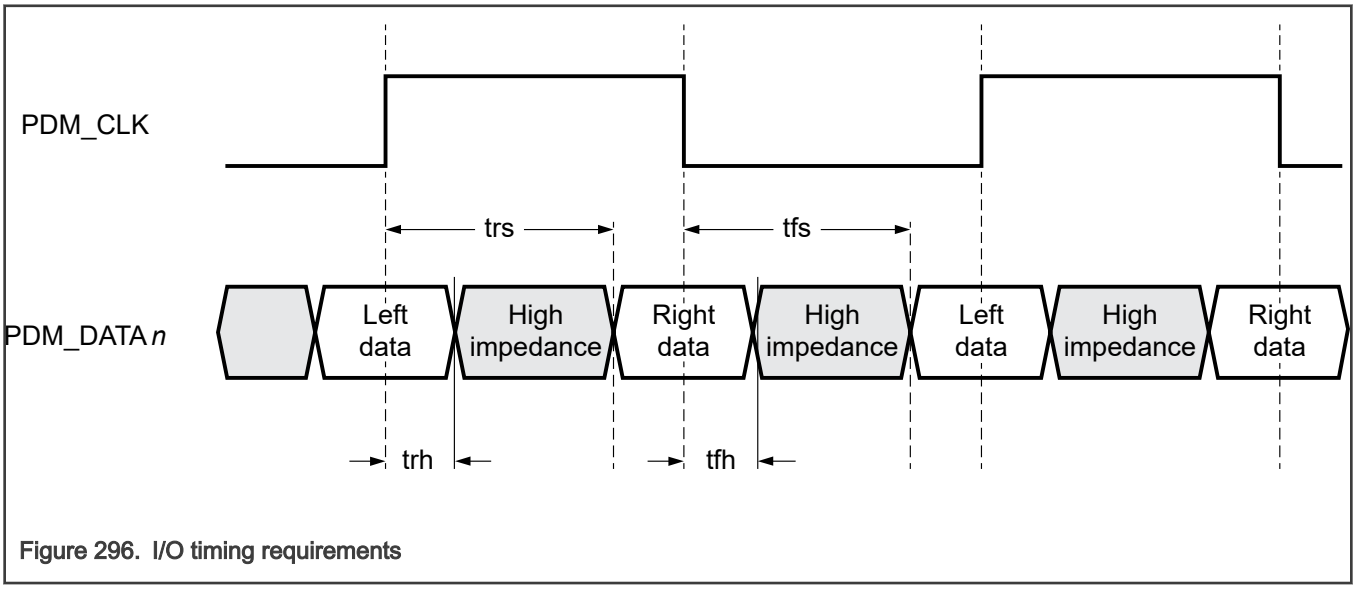

Figure 296. I/O timing requirements

Table 333. Timing parameters

Parameter	Value
trs, tfs	$\leq \frac{\text{floor}(\text{K x } CLKDIV) - 1}{\text{MICFIL\_CLK\_ROOT rate}}$ Depending on the value of "K," you must ensure that "floor(K x CTRL_2[CLKDIV])" > 1 to avoid timing problems.
trh, tfh	≥ 0

50.3.2 Input interface

Figure 297 shows the timing diagram of the input interface signals . The bitstream incoming from the microphone data input "n" (PDM_DATAn) in the first half (right microphone) of the PDM_CLK is directed to channel "2n+1" and the data generated during the last half (left microphone) is directed to channel "2n".

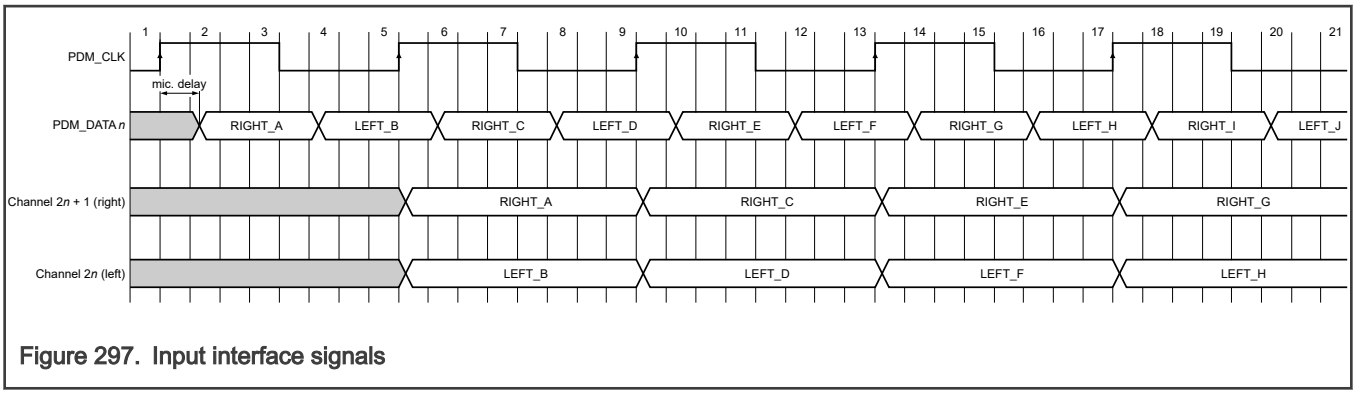

Figure 297. Input interface signals

50.3.3 Decimation filter

A decimation filter facilitates PDM to PCM conversion.

Figure 298 shows the block diagram of the decimation filter. The block consists of:

- A cascade integrator comb (CIC) filter, which is a low-pass filter that you commonly use to filter sigma-delta modulator output signals. The filter is implemented in the audio band (20 Hz–22.5 kHz @48 kHz output sampling rate by default) with a configurable decimation rate. You can implement it using a series of CIC, compensation, and DC remover filters.
- A DC remover, which is a high-pass filter that you use to remove the DC component of the processed signal with a configurable cut-off frequency. Two DC removers exist: one in the input of the decimation filter, embedded in the CIC filter, and another in the last stage of the decimation filter.
- Two compensation filters for each channel, which implement a low-pass digital filter with decimation by 2. You can use them to compensate the high CIC drop in passband. These filters help the FIR filter block to flatten the overall passband response.

You activate the "Sampler" block depending on the quality mode selected (using CTRL_2[QSEL]). In Low-Quality and Very-Low-Quality 2 modes, the sampling rate is doubled.

The decimation filter output depends on the quality mode that you select by using CTRL[QSEL], based on different compensation filter output. You can supply the DC remover with the 2 FS signal, instead of the 1 FS signal, to achieve lower-power consumption, bypassing the second compensation decimation filter. The second compensation filter is bypassed when CTRL_2[QSEL] = 110b, 101b, or 100b (in Very-Low Quality modes).

You can adjust the range of each decimation filter by using a range adjustment block so that you can raise an error interrupt in case an adjustment overflow or underflow is detected.

The output of a decimation filter is stored into a FIFO buffer, and each FIFO is mapped to MICFIL Output Result (DATACH0 - DATACH7). It is possible to generate either an interrupt or a DMA request when, in each FIFO of all enabled channels, the number of data stored surpasses a configured watermark.

Also, independently on decimation filters, there is a Hardware Voice Activity Detector (HWVAD) which implements voice-detection algorithms to generate wake-up interrupts. See Hardware voice activity detector.

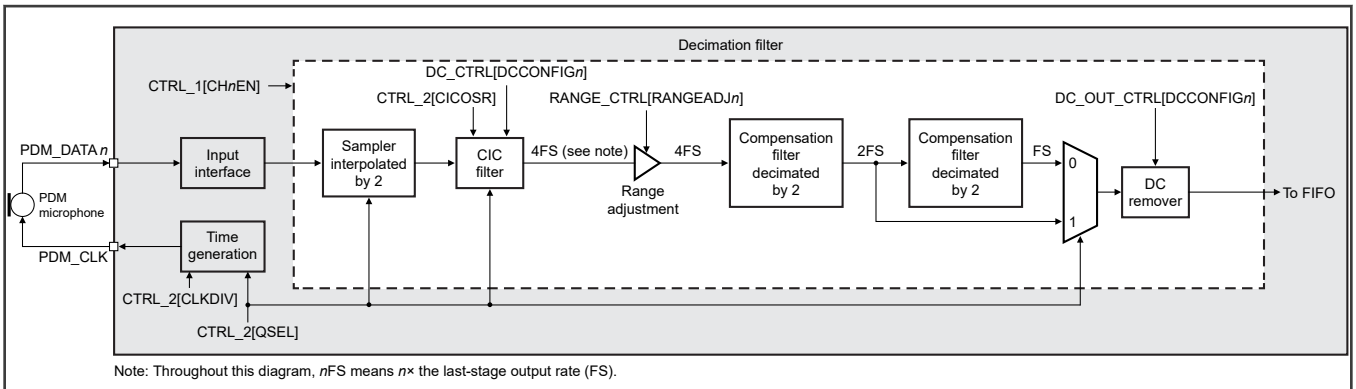

Figure 298. Decimation filter block diagram

50.3.3.1 CIC filter

The CIC filter is an optimized implementation of the low-pass SINC filter, with multiple stages. It is widely used because it requires just adders and subtracters. The CIC filter comprises an integrator and a comb as its sub-blocks. As shown in the following figure, CTRL_2[CICOSR] and the quality mode you select (see Quality modes) define the CIC decimation rate.

$$OSR = 16 - CICOSR$$

$$\text{CIC decimation rate} = \begin{cases} 2 \times OSR & \text{; If HQ, VLQ0} \\ OSR & \text{; others} \end{cases}$$

Equation 8. CIC decimation rate

50.3.3.2 DC remover

Two DC removers exist in the filter chain, one in the input and another in the output. The former is integrated in the CIC filter, and the latter is placed just before the FIFO. Both can be bypassed independently.

The DC remover eliminates the DC level component of the signal using a high-pass filter with a very low cut-off frequency that you select using DC_CTRL[DCCONFIGn]. This filter is bypassed when the value of this field is 11b.

50.3.3.3 Compensation filters

A compensation filter divides the baseband signal into two equal subbands before it could to be decimated by 2. It also compensates the CIC filter drop in passband and helps to flatten the overall passband response. MICFIL includes two compensation filter stages, with the possibility of bypassing the last one.

50.3.3.4 Filter performance

50.3.3.4.1 Overall filter gain

As shown in Equation 9, the overall filter gain depends on:

- The quality mode you select (see Quality modes).
- The CIC decimation rate (see Equation 8).
- Dynamic range adjustment of the CIC filter (see RANGE_CTRL[RANGEADJn]).

NOTE

To get a better audio performance, you must configure and adjust RANGE_CTRL[RANGEADJn] depending on the quality mode selected, as pointed out in the register description.

$$\text{Overall filter gain (dB)} = \begin{cases} 100 \times \log_{10}(32 - 2 \times \text{CICOSR}) + 6.02 \times \text{RANGE\_CTRL[RANGEADJ}n\text{]} - 150.50 & ; \text{if QSEL} \in [\text{HQ,VLQ0}] \\ 100 \times \log_{10}(16 - \text{CICOSR}) + 6.02 \times \text{RANGE\_CTRL[RANGEADJ}n\text{]} - 150.50 & ; \text{others} \end{cases}$$

Equation 9. Overall filter gain

Finally, the input and output dBFS levels relate to each other, as shown in Equation 10.

$$\text{Output (dBFS)} = \text{input (dBFS)} + \text{overall filter gain (dB)}$$

Equation 10. Filter input and output relationship

50.3.3.4.2 Overall passband

The decimation filter passband depends on the quality mode and output rate (FS). For instance, the overall filter passband for different output data rates when MICFIL is in High (HQ), Medium (MQ), and Low-Quality (LQ) modes is shown in Table 334.

Table 334. Filter passband in HQ, MQ, and LQ modes (DC_CTRL[DCCONFIGn] = 0)

Output data rate	Overall filter passband
FS	**0.0004FS - 0.4688FS**
16 kHz	6.67 Hz - 7.50 kHz
48 kHz	20 Hz - 22.5 kHz

The overall filter passband for different output data rates when MICFIL is in Very-Low Quality (VLQ) modes is shown in Table 335.

Table 335. Filter passband in VLQn modes (DC_CTRL[DCCONFIGn] = 0)

Output data rate	Overall filter passband
FS	**0.0002FS - 0.2344FS**
16 kHz	3.33 Hz - 3.75 kHz
48 kHz	10.00 Hz - 11.25 kHz
96 kHz	20 Hz - 22.5 kHz

50.3.3.5 Quality modes

If the decimation filter is running independently on the selected power mode, MICFIL can operate in multiple different quality modes that you can select by using CTRL_2[QSEL]. The decimation and interpolation rates in internal blocks are shown in Table 336, where the oversampling rate (OSR) depends on the value of CTRL_2[CICOSR], as shown in the following equation.

$$\text{OSR} = 16 - \text{CICOSR}$$

Equation 11. OSR

You can configure the selected quality dynamically when the decimation filter is running; the output rate is maintained in every quality selected.

The passband of the decimation filter depends on the quality mode (see Overall passband).

To maintain the same output rate in the decimation filter when the quality is changed, the PDM_CLK rate changes depending on the quality selected. For more on PDM_CLK, see Time generator.

You can enable or disable the sampler and compensation filters according to the selected quality. When they are disabled, you can achieve a low-power consumption. The selected quality also determines whether the CIC filter decimation rate is doubled. For more, see Decimation filter.

With an increase of the clock rate and OSR, you can expect a better signal-to-noise ratio (SNR) performance, which in turn leads to a higher audio quality.

Table 336. Quality modes

Quality mode	CTRL_2[QSEL]	Sampler interpolation	CIC filter decimation	First-compensation filter decimation	Second-compensation filter decimation	PDM_CLK rate	Passband
High Quality	001	—	:(2OSR)	:2	:2	Output rate × 8 × OSR	To ~0.5 × output rate
Medium Quality	000	—	:OSR	:2	:2	Output rate × 4 × OSR	To ~0.5 × output rate
Low Quality	111	× 2	:OSR	:2	:2	Output rate × 2 × OSR	To ~0.5 × output rate
Very-Low Quality 0	110	—	:(2OSR)	:2	—	Output rate × 4 × OSR	To ~0.25 × output rate
Very-Low Quality 1	101	—	:OSR	:2	—	Output rate × 2 × OSR	To ~0.25 × output rate
Very-Low Quality 2	100	× 2	:OSR	:2	—	Output rate × OSR	To ~0.25 × output rate

50.3.3.6 Output rate

The output rate is the sampling rate at the decimation filter output. It depends on the sampling rate of the microphone input and the configured quality mode (see Quality modes). Common audio sampling rates are 48 kHz and 16 kHz. In this chapter, the output rate is sometimes referred to as FS.

50.3.4 Hardware voice activity detector

The Hardware Voice Activity Detector (HWVAD) is a block responsible for detect voice activity in a channel selected by the user as shown in the Figure 299 and Figure 300. The HWVAD takes data from the input of a selected PDM microphone to detect if there is any voice activity. If a voice activity is detected, an interrupt could be delivered to the system. It can be configured in Envelope-based or Energy-based mode and it should be configured as described in Initialization.

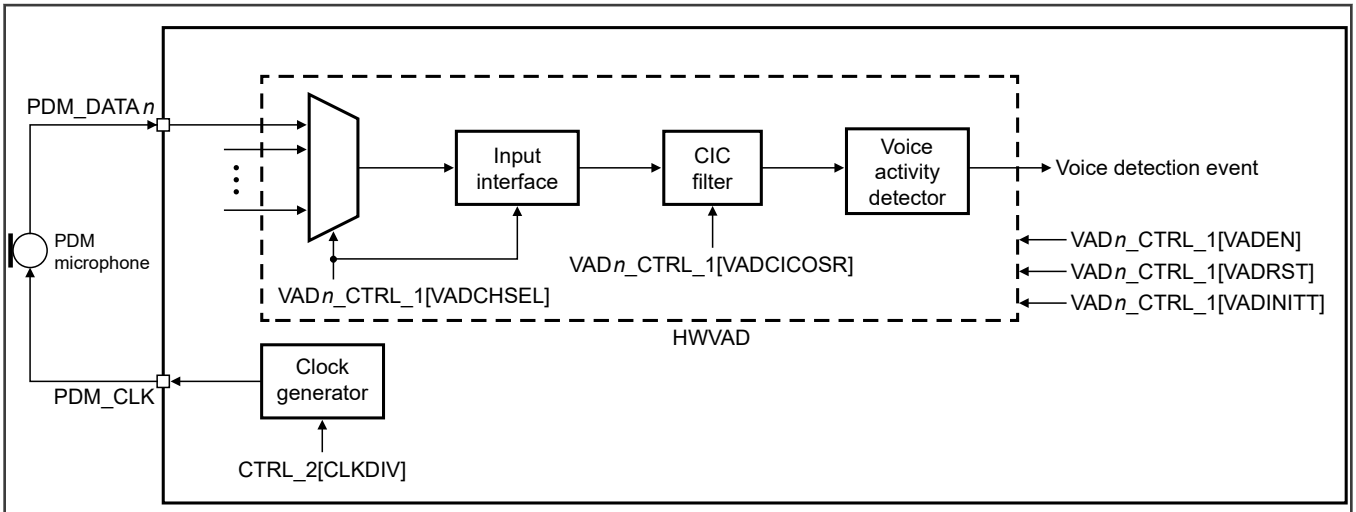

Figure 299. HWVAD block diagram

The HWVAD can divide the incoming PCM signal from its internal CIC in frames, the frame energy is used to estimate the background noise. Both frame energy and noise energy are examined, a voice activity is detected when a specific delta between them is detected, then a interrupt will be issued. Optionally a Zero-Crossing Detection block (ZCD) could be enabled to avoid low energy voiced speech be missed, improving the voice detection performance.

The HWVAD detector can be enabled by the VADEN bit (VAD_CTRL_1 register) and could be reset by software through the VADRST bit (VAD_CTRL_1 register) . It is important to remark that the HWVAD detector could be enabled and/or reset only when the MICFIL isn't running i.e. when the BSY_FIL bit in STAT register is cleared.

To perform voice detection a Noise Filter and Signal Filter are used as shown Figure 300. In addition, a minimum block in the output of the Noise Filter and a maximum block in the output of the Signal Filter can be used. The result of both blocks can be scaled by gain blocks. Finally, the signal and noise estimated are compared, voice is detected when signal is greater than noise.

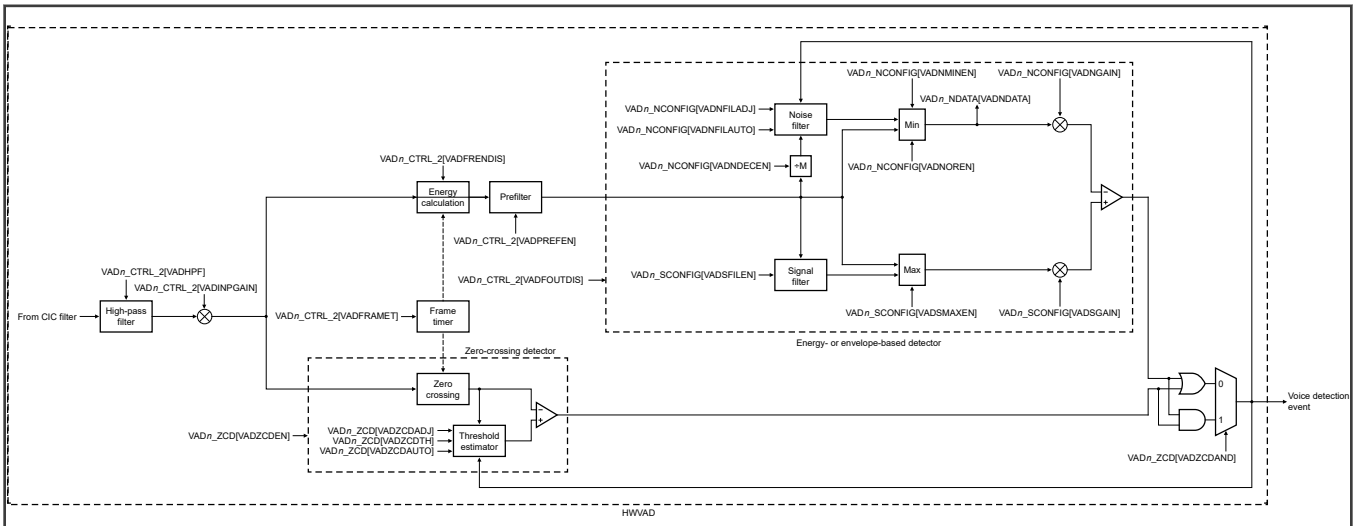

Figure 300. HWVAD block diagram (continued)

50.3.4.1 High-pass filter

The purpose of the High-Pass Filter is to remove the low frequency components. The cut-off frequency is selected by the VADHPF field. This filter is bypassed when VADHPF=00.

50.3.4.2 Input setting

The HWVAD input has internally a user configurable High-Pass filter (see VADHPF bit description) and a user configurable gain (see VADINPGAIN). Both controls could be used to configure the module based on external noise conditions.

50.3.4.3 Frame time setting

In order to perform voice detection the signal frames incoming from the CIC filter can be divided in frames whose duration can be configured. The frame time will depend on the CIC output rate, the value of VADFRAMET and a constant as is defined in Equation 12.

$$frame\ \ time = \frac{VADFRAMET \times 192}{CIC\ \ output\ \ rate}$$

Equation 12. Frame time

For instance, in the typical case of the CIC filter output rate would be 192 kHz, the frame time would be 10 ms when VADFRAMET is 10.

50.3.4.4 Initialization time

An initialization time can be configured by the VADINITT field. During this initialization time no voice detection event is issued, all detectors are kept disabled.

For instance, in case that frame time is 10ms and VADINITT = 10, the initialization time would be 110ms.

$$initialization\ \ time = (\mathrm{VADINITT}+1) \times frame\ \ time$$

Equation 13. Initialization time

50.3.4.5 Energy calculation

In case VADFRENDIS = 0, the sum of the absolute values of all the samples of each frame are used to detect voice. Otherwise, if VADFRENDIS = 1, the absolute value of the samples are used to detect voice i.e. the data incoming from CIC is not divided in frames.

50.3.4.6 Pre-filter

The Pre-Filter block is a low-pass filter which can be enabled when VADPREFEN = 1.

50.3.4.7 Energy/Envelope-based detector

To perform voice detection a Noise Filter and Signal Filter are used as shown Figure 300. In addition, a minimum block in the output of the Noise Filter and a maximum block in the output of the Signal Filter can be used. The result of both blocks can be scaled by gain blocks. Finally, the signal and noise estimated are compared, voice is detected when signal is greater than noise.

50.3.4.7.1 Noise filter

The Noise Filter is a low-pass filter . This filter could be adjusted by the VADNFILADJ field . In case VADNFILAUTO = 1 the noise filter is enabled only when voice is not detected, when voice is detected the filter output does not change. In case VADNFILAUTO = 0 the filter is always enabled.

A decimation stage in the input of the Noise Filter can be enabled by the VADNDECEN field.

50.3.4.7.2 Minimum noise

In order to estimate the noise, a block which calculates the minimum value between the input and output of the noise filter is used. This block can be enabled by VADNMINEN, otherwise the output of the noise filter is passed directly.

The estimated noise of the output of this block is stored in the VADNDATA register for post-processing via software.

50.3.4.7.3 Signal filter

The Signal Filter is a low-pass filter . This filter will be enabled when VADSFILEN=1, otherwise the filter will be bypassed.

50.3.4.7.4 Maximum signal

In order to estimate the signal, a block which calculates the maximum value between the input and output of the signal filter can be used. This block can be enabled by VADSMAXEN.

50.3.4.7.5 Filter result gain setting

There are two gain adjustment controls, one for the estimated noise (VADNGAIN) and another for signal estimated (VADSGAIN). Both gain adjustments outputs are compared, the comparison result determines whether or not there is voice in the channel.

50.3.4.8 Zero-crossing detector

Optionally, the HWVAD performance can be increased by the use of a Zero-Crossing Detection (ZCD) circuit. It is enabled by a VADZCDEN bit.

The threshold of the ZCD could be static or calculated dynamically depending on the VADZCDAUTO bit. When it is dynamically determined (VADZCDAUTO = 1) the threshold is calculated automatically taking VADZCDTH as initial value, otherwise (VADZCDAUTO = 0) the threshold is static in the VADZCDTH user configurable value.

You can use AND or OR to combine the ZCD result with the energy-based or envelope-based detection, it is selected by the VADZCDAND bit. The filter coefficient is equal to (VADZCDADJ + 1) × 2^{-4}.

50.3.4.9 Interrupt

The HWVAD issues an interrupt when voice activity is detected and the VADIE bit in the VAD_CTRL_1 register is enabled. The voice activity event also will set the VADIF flag in the VAD_STAT register, this bit will be cleared when it is written 1.

50.3.4.10 Extended operation

The VADIF bit could be used for a HWVAD extended operation i.e. using the VADNDATA value to determine a more accurate voice detection event by software. The procedure to follow will be:

1. An interrupt is issued by the HWVAD, the VADIF is set.
2. Leave the VADIF asserted while software is processing the VADNDATA field content.
3. When software finishes to process the VADNDATA and detects voice activity:
   - If Envelope-based Detection is used, pulse VADST10 by more than 2-cycles and clear VADIF flag.
   - If Energy-based Detection is used, clear VADIF flag.

50.3.4.11 VAD soft-reset

The VAD soft-reset is requested by writing 1 to the VADRST bit. It resets the following blocks and/or registers:

- VADIF, VADINSATF fields.
- All internal VAD buffers.

50.3.5 Bus interface

The bus interface manages DMA transactions, interrupt requests, and user register interface with the chip.

MICFIL can deliver an interrupt request or DMA request. Then, the chip or DMA, respectively, could access the filter results stored in FIFOs via the internal bus interface.

For detailed information on DMA transactions and interrupt requests, see DMA and Interrupts.

50.3.5.1 FIFO

This is the first-in, first-out (FIFO) buffer that saves the overall filtering results. The length of each FIFO is 8 entries, and there exists one FIFO for each channel. A push writes data into the FIFO, and a read pops data from FIFO. The push and pop operations from FIFO are in different clock domains. The push operation uses the MICFIL clock while the pop operation uses the CPU clock. The FIFO has a configurable watermark (see FIFO_CTRL[FIFOWMK]). When the amount of data in all FIFOs of the enabled channels is greater than the watermark value (FIFO_CTRL[FIFOWMK]), a DMA or IRQ is requested, depending on the value of CTRL_1[DISEL]. After CTRL_1[PDMIEN] enables the filters, the initial FIR results are discarded and not written into the FIFOs. Approximately 68 initial FIR results are not stored in FIFOs (FIR_RDY=0). After the filter generates valid data, the results are pushed into the FIFO.

A new filtered result is discarded (not stored) when the FIFO is full and CTRL_1[FIFOOVFn] becomes 1. Similarly, when trying a pop operation, if the FIFO is empty, no valid data is read and CTRL_1[FIFOUNDn] becomes 1. In both cases, when overflow or underflow occurs, they are flagged in MICFIL FIFO Status (FIFO_STAT) to the respective channel, and an error interrupt is generated if CTRL_1[ERREN] is 1.

When you reset the FIFO by writing 1 to CTRL_1[SRES], zero values fill all FIFO positions, as well as push and pop pointers are set to their initial positions.

50.3.6 Modes of operation

This section describes the MICFIL operating modes that depend on:

- The chip's power mode
- The chip's Doze mode .
- The chip's Debug mode .
- Configuration of CTRL_1[MDIS], CTRL_1[DBGE], CTRL_1[DBG], and CTRL_1[DOZEN], as summarized in the following table.

Table 337. Mode selection

<table>
<tr><th>Mode</th><th>CTRL_1[MDIS]</th><th>Chip Doze and DOZEN = 1</th><th>Chip Power mode</th><th>CTRL_1[DOZEN]</th><th>Chip Debug | CTRL_1[DBG]</th><th>CTRL_1[DBGE]</th><th>CPU clock</th><th>MICFIL internal clock</th><th>Decimation Filter state</th><th>HWVAD[n] state</th></tr>
<tr><td>Normal</td><td rowspan="6">0</td><td rowspan="4">0</td><td rowspan="2">RUN</td><td rowspan="2">Any</td><td>0</td><td>Any</td><td rowspan="3">Enabled</td><td rowspan="4">Enabled</td><td>Run (depends on PDMIEN and CHnEN)</td><td>Run (depends on PDMIEN and VADEN)</td></tr>
<tr><td>Debug</td><td rowspan="2">1</td><td>1</td></tr>
<tr><td>Low-Power</td><td rowspan="2">SLEEP</td><td rowspan="2">0</td><td>0</td><td rowspan="3">Any</td><td rowspan="3">Any</td><td>Stop</td><td>Stop</td></tr>
<tr><td>DEEPSLEEP</td><td rowspan="3">Gated (externally)</td><td>Run (depends on PDMIEN and CHnEN)</td><td rowspan="2">Run (depends on PDMIEN and VADEN)[1]</td></tr>
<tr><td>Disable/ Low-Leakage</td><td>SLEEP/ DEEPSLEEP</td><td>1</td><td rowspan="2">Gated</td><td rowspan="2">Stop</td><td rowspan="2">Stop</td></tr>
<tr><td>1</td><td>Any</td><td>Any</td><td>Enabled</td></tr>
</table>

Table continues on the next page...

Table 337. Mode selection (continued)

Mode	CTRL_1[MDIS]	Chip Doze and DOZEN = 1	Chip Power mode	CTRL_1[DOZEN]	Chip Debug | CTRL_1[DBG]	CTRL_1[DBGE]	CPU clock	MICFIL internal clock	Decimation Filter state	HWVAD[n] state
	1	Any					Gated (internally)			

1. HWVAD[n] will run in DEEPSLEEP only if it is placed on an always-on power domain in the chip.

50.3.6.1 Normal mode

This is the default operational mode for MICFIL. In this mode, you can enable the channel functionality to perform the filtering operation.

50.3.6.2 Debug mode

You could use this mode to check the status of the module, when requested. In this mode, you can stop MICFIL after the remaining data processing is complete, depending on the value of CTRL_1[DBGE]. You can activate this mode by writing 1 to CTRL_1[DBG].

If CTRL_1[DBGE] = 0, and CTRL_1[DBG] = 1 when MICFIL is running, MICFIL stops after processing the remaining data. Otherwise, if DBGE = 1, MICFIL continues to run.

MICFIL cannot enter Debug mode after entering DLL or Low-Power mode.

The Debug mode affects all channels in MICFIL. Access to output buffers, as well as their related flags, remains operational.

50.3.6.3 Low-Power mode

MICFIL enters In Low-Power mode, MICFIL is able to filter the PDM microphone data and perform voice detection such as in Normal mode, and can generate a wake-up event through asynchronous DM or IRQ requests, depending on the values of CTRL_1[CHnEN], VADEN, and CTRL_1[PDMIEN].

The Low-Power mode is entered when the SoC enters to SLEEP or DEEPSLEEP modes and DOZEN=0. In this mode the CPU clock is gated externally and MICFIL could be kept running.

In case a SoC SLEEP mode is requested, the decimation filter is kept running such as Normal mode and the SoC SLEEP mode is acknowledged immediately.

In case a SoC DEEPSLEEP mode is requested it is waited until the last input samples are processed to acknowledge the SoC mode and stop the decimation filter.

During this mode, VADEN will continue running if it was previously enabled (VADEN=1) during Normal mode.

You can generate DMA and IRQ requests asynchronously to wake up the CPU.

NOTE

The asynchronous DMA or interrupt requests are generated only in this mode.

50.3.6.4 DLL mode

In this mode, MICFIL stops after the remaining data processing is complete. MICFIL is in DLL mode when:

- The chip is in SLEEP and DEEPSLEEP modes and CTRL_1[DOZEN] = 1.
- The chip is in Doze mode and CTRL_1[DOZEN] = 1.
- CTRL_1[MDIS] = 1.

If you request DLL mode when MICFIL is running, MICFIL stops after completion to process the remaining data.

You can write only to CTRL_1 and CTRL_2, with the exception of writes to CTRL_1[DBG] and CTRL_1[SRES], which are ignored. However, you can still read these fields.

50.3.7 Clocking

Table 338. MICFIL clocks

Clock name	Description
MICFIL_CLK, MICFIL_CLK_S	Clock that controls the registers
MICFIL_CLK_APP	Application clock that operates the filter

Besides the above clock signals, MICFIL generates PDM_CLK for PDM microphones based on MICFIL_CLK_APP frequency and the value in CLKDIV.

50.3.8 Interrupts

If CTRL_1[DISEL] = 10b, an interrupt request indicates that filtering results are stored in the FIFOs to be read by the CPU. In this case, you can read the data in DATACHn[DATA], and STAT[CHnF] becomes 1 for the enabled channels when the CHn FIFO surpasses the watermark level.

When MICFIL is in Low-Power mode, the CPU clock is disabled, but the MICFIL clock remains enabled. In this case, an asynchronous interrupt is delivered to the system. This wakes up the CPU clock, which returns to Normal mode. The system could read the FIFO data, after which it must clear STAT[CHnF] to get a new interrupt request.

An error interrupt request can also be generated when an exceptional condition happens, such as an overflow or underflow in a channel output, or an overflow or underflow of a FIFO buffer, or the MICFIL clock rate is not the minimum value required to the MICFIL working (see Minimum required CLKDIV).

CTRL_1[ERREN] enables error interruption and the respective status flag signalizes the type of error:

- OUTOVFn and OUTUNFn for channel outputs errors
- FIFO_STAT[FIFOOVFn] and FIFO_STAT[FIFOUNDn] for FIFO errors
- LOWFREQF for MICFIL clock rate

50.3.9 DMA

If CTRL_1[DISEL] = 1, the FIFO stored samples are read through DMA transactions. Then if there is at least one enabled channel and all FIFOs of all enabled channels reach their watermark levels, the output interface makes a request for a DMA transaction.

If CTRL_1[PDMIEN] = 1 and the filters start to operate, you must wait until the filter results stabilize and no filter results are stored in the FIFOs. Therefore, the first DMA request takes longer to occur than the ones that follow.

STAT[CHnF] becomes 1 after a DMA transaction is complete.

If MICFIL is in Low-Power mode and the watermark level is surpassed, an asynchronous DMA request is delivered to the system. Then, the system wakes up the CPU clock, returning to Normal mode to read the FIFO data.

50.4 External signals

Table 339. PDM microphone interface external signals

Signal	Description	Direction
PDM_DATAn	Data bitstream received from the n^{th} PDM microphone pair throughout the input interface (see Input interface)	I
PDM_CLK	Clock that is delivered to the PDM microphones from the clock generator (see Time generator)	O

NOTE

MICFIL does not provide metastability protection or filtering for input data. You must generate the data using the provided PDM_CLK.

50.5 Initialization

50.5.1 Procedure without HWVAD

Perform this procedure for MICFIL initialization without enabling voice activity detector, i.e. (by using only decimation filters):

1. Program CTRL_2[CLKDIV], CTRL_1[CHnEN], FIFO_CTRL[FIFOWMK], CTRL_1[DISEL], CTRL_1[ERREN], and so on, as required. For more details see MICFIL_CLK_ROOT rate and CLKDIV calculation examples.
2. Start the module operation by writing 1 to CTRL_1[PDMIEN].

The module is ready to receive data from the input ports of the enabled channels.

50.5.2 Initialization procedure with HWVAD

In this section is described the initialization procedures to initialize MICFIL with the voice activity detector.

The voice activity detector can work in two modes: Energy-based mode or Envelope-based mode. Optionally, a Zero-Crossing Detector can be enabled to improve the voice detection.

The Energy-based method separates the audio signal in frames and estimates the energy of these frames to detect voice activity. In the other hand, the Envelope-based method calculates the audio signal envelope to detect voice.

Both methods have the same detection performance, but the Energy-based is recommended for low power applications where is expected that the chip is asleep for long periods. Envelope-based detection is recommended for applications where the device require to wake faster and it is not asleep for long periods.

The Zero-Crossing Detector is recommended to improve detection with fricatives phonemes (/e.g. /f/ or /s/) in noisy environments.

50.5.2.1 HWVAD in Energy-based mode

The sequence of steps to initialize the voice activity detector in Energy-based mode is as follows:

1. Program the control bitfields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DISEL, ERREN etc.). For more details see MICFIL_CLK_ROOT rate and CLKDIV calculation examples.
2. Configure general HWVAD parameters:
    a. CIC oversampling rate (VADCICOSR).
    b. Configure the voice source channel (VADCHSEL).
    c. Configure the internal initialization timer (VADINITT) if required. More details in Initialization time.
    d. Assert VADEN.
3. Configure input, noise and signal gains according to the environmental noise conditions:
    a. Configure the input gain (VADINPGAIN).
    b. Configure the signal gain (VADSGAIN).
    c. Configure the noise gain (VADNGAIN).
4. Enable the high-pass filter if required (VADHPF).
5. Configure the VADNFILADJ field according to environmental noise conditions (VADNFILADJ = 16 is recommended).
6. Put HWVAD in energy-based mode (default values):
    a. Keep the VADFRENDIS field cleared.
    b. Keep the VADPREFEN field cleared.

c. Keep the VADSFILEN field cleared.

d. Keep the VADSMAXEN field cleared.

e. Keep the VADNFILAUTO field asserted.

f. Keep the VADNMINEN field cleared.

g. Keep the VADNDECEN field cleared.

h. Keep the VADNOREN field cleared.

7. Initialize the Zero-Crossing Detector (Zero-crossing detector initialization) if required.
8. Enable interrupts if required (VADIE and VADERIE).
9. Start the overall module asserting the PDMIEN field.
10. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when voice is detected.

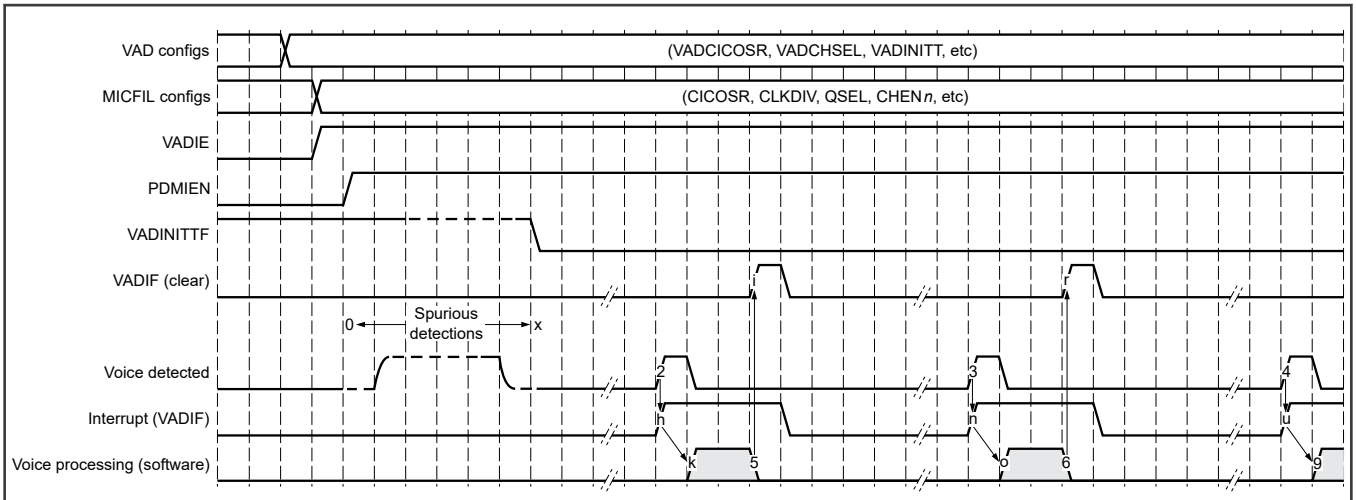

Figure 301. Energy-based initialization sequence

50.5.2.2 HWVAD in Envelope-based mode

The sequence of steps to initialize MICIL with the voice activity detector in Envelope-based mode is as follows:

1. Program the control bitfields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DISEL, ERREN etc.). For more details see MICFIL_CLK_ROOT rate and CLKDIV calculation examples.
2. Configure general HWVAD parameters:
   a. CIC oversampling rate (VADCICOSR).
   b. Configure the voice source channel (VADCHSEL).
   c. Configure the internal initialization timer (VADINITT) if required. More details in Initialization time.
   d. Assert the VADEN field.
3. Configure input, noise and signal gains according the environment noise conditions:
   a. Configure the input gain (VADINPGAIN).
   b. Configure the signal gain (VADSGAIN).
   c. Configure the noise gain (VADNGAIN).
4. Enable the high-pass filter if required (VADHPF).

5. Put HWVAD in envelope-based mode:
    a. Keep VADNFILADJ field cleared.
    b. Assert the VADFRENDISfield.
    c. Assert the VADPREFEN field.
    d. Assert the VADSFILEN field.
    e. Assert the VADSMAXEN field.
    f. Clear the VADNFILAUTO field.
    g. Assert the VADNMINEN field.
    h. Assert the VADNDECEN field.
    i. Assert the VADNOREN field.
6. Initialize the Zero-Crossing Detector (Zero-crossing detector initialization) if required.
7. Start the overall module asserting the PDMIEN bit.
8. Wait for VADINITF to be cleared.
9. Write VADST10 field three times.
10. Enable interrupts if required (VADIE and VADERIE).
11. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when voice is detected.

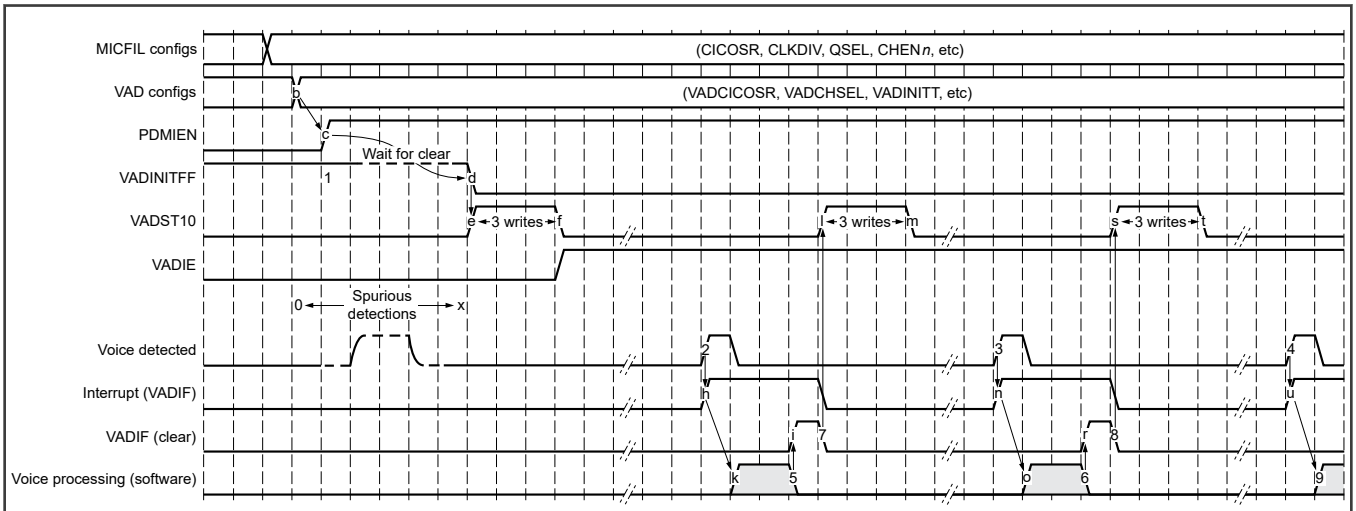

Figure 302. Envelope-based initialization sequence

50.5.2.3 Zero-crossing detector initialization

The sequence of steps to initialize the Zero-Crossing Detector in Automatic mode is as follows:

1. Configure VADZCDADJ field.
2. Configure an initial threshold in VADZCDTH field according to the environmental noise conditions if required.
3. Configure VADZCDAND field.
4. Keep VADZCDAUTO field asserted.
5. Assert VADZCDEN field.

The sequence of steps to initialize the Zero-Crossing Detector in Manual mode is as follows:

1. Configure a threshold in VADZCDTH field according to the environmental noise conditions if required.
2. Configure VADZCDAND field.
3. Clear VADZCDAUTO field.
4. Assert VADZCDEN field.

50.6 Application information

50.6.1 Reconfiguration procedure

Perform this procedure to reconfigure MICFIL:

1. Write 0 to CTRL_1[PDMIEN].
2. Wait for STAT[BSY_FIL] to clear.
3. Run a soft-reset cycle.
4. Run an initialization procedure as described in Procedure without HWVAD or Initialization procedure with HWVAD.

50.7 MICFIL register descriptions

This section provides the memory map and detailed description of all MICFIL registers. Any access to reserved areas can issue a slave bus error indication.

You must implement the registers allocated in this memory map for up to 4 pairs of microphones, indicating that 8 channels are available.

50.7.1 MICFIL memory map

PDM base address: 42BE_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	MICFIL Control 1 (CTRL_1)	32	RW	0000_0000h
4h	MICFIL Control 2 (CTRL_2)	32	RW	0000_0000h
8h	MICFIL Status (STAT)	32	RW	0000_0000h
10h	MICFIL FIFO Control (FIFO_CTRL)	32	RW	0000_0007h
14h	MICFIL FIFO Status (FIFO_STAT)	32	RW	0000_0000h
24h - 40h	MICFIL Output Result (DATACH0 - DATACH7)	32	R	0000_0000h
64h	MICFIL DC Remover Control (DC_CTRL)	32	RW	0000_0000h
74h	MICFIL Range Control (RANGE_CTRL)	32	RW	0000_0000h
7Ch	MICFIL Range Status (RANGE_STAT)	32	RW	0000_0000h
90h	Voice Activity Detector 0 Control (VAD0_CTRL_1)	32	RW	0000_0000h
94h	Voice Activity Detector 0 Control (VAD0_CTRL_2)	32	RW	000A_0000h
98h	Voice Activity Detector 0 Status (VAD0_STAT)	32	RW	8000_0000h
9Ch	Voice Activity Detector 0 Signal Configuration (VAD0_SCONFIG)	32	RW	0000_0000h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
A0h	Voice Activity Detector 0 Noise Configuration (VAD0_NCONFIG)	32	RW	8000_0000h
A4h	Voice Activity Detector 0 Noise Data (VAD0_NDATA)	32	R	0000_0000h

50.7.2 MICFIL Control 1 (CTRL_1)

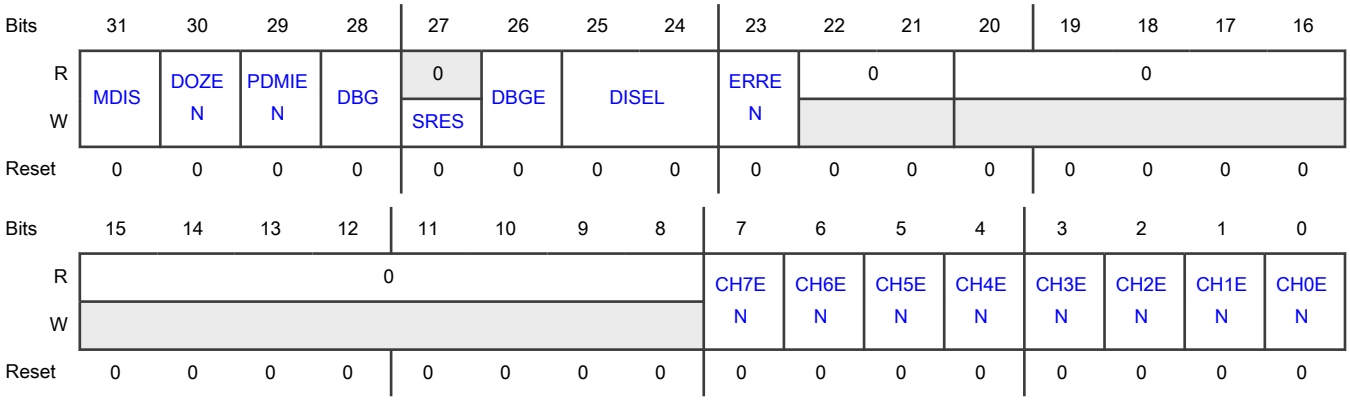
Offset

Register	Offset
CTRL_1	0h

Function

Contains control fields for MICFIL.

Diagram



Fields

Field	Function
31 MDIS	Module Disable Places MICFIL in DLL mode (see DLL mode). The generated PDM_CLK stops, and consequently, the microphone generates no data. **NOTE** When this field = 1, only writes to MICFIL Control 1 (CTRL_1) and MICFIL Control 2 (CTRL_2) are allowed with the exception of writes to CTRL_1[DBG] and CTRL_1[SRES]. A slave bus error indication is issued if you write to any other register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Normal mode 1b - DLL mode
30 DOZEN	Doze Enable Enables Doze mode. When the chip is in Doze mode and this field is active, MICFIL enters Stop mode (see DLL mode). 0b - Disables 1b - Enables
29 PDMIEN	MICFIL Enable Starts the module operation. Only the channels that CTRL_1[CHnEN] enables or VAD enabled by VADEN start operating. When this field becomes 0, MICFIL stops after it completes the remaining filter processing. **NOTE** You must enable this field as the last step when initializing the module (see Initialization). 0b - Stops MICFIL operation 1b - Starts MICFIL operation
28 DBG	Debug Mode Specifies the mode (Debug or Normal) that MICFIL operates in. MICFIL operates in Debug mode, depending on the value of CTRL_1[DBGE]. When Debug mode is disabled, MICFIL operates in Normal mode. See Debug mode for more on Debug mode. **NOTE** You can write to this field only when CTRL_1[MDIS] = 0. 0b - Normal 1b - Debug
27 SRES	Software Reset Provides the CPU with the capability to initialize MICFIL through the slave-bus interface. The field always reads 0, and is effective only when CTRL_1[MDIS] = 0. It is a self-clearing field. **NOTE** You must write 1 to this field only when STAT[BSY_FIL] = 0. You can use this field to clear data in all filters. It resets the following blocks and registers: • All internal buffers in decimation filters and voice activity detectors • All FIFOs • STAT[CHnF] and LOWFREQF flag and MICFIL FIFO Status (FIFO_STAT)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Time generator 0b - No action 1b - Software reset
26 DBGE	Module Enable in Debug Enables operation in Debug mode (see Debug mode). 0b - Disables after completing the current frame 1b - Enables operation
25-24 DISEL	DMA Interrupt Selection Specifies the type of interrupt requests (DMA or filter) that MICFIL performs when the number of FIFO elements surpasses the configured watermark. Note that requests are only generated from the channels for which CTRL_1[CHnEN] = 1. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 00b - Disables DMA and interrupt requests 01b - Enables DMA requests 10b - Enables interrupt requests 11b - Reserved
23 ERREN	Error Interruption Enable Enables error interrupts (exceptions). The following conditions can lead to errors: • An overflow or underflow in the FIFOs (indicated by FIFO_STAT[FIFOOVFn] or FIFO_STAT[FIFOUNDn], respectively) • An overflow or underflow in the decimations filters (indicated by RANGE_STAT[RANGEOVFn] or RANGE_STAT[RANGEUNFn], respectively) • not enough MICFIL internal clock frequency (LOWFREQF bit). **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0b - Disables 1b - Enables
22-21 —	Reserved
20-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7-0 CHnEN	Channel n Enable Enables the decimation filter channel n (see Initialization for more information). **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1.

50.7.3 MICFIL Control 2 (CTRL_2)

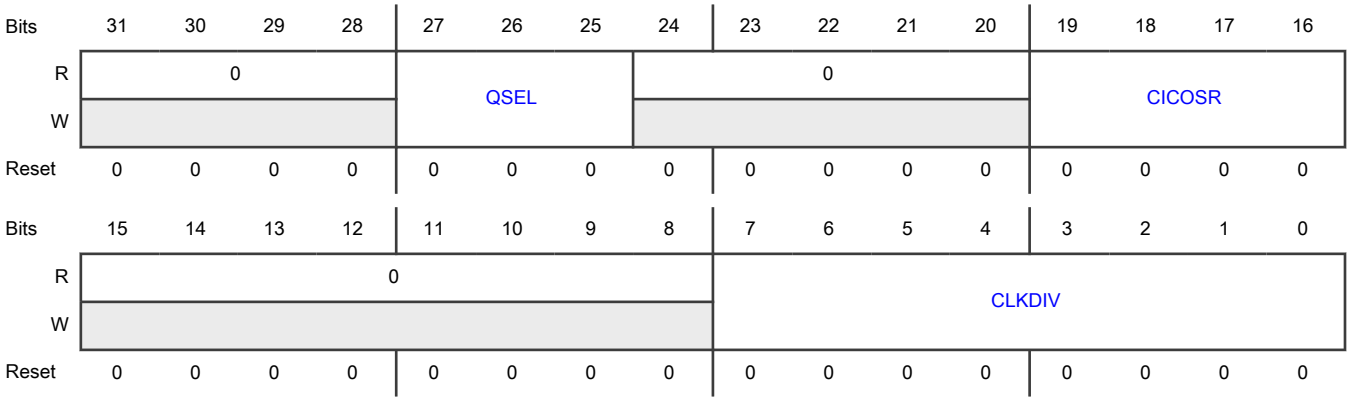
Offset

Register	Offset
CTRL_2	4h

Function

Contains control fields for MICFIL.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-25 QSEL	Quality Mode Defines the actual quality mode (see Quality modes) of the decimation filter.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE You must not change the value of this field when STAT[BSY_FIL] = 1. 000b - Medium-Quality mode 001b - High-Quality mode 100b - Very-Low-Quality 2 mode 101b - Very-Low-Quality 1 mode 110b - Very-Low-Quality 0 mode 111b - Low-Quality mode
24-20 —	Reserved
19-16 CICOSR	CIC Decimation Rate Helps you configure the CIC filter decimation rate (see Equation 8 for more information). **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0000b - CIC oversampling rate = 0 0001b - CIC oversampling rate = 1 0010b-1110b - ... 1111b - CIC oversampling rate = 15
15-8 —	Reserved
7-0 CLKDIV	Clock Divider Configures the internal clock divider value (see Clock divider for more information) using the following equation: $\text{PDM\_CLK rate} = \frac{\text{MICFIL\_CLK\_ROOT}}{2 \times \text{floor} \times (\text{K} \times \text{CLKDIV})}$ **NOTE** • You must not change the value of this field when STAT[BSY_FIL] = 1. • CLKDIV = 0 has the same effect as CLKDIV = 1. In Medium Quality mode, CLKDIV = 0 or 1 has the same effect as CLKDIV = 2. In High Quality mode, CLKDIV = 0 or 1 is not allowed. 0000_0000b - Internal clock divider value = 0 0000_0001b - Internal clock divider value = 1 0000_0010b-1111_1110b - ...

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1111_1111b - Internal clock divider value = 255

50.7.4 MICFIL Status (STAT)

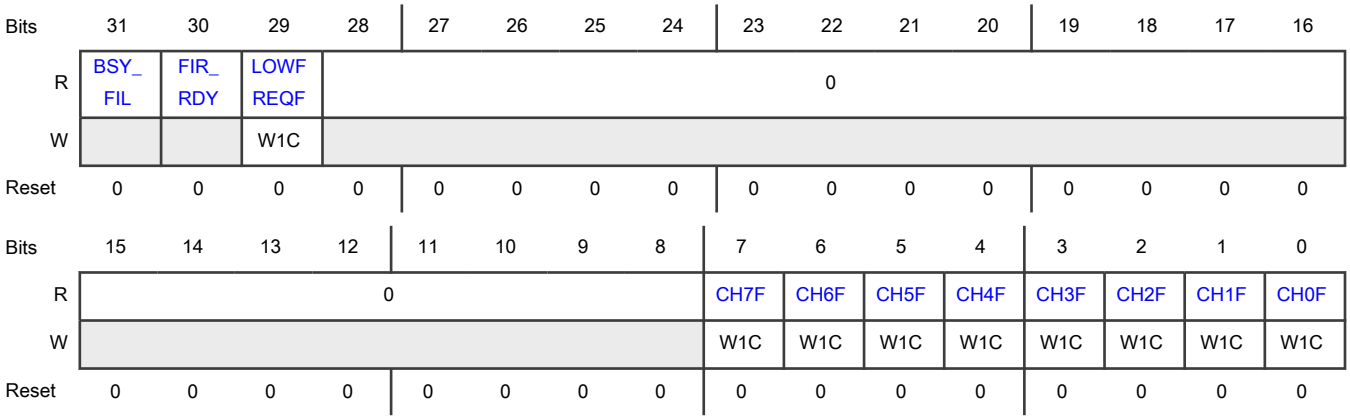
Offset

Register	Offset
STAT	8h

Function

Contains status flags for MICFIL.

Diagram



Fields

Field	Function
31 BSY_FIL	Busy Flag Signalizes when at least a decimation filter channel or at least a HWVAD is running and the PDM_CLK is being generated. You could use this field as a confirmation that all decimation filters are stopped in a transition to Debug mode (when CTRL_1[DBGE] = 0) or DLL mode. 0b - MICFIL is stopped 1b - MICFIL is running
30 FIR_RDY	Filter Data Ready Indicates whether all the decimation filter buffers are updated, and all filter data provided from now on is reliable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not reliable 1b - Reliable
29 LOWFREQF	Low Frequency Flag Indicates that the CLKDIV field value is not high enough to filter all enabled channels , and the compensation filters didn't finish their operations before the next sample arrived. See Minimum required CLKDIV. Write a logic 1 to this field to clear this flag. **NOTE** The filtering results in this condition are unpredictable. 0b - CLKDIV value is OK 1b - CLKDIV value is too low
28-16 —	Reserved
15-8 —	Reserved
7-0 CHnF	Channel n Output Data Flag Indicates whether this channel's FIFO has surpassed its watermark value and the data is available in MICFIL Output Result (DATACH0 - DATACH7). This flag contributes to generate an interrupt or DMA request if CTRL_1[DISEL] enables it. Write 1 to CTRL_1[DISEL] to clear this flag. If the DMA request is set (CTRL_1[DISEL] = 1), CHnF is set according to the watermark level . In other cases (IRQ included), CHnF is set according to the watermark level and is cleared when you write 1 to it. **NOTE** If DMA is enabled, this flag clears itself after the DMA transaction is complete. 0b - Not surpassed 1b - Surpassed

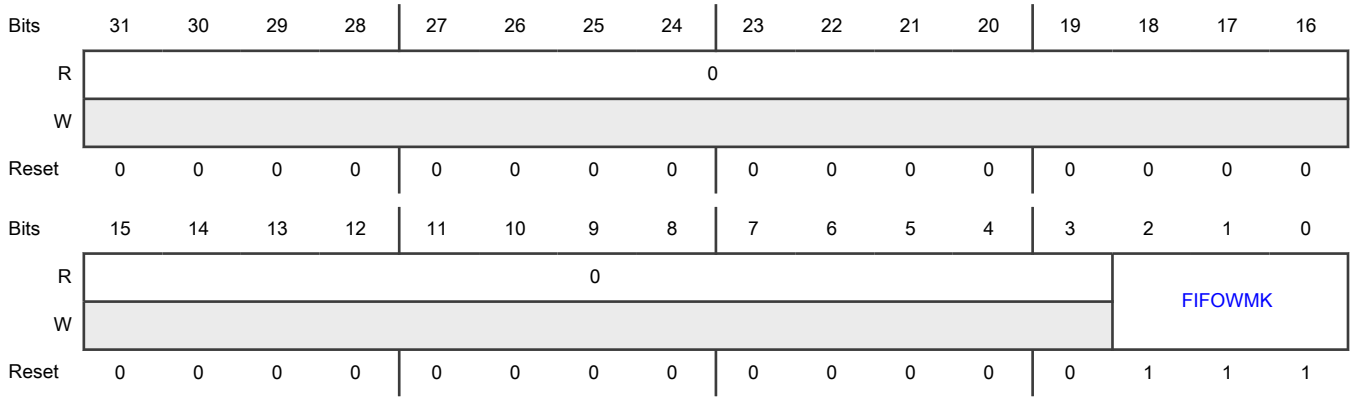
50.7.5 MICFIL FIFO Control (FIFO_CTRL)

Offset

Register	Offset
FIFO_CTRL	10h

Function
Contains MICFIL FIFO control fields.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 FIFOWMK	FIFO Watermark Control Controls the watermark of the FIFO used to set STAT[CHnF]. If the number of results in the FIFO is greater than the value of this field, STAT[CHnF] is set. A DMA request or interrupt can be also generated according to the configuration of CTRL_1[DISEL]. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. Before changing the watermark value, you must service all filtered data and clear channel flags.

50.7.6 MICFIL FIFO Status (FIFO_STAT)

Offset

Register	Offset
FIFO_STAT	14h

Function

Contains MICFIL FIFO status flags.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 —	Reserved
15-8 FIFOUNDn	FIFO Underflow Exception Flag for Channel n Indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested, then this flag is set. 0b - No exception by FIFO underflow 1b - Exception by FIFO underflow
7-0 FIFOOVFn	FIFO Overflow Exception Flag for Channel n Indicates an exceptional overflow condition in the FIFO. If the FIFO is full and you receive an additional result to be written, this flag is set. 0b - No exception by FIFO overflow 1b - Exception by FIFO overflow

50.7.7 MICFIL Output Result (DATACH0 - DATACH7)

Offset

For a = 0 to 7:

Register	Offset
DATACHa	24h + (a × 4h)

Function

Contains the word value stored at the top of the channel's n FIFO.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-16 RANGEUNFn	Channel n Range Underflow Error Flag Indicates an exceptional underflow condition in MICFIL range. **NOTE** If this error flag is asserted, channel n data is not reliable. You must adjust the value of RANGE_CTRL[RANGEADJn] until this flag is not asserted anymore. 0b - No exception by range underflow 1b - Exception by range underflow
15-8 —	Reserved
7-0 RANGEOVFn	Channel n Range Overflow Error Flag Indicates an exceptional overflow condition in MICFIL range. **NOTE** If this error flag is asserted, channel n data is not reliable. You must adjust the value of RANGE_CTRL[RANGEADJn] until this flag is not asserted anymore. 0b - No exception by range overflow 1b - Exception by range overflow

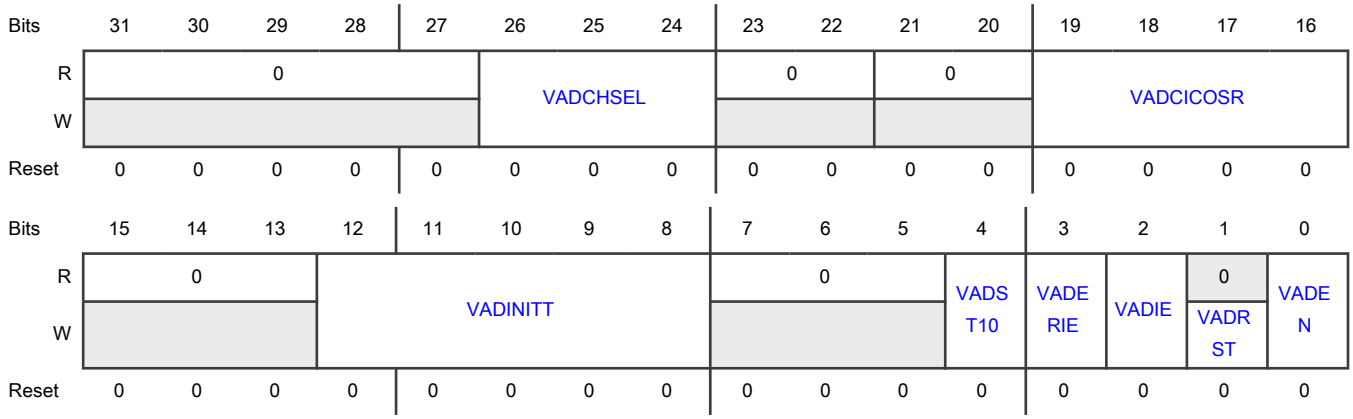
50.7.11 Voice Activity Detector 0 Control (VAD0_CTRL_1)

Offset

Register	Offset
VAD0_CTRL_1	90h

Function
Contains HWVAD configuration bits.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 VADCHSEL	Voice Activity Detector Channel Selector Selects the number of channel which the hardware voice activity detector will work. **NOTE** This field mustn't change when BSY_FIL is asserted. 000b - PDM Microphone 0 Left 001b - PDM Microphone 0 Right 010b - PDM Microphone 1 Left 011b-101b - ... 110b - PDM Microphone 3 Left 111b - PDM Microphone 3 Right
23-22 —	Reserved
21-20 —	Reserved
19-16 VADCICOSR	Voice Activity Detector CIC Oversampling Rate Defines the oversampling rate of the CIC filter. The oversampling rate is (16-CICOSR). **NOTE** This field mustn't change when BSY_FIL is asserted.
15-13	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
12-8 VADINITT	Voice Activity Detector Initialization Time Selects the number of frames to be used to initialize the voice detection. During this period the output of the voice activity detector is forced to inactive. For more information, see Initialization time. **NOTE** The initialization time will be the time taken by [VADINITT+1] frames. **NOTE** This field mustn't change when BSY_FIL is asserted. 0_0000b - VADINITT = 0 0_0001b - VADINITT = 1 0_0010b-1_1110b - ... 1_1111b - VADINITT = 31
7-5 —	Reserved
4 VADST10	Voice Activity Detector Internal Filters Initialization Initializes the signal and noise filter with pre-filter value. **NOTE** If the use of this bit is required, it should be stay pulsed by more than 2 cycles of system clock . **NOTE** There is not voice activity detection when VADST10 is asserted. 0b - Normal operation 1b - Filters initialized
3 VADERIE	Voice Activity Detector Error Interruption Enable Enables Error Interrupts in MICFIL. This error could be caused by an overflow in the input of the HWVAD and it is signalized by the VADINSATF flag. 0b - Disables 1b - Enables
2 VADIE	Voice Activity Detector Interruption Enable Enables interrupts in MICFIL when voice activity event has been detected by the Hardware Voice Activity Detector (HWVAD). See the VADIF for more information. 0b - Disables

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enables
1 VADRST	Voice Activity Detector Reset Provides the CPU with the capability to initialize the VAD through the slave-bus interface. This bit always reads as zero. This bit is self-cleared. See VAD soft-reset.
0 VADEN	Voice Activity Detector Enable Enables the use of the Hardware Voice Activity Detector. **NOTE** This field mustn't change when BSY_FIL is asserted. 0b - Disables 1b - Enables

50.7.12 Voice Activity Detector 0 Control (VAD0_CTRL_2)

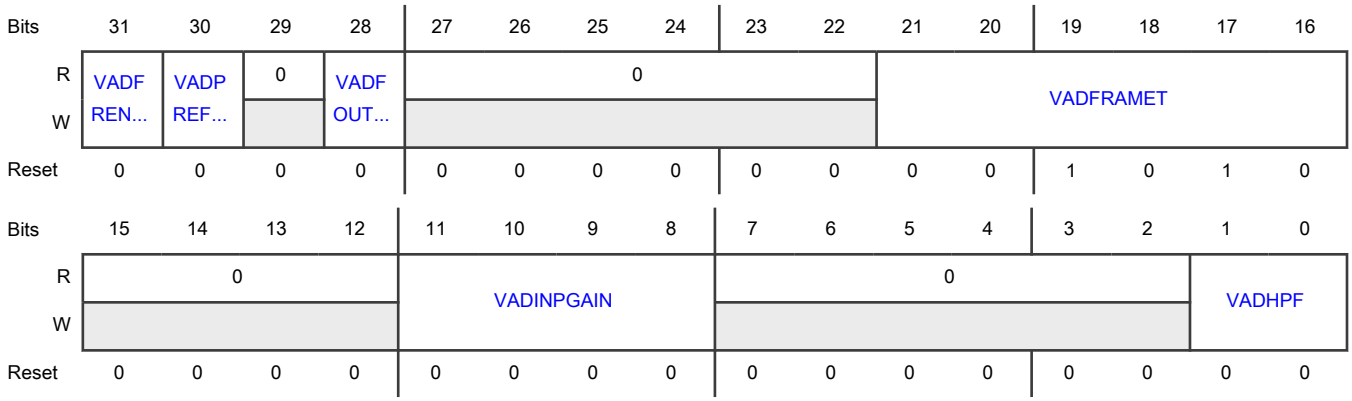
Offset

Register	Offset
VAD0_CTRL_2	94h

Function

NOTE
This register mustn't change when BSY_FIL is asserted.

Diagram



Fields

Field	Function
31 VADFRENDIS	Voice Activity Detector Frame Energy Disable Disables the calculus of energy in a frame. For more information, see Noise filter. 0b - Enables 1b - Disables
30 VADPREFEN	Voice Activity Detector Pre Filter Enable Enables a pre-filter in the input of Noise and Signal filters. For more information, see Pre-filter. 0b - Pre-filter bypassed 1b - Pre-filter enabled
29 —	Reserved
28 VADFOUTDIS	Voice Activity Detector Force Output Disable Disables the output of the Energy/Envelope-based Detector. 0b - Enables 1b - Disables
27-22 —	Reserved
21-16 VADFRAMET	Voice Activity Detector Frame Time Selects the scale value to control the frame time duration as is described in Frame time setting. **NOTE** VADFRAMET = 0 is not allowed. 00_0000b - VADFRAMET = 1 00_0001b - VADFRAMET = 2 00_0010b-11_1110b - ... 11_1111b - VADFRAMET = 63
15-12 —	Reserved
11-8 VADINPGAIN	Voice Activity Detector Input Gain Configures the gain value in the HWVAD input as a positive or negative (two's complement) number of bits to shift. 0000b - No shift 0001b - Shift 1 bit to the left

Table continues on the next page...

Table continued from the previous page...

Field	Function

7-2 —	Reserved
1-0 VADHPF	Voice Activity Detector High-Pass Filter Configures the internal high-pass filter. 00b - Filter bypassed 01b - Cut-off frequency at 1750 Hz 10b - Cut-off frequency at 215 Hz 11b - Cut-off frequency at 102 Hz

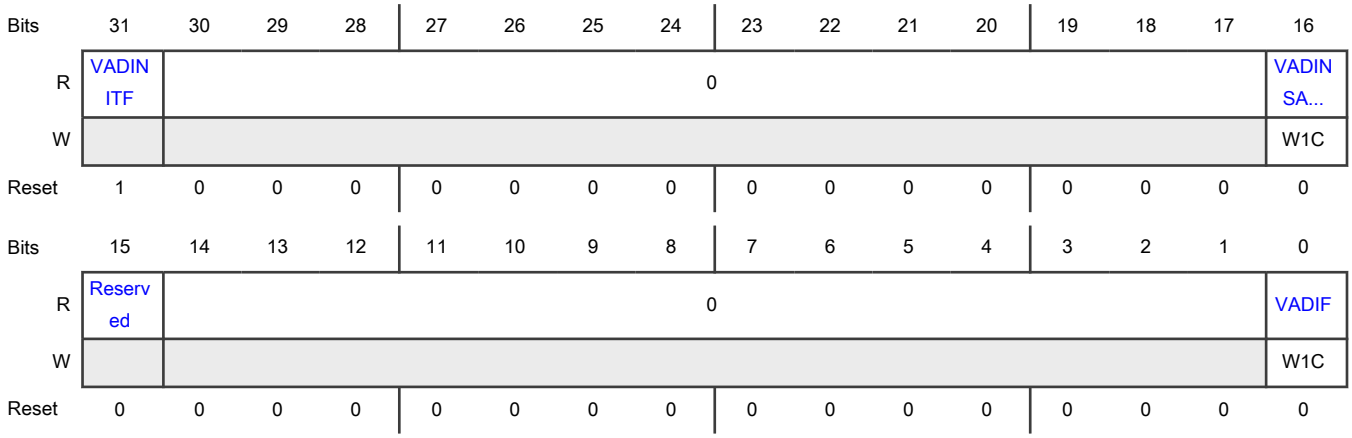
50.7.13 Voice Activity Detector 0 Status (VAD0_STAT)

Offset

Register	Offset
VAD0_STAT	98h

Function
Contains HWVAD status bits.

Diagram



Fields

Field	Function
31 VADINITF	Voice Activity Detector Initialization Flag Signalizes when the HWVAD is being initialized according to the VADINITT field value. 0b - Not being initialized 1b - Being initialized
30-17 —	Reserved
16 VADINSATF	Voice Activity Detector Input Saturation Flag Indicates an exceptional saturation condition by an overflow or underflow in the HWVAD input. 0b - No exception 1b - Exception
15 —	Reserved
14-1 —	Reserved
0 VADIF	Voice Activity Detector Interrupt Flag Indicates when voice activity has been detected by the HWVAD. Write a logic 1 to this field to clear this flag. 0b - Not detected 1b - Detected

50.7.14 Voice Activity Detector 0 Signal Configuration (VAD0_SCONFIG)

Offset

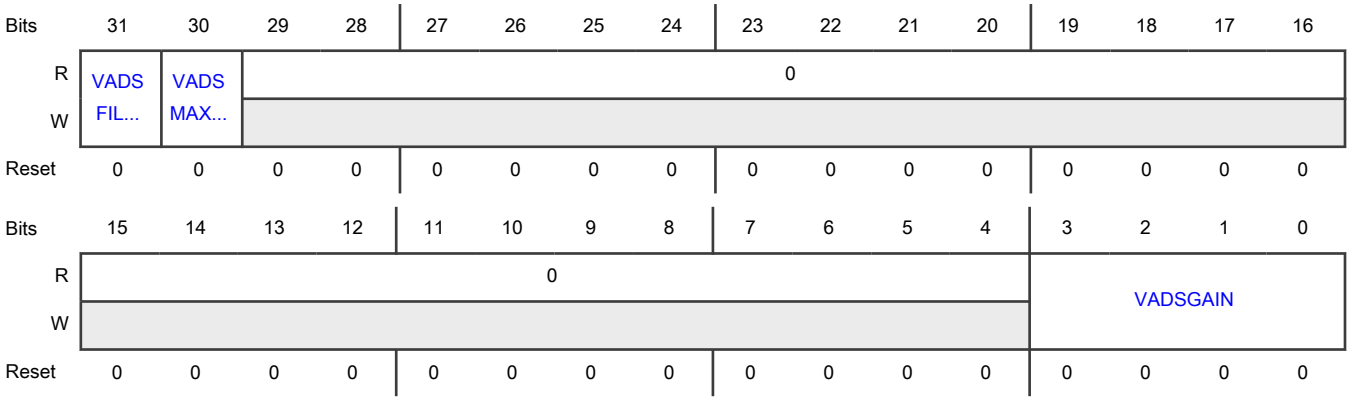
Register	Offset
VAD0_SCONFIG	9Ch

Function

NOTE

These bit-fields must be configured when MICFIL is not running.

Diagram



Fields

Field	Function
31 VADSFILEN	Voice Activity Detector Signal Filter Enable Enables the signal filter. For more information, see Signal filter. 0b - Disables 1b - Enables
30 VADSMAXEN	Voice Activity Detector Signal Maximum Enable Selects whether or not a block to calculate the maximum value between the input and output of signal filter is used as signal estimation. For more information, see Signal filter. 0b - Maximum block bypassed 1b - Maximum block enabled
29-4 —	Reserved
3-0	Voice Activity Detector Signal Gain

Table continues on the next page...

Table continued from the previous page...

Field	Function
VADSGAIN	Configures the gain value for the signal energy or envelope estimated. It is a unsigned value which is multiplied with the estimated signal data. **NOTE** VADSGAIN = 0 gain corresponds to 1. 0000b,0001b - Multiplier = 1 0010b - Multiplier = 2 0011b-1110b - ... 1111b - Multiplier = 15

50.7.15 Voice Activity Detector 0 Noise Configuration (VAD0_NCONFIG)

Offset

Register	Offset
VAD0_NCONFIG	A0h

Function

NOTE

These bit-fields must be configured when MICFIL is not running.

51.2 Overview

SAI provides an interface that supports full-duplex serial digital audio interfaces with frame synchronization formats such as I^2S, AC97, TDM, and Codec/DSP interfaces.

51.2.1 Block diagram

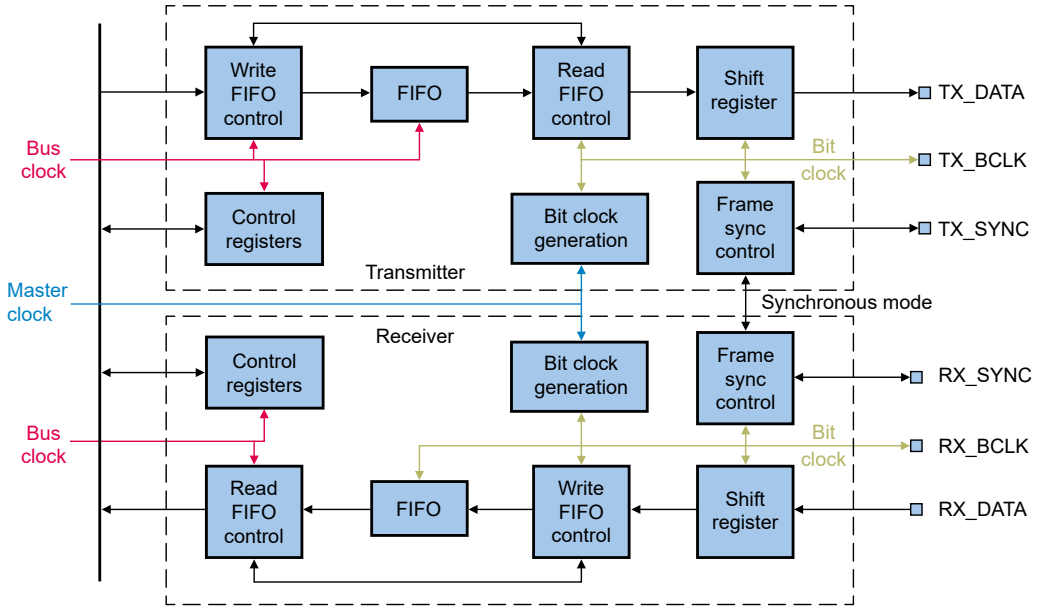

Figure 303. Block diagram

51.2.2 Features

Features can vary among chips and also among SAI modules on the same chip. See the chip-specific SAI information at the beginning of this chapter.

- Transmitter with independent bit clock and frame sync supporting 1 data line
- Receiver with independent bit clock and frame sync supporting 1 data line
- Each data line supports a maximum frame size of 32 words
- Word length of 8 to 32 bits
- Word length configured separately for the first word and remaining words in a frame
- Asynchronous 32 × 32-bit FIFO for each transmit and receive data line supports:
  - Graceful restart after FIFO error
  - Automatic restart after FIFO error without software intervention
  - 8- and 16-bit data packing into each 32-bit FIFO word

51.3 Functional description

This section provides a complete functional description of SAI.

51.3.1 Modes of operation

Module power modes include:

- Run mode
- Stop mode
- Debug mode

51.3.1.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

51.3.1.2 Stop mode

There are two situations in which the SAI transmitter or receiver can be configured to continue operating in Stop mode:

- The SAI transmitter or receiver is using an externally generated bit clock.
- The SAI transmitter or receiver is using an audio master clock that operates when the chip is in Stop mode.

Write 1 to TCSR[STOPE] to configure the transmitter to run in Stop mode. Write 1 to RCSR[STOPE] to configure the receiver to run in Stop mode.

The SAI transmitter and receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

When the chip enters Stop mode, if TCSR[STOPE] = 0, the transmitter is disabled after completing the current transmit frame. Similarly, when the chip enters Stop mode, if RCSR[STOPE] = 0, the receiver is disabled after completing the current receive frame. Entry into Stop mode is blocked (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

51.3.1.3 Debug mode

You can configure either or both the SAI transmitter and receiver to continue operating in Debug mode.

- Write 1 to TCSR[DBGE] to configure the transmitter to run in Debug mode.
- Write 1 to RCSR[DBGE] to configure the receiver to run in Debug mode.

When TCSR[DBGE] = 0 and RCSR[DBGE] = 0 and the chip enters Debug mode, SAI is disabled after completing the current transmit or receive frame. Debug mode does not affect the transmitter and receiver bit clocks.

51.3.2 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other. You can configure the SAI transmitter and receiver to operate with synchronous bit clock and frame sync (see TCR2[SYNC] and RCR2[SYNC]).

If both the transmitter and receiver use the transmitter bit clock and frame sync:

- Configure the transmitter for asynchronous operation and the receiver for synchronous operation.
- Enable the receiver in Synchronous mode only after enabling both the transmitter and receiver.
- Enable the transmitter last and disable the transmitter first.

If both the transmitter and receiver use the receiver bit clock and frame sync:

- Configure the receiver for asynchronous operation and the transmitter for synchronous operation.
- Enable the transmitter in Synchronous mode only after enabling both the receiver and transmitter.
- Enable the receiver last and disable the receiver first.

When operating in Synchronous mode, the transmitter and receiver share only the bit clock, frame sync, and transmitter/receiver enable. Otherwise, the transmitter and receiver operate independently, although the configuration register settings must be consistent across both the transmitter and receiver.

51.3.3 Frame sync configuration

When enabled, SAI continuously transmits and receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, you can mask any word, causing the receiver to ignore that word and the transmitter to 3-state during that word.

The frame sync signal indicates the start of a frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected. The transmitter or receiver cannot be busy with a previous frame. A valid frame sync is ignored (Slave mode) or not generated (Master mode) for the first four bit-clock cycles after enabling the transmitter or receiver.

You can configure the transmitter and receiver frame sync independently with any of the following options:

- Can be generated externally or internally.
- Can be active high or active low.
- Can assert with the first bit in frame or assert one bit early.
- Can assert for a duration of between one bit-clock cycle and the first word length.
- Frame length can be from 1 to 32 words.
- Word length of 8 to 32 bits
  - First word length and remaining word lengths can be configured separately.
- Transmit/Receive words MSB first or LSB first

These configuration options cannot be changed after enabling the SAI transmitter or receiver.

51.3.4 Data FIFO

Each transmit and receive channel includes a 32 × 32-bit FIFO. Use the Transmit (TDR*n*) and Receive (RDR*n*) Data registers to access FIFO data.

51.3.4.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit-wide register via the First Bit Shifted configuration field. This field selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are shown in Figure 304 for LSB-first configurations and Figure 305 for MSB-first configurations.

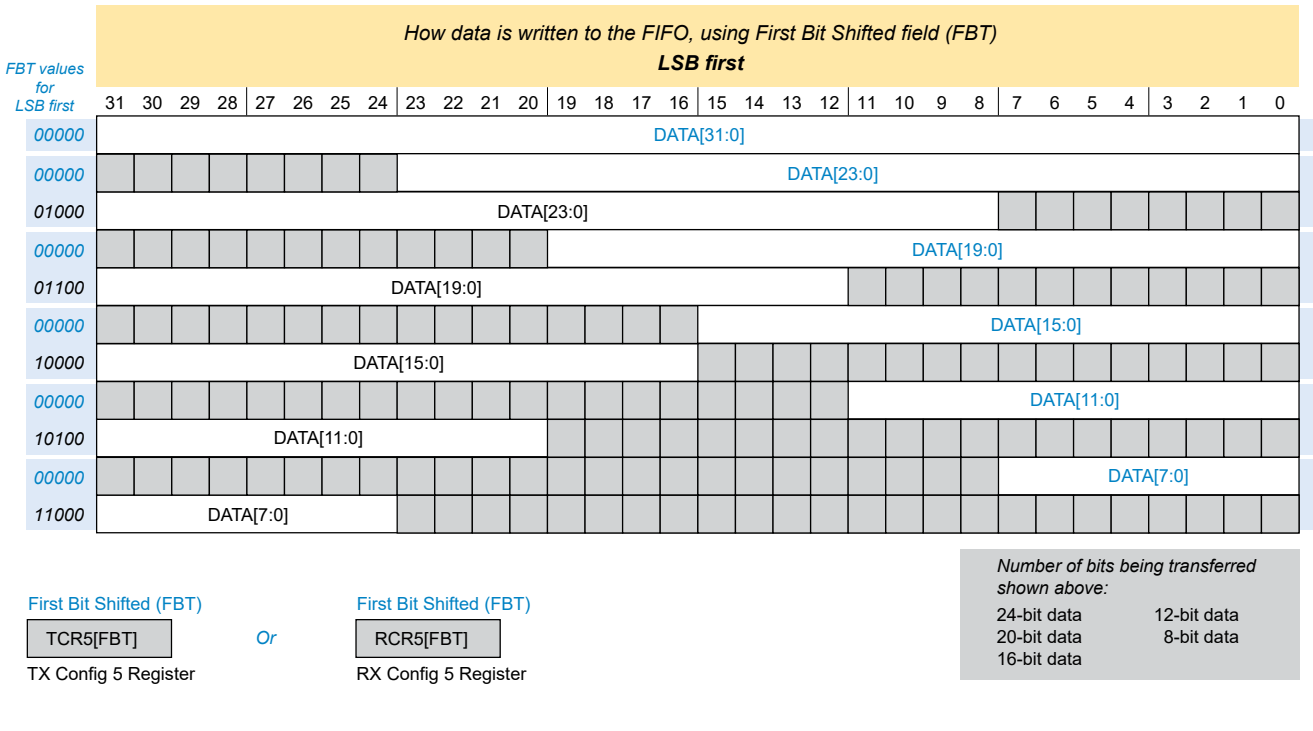

Figure 304. SAI first bit shifted, LSB-first

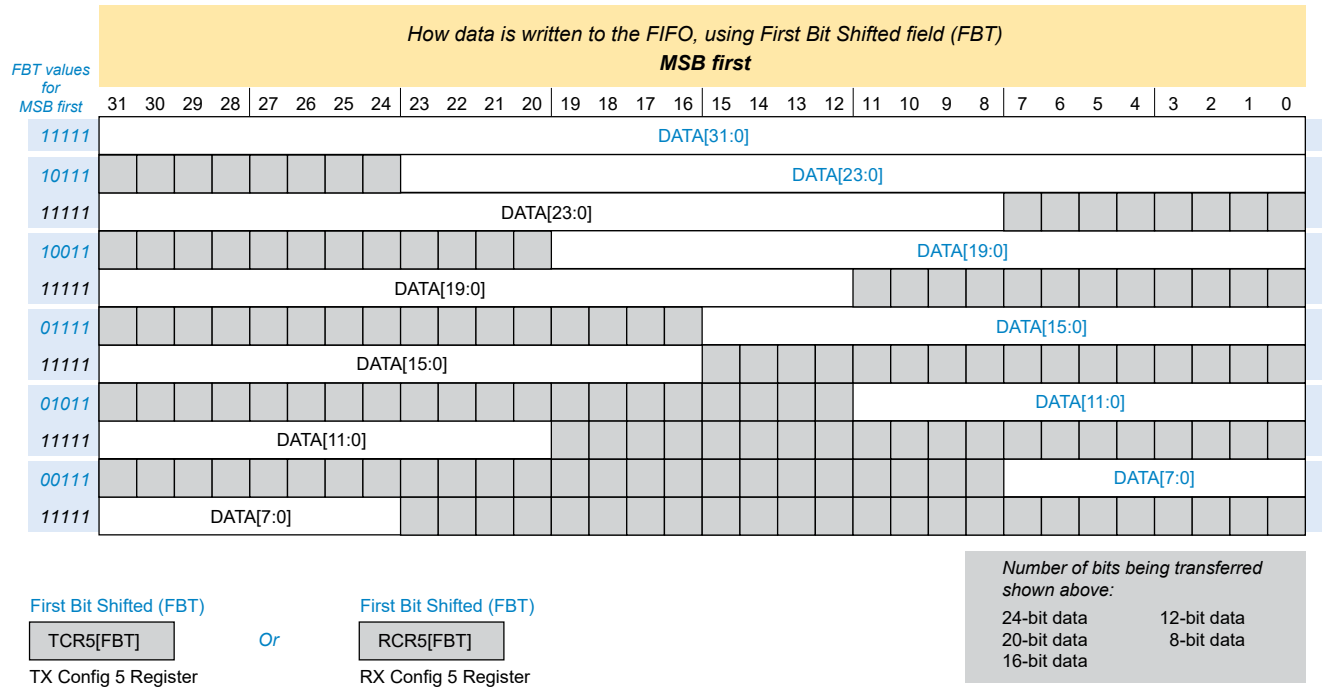

Figure 305. SAI first bit shifted, MSB-first

51.3.4.2 FIFO pointers

When writing to a Transmit Data register (TDR*n*), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO register (TFR*n*) increments after each valid write. SAI supports 8-, 16-, and 32-bit writes to TDR*n* and the FIFO pointer increments after each individual write. Only use 8-bit writes when transmitting up to 8-bit data; only use 16-bit writes when transmitting up to 16-bit data.

- If the transmit FIFO is full, writes to TDR*n* are ignored.
- If the transmit FIFO is empty, write to TDR*n* at least three bit-clock cycles before the start of the next unmasked word. This write avoids a FIFO underrun.
- Before enabling the transmitter, initialize the transmit FIFO with data. The transmitter starts a new frame after enabling the transmitter. If no data is in the FIFO, the transmitter immediately generates an error.

When reading a Receive Data register (RDR*n*), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO register (RFR*n*) increments after each valid read. SAI supports 8-, 16-, and 32-bit reads from RDR*n* and the FIFO pointer increments after each individual read. Only use 8-bit reads when receiving up to 8-bit data; only use 16-bit reads when receiving up to 16-bit data.

- If the receive FIFO is empty, reads to RDR*n* are ignored.
- If the receive FIFO is full, read RDR*n* at least three bit-clock cycles before the end of an unmasked word. This read avoids a FIFO overrun.

51.3.4.3 FIFO packing

Using FIFO packing, you can store multiple 8- or 16-bit data words in one 32-bit FIFO word for the transmitter or receiver. You could emulate this feature by adjusting the number of bits per word and number of words per frame. FIFO packing, however, does not require even multiples of words per frame, and it fully supports word masking.

When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive). In this way, FIFO packing supports scenarios where different words within each frame are stored in different areas of memory.

Using 16-bit FIFO packing for transmitting, the transmit shift register loads at the start of each frame and after every second unmasked transmit word. The first transmitted word is taken from 16-bit word at byte offset 0h. (The first bit is selected by TCR5[FBT] and must be configured within this 16-bit word.) The second transmitted word is taken from the 16-bit word at byte offset 2h (The first bit is selected by TCR5[FBT][3:0].) The transmitter transmits logic zeroes until the start of the next word after the 16-bit word has been transmitted.

Using 16-bit FIFO packing for receiving, the receive shift register is stored after every second unmasked received word. If there is an odd number of unmasked-received words in each frame, the receive register is also stored and at the end of each frame. The first received word is stored in the 16-bit word at byte offset 0h. (The first bit is selected by RCR5[FBT] and must be configured within this 16-bit word.) The second received word is stored in the 16-bit word at byte offset 2h. (The first bit is selected by RCR5[FBT][3:0].) The receiver ignores received data until the start of the next word after the 16-bit word has been received.

8-bit FIFO packing is similar to 16-bit packing, except four words are loaded or stored into each 32-bit FIFO word. The first word is stored in byte offset 0h, the second word in byte offset 1h, and so on. TCR5[FBT] and/or RCR5[FBT] must be configured within byte offset 0h.

51.3.5 Word mask register

The SAI transmitter and receiver each have a word mask register (Transmit Mask (TMR) and Receive Mask (RMR)) that you can use to mask any word in the frame. The word mask register is double buffered. You can update it before the end of each frame to mask a particular word in the next frame.

TMR causes the Transmit Data pin to be 3-stated for the length of each selected word and the transmit FIFO is not read for masked words.

RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

51.3.6 Clocking

SAI clocks include:

- Audio master clock
- Bit clock
- Bus clock

51.3.6.1 Audio master clock

The audio master clock generates the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. See chip-specific clocking information about how the audio master clocks are generated.

51.3.6.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, the transmitter and receiver each use their own bit clock and frame sync.
- If the transmitter is configured for asynchronous operation and the receiver is configured for synchronous operation, both use the transmitter bit clock and frame sync.
- If the receiver is configured for asynchronous operation and the transmitter is configured for synchronous operation, both use the receiver bit clock and frame sync.

The software configures synchronous or asynchronous operation, and that choice selects the bit clock and frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled.
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames.

In asynchronous operation, an SAI transmitter or receiver may use a bit clock externally generated by an SAI that is disabled in Stop mode. In this case, software should disable the transmitter or receiver before entering Stop mode. This issue does not apply when the transmitter or receiver is in synchronous operation because all synchronous SAI modules are enabled and disabled simultaneously.

51.3.6.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although no minimum bus clock frequency is specified, the frequency must be fast enough (relative to the bit clock frequency) to serve the FIFOs. This requirement must be met without generating a transmitter FIFO underrun or receiver FIFO overflow condition.

51.3.7 Reset

SAI is asynchronously reset on system reset. SAI has a Software reset and a FIFO reset.

51.3.7.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags, and FIFO pointers.

These software resets do not reset the configuration registers. The software resets remain asserted until cleared by software.

51.3.7.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the value of the FIFO read pointer. This FIFO reset empties the FIFO contents and is used after TCSR[FEF] becomes 1, and before the FIFO is reinitialized and TCSR[FEF] becomes 0. The FIFO reset is asserted for one cycle only.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the value of the FIFO write pointer. This FIFO reset empties the FIFO contents. Use after the RCSR[FEF] becomes 1 and any remaining data has been read from the FIFO, and before RCSR[FEF] becomes 0. The FIFO reset is asserted for one cycle only.

51.3.8 Interrupts and DMA requests

In SAI, the transmitter and receiver generate separate interrupts and separate DMA requests, but use the same status flags. SAI generates asynchronous versions of the transmitter and receiver interrupts to wake up the CPU from Stop mode. Asynchronous interrupts are only generated when the system clock is gated but the corresponding BCLK is active.

51.3.8.1 FIFO request flag

The transmit FIFO request flag (TCSR[FRF]) becomes 1 when the number of entries in any enabled transmit FIFO is less than or equal to the transmit FIFO watermark configuration (TCR1[TFW]). This flag becomes 0 when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag (RCSR[FRF]) becomes 1 when the number of entries in any enabled receive FIFO is greater than the receive FIFO watermark configuration (RCR1[RFW]). This flag becomes 0 when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt (TCSR[FRIE] = 1) or a DMA request (TCSR[FRDE] = 1).

51.3.8.2 FIFO warning flag

The transmit FIFO warning flag (TCSR[FWF]) becomes 1 when the number of entries in any of the enabled transmit FIFOs is empty. This flag becomes 0 when the number of entries in each enabled transmit FIFO is not empty.

The receive FIFO warning flag (RCSR[FWF]) becomes 1 when the number of entries in any of the enabled receive FIFOs is full. This flag becomes 0 when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an interrupt (TCSR[FWIE] = 1) or a DMA request (TCSR[FWDE] = 1).

51.3.8.3 FIFO error flag

The Transmit FIFO Error Flag (TCSR[FEF]) becomes 1 when any of the enabled transmit FIFOs underrun. After the error flag becomes 1, all enabled transmit channels transmit zero data before TCSR[FEF] becomes 0.

When FIFO Continue on Error is enabled (TCR4[FCONT] = 1), the FIFO continues transmitting data following an underrun without software intervention. To ensure that data transmits in the correct order, the transmitter continues from the same word number in the frame that caused the FIFO to underrun. It continues only after new data writes to the transmit FIFO. Software should still write 0 to the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

The Receive FIFO Error Flag (RCSR[FEF]) becomes 1 when any enabled receive FIFO overflows. After the flag becomes 1, all enabled receive channels discard received data until RCSR[FEF] becomes 0 and the next receive frame starts. Empty all enabled receive FIFOs before RCSR[FEF] becomes 0.

When Receive FIFO Continue on Error is enabled (RCR4[FCONT] = 1), the FIFO continues receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver continues from the same word number in the frame that caused the FIFO to overflow. It continues only after data has been read from the receive FIFO. Software should still write 0 to the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO Error Flag can generate only an interrupt.

51.3.8.4 Sync error flag

The Sync Error Flag (TCSR[SEF] or RCSR[SEF]) becomes 1 when both of these conditions are true:

- The frame sync is generated externally.
- The external frame sync asserts when the transmitter or receiver is busy with the previous frame.

The external frame sync assertion is ignored and the Sync Error Flag becomes 1. When the Sync Error Flag becomes 1, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The Sync Error Flag can only generate an interrupt.

51.3.8.5 Word start flag

The Word Start Flag (TCSR[WSF]) becomes 1 at the start of the second bit-clock cycle for the selected word. This word is selected via the Word Flag Configuration field (TCR3[WDFL]).

The Word Start Flag can generate an interrupt only.

51.4 External signals

Name	Function	I/O
TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O

Table continues on the next page...

Table continued from the previous page...

Name	Function	I/O
TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated. It is an output generated synchronously by the bit clock when internally generated.	I/O
TX_DATA	Transmit Data. The transmit data is generated synchronously by the bit clock and is 3-stated whenever not transmitting a word.	O
RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated. It is an output generated synchronously by the bit clock when internally generated.	I/O
RX_DATA	Receive Data. The receive data is sampled synchronously by the bit clock.	I

51.5 Initialization

To initialize the SAI:

- Enable the clock to SAI.
- Reset the internal transmitter logic and receiver logic by TCSR[SR] and RCSR[SR].

51.6 Memory map and register definition

A read or write access to an address from offset 100h and above will result in a bus error.

NOTE
The descriptions of the field settings vary by module instance.

Instance	Field value and description
SAI1	0000b - 1 FIFO word 0001b - 2 FIFO words 0010b-1110b - (TFW +1) FIFO words 1111b - 16 FIFO words

Field	Function

Instance	Field value and description
SAI2	0_0000b - 1 FIFO word 0_0001b - 2 FIFO words 0_0010b-1_1110b - (TFW +1) FIFO words 1_1111b - 32 FIFO words
SAI3	0_0000b - 1 FIFO word 0_0001b - 2 FIFO words 0_0010b-1_1110b - (TFW +1) FIFO words 1_1111b - 32 FIFO words
SAI4	0_0000b - 1 FIFO word 0_0001b - 2 FIFO words 0_0010b-1_1110b - (TFW +1) FIFO words 1_1111b - 32 FIFO words

51.6.1.6 Transmit Configuration 2 (TCR2)

Offset

Register	Offset
TCR2	10h

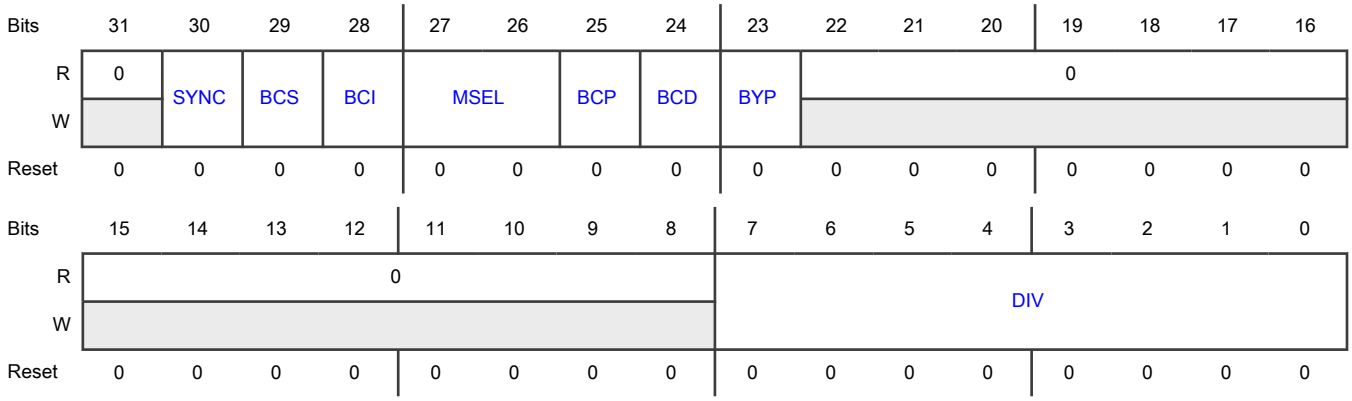
Function

Contains the SYNC mode and clock setting fields.

NOTE

This register must not be altered when TCSR[TE] is 1.

Diagram



Fields

Field	Function
31 —	Reserved
30 SYNC	Synchronous Mode Configures Asynchronous and Synchronous modes of operation. When configured for Synchronous mode, the receiver must be configured for Asynchronous operation. 0b - Asynchronous mode 1b - Synchronous with receiver
29 BCS	Bit Clock Swap Swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (TX_SYNC). When the transmitter is configured in Synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but use the receiver frame sync (RX_SYNC). 0b - Use the normal bit clock source. 1b - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is 1 and when using an internally generated bit clock in Synchronous or Asynchronous mode, the bit clock used by the transmitter is delayed by the pad output delay. (The transmitter is clocked by the pad input as if the clock was externally generated.) This setting decreases the data input setup time, but increases the data output valid time. The Slave mode timing from the datasheet should be used for the transmitter when this bit is 1. In Synchronous mode, this bit allows the transmitter to use the Slave mode timing from the datasheet, while the receiver uses the Master mode timing. This field has no effect when configured for an externally generated bit clock .

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When BCI = 1, both the input buffer and output buffer must be enabled for the BCLK pad. 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23 BYP	Bit Clock Bypass Bypasses the bit clock divider. Internal bit clock is divide-by-one of the audio master clock. 0b - Internal bit clock is generated from bit clock divider. 1b - Internal bit clock is divide-by-one of the audio master clock.
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

51.6.1.7 Transmit Configuration 3 (TCR3)

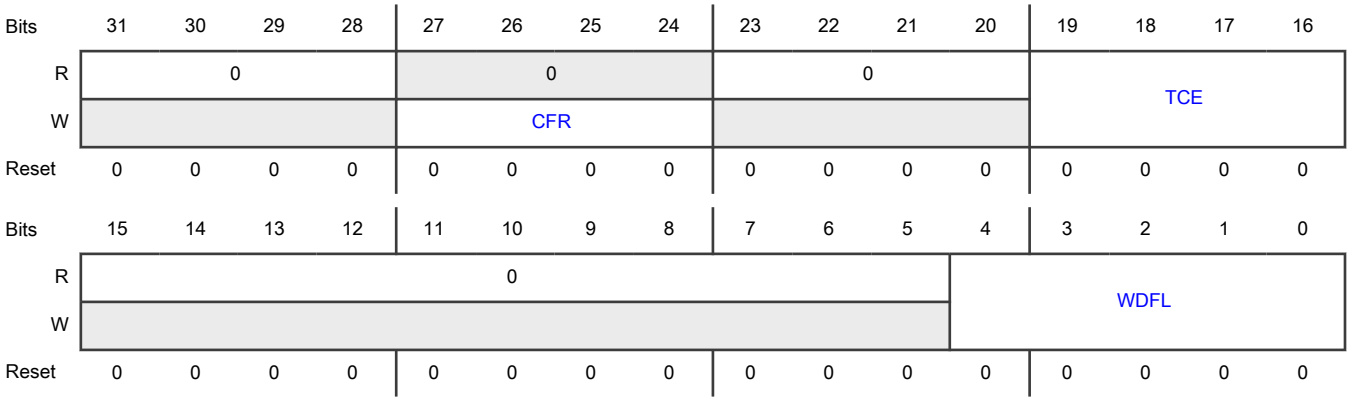
Offset

Register	Offset
TCR3	14h

Function

Contains the transmit channel settings.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field always returns zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Writing 1 to bit 24 resets transmit channel 1 FIFO pointer, and writing 1 to bit 25 enables transmit channel 2 FIFO pointer. Writing 1 to bit N resets transmit channel N FIFO pointer. **NOTE** When there is only a single channel, there is no need for individual channel FIFO reset (TCR3[CFR]). In the case of a single channel, use the global FIFO reset (TCSR[FR]). 0b - No effect. 1b - Transmit data channel N FIFO is reset.

28	FIFO Continue on Error

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>FCONT</td><td>Configures when SAI continues transmitting after a FIFO error has been detected.
0b - On FIFO error, SAI continues from the start of the next frame after the FIFO error flag has been cleared.
1b - On FIFO error, SAI continues from the same word that caused the FIFO error to become 1 after the FIFO warning flag returns to 0.</td></tr>
<tr><td>27-26
FCOMB</td><td>FIFO Combine Mode
When FIFO Combine mode is enabled for FIFO writes, software writing to any FIFO data register alternates the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write is performed to the first enabled data channel FIFO and the second write is performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO Combine mode for FIFO writes resets the pointer back to the first enabled data channel.
When FIFO Combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output alternated between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word is transmitted from the first enabled data channel FIFO and the second unmasked word is transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.
NOTE
This field is not supported in every instance. The following table includes only supported registers.
<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI1</td><td>TCR4</td><td>—</td></tr><tr><td>SAI2</td><td>—</td><td>TCR4</td></tr><tr><td>SAI3</td><td>—</td><td>TCR4</td></tr><tr><td>SAI4</td><td>TCR4</td><td>—</td></tr></table>

01b - FIFO Combine mode enabled on FIFO reads (from transmit shift registers).
10b - FIFO Combine mode enabled on FIFO writes (by software).
11b - FIFO Combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).</td></tr>
<tr><td>25-24
FPACK</td><td>FIFO Packing Mode
Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8 or 16 bits then only the first 8 or 16 bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	FIFO packing is enabled, the FIFO write pointer only increments when the full 32-bit FIFO word has been written by software. 00b - FIFO packing is disabled. 01b - Reserved 10b - 8-bit FIFO packing is enabled. 11b - 16-bit FIFO packing is enabled.
23-21 —	Reserved
20-16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit-clock cycles. The value written must be one less than the number of bit-clock cycles. For example, write 0 for the frame sync to assert for one bit-clock cycle only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Configures whether transmit data pins are configured for TDM mode or Output mode. 0b - TDM mode, transmit data pins are 3-stated when slots are masked or channels are disabled. 1b - Output mode, transmit data pins are never 3-stated and output zero when slots are masked or channels are disabled.
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0b - LSB is transmitted first. 1b - MSB is transmitted first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2	On Demand Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
ONDEM	When 1, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is 0. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is 0.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame sync is generated externally in Slave mode. 1b - Frame sync is generated internally in Master mode.

51.6.1.9 Transmit Configuration 5 (TCR5)

Offset

Register	Offset
TCR5	1Ch

Function

Contains transmit word width and bit index settings.

NOTE

This register must not be altered when TCSR[TE] is 1.

Fields

Field	Function
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported. Bit settings 0 - 6 (0b - 0_0110b) not supported. 0_0111b - 8 bits per word 0_1000b - 9 bits per word 0_1001b-1_1110b - (WNW value + 1) bits per word 1_1111b - 32 bits per word
23-21 —	Reserved
20-16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame. Bit settings 0 - 6 (0b - 0_0110b) not supported. 0_0111b - 8 bits per word 0_1000b - 9 bits per word 0_1001b-1_1110b - (W0W value + 1) bits per word 1_1111b - 32 bits per word
15-13 —	Reserved
12-8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB-first, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB-first, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB-first. The value written must be less than or equal to 31-word width when configured for LSB-first. See Data alignment. 0_0000b - Bit index is 0. 0_0001b-1_1110b - Bit index is FBT value. 1_1111b - Bit index is 31.
7-0 —	Reserved

51.6.1.10 Transmit Data (TDR0 - TDR3)

Offset

Register	Offset
TDR0	20h
TDR1	24h
TDR2	28h
TDR3	2Ch

Function

When the transmit FIFO is not full, writes to this register push the data written into the transmit data FIFO. When the transmit FIFO is full, writes to this register are ignored.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
SAI1	TDR0–TDR1	TDR2–TDR3
SAI2	TDR0	TDR1–TDR3
SAI3	TDR0	TDR1–TDR3
SAI4	TDR0–TDR3	—

51.6.1.12 Transmit Mask (TMR)

Offset

Register	Offset
TMR	60h

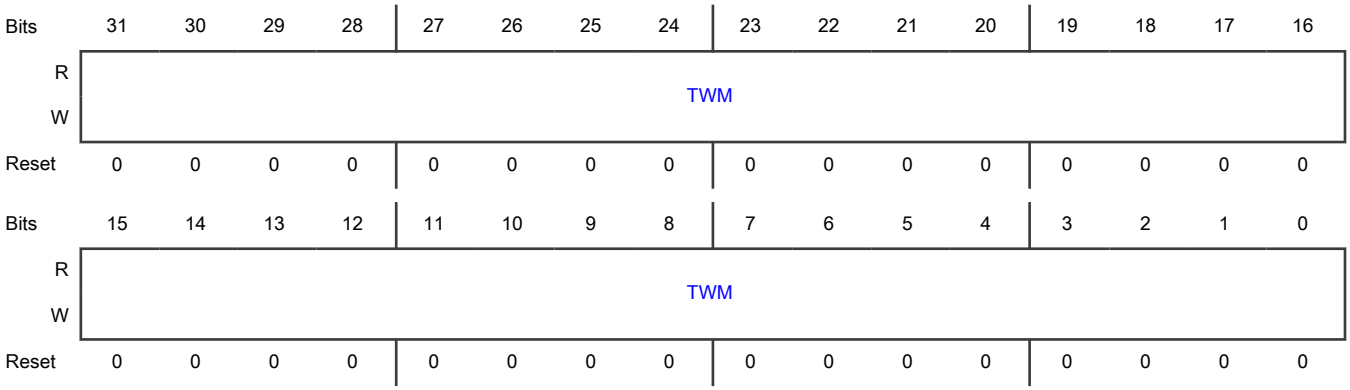
Function

This register is double-buffered and updates:

1. When TCSR[TE] first becomes 1.
2. At the end of each frame.

This setup allows the masked words in each frame to change from frame to frame.

Diagram



Fields

Field	Function
31-0 TWM	Transmit Word Mask Configures whether the transmit word is masked for the corresponding word in the frame. In this case, being masked means that transmit data pins are 3-stated or drive zero and transmit data is not read from the FIFO. 0000_0000_0000_0000_0000_0000_0000_0000b - Word N is enabled. 0000_0000_0000_0000_0000_0000_0000_0001b - Word N is masked. The transmit data pins are 3-stated or drive zero when masked.

51.6.1.13 Receive Control (RCSR)

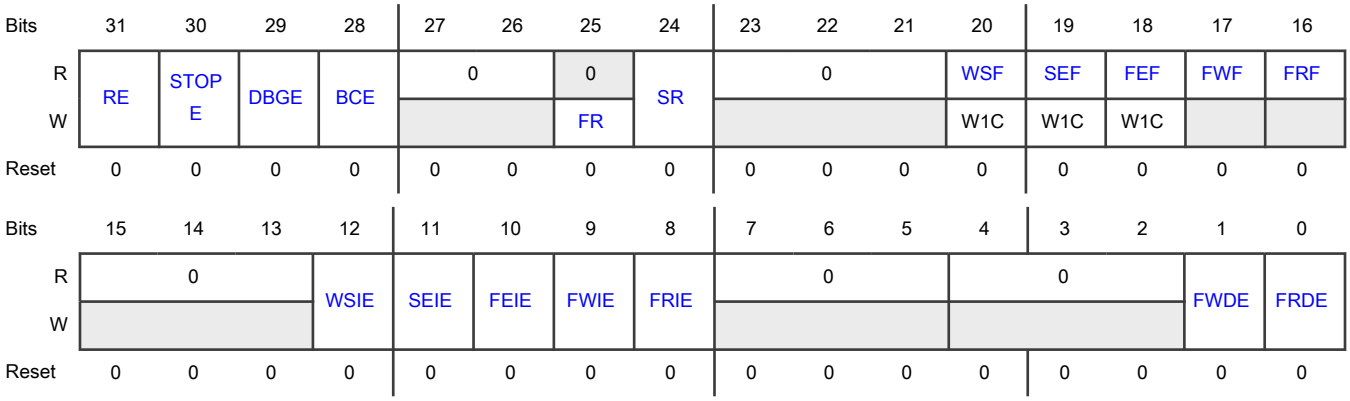
Offset

Register	Offset
RCSR	88h

Function

Contains receiver enable fields including resets, error and interrupt enable fields, and error flag fields.

Diagram



Fields

Field	Function
31 RE	Receiver Enable Enables and disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains 1, until the end of the current frame. 0b - Receiver is disabled. 1b - Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures receiver operation in Stop mode. 0b - Receiver disabled in Stop mode. 1b - Receiver enabled in Stop mode.
29 DBGE	Debug Enable Enables and disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode. 0b - Receiver is disabled in Debug mode, after completing the current frame. 1b - Receiver is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame. 0b - Receive bit clock is disabled. 1b - Receive bit clock is enabled.
27-26	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field always returns zero. **NOTE** The FIFO reset is asserted for one cycle only. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is 1. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. **NOTE** The software reset remains asserted until cleared by software. Software clears the bit by writing 0. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0b - Receive overflow not detected. 1b - Receive overflow detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0b - No enabled receive FIFO is full. 1b - Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0b - Receive FIFO watermark not reached. 1b - Receive FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables and disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables and disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables and disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables and disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables and disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.

Table continues on the next page...

Fields

Field	Function
31 —	Reserved
30	Synchronous Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
SYNC	Configures Asynchronous and Synchronous modes of operation. When configured for a Synchronous mode of operation, the transmitter must be configured for asynchronous operation. 0b - Asynchronous mode 1b - Synchronous with transmitter
29 BCS	Bit Clock Swap Swaps the bit clock used by the receiver. When the receiver is configured in Asynchronous mode and this bit is 1, the receiver is clocked by the transmitter bit clock (TX_BCLK). This setting allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (RX_SYNC). When the receiver is configured in Synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but use the transmitter frame sync (TX_SYNC). 0b - Use the normal bit clock source. 1b - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either Synchronous or Asynchronous mode, the bit clock used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This setting decreases the data input setup time, but increases the data output valid time. The Slave mode timing from the datasheet should be used for the receiver when this bit is 1. In Synchronous mode, this bit allows the receiver to use the Slave mode timing from the datasheet, while the transmitter uses the Master mode timing. This field has no effect when configured for an externally generated bit clock. **NOTE** When BCI = 1 both the input buffer and output buffer must be enabled for the BCLK pad. 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25	Bit Clock Polarity

Table continues on the next page...

Table continued from the previous page...

Field	Function
BCP	Configures the polarity of the bit clock. 0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23 BYP	Bit Clock Bypass Bypasses the bit clock divider, internal bit clock is divide-by-one of the audio master clock. 0b - Internal bit clock is generated from bit clock divider. 1b - Internal bit clock is divide-by-one of the audio master clock.
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock, when configured for an internal bit clock. The division value is (DIV + 1) * 2.

51.6.1.16 Receive Configuration 3 (RCR3)

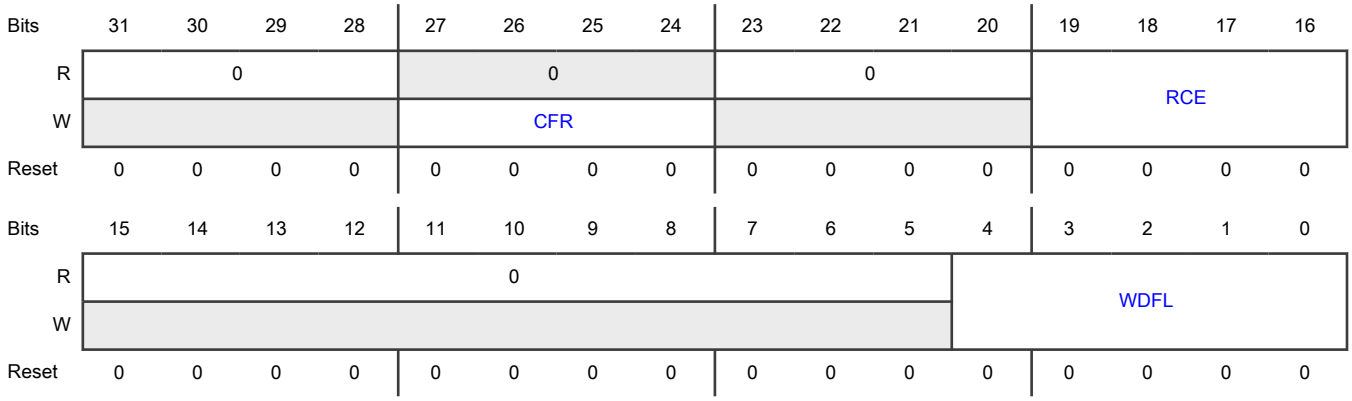
Offset

Register	Offset
RCR3	94h

Function

Contains the receive channel settings.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field always returns zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is 1. The width of CFR field = the number of receive channels (call it N). For example, if CFR is two bits wide, then bit position 24 refers to receive channel 1 FIFO pointer and bit position 25 refers to receive channel 2 FIFO pointer. Writing 1 to bit 24 resets receive channel 1 FIFO pointer, and writing 1 to bit 25 enables receive channel 2 FIFO pointer. Writing 1 to bit N resets receive channel N FIFO pointer. 0b - No effect. 1b - Receive data channel N FIFO is reset. **NOTE** This field is not supported in every instance. The following table includes only supported registers.
23-20 —	Reserved

52.2 Overview

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio.

52.2.1 Block diagram

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

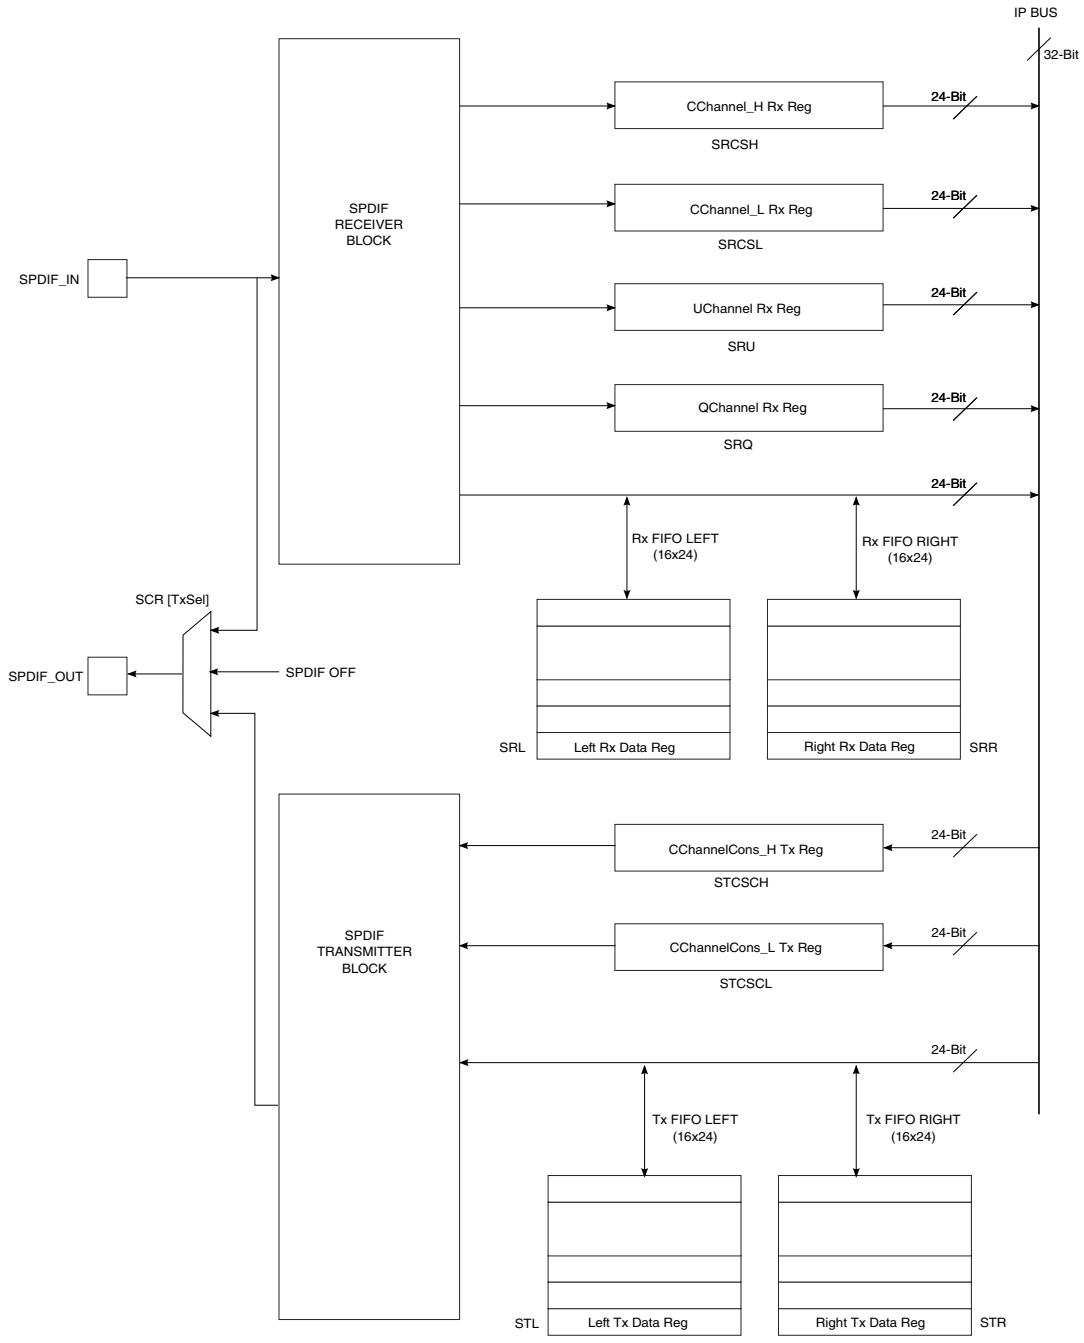

Figure 306. SPDIF transceiver data interface block diagram

52.2.2 Features

- Allows the handling of both SPDIF channel status (CS) and User (U) data
- Includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency

- Provides a recovered clock to drive both internal components in the system, such as SAI ports, and external components, such as A/Ds or D/As, with clocking control provided via related registers

52.3 Functional description

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphase mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphase bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock.

The Tx clock is sent to the ASRC.

The Rx clock is sent to the ASRC.

NOTE

ASRC (Asynchronous Sample Rate Converter) is not part of SPDIF. See the dedicated ASRC module for more information.

Figure 307 shows the clock structure of the SPDIF transceiver.

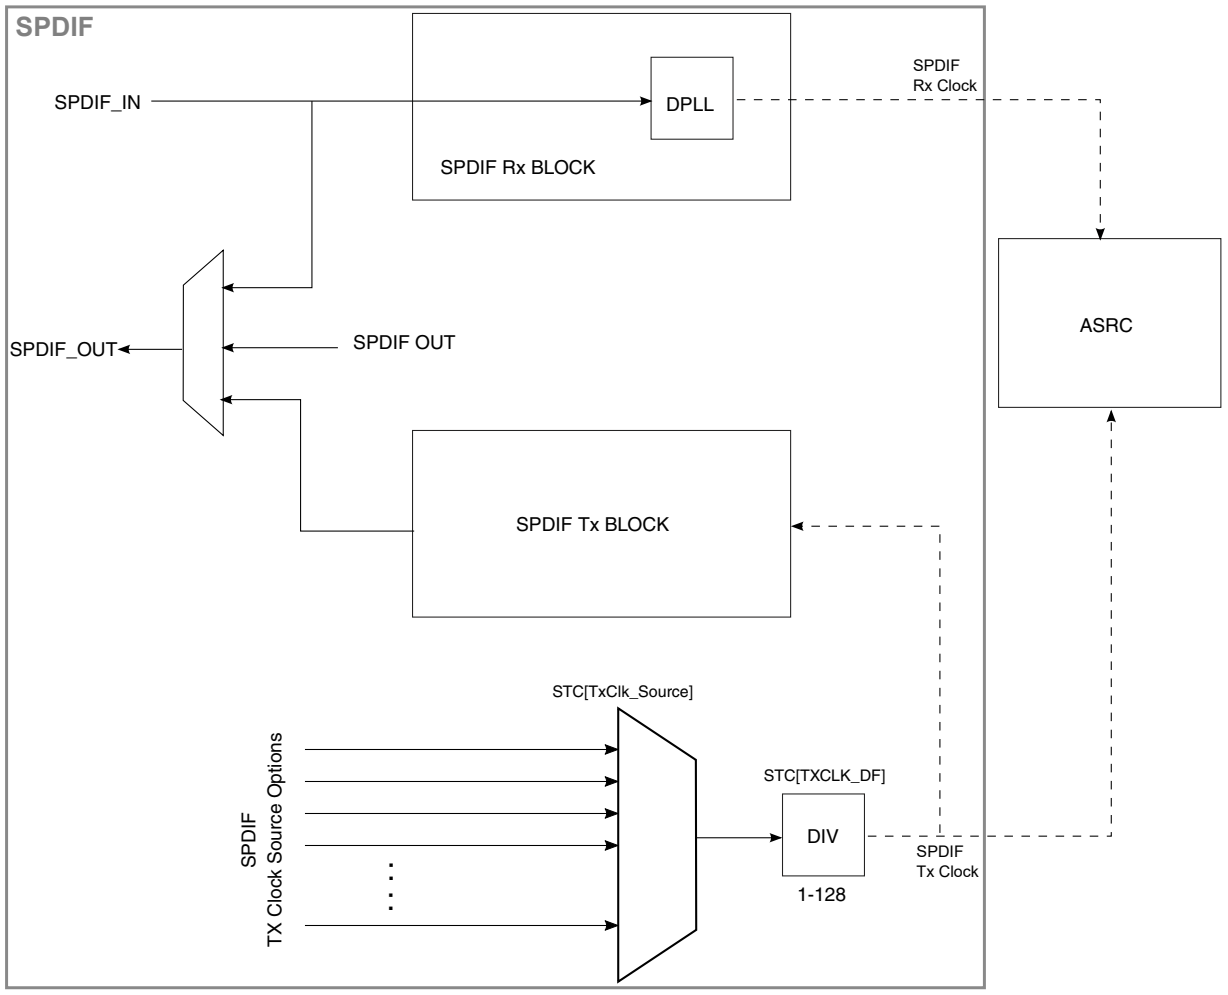

Figure 307. SPDIF transceiver clock diagram

52.3.1 SPDIF receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-bit-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

52.3.1.1 Audio data reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight.

Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

SPDIF receiver data registers - Behavior on overrun, underrun

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

SPDIF receiver data registers - Automatic resynchronization of FIFOs

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

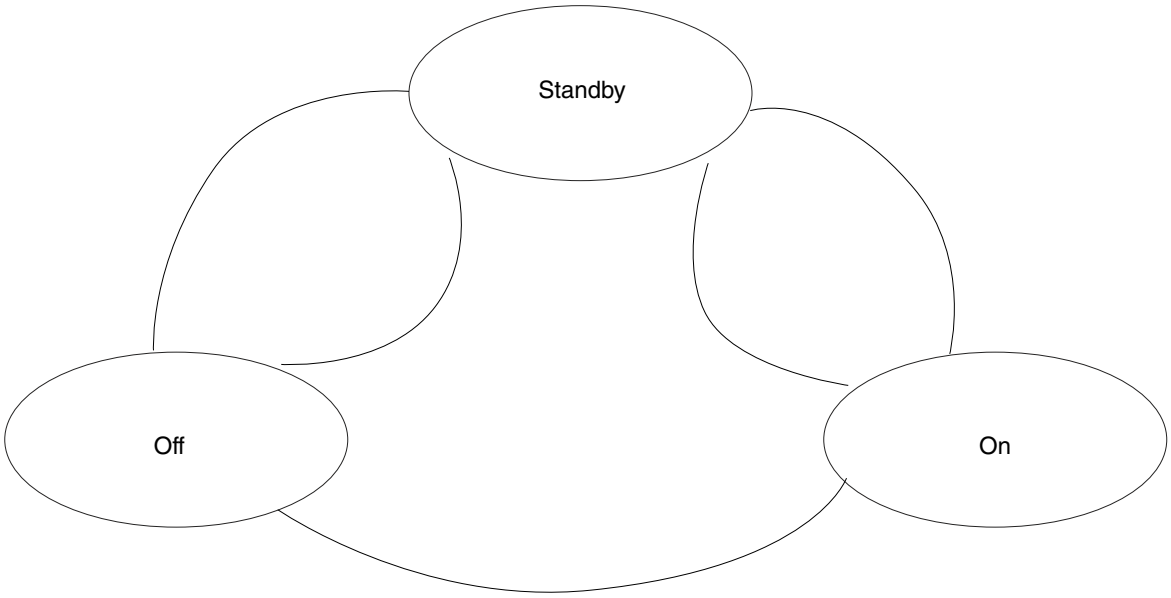

Figure 308. FIFO auto-resync controller state machine

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIF Configuration Register (SCR) to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

See Application information for additional details.

52.3.1.2 Channel status reception

There are 2 modes of Channel Status Reception: 48-bit and 192-bit.

48-bit mode

In 48-bit mode, a total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCChannel_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCChannel_l.

192-bit mode

In 192-bit mode, set RXCChannel_192b_en located in the SPDIF Configuration Register bit[25] to "1". A total of 192 channel status bits are received in six registers.

Channel Status Bits are ordered first bit left.

- CS-channel MSB bit "0" is located in bit position 31 in the memory-mapped register SPIDFRxCChannel_Addr_31_0, CS-channel bit "31" is the LSB bit 0 in this register
- C-channel bit 32 to 63 is seen as [31:0] bits of register SPDIFRxCChannel_Addr_63_32
- C-channel bit 64 to 95 is seen as [31:0] bits of register SPDIFRxCChannel_Addr_95_64
- C-channel bit 96 to 127 is seen as [31:0] bits of register SPDIFRxCChannel_Addr_127_96
- C-channel 128 to 159 is seen as [31:0] bits of register SPDIFRxCChannel_Addr_159_128
- C-channel 160 to 191 is seen as [31:0] bits of register SPDIFRxCChannel_Addr_191_160

52.3.1.2.1 Channel status interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptStat register.

52.3.1.3 User bit reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText_Control register).

Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver

This mode is selected if UsyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

Table 343. Sync control bits

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0

Table continues on the next page...

Table 343. Sync control bits (continued)

Number of U Channel zero bits	Corresponding number of sync symbols
11-22	1
23-34	2
35-46	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated. Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.
- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
- As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
- Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.

Behavior of U Channel receive interface on incoming non-CD data

This mode is selected if UsyncMode, bit 1 in register CD Text control is set'0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

52.3.1.4 Validity flag reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

52.3.1.5 SPDIF receiver interrupt exception definition

Several SPDIF exceptions can trigger an interrupt. They are:

- Control Status channel change. Set when SPDIFRxCChannel_l register is updated. The register is updated for every new C-Channel received. The exception is reset on write to SIS register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.[5]
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overrun. Set when there is a underrun/overrun on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overrun. Set when Q channel buffer overrun.
- Receive U Channel buffer overrun. Set on U channel buffer overrun.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

52.3.1.6 Standards compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

Supported input frequency range is 12 kHz up to 96 kHz. (fully compliant) and 96 kHz up to 176 kHz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel reception

[5] The SPDIF input is a biphase/mark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

52.3.1.7 SPDIF PLOCK detection and Rxclk output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin SPDIF_LOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency.(For a 44.1 kHz input sampling frequency, the average pulse rate = 128 x 44.1 kHz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

52.3.1.8 Measuring frequency of SPDIF_RxClk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS_CLK.

FreqMeas[23:0] = FreqMeas_CLK / BUS_CLK * 2^{10} * GAIN.

For example, if the GAIN is selected as 8*(2**10) (PhaseConfig[5:3] = 3'b011), the actual result

FreqMeas_CLK / BUS_CLK is equal to FreqMeas[23:0] / 2^{23}.

52.3.2 SPDIF transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is selected through a multiplexer from several clock sources (see register bitfield description STC[TxClk_Source] for transmit clock source inputs). The SPDIF transmitter clock source can be divided down as needed using Txclk_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphase mark format, consisting of audio data, channel status.

52.3.2.1 Audio data transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

SPDIF transmitter data registers - Behavior on overrun, underrun

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

SPDIF transmitter data registers - Automatic resynchronization of FIFOs

See Audio data reception and Application information.

52.3.2.2 Channel status transmission

There are 2 modes of Channel Status Transmission: 48-bit and 192-bit.

48-bit mode

In 48-bit mode, a total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCChannelCons_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCChannelCons_l.

192-bit mode

In 192-bit mode, a total of 192 Consumer channel status bits are transmitted from six registers. Channel Status Bits are ordered first bit left.

Channel Status Bits are ordered first bit left.

- CS-channel MSB bit "0" is located in bit position 31 in the memory-mapped register SPDIFTxCChannel_Addr_31_0, CS-channel bit "31" is bit 0 in this register
- CS-channel bit 32 to 63 is seen as [31:0] bits of register SPDIFTxCChannel_Addr_63_32
- C-channel bit 64 to 95 is seen as [31:0] bits of register SPDIFTxCChannel_Addr_95_64
- C-channel bit 96 to 127 is seen as [31:0] bits of register SPDIFTxCChannel_Addr_127_96
- C-channel 128 to 159 is seen as [31:0] bits of register SPDIFTxCChannel_Addr_159_128
- C-channel 160 to 191 is seen as [31:0] bits of register SPDIFTxCChannel_Addr_191_160

52.3.2.3 Validity flag transmission

The validity bit setting is performed via the ValCtrl bit of the SPDIF_SCR register.

52.3.3 Clocking

The table found here describes the clock sources for SPDIF.

Please see clock control block for clock setting, configuration and gating information.

Table 344. SPDIF clocks

Clock name	Description
gclkw_t0	Global clock
ipg_clk_s	Peripheral access clock
tx_clk	Module Tx clock

52.4 External signals

The following table describes the external signals of SPDIF:

Table 345. SPDIF external signals

Signal	Description	Direction
SPDIF_EXT_CLK	External clock signal	I
SPDIF_IN	Input line	I
SPDIF_LOCK	Lock signal	O
SPDIF_OUT	Output line signal	O
SPDIF_SR_CLK	RX Clock	O
SPDIF_OUT_CLK	TX Clock	O

52.5 Application information

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules:

1. When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 kHz, approximately 10 micro-seconds. For 88 kHz, approximately 5 micro-seconds.)
2. Write/read data to FIFOs at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.
3. After DPLL lock, the user must bypass the first 2 CNEW interrupt/events, and start sampling data from the 3rd CNEW event. The user must do the following:
   - Sample data must be discarded for a minimum of 128 to a maximum of 384 samples.
   - Clear all error flags after the 3rd CNEW event flag.

SPDIF receiver details

There are three exceptions associated with the SPDIF Receiver FIFOs

- full
- under/overrun
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overrun occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overrun" are set when one of the FIFOs do underrun or do overrun. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

Rx FIFO on and Rx FIFO reset

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

SPDIFTxLeft, SPDIFTxRight details

With SPDIF Tx FIFOs three exceptions are associated:

- empty
- under/overrun
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

3 RxFIFOResyn	RxFIFOResyn Rx FIFO resync
2 LockLoss	LockLoss SPDIF receiver loss of lock
1 TxEm	TxEm SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write to Tx FIFO.
0 RxFIFOFul	RxFIFOFul SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO.

52.6.1.6 InterruptStat Register (SIS)

Offset

Register	Offset
SIS	10h

Function

The InterruptStat (SPDIF_SIS) register is a read only register that provides the status on interrupt operations.

53.2 Introduction

The NETC complex is comprised of two main components:

- Ethernet switch and controller (NETC) Integrated Endpoint
- PCIe Integrated Endpoint Root Complex (iEPRC)

NETC presents itself as a multi-function PCIe Root Complex Integrated Endpoint (RCiEP or simply iEP). As such, it contains multiple PCIe functions related to Ethernet functionality such as Ethernet switching and Network Interface Controller (NIC) functionality. As an iEP device, NETC does not integrate real PCIe hardware; there are no PCIe physical, data link or transaction layers involved.

The PCIe compliance brings the major benefit of each NETC function being able to be isolated, initialized, quiesced and reset independently of each other which is clearly a benefit for any device that runs multiple software partitions. Another benefit is the ability to use standard PCIe device drivers to optionally discover what features/capabilities exists on the device.

The implications of using PCIe compliant programming model are:

- The main programming model constraint that results from NETC PCIe compliance is that some of the NETC registers are structured and laid out in the address space according to the PCIe specification.
- Another programming model implication of NETC PCIe compliance is usage of Message Signal Interrupts (MSI-X) replacing interrupt wires.
- Although NETC is presented as a PCIe iEP it is possible to use it as a set of more traditional peripheral devices with driver software which does not have support for PCIe and its discovery processes. This requires some configuration during

the boot and initialization of the device. For more information, see Use of Integrated End-Points by Non-PCIe Aware Operating Systems.

The iEPRC provides support for PCIe enumeration and the interface for the host to access the NETC PCIe configuration registers (standardized set of registers) and NETC specific registers. The iEPRC also includes a component called event collector, which allows NETC to report, for instance, power management events and certain errors to the host. The iEPRC is described in the following sections in general terms as a host for one or more iEPs with its own address map.

53.3 PCIe Integrated End-Point Root Complex (iEPRC)

53.3.1 Overview

The iEP-RC provides the necessary infrastructure to present NETC as a PCIe Integrated Endpoint so that it appears to be a PCIe device to system software. That is the device makes use of the support provided by system software such as boot firmware, operating systems, and Virtual Machine Managers (VMM, such as, Xen or KVM) for PCIe devices. This despite the fact that the functionality does not use PCIe serial links but is integrated into the SoC.

By PCIe definition, a Root Complex includes at least one Host Bridge, Root Port, or Root Complex integrated End-Point (RCiEP). As there are no PCIe physical links, the iEP-RC contains no Host Bridge and no Root Ports. In this instance of the iEP-RC, it hosts the NETC iEP along with the support of one Root Complex Event Collector (RCEC).

Use of the PCIe infrastructure simplifies adding support for the integrated devices to this system software and facilitates:

- Device discovery and location
- Resource requirement discovery and allocation (such as interrupt assignment, device register address)
- Event reporting (such as catastrophic internal errors, power management events) for events which are system level and outside of the scope of the devices' normal operation

In the case of VMMs it allows integration with no changes to the VMM software (for example, VFIO). Boot firmware and OSes can discover and support many different physical configurations of integrated devices with at most the addition of a driver for a pseudo "PCI controller" (the iEP-RC).

This simplifies software support and "up streaming" of device specific software by limiting the changes to the device specific drivers.

Figure 309 shows a simplified block diagram of the iEP-RC architecture. This consists of the iEP-RC, one RCEC and support for the NETC iEP.

NOTE

This diagram shows logical connections to the SoC Interconnect based on the different types of access required to the various blocks. This is not intended to dictate the number of actual connections as a physical connection to the interconnect can be used for multiple purposes. The ability to combine uses of a connection usually depends on factors such as whether the address ranges assigned for the different types of accesses can be adjacent in the SoC address map to facilitate address decode in the interconnect.

53.3.1.1 Block diagram

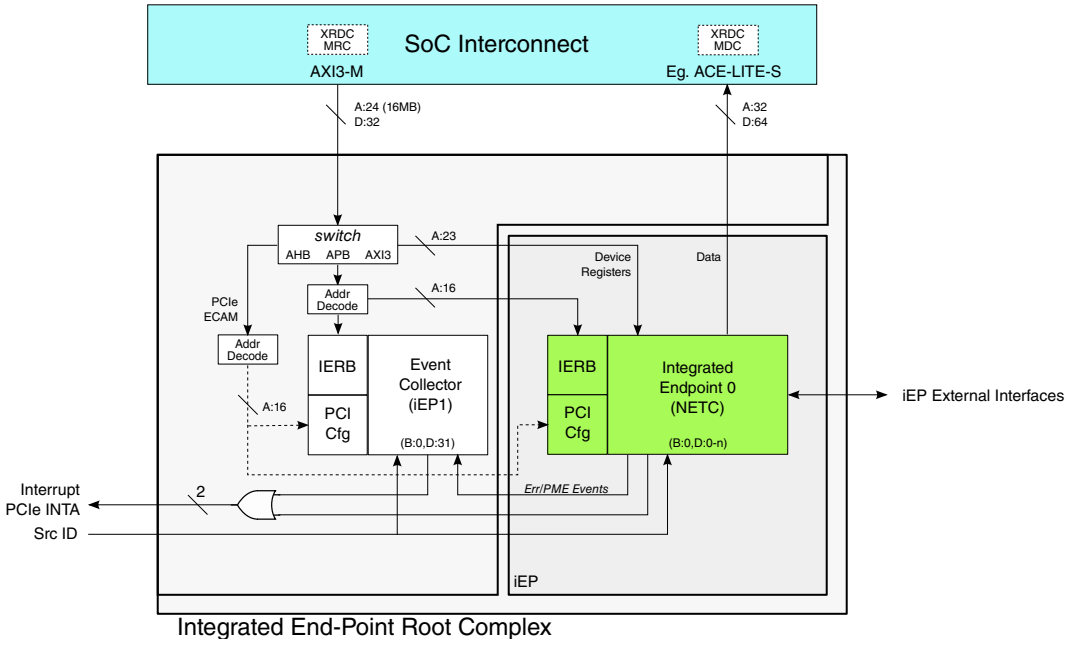

Figure 309. iEP Architecture

53.3.2 Functional Description

53.3.2.1 PCI/PCIe Background

It is useful to have an understanding of PCI/PCIe to be able to understand PCI Root Complex Integrated Endpoints. This section is intended to give an overview for those not familiar with PCI, not to provide a detailed explanation.

53.3.2.1.1 Overview

PCI and its successor PCI Express (PCIe) provide a framework for connecting peripheral devices to a computer consisting of one or more CPU(s) and memory. PCI defines how such devices are discovered and integrated into the system. This includes:

- Assignment of addresses for registers and memory in the device, determining how the "host system" accesses these
- Assignment, configuration, and control of interrupts including various types of message signaled interrupts (MSI)
- Reporting and handling certain errors
- Handling power management including events that will cause the system to exit low power modes
- Adding and removing such devices to a “live” system (hotplug)

PCI is defined for a multi-connect, parallel bus and PCIe for a serial interconnect. Devices can be arranged into a tree topology through the use of bridges or switches. Both PCI and PCIe are intended to be used with pluggable cards and are often used with peripherals on the same circuit board. None the less the use of PCI with peripheral devices which are integrated into an SoC is becoming common as it allows using the extensive standardized approaches and software infrastructure created for PCI with these integrated peripherals simplifying software development and portability across different SoCs.

With PCI, system software (boot firmware, OS, …) is initially only aware of a PCI controller -- a device which acts as the bridge between the host and the PCI/PCIe. It is not aware of any devices connected to this controller. Software identifies the PCI connected devices through a process known as enumeration.

53.3.2.1.2 Routing/Requester ID (RID)

PCI is organized in a tree like hierarchy with levels in the tree identified by Bus number and components at each level identified by Device and Function within a Device. A specific Function is identified by its Routing (or Requester) ID (RI or RID) consisting of Bus, Device, and Function numbers. Bus, Device, and Function numbers are 8, 5, and 3 bits respectively so RIDs are 16 bits allowing for 256 buses, 32 Devices per Bus, and 8 Functions per Device. Since PCIe uses serial links a Bus will often have only a single Device (although that Device may support multiple diverse functions). PCIe therefore supports Alternative Routing ID (ARI) which assumes that only Device 0 is present on a Bus and allows the Device ID bits to be used as additional Function IDs on that Bus. This allows a single multi-function PCIe Device to have up to 256 Functions.

Buses are connected to each other using components that bridge or switch between the buses. These components are configured by system software as they are discovered. Bus numbers are assigned during the enumeration process as the process proceeds. Each bridge or switch is assigned a range of bus numbers that depend on the needs of the devices and topology downstream of it.

A PCI Function can be considered to be the basic set functionality that a peripheral device would present to software. A network interface (Ethernet controller) would be a Function. A Device is a collection of (usually related) Functions. Typically PCI plugin card would be a single Device although it is also possible for a card to represent multiple Devices.

53.3.2.1.3 Config Space

On PCI each Function has a 256 B space of configuration registers. For PCIe this is expanded to 4 KB which incorporates the 256 B set of registers defined for PCI at offset 0 so that PCIe maintains compatibility with PCI.

The format of the first 64B of the configuration space (called the header) is standardized. Two different types of headers are defined: Type 0, used for port/bridge/switch functions, and Type 1, used for all others.

Sets of registers in the remaining Config space are defined using a tag-length-value like structure. These sets of registers are known as capability structures. Several capability structures are standardized and provision exists for a vendor to define their own capability structures. The TLV format of the capability structures allows system software to step over structures that it doesn't understand and find the standard capability structures it needs to configure the Function in the system.

Registers defined within the header and in standardized capability structures allow system software to assign or discover system resources (such as interrupts and address space for access to the PCI Device from the host system) and to configure and control functions such as power management, device hot plug, and reporting/handling certain errors.

Switch or bridge devices have registers within their headers which control the range of buses that are allocated to their downstream devices and the address ranges assigned to downstream devices thus describing the tree topology.

53.3.2.1.4 Config Space Access

Configuration space is addressed using a combination of the 16b RID in the upper bits and the offset within the Config space, 8b in the PCI standard 256B space or 12b in the 4KB PCIe extended Config space.

PCIe defines the Enhanced Configuration Access Mechanism (ECAM). ECAM uses a range of addresses in the host systems memory space large enough to allow direct, linear addressing of Config spaces of all Buses, Devices, and Functions in the hierarchy. Software simply performs a read or write within this range using the RID plus offset within Config space as the offset inside the ECAM range.

The full range of potential RIDs for a PCIe (Bus/Device/Function) with a 4KB Config space requires an ECAM space of 256MB.

53.3.2.1.5 Enumeration

Enumeration is the process performed by software to discover all Devices connected to a given PCIe hierarchy and to configure the bridge/switch functions appropriately. Enumeration is performed by reading a specific 16b configuration register (the Vendor ID register) for Function 0 of each potential Device using a process specific to the PCI controller. This will return 0xFFFF for any device which does not exist and a valid vendor ID for those that do. If Function 0 of a Device is discovered then the software can probe for other functions in that Device.

In addition to the Vendor ID another register provides a 16b Device ID which is assigned by the vendor. The Device ID identifies the specific device so that the appropriate driver can be loaded and used to interact with the device. Drivers register with the OS indicating what Device ID/Vendor IDs they support using an OS specific mechanism.

53.3.2.1.6 Function Address Space Allocation or Discovery

RIDs are used to access a Function's Config space and, for instance, by host system software to identify the source of an error or event interrupt. Normal driver software does not use the RID to access a peripheral's functionality. It does this using registers within an address space assigned to the function within the system/host address space. PCI/PCIe inherently provides memory mapped access.

Base Address Registers (BARs) in the header of Config space support up to six 32b addressed memory spaces or three 64b addressed spaces per Function (by combining two 32b BARs). Functions indicate the amount of address space required in the system's address map to access various components in the Function. This can include device registers or memory. PCI defines a standard way for a Function to indicate the amount of memory space required as well as certain attributes such as whether the host can prefetch data from that space (e.g. whether reads have side effects) and for system software to set the address range allocated.

The details of use of these address spaces is not defined by the standard. A typically use is to allow software to access operational registers required by the Function. A specific driver for the device, determined by the Vendor ID and Device ID, must be loaded which understands the use of the address space(s) assigned using the BARs. Standard system software can, however, can allocate address space without knowing the details of its use.

A PCI Root Complex (controller) has a range or window of addresses assigned to it within the host or systems address map. Accesses from the host (e.g. by the host GPPs) are directed to the RC. During enumeration system software assigns ranges of addresses to the Functions it discovers, as needed by those functions.

A Function may alternatively make use of an Enhanced Allocation capability structure in its Config space to inform the system of fixed addresses within the SoC's memory map at which its registers or memory can be accessed. This Enhanced Allocation mechanism can be used instead of using the BARs found in the Config header. Enhanced Allocation is especially useful for iEPs since they do not need to connect to the SoC/system interconnect through the Root Complex. They can use addresses which are not allocated within the RC's address window. Using Enhanced Allocation not only simplifies verification of the iEP but can greatly simplify integration of the iEP IP into an SoC.

53.3.2.1.7 Interrupts

PCI supports up to 4 interrupt signals known as INTx (x = A..D). PCI also supports 2 types of message signaled interrupts (MSI and MSI-X).

Wired interrupts (INTx) are configured and controlled through registers in the header of Config space. MSI are configured and controlled through registers in an MSI capability structure. MSI-X are configured and controlled through registers within a BAR specified address space with a reference (BAR id and offset within the BAR) provided in an MSI-X capability structure. The format of the MSI/MSI-X configuration registers is specified by the PCI standards.

Functions indicate their requirements and capabilities to support the various types of interrupts through settings in defined registers (in the header) and registers in the MSI and MSI-X capability structures. System software can examine these registers and allocate interrupts accordingly. Similar to address assignment, system software can do this allocation without any detailed knowledge of the intended use of the interrupts thus separating the process of allocating of resource (interrupts) from their use.

PCI Functions can make use of one of the 4 (potentially) available wire signaled interrupts and this is selected using a register in the Config header. This requires multiplexing all interrupt sources onto a single interrupt signal, and then the interrupt service routine must determine the actual source of the interrupt before calling the appropriate handler. In addition, only a single core in a multi-core system can handle the interrupts from a Function which uses wire signaled interrupts. Different MSI(-X)s can be allocated and used for different interrupt sources and these can be serviced by different cores thus spreading the load of responding to these interrupts. As a result MSI(-X) are usually preferred over wire signaled interrupts.

53.3.2.1.8 Virtualization

The Single Root I/O Virtualization and Sharing Specification (SR-IOV) is an extension to PCIe that defines how PCIe devices support virtualization. It does so by defining a special type of Function known as a Virtual Function (VF). A VF is always associated with a Physical Function (PF) and a PF may have multiple VFs.

A PF is a PCIe Function and represents a set of functionality presented by a peripheral device to software. A VF typically supports a subset of the PF's functionality which can be provided to software for use by a Virtual Machine, container, or other software entity.

The PF has some management and control capability over its VFs and over the underlying device functionality. Devices will often provide a means for the VF to request configuration and control changes, mediated by the PF and its driver software. For instance, a messaging system may be provided so that VF drivers can request that a PF driver make changes on its behalf.

Functions are isolated from each other so VFs are isolated from other VFs and from their PF. Because of its reduced capabilities a VF is restricted, to some extent, from interfering with other VFs. VFs can be directly assigned to a Virtual Machine, container, or user space process with direct access to the hardware.

Taking an Ethernet controller (ENETC) as an example, an Ethernet port would have a PF and some number of VFs. The controller would provide classification mechanisms to send different frames to specific Functions, for instance based on different destination MAC addresses. It might also have the capability to replicate some frames, such as broadcast frames, for all Functions. (Alternatively, this function could be performed by the PF driver software.) The PF would have the ability to control this selection mechanism. VFs would not. If the system using this controller ran several Virtual Machines it could assign a VF to each VM. The host OS would use the PF. Each VM would, in some sense, see the Ethernet port as belonging to it.

As PCI Functions, VFs have RIDs and Config space. Address assignments for VFs are not handled through the normal PCI BAR mechanism and they support a subset of the Config registers that their PFs support. Certain settings in the VF Config registers are hardwired to match their PFs settings.

53.3.2.1.9 PCIe Topologies

In PCIe, the host PCIe controller (Root Complex) contains Bus 0 for that PCIe hierarchy. There are typically one or more bridge or switch components, known as Root Ports (RP), on that Bus which connect to serial PCIe links. Each of these links then connects to either a PCIe Endpoint (EP) and/or a PCI(e) switch.

It is the PCIe EPs which provides the actual peripheral device functionality.

The RC may also include integrated components such as RCiEP (or simply iEP) and RCEC.

The RCEC is a component provided to allow iEPs to report, for instance, power management events and certain errors to system software. With non-integrated devices these are reported with messages across a PCIe serial link and it is the responsibility of upstream infrastructure components such as an RP or a switch or bridge port to take this messages and turn them into interrupts to the system. Since such upstream components do not exist for an iEP the RCEC provides this capability. Note that having the iEP generate these interrupts directly violates the concept that an iEP should appear like a regular PCIe EP to system software since regular EPs do not themselves generate these interrupts.

Since we are only dealing with iEPs and ECs in this Root Complex, examples of this topology will only be discussed further.

53.3.2.2 Integrated Endpoint Architecture

The iEPRC is architected to support one or more integrated End-Points (iEP) and zero or more RCEC. This section describes in general terms, the overall architecture of the Integrated Endpoint Root Complex IP and the Integrated Endpoint.

NOTE

This instance of the iEP-RC, includes a single iEP (that is NETC) and a single RCEC.

53.3.2.2.1 Root Complex Functionality

The iEP-RC implements ECAM to provide access to the PCIe Config space of the iEPs and the main function of the Root Complex logic is to route accesses from software to the PCI Config space to the appropriate destination, either an iEP, RCEC, or the Root Complexes' own Config space.

In addition to routing Config accesses to the correct iEP or RCEC. the Root Complex routes accesses to a block of registers in each iEP and RCEC, the iEP Register Block (iERB). There is an iERB for each Device on Bus 0 for a total of 32 possible iERBs for an iEP-RC.

The Root Complex also routes legacy wired interrupt requests to the system from iEPs that require the ability to use PCIe INTx interrupts. The spec allows a Root Complex to have up to 4 wired interrupts corresponding to the 4 PCI interrupts (INTA thru INTD) but normally only a single wired interrupt is supported per RC. If multiple iEPs require use of wired interrupts then the RC is responsible for logically OR'ing those requests onto the interrupt signals as required.

53.3.2.2.2 RCEC Functionality

The RCEC provides functionality for iEPs which would otherwise be provided by PCIe components downstream of the iEP, if the iEP were an Endpoint on an actual PCIe topology. This includes error reporting for certain catastrophic errors in an iEP (e.g. fatal memory error in an internal memory, PCIe Advanced Error Reporting) and reporting and managing power management events (e.g. requests to exit low power states, PCIe Power Management Events). These are reported as in-band messages on a PCIe topology. These in-band messages are converted to interrupts which can be understood by the host by the downstream component such as a Root Port.

A given RCEC can support either wired or MSI-X interrupts for reporting these events and errors to software.

The iEP-RC includes zero or more RCECs. Normally at least one RCEC is required in an iEP-RC. Legacy (reused) IP converted to an iEP may not make use of RCEC for error and power management event reporting. If all iEPs are legacy logic which do not support using an RCEC then no RCEC may exist in the iEP-RC.

In many cases a single RCEC can be used by all iEPs connected to an iEP-RC provided all iEPs have the same requirements for how their events/errors are signaled to software. A scenario where multiple RCECs would be required is when one of the iEPs has a need to cause the system to exit from a low power mode (for wake-on-LAN). This would normally require the use of a wired interrupt on the part of the RCEC to cause an exit from the low power mode since MSI(-X) will not work when significant portions of the SoC are powered down. The PCI programming model for event reporting does not allow a single RCEC to use both wire signaled interrupts and MSI at the same time for different iEPs. To allow the use of a wired interrupt for the iEP requiring wakeup and MSI for the remainder of the iEPs two RCEC can be used one of which uses an INTx and the other which uses MSI.

NOTE

This instance of the iEP-RC IP includes a single RCEC, which supports only wire signaled interrupts. These are used to report both errors and power management events.

53.3.2.2.3 Integrated Endpoint Functionality

iEPs present their native functionality, such as NETC, to the system as multiple PCI Functions. In addition to whatever native functionality they provide iEPs must provide functionality as part of their role as PCI integrated Endpoints.

Primarily, this consists of accepting and responding to accesses to the PCI Configuration space of each of the Functions they support. Registers in the Config space are used to inform software of the capabilities and status of the Function as well as configure and control its functionality.

Specifically, this includes:

- Function reset
- Enabling/disabling of the Function as a whole
- Enabling/disabling of some types of error reporting
- Enabling/disabling isolation functionality
- Enabling/disabling interrupts

53.3.2.2.4 SR-IOV Support

iEPs such as NETC, which support virtualized or isolated access to their functionality, for instance by containers or Virtual Machines running on the SoC, do so using PCI SR-IOV. iEPs can implement from one to 1000’s of Virtual Functions.

An iEP which implements SR-IOV must support the SR-IOV Extended Capabilities structure. VF Migration is used only with MR-IOV and is not supported by iEPs. VFs of an SR-IOV RCiEP device are associated with the same Root Complex Event Collector (if any) as their PF.

53.3.2.2.5 Addressing

53.3.2.2.5.1 Page Size and Alignment

iEPs uses a minimum page size and alignment of 64KB. Register allocations are rounded up to the next 64KB regardless of actual requirements. This ensures proper alignment and address space allocation when system software requests a page size of less than 64KB (e.g. 4KB). iEPs can claim support for smaller page sizes with minimal complexity at the expense of potentially using more address space than actually required.

53.3.2.2.5.2 PCI BAR Usage

PCI supports both 32 bit and 64 bit Base Address Registers (BARs). iEPs uses 64b BARs.

53.3.2.2.5.3 PCI Enhanced Addressing

iEPs use Enhanced Addressing to communicate their addresses to software. Software is informed of base addresses and apertures rather than assigning them using writable BARs in the Config header. The addresses assigned to iEPs are not within address windows in the SoC's address map assigned to the iEP-RC or within the address windows assigned to any PCIe controller.

iEPs connect directly to the SoC Interconnect to accept transactions targeting their registers or embedded memories. The iEP-RC is not involved in routing such accesses to the iEPs.

53.3.2.2.6 Interrupts

iEPs may support MSI-X or INTx for functional interrupts. If INTx is used it is routed through the iEP-RC and follows the interrupt standard described by the RCEC. It should be noted that, if wired interrupts are used by an iEP, all interrupt sources will share a single interrupt to the cores. The iEP must provide mechanisms for software to distinguish between different interrupt sources within its own programming model.

53.3.2.2.7 Device and Function Number Assignment

iEPs claim an integer number of contiguous Devices in the RID space, to hold non-virtual and physical function. This does not mean that an iEP implements all Functions within that space. Holes may be left in the RID space claimed by an iEP including the end of the RID space it occupies.

If an iEP (for example, NETC) has PFs that can implement a large number of VFs, then it is assigned a secondary Bus number and secondary base Device number. It uses this secondary Bus and Device as the starting point for the RIDs of any sets of VFs which meet this criteria. The goal is to minimize consumption of Device numbers on Bus 0 to allow other iEPs use of this space as well.

The RID of the first VF for this iEP is:

- *secondary-Bus:secondary-base-Device:0*

and the remaining iEP's VFs following this occupies as much Device and Bus space as required.

All (non-Virtual, Physical) iEP Functions are in Bus 0. Buses 1 through 7 are used for Virtual Functions only.

RCECs also occupy RID and Config space. RCECs are implemented as Functions in Bus 0, Device 31. The first RCEC is Function 0 of Device 31 and any other RCEC's take sequential Function numbers in that Device.

53.3.2.2.8 Device ID Assignment

The Device ID identifies a particular PCIe Function and is assigned by the vendor. It is used in conjunction with the Vendor ID and Revision ID for software to determine which driver should be loaded.

The table below indicates the defined values for Device ID (0xE*xxx* family) as it relates to Integrated End Points. All other values are reserved.

Table 347. Device ID Assignment

Vendor ID	Device ID	
Freescale (0x1957)	E001	RCEC which support only INTx
	E002	RCEC which support MSI/MSI-X + INTx
	E100	ENETC rev 1
	E101	ENETC rev 2
	E110	ENETC rev 2 acting as a NETC switch management port
	E111	TSN Ethernet switch management port
	E200	PON Port
	EE00	EMDIO controller rev 2
	EE01	EMDIO controller rev 1
	EE02	IEEE 1588/1722
	EEF0	TSN Ethernet Switch
	EEF2	Switch config and control
	EF00	ENETC VSI

53.3.2.2.9 Power Management and Power Management Events (PME)

Power management is used to place portions of an SoC into low power states, possibly removing their clock and power. This may be done if those portions of the SoC are not required by the system or if the system itself is entering a low power state. Power management of the iEP-RC and iEPs is performed by software using the registers in the Power Management Capability structure.

PCI defines a number of power states. Software can determine the power state of a Function and can transition it between states to either reduce the power required by a Function when it is not required or to increase its power in preparation for using it's functionality. It also defines capabilities for a Function to request a change from a low power state to a higher power state if, for instance, an external event is detected which requires bringing the system out of a low power state.

iEP Functions which require the ability to wake the system from a low power state do so using PCI Power Management Events (PME). iEPs signal PMEs to their RCEC using a wired signal. RCECs in turn indicate that a PME has occurred using an interrupt. If the intent is to cause the system to exit a low power state (e.g. for wake-on-LAN) then a wire signaled interrupt must be used.

53.3.2.2.10 Error Reporting

iEPs report certain errors using PCI error reporting mechanisms. Most of the PCI and PCIe specific errors do not apply to an iEP due to the fact that iEPs do not have serial links and the majority of the error types supported are related failures on these links.

53.3.2.2.10.1 PCIe Advanced Error Reporting Support

iEPs that support AER must support reporting of Internal errors RCEC. Support of other AER errors is not required.

This type of error is used to report unexpected errors and faults such as bit errors in internal memories in an iEP. Only one Function within an iEP should report any single error which occurs in shared resources in the iEP.

AER does not distinguish between different types of Internal errors. AER allows these errors to be classified as "recoverable" or unrecoverable" but all errors of a given type (e.g. Internal) are treated in the same way.

iEPs do not use this mechanism to report normal operational errors such as CRC errors in packets received over an external Ethernet port.

53.3.2.2.11 Reset

PCIe defines a means for software to initiate a soft reset of individual Functions called Function Level Reset (FLR). Requirements for FLR are described in the section PCI Function Level Reset Support.

53.3.2.2.12 Pre-boot Initialization

PCI devices commonly support a mechanism to perform some type of pre-boot initialization by reading configuration from nonvolatile memory at boot-up, before enumeration can occur. This can include allocating internal resources between Functions, and simply setting initial defaults for some user visible registers. This configuration is changeable only by rewriting the configuration data in nonvolatile memory and requires a full (such as, Conventional) reset to cause this to take effect. FLR does not cause this initialization to take place.

53.3.2.2.13 iEP Register Block

An iEP Register Block (iERB) is a 64 KB size page containing registers that are used for pre-boot initialization, debug, and non-customer configuration. There is a an iERB per Device.

The lower 32 KB of the iERB are reserved for architected registers required for iEPs. The upper 32 KB are available for an iEP to use as it sees fit.

53.3.2.3 INTx Signaling

iEPs which require the use of wire signaled (SPI) interrupts do so through the iEP-RC, not directly to the SoC interrupt controller. Each such iEP has a single INTx request line to the iEP-RC.

The iEP-RC supports one wire signaled interrupt. All INTx interrupt sources are muxed (logically ORed) onto this single line to the host/SoC by the iEP-RC. Similarly, multiple Functions within an iEP may use wire signaled interrupts and the iEP is responsible for muxing (logically ORing) these requests. The INTx request to iEP-RC remains asserted as along as any source in the iEP is asserting its request.

If PM-PCI power management is used, any request for D3 power state or while in D3 power state will deassert INTx.

53.3.2.4 Power Management Signaling

To reduce power consumption portions of an SoC can be placed in low power modes and possibly have their power removed. This includes iEPs. When in this low power mode some iEPs may wish to signal the system requesting that it be brought out of this state to a more fully functional state, for instance, an iEP implementing an Ethernet controller may provide wake-on-LAN functionality. This capability is provided in PCI using Power Management Event (PME) signaling.

A PME message is delivered to the Root Complex Event Collector which is configured to wake the system by generating a wire signaled interrupt (i.e. INTx) by setting the PME Interrupt Enable bit in the Root Control register of its PCI Express Capabilities structure.

Functions indicate PME to the RCEC using their own signal. A Function which asserts this signal continues to do so until the condition is cleared by software by writing the PME Status bit in the Function’s PMCSR register in its PCI Power Management Capability structure.

The RCEC is aware of the RID associated with each PME signal it receives from iEPs and reports that RID in the Root Status Register of its PCI Express Capabilities structure. This RID is valid and the interrupt to the host asserted as long as the PME Status bit in the Root Status register is set.

Software must clear the RCEC’s Root Status register’s PME Status bit when it has finished bringing the associated Function out of its low power state. If any PME request signal is asserted the RCEC will continue to assert the interrupt if enabled and the PME Status bit will remain set.

If multiple Functions have their PME signal asserted then the RCEC can select the Function to report using any means. It is not required to report PMEs in order of assertion. Software should take note of this especially if the RCEC’s Root Status PME Status is cleared before the Function’s PMCSR PME Status is cleared. The RCEC may choose to report a different Function’s PME rather than continue to report the PME from that Function.

53.3.2.5 Advanced Error Reporting Signaling

Advanced Error Reporting is used to report PCIe related errors such as problems with the link, Access Control errors and internal errors such as memory failures. These errors are typically not normal operational errors of the Function reporting the error and can not be addressed by its specific driver.

Each iEP must report the severity of the error and the RID of the Function reporting the error. Each Function may independently report errors and the iEP is responsible for collecting and correctly reporting error severities and RIDs sequentially. If multiple Functions report AER errors then the iEP is responsible for selecting what order to report the errors in. It may do so in any order, not necessarily in the order of assertion. Once it has started reporting a given error the iEP continues to report that error until the source of the request no longer requests it. The iEP may then start reporting a different error by deasserting it's AER error indication, updating the severity and RID, and reasserting the error indication.

The RCEC is configured to signal the host/SoC when an AER error is reported using an interrupt (i.e. INTx) through the various Error Reporting Enable bits in the Root Error Command register in their AER Capabilities structure. The RCEC asserts the interrupt as long as any iEP's AER indication signal is asserted.

If multiple AER errors are reported simultaneously the RCEC will select which to report and in what order. It may do so in any order not necessarily in the order that the signals are asserted. Once the RCEC has chosen to report a given error it continues to do so until that AER error indication is deasserted.

NOTE

Note that only non-virtual (Physical) Functions are required to implement AER.

53.3.2.6 Reset

RCECs do not support reset.

53.3.3 Use of Integrated End-Points by Non-PCIe Aware Operating Systems

53.3.3.1 Overview

Many real-time environments and operating systems (RTOS) do not have support for PCIe. Although NETC is presented as a PCIe RCiEP it is not necessary to implement full PCIe support to make use of NETC's functionality.

NETC is divided into several PCIe Functions. Each Function is a logically distinct peripheral device. These include a PTP/IEEE 1588 timer device, a shared access MDIO interface for configuring and controlling Ethernet PHYs, optionally one or more Ethernet Network Interfaces and optionally a switch management Function.

With some minimal configuration during the boot and initialization of the SoC it is possible to use NETC Functions with more traditional device driver software without relying on any PCIe aware software. The appropriate registers and settings are described here. In the case that some Functions are Virtual Functions (VFs), when Single Root I/O Virtualization (SR-IOV) is supported, some run time support must also be implemented in the driver for the Physical Function (PF) to support the VFs.

53.3.3.2 Enhanced Configuration Access Mechanism (ECAM)

PCIe has the concept of a Configuration Mechanism as a way to discover PCIe devices and perform basic configuration and control such as enable/disable and reset. See Config Space.

PCIe has defined the Enhanced Configuration Access Mechanism (ECAM) which provides a memory-mapped, common set of registers for each Function, occupying up to 4KB per Function, and following a specified format. To allow NETC to appear to be a PCIe End Point (that is be an RCiEP) the iEP-RC supports ECAM. The address of the ECAM can be found by referring to Memory Map and Table 4. NETC PCI Express ECAM Memory Space.

The offset within the ECAM to a specific Function's 4KB space is determined by an offset from this base using the Function's RID. Refer to Table 353 to find the RID of the various Functions.

This section lists the ECAM registers which need to change during boot/initialization of NETC.

53.3.3.3 Integrated Endpoint Register Block (IERB)

The Integrated Endpoint Register Block (IERB) is a set of registers provided to allow configuring the RCiEPs to set, for instance, default values or allocate resources between RCiEPs. Conceptually it provides the same functionality for the RCiEPs that PCIe peripheral's nonvolatile memory would provide. See Root Complex Event Collector iERB Memory Map.

IERB is not a PCIe standard concept, however its use can be important when initializing NETC. Registers in IERB are used to determine allocation of resources such as buffer and table memory.

53.3.3.4 Privileged Register Block (PRB)

The Privileged Register Block (PRB) is a set of registers provided to allow operational control of RCiEP for reset and global error management.

PRB is not a PCIe standard concept, however its use can be important during operation of NETC. Refer to the privileged register section of each iEP's register descriptions for more details.

53.3.3.5 Root Complex Event Collector (RCEC)

The iEP-RC includes a Root Complex Event Collector (RCEC). This functionality is included for use with a full PCIe stack and can generally be ignored if such a stack is not being implemented.

53.3.3.6 Peripheral Device Register Addresses

Each Function's registers are located in one (or more) 64KB, aligned, page(s) in the address map of the SoC. PCIe generally uses Base Address Registers (BARs), in ECAM, to assign addresses to a Function's registers in the SoC address map during the PCIe enumeration (discovery) process. NETC makes use of a PCIe concept known as Enhanced Allocation (EA), which is only permitted for iEPs, and which allows the peripheral device registers to be at fixed location within an SoC's address map.

These addresses are then listed in PCIe Capability structures for each Function in ECAM and can be discovered during the enumeration process. However, it is not necessary to discover these addresses through PCIe enumeration because these addresses are fixed and known for a given SoC address map. The BARs in ECAM are not used.

Refer to Memory Map and the iEP-RC memory map tables (Table 348 and Table 349) to determine the location of the peripheral device registers for each NETC Function in the SoC address map. The registers are then laid out as described in the address maps for the individual Functions. These address ranges can then be communicated to the device drivers using the mechanism supported by the RTOS or run time environment in use, e.g. device tree entries or XML or json config files.

53.3.3.7 Steps to Initialize RCiEP Peripherals for Direct Use

After initializing any static configuration values in the Integrated Endpoint Register Block (IERB) the following are the high level steps for initializing an RCiEP Function for use:

1. Enable the Function
2. Initialize Message Signaled Interrupts (MSI) for use with the Function

Each of these steps may involve multiple sub-steps and are outlined in following sections. These steps will need to be repeated following a Function Level Reset, for that Function.

53.3.3.8 Enabling Peripheral Devices

Each Function must be enabled through configuration registers in it's ECAM space. These registers are described here. If SR-IOV is supported, then so-called Virtual Functions are handled differently than non-virtual (Physical) Functions. All non-virtual Functions require the same steps for enabling.

53.3.3.8.1 Enabling Non-virtual Functions

The Bus Master Enable and Memory Access enable bits in the PCI command register in a Function's ECAM must be set (to 1) in order to enable the Function.

53.3.3.8.2 Enabling Virtual Functions (VFs)

VFs must be enabled in their corresponding PF's ECAM registers. The number of VFs must be set in the PF's PCIE_CFC_SRIOV_NUM_VFS register and the VFs must be enabled by setting VF_ENABLE and VF_MSE in the PFs PCIE_CFC_SRIOV_CTL register in ECAM.

Each VF must then be enabled by setting the Bus Master Enable in PCI_CFH_CMD register in the VF's ECAM.

53.3.3.9 Interrupts

NETC peripheral devices make use of Message Signaled Interrupts (MSI's) specifically the "eXtended" PCIe version (MSI-X). When using the MSI paradigm a device signals an interrupt by writing a "message" to a specified address. This write is then translated into an interrupt at a core associated with the address/message pair. See Message Signaled Interrupt (MSI-X) for more information on this.

Each Function has a (possibly single entry) table of MSI {address, message} tuples which must be populated for it during initialization. The driver then selects which interrupt to associate with a specific event (e.g. transmit completion) by configuring an index into this table in a device register.

The MSI table for each Function is located in a separate 64KB, aligned, page for each Function and, as for device registers, the address of these pages can be found by referring to the iEP-RC memory map tables in Memory Map (Table 348 and Table 349). Note that PCIe allows for this table to be at an offset within this page, as indicated by the Function's PCI_CFC_MSIX_TABLE_OFF_BIR, however this offset is normally 0 for NETC Functions.

See Message Signaled Interrupt (MSI-X) for more information on MSI-X and the format of the MSI-X vector table.

53.3.3.9.1 Setting the Size of the MSI Tables

During initialization the sizes of the various Function's MSI-X vector tables can be changed by setting values in the IERB, within the supported ranges.

For ENETC the number of vectors assigned to each SI (PF and any VFs) must be set using the PSI*a*CFGR2 register (a is the SI number) in the PF's register space.

Number of MSI-X entries allocated should at least meet the minimum expectations of the drivers for each device.

53.3.3.9.2 Populating the MSI-X Vector Table and Enabling MSI-X

Each Function's MSI-X vector table must then be populated with entries appropriate for the SoC MSI-X translation mechanism.

Finally, MSI-X must be enabled by setting MSIX_EN and clearing FUNC_MASK in the Function's PCI_CFC_MSIX_MSG_CTL register in ECAM.

53.3.3.10 Functionality Provided by PFs for Their VFs

This section is just a brief summary of the functionality provided by a PF for its VFs. For a more comprehensive understanding of the full set of functionalities, refer to the following sections of this document.

The intent for VFs in SR-IOV is that they be assigned to Virtual Machines. As a result, they do not have full, direct control over some of the capabilities available to them. The entity controlling the PF controls these capabilities and the entity using the VF must ask the entity controlling the PF to make changes on the VF's behalf.

A mailbox style communications mechanism is provided in hardware to allow the driver software on a VF to send a message to the driver software on the PF requesting the PF driver to make changes for the VF driver. See PSI-VSI Messaging for more information about this mechanism.

53.3.4 Memory Map

NOTE

Systems may have software which runs at different privilege levels. In this document the term privileged or privileged software refers to the most privileged software layer, which could be Virtual Memory Manager (VMM) an operating system or software hypervisor.

This section provides a detailed description of all accessible iEP-RC memory and registers. Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect. The mapping of iEPs within the PCI Express ECAM (Enhanced Configuration Access Mechanism) memory allocated for iEP-RC, can be seen in table Table 348.

The Root Complex memory map is 16MB, of which ECAM space accounts for 8MB. The ECAM size limits the PCIe hierarchy an 8 bus topology. The remaining Root Complex memory space is reserved for iEP device registers.

The base address location of this memory map in SoC is 0x60000000.

Table 348. Root Complex Memory Space (16MB)

Address Offset	Registers
0x00_0000-0x7F_FFFF (8MB)	iEP PCIe ECAM Config (4KB per function, 32KB per device, 1MB per bus, supporting an 8 bus PCIe topology)
iEP 0: 0x00_0000 - 0x00_7FFF(8 x 4KB)	NETC: (device 0)
iEP 1: 0x0F_8000 - 0x0F_FFFF (8 x 4KB)	RCEC: (device 31)
0x80_0000 - 0x8F_FFFF (1MB)	iEP Register Blocks (64KB per endpoint)
iEP 0: 0x80_0000 - 0x80_FFFF (64KB)	NETC
iEP 1: 0x81_0000 - 0x81_FFFF (64KB)	RCEC
0x90_0000 - 0x9F_FFFF (1MB)	Privileged Register Blocks (64KB per endpoint)
iEP 0: 0x90_0000 - 0x90_FFFF (64KB)	NETC
0xA0_0000 - 0xFF_FFFF (6MB)	iEP 0: NETC device registers

Table 349. NETC Root Complex Memory Map Layout

Aperture Size of BAR	Function	EA Address Offset in NETC Root Complex space	PCIe EA BAR Equivalent Index
8MB	PCIe Config (ECAM)	0x00_0000	n/a
1MB	IERB	0x80_0000	n/a
1MB	Privileged	0x90_0000	n/a
1MB	F2 Switch	0xA0_0000	0
256KB	PF3 ENETC instance 0	0xB0_0000	0
256KB	PF4 ENETC instance 1	0xB4_0000	0
128KB	F0 Timer	0xB8_0000	0
128KB	F1 EMDIO	0xBA_0000	0
64KB	F0 MSI-X	0xBC_0000	2
64KB	F1 MSI-X	0xBD_0000	2

Table continues on the next page...

Table 349. NETC Root Complex Memory Map Layout (continued)

Aperture Size of BAR	Function	EA Address Offset in NETC Root Complex space	PCIe EA BAR Equivalent Index
64KB	F2 MSI-X	0xBE_0000	2
64KB	PF3 MSI-X	0xBF_0000	2
64KB	PF4 MSI-X	0xC0_0000	2
64KB	PF4 VF1	0xC1_0000	9
64KB	PF4 VF1 MSI-X	0xC2_0000	11

53.3.4.1 Root Complex Event Collector iERB Memory Map

Within the 8MB ECAM address space allocated to the Integrated Endpoint Root Complex by the SoC, a 64KB Integrated Endpoint Register Block (iERB) exists per iEP. The RCEC is an iEP on bus 0 and hence has its own iERB space. The iERB is used for pre-boot initialization, debug and non-customer configuration. The lower 32KB of the iERB are reserved for architected registers required for Integrated Endpoints. The upper 32KB is available for use by RC(EC). The table below shows how the iERB memory space is divided for the Event Collector.

Table 350. Event Collector Integrated Endpoint Register Block (iERB) Memory Map

Address Offset	Registers
0x0000-0x0FFF	Function 0 configuration (RCEC 0)
0x1000-0x7FFF	Reserved (architected for expansion of additional functions)
0x8000-0xFFFF	Reserved (user space)

53.3.4.2 PCI Express ECAM Event Collector config register descriptions

This section describes the PCI Express Type0 config header and capabilities as they relate to the Event Collector of the iEPRC. The Event Collector uses a single function and PCIe function that is not present will return a Vendor ID of 0xFFFF and 0's for all other register accesses within that function.

53.3.4.2.1 PCI_Config_Header_Type0 memory map

IERC_F0_PCI_HDR_TYPE0 base address: 600F_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	PCI device ID and vendor ID register (PCI_CFH_DID_VID)	32	R	E001_1957h
4h	PCI command register (PCI_CFH_CMD)	16	RW	0000h
6h	PCI status register (PCI_CFH_STAT)	16	R	0010h
8h	PCI revision ID and classcode register (PCI_CFH_REVID_CLASSCODE)	32	R	0807_0002h

53.3.4.2.2 PCI device ID and vendor ID register (PCI_CFH_DID_VID)

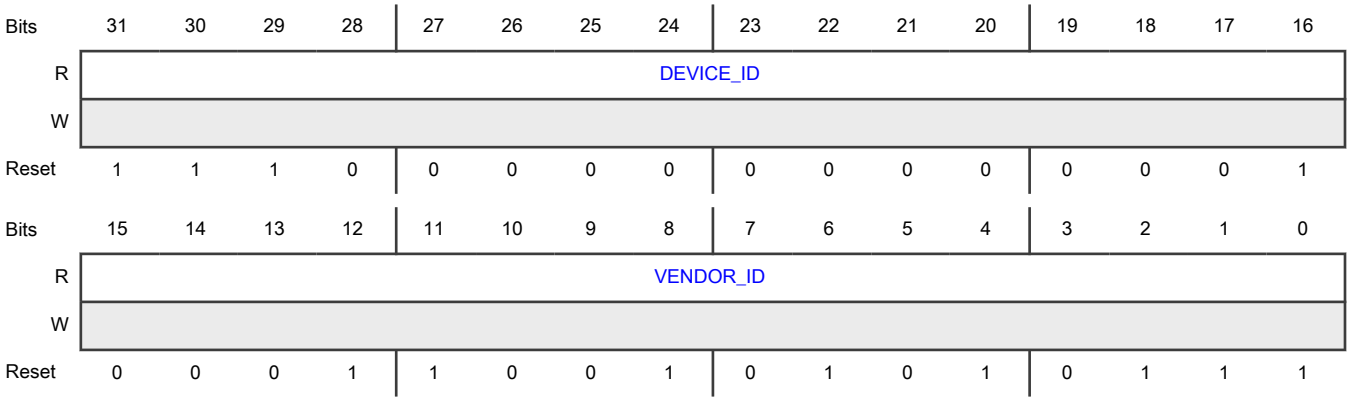
Offset

Register	Offset
PCI_CFH_DID_VID	0h

Function

This is the PCI config header device and vendor ID register.

Diagram



Fields

Field	Function
31-16 DEVICE_ID	Device ID This field identifies the device ID of the device. The reset value is determined from iERB F0_EC_CFH_DIDVID[DEVICE_ID]
15-0 VENDOR_ID	Vendor ID This field identifies the manufacturer of the device. The reset value is determined from iERB F0_EC_CFH_DIDVID[VENDOR_ID].

53.3.4.2.3 PCI command register (PCI_CFH_CMD)

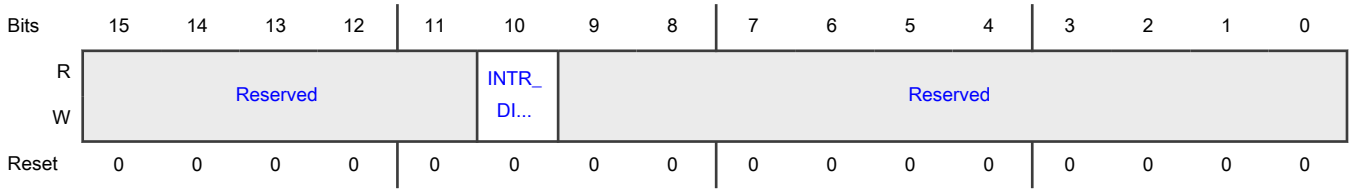
Offset

Register	Offset
PCI_CFH_CMD	4h

Function

This is the PCI config header command register.

Diagram



Fields

Field	Function
15-11 —	Reserved
10 INTR_DISABLE	Interrupt disable This field controls the ability of an Event Collect to assert the INTx wired interrupts. 0: Assertion of the INTx wired interrupts are enabled. 1: Assertion of the INTx wired interrupts are disabled.
9-0 —	Reserved

53.3.4.2.4 PCI status register (PCI_CFH_STAT)

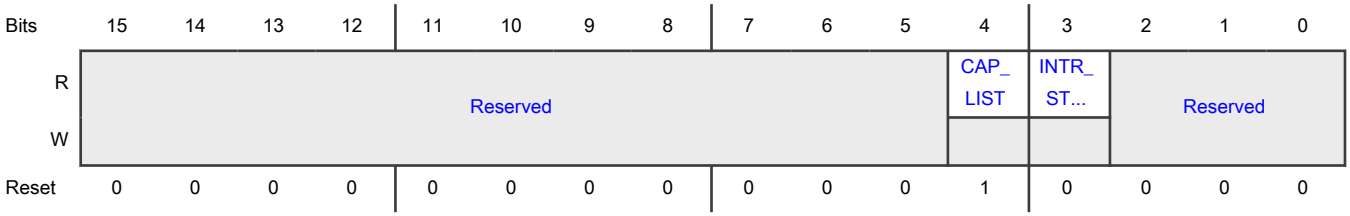
Offset

Register	Offset
PCI_CFH_STAT	6h

Function

This is the PCI config header status register.

Diagram



Fields

Field	Function
15-5 —	Reserved
4 CAP_LIST	Capabilities List Indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, this bit must be hardwired to 1b.
3 INTR_STATUS	Interrupt Status When set, indicates that an INTx interrupt is pending for the Event Collector. This bit will clear automatically if interrupts are disabled (INTR_DISABLE=0b1) or the interrupt source is cleared.
2-0 —	Reserved

53.3.4.2.5 PCI revision ID and classcode register (PCI_CFH_REVID_CLASSCODE)

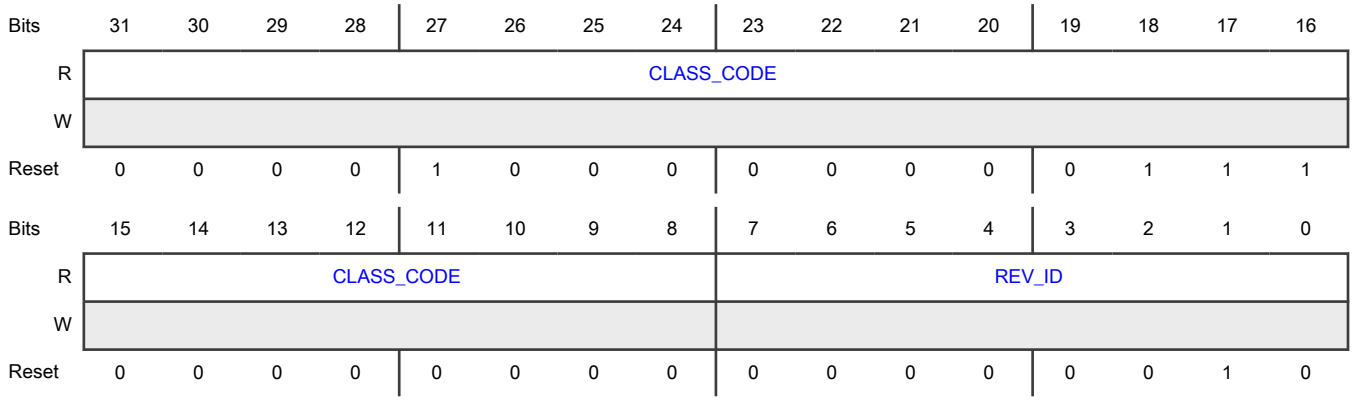
Offset

Register	Offset
PCI_CFH_REVID_CLASSCODE	8h

Function

This is the PCI config header revision ID and classcode register.

Diagram



Fields

Field	Function
31-8 CLASS_CODE	Class code The Class Code register is read-only and is used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. Hardcoded to 0x080700 to indicate Event Collector.
7-0 REV_ID	Revision ID This register specifies a device specific revision identifier and is a vendor defined extension to the Device ID.

53.3.4.2.6 PCI cache line size register (PCI_CFH_CL_SIZE)

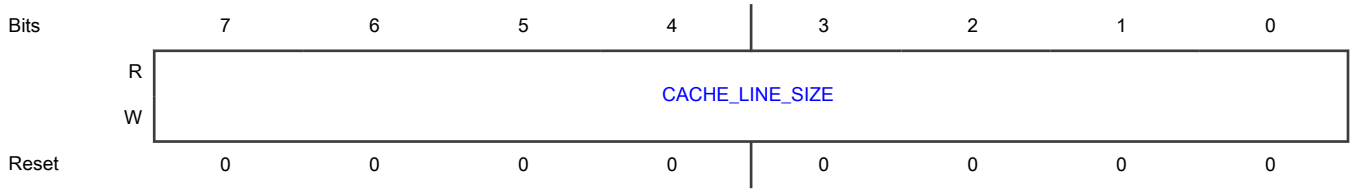
Offset

Register	Offset
PCI_CFH_CL_SIZE	Ch

Function

This is the PCI config header cache line size register.

Diagram



Fields

Field	Function
7-0 CACHE_LINE_SIZE	Cache line size The Cache Line Size register is set by the system firmware or the operating system to system cache line size. This field is implemented by PCI Express devices as a readwrite field for legacy compatibility purposes but has no effect on any PCI Express device behavior.

53.3.4.2.7 PCI header type register (PCI_CFH_HDR_TYPE)

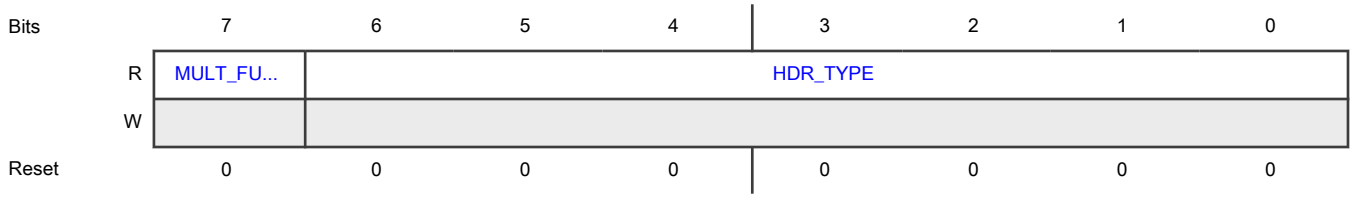
Offset

Register	Offset
PCI_CFH_HDR_TYPE	Eh

Function

This is the PCI config header header type register.

Diagram



Fields

Field	Function
7 MULT_FUNC_DEV	Multi-function device When set, indicates that the Root Complex contains multiple Event Collectors.
6-0 HDR_TYPE	Header type This field identifies the layout of the second part of the predefined header (beginning at byte 10h in Configuration Space). This register is hardwired to 00h (Type 0 header for Event Collector).

53.3.4.2.8 PCI subsystem vendor ID register (PCI_CFH_SUBSYS_VID)

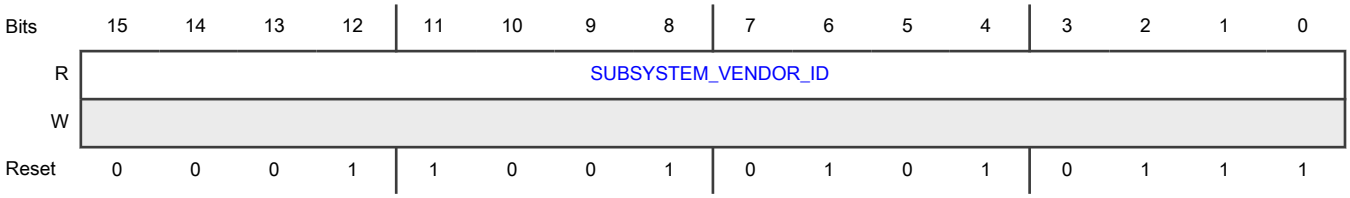
Offset

Register	Offset
PCI_CFH_SUBSYS_VID	2Ch

Function

This is the PCI config header subsystem vendor ID register.

Diagram



Fields

Field	Function
15-0 SUBSYSTEM_VENDOR_ID	This read only field identifies the manufacturer of the subsystem. The reset value is determine from iERB F0_EC_CFH_SIDSVID[SUBSYSTEM_VENDOR_ID].

53.3.4.2.9 PCI subsystem ID register (PCI_CFH_SUBSYS_ID)

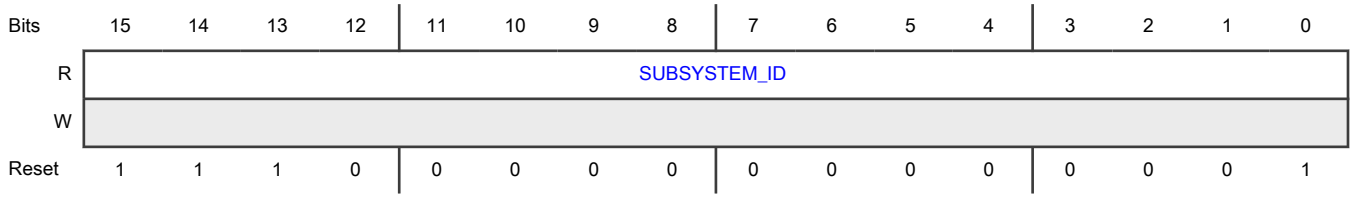
Offset

Register	Offset
PCI_CFH_SUBSYS_ID	2Eh

Function

This is the PCI config header subsystem ID register.

Diagram



Fields

Field	Function
15-0 SUBSYSTEM_ID	This read only field identifies the particular subsystem. The reset value is determine from iERB F0_EC_CFH_SIDSVID[SUBSYSTEM_ID].

53.3.4.2.10 PCI capabilities pointer register (PCI_CFH_CAP_PTR)

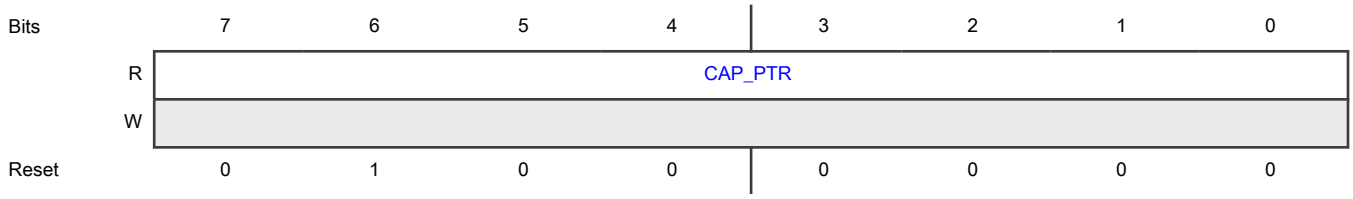
Offset

Register	Offset
PCI_CFH_CAP_PTR	34h

Function

This is the PCI config header capabilities pointer register.

Diagram



Fields

Field	Function
7-0 CAP_PTR	This register is used to point to a linked list of new capabilities implemented by this device. This register is only valid if the “Capabilities List” bit in the Status Register is set. If implemented, the bottom two bits are reserved and should be set to 00b. Software should mask these bits off before using this register as a pointer in Configuration Space to the first entry of a linked list of new capabilities. Hardwired to 40h.

53.3.4.2.11 PCI interrupt line register (PCI_CFH_INT_LINE)

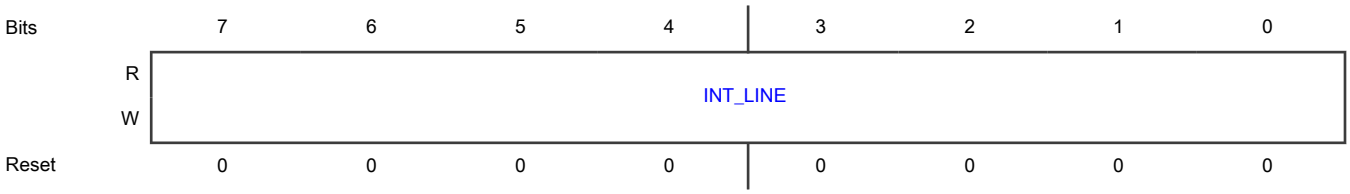
Offset

Register	Offset
PCI_CFH_INT_LINE	3Ch

Function

This is the PCI config header interrupt line register.

Diagram



Fields

Field	Function
7-0 INT_LINE	Interrupt Line register communicates interrupt line routing information. The register is read/ write and must be implemented by any Function that uses an interrupt pin. Values in this register are programmed by system software and are system architecture specific. The Function itself does not use this value; rather the value in this register is used by device drivers and operating systems.

53.3.4.2.12 PCI interrupt pin register (PCI_CFH_INT_PIN)

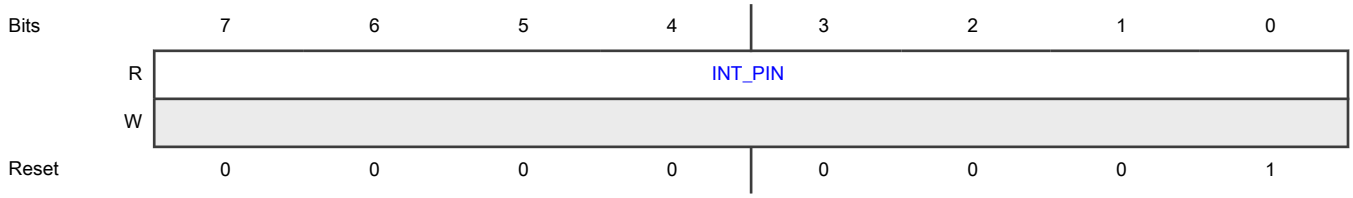
Offset

Register	Offset
PCI_CFH_INT_PIN	3Dh

Function

This is the PCI config header interrupt pin register.

Diagram



Fields

Field	Function
7-0 INT_PIN	The Interrupt Pin register is a read-only register that identifies the legacy interrupt Message(s) the function uses. Valid values are 01h, 02h, 03h, and 04h that map to legacy interrupt Messages for INTA, INTB, INTC, and INTD respectively. A value of 00h indicates that the Function uses no legacy interrupt Message(s).

53.3.4.2.13 PCI PCIe capabilities list register (PCI_CFC_PCIE_CAP_LIST)

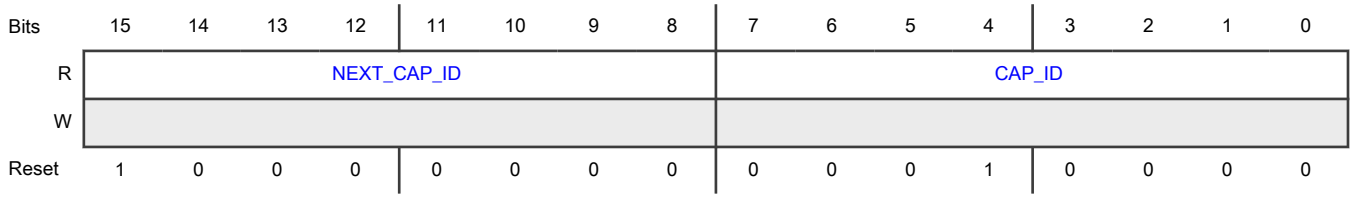
Offset

Register	Offset
PCI_CFC_PCIE_CAP_LIST	40h

Function

This is the PCI config capability PCIe capabilities list register.

Diagram



Fields

Field	Function
15-8 NEXT_CAP_ID	This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of capabilities. Hardwired to 80h.
7-0 CAP_ID	Indicates the PCI Express Capability structure. Hardwired to 10h.

53.3.4.2.14 PCI PCIe capabilities register (PCI_CFC_PCIE_CAP)

Offset

Register	Offset
PCI_CFC_PCIE_CAP	42h

Function

This is the PCI config capability PCIe capabilities register.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved		INT_MSG_NUM					Reserved	DEV_PORT_TYPE				CAP_VER			
W																
Reset	0	0	0	0	0	0	0	0	1	0	1	0	0	0	1	0

Fields

Field	Function
15-14 —	Reserved
13-9 INT_MSG_NUM	Interrupt message number This field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this capability structure. For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant. If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined. Hardwired to 00h, this Event Collector does not support MSI or MSI-X.
8 —	Reserved
7-4 DEV_PORT_TYPE	Device/Port type Indicates the specific type of this PCI Express Function. Hardwired to Ah to indicate Root Complex Event Collector.
3-0 CAP_VER	Capability Version Indicates PCI-SIG defined PCI Express Capability structure version number. Hardwired to 2h.

53.3.4.2.15 PCI PCIe device capabilities register (PCI_CFC_PCIE_DEV_CAP)

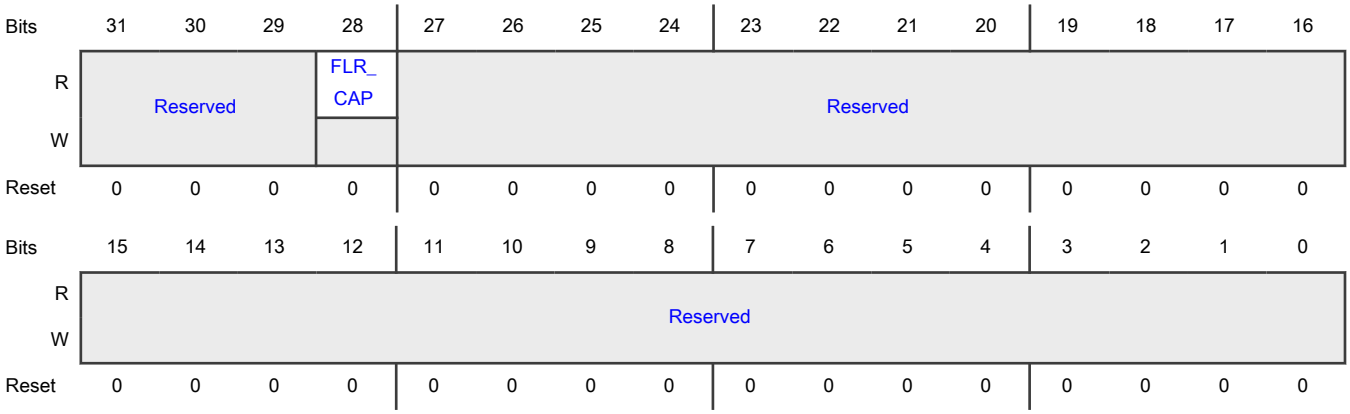
Offset

Register	Offset
PCI_CFC_PCIE_DEV_CAP	44h

Function

This is the PCI config capability PCIe device capabilities register.

Diagram



Fields

Field	Function
31-29 —	Reserved
28 FLR_CAP	Function level reset capability This bit applies to Endpoints only, hardwired to 0b.
27-0 —	Reserved

53.3.4.2.16 PCI PCIe device status register (PCI_CFC_PCIE_DEV_STAT)

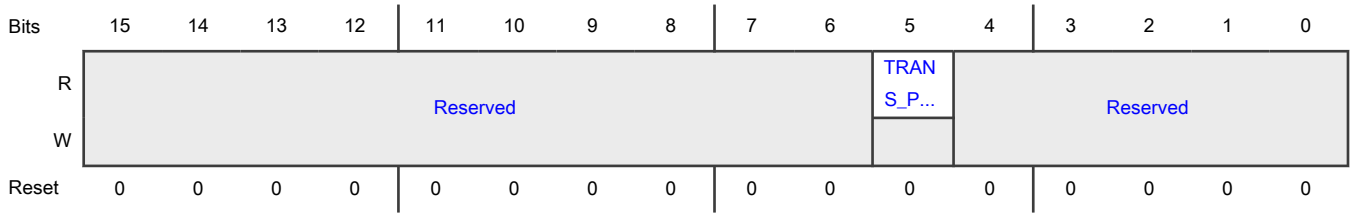
Offset

Register	Offset
PCI_CFC_PCIE_DEV_STAT	4Ah

Function

This is the PCI config capability PCIe device status register.

Diagram



Fields

Field	Function
15-6 —	Reserved
5 TRANS_PEND	Transaction pending When set, this bit indicates that the Event Collector has issued Non-Posted Requests that have not been completed. The event collector reports this bit cleared only when all outstanding Non-Posted Requests have completed or have been terminated by the Completion Timeout mechanism. Will only be non-zero if MSI-X is supported.
4-0 —	Reserved

53.3.4.2.17 PCI PCIe root control register (PCI_CFC_PCIE_ROOT_CTL)

Offset

Register	Offset
PCI_CFC_PCIE_ROOT_CTL	5Ch

Function

This is the PCI config capability PCIe root control register.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Fields

Field	Function
31-18 —	Reserved
17 PME_PEND	PME pending This bit indicates that another PME is pending when the PME Status bit is Set. When the PME Status bit is cleared by software; the PME is delivered by hardware by setting the PME Status bit again and updating the PME Requester ID field appropriately. The PME Pending bit is cleared by hardware if no more PMEs are pending.
16 PME_STATUS	PME status This bit indicates that PME was asserted by the PME Requester indicated in the PME Requester ID field. Subsequent PMEs are kept pending until the status register is cleared by software by writing a 1b. Default value of this bit is 0b.
15-0 PME_REQ_ID	PME requester ID This field indicates the PCI Requester ID of the last PME Requester. This field is only valid when the PME Status bit is Set.

53.3.4.2.19 PCI PCI-PM capabilities list register (PCI_CFC_PCIPM_CAP_LIST)

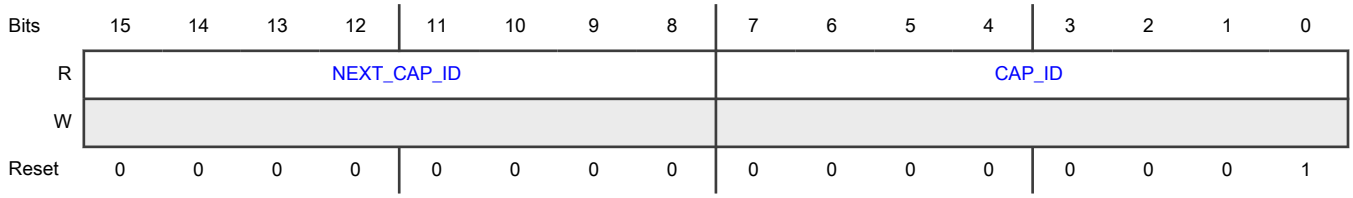
Offset

Register	Offset
PCI_CFC_PCIPM_CAP_LIST	80h

Function

This is the PCI config capability PCI-PM capabilities list register.

Diagram



Fields

Field	Function
15-8 NEXT_CAP_ID	This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of capabilities. Hardwired to 00h.
7-0 CAP_ID	Indicates the PCI-PM Capability structure. Hardwired to 01h.

53.3.4.2.20 PCI PCI-PM capabilities register (PCI_CFC_PCIPM_CAP)

Offset

Register	Offset
PCI_CFC_PCIPM_CAP	82h

Function

This is the PCI config capability PCI-PM capabilities register.

Diagram

Field	Function
15-11 PME_SUPPORT	PME support Event Collector does not support generating PM_PME notifications, hardwired to 00h.
10-3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2-0 VERSION	Version RCEC complies with the PCI PM specification, rev 1.2.

53.3.4.2.21 PCI PCI-PM control and status register (PCI_CFC_PCIPM_CTL_STAT)

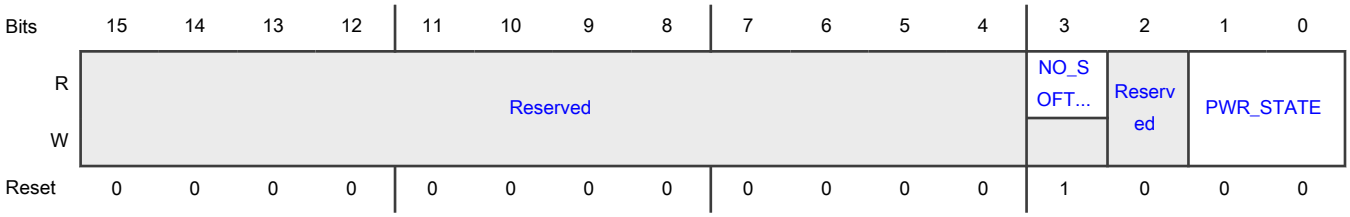
Offset

Register	Offset
PCI_CFC_PCIPM_CTL_STAT	84h

Function

This is the PCI config capability PCI-PM control and status register.

Diagram



Fields

Field	Function
15-4 —	Reserved
3 NO_SOFT_RST	No soft reset When set ("1"), this bit indicates that when RCEC transitions from $D3_{hot}$ to $D0_{active}$ because of modifying Power State bits in the PCI_CFC_PCIPM_CTL_STAT register, no internal reset is issued and Configuration Context is preserved. Upon transition from the $D3_{hot}$ to the $D0_{active}$ state, no additional operating system intervention is required to preserve PCIe Configuration Context beyond writing the Power State bits. When clear ("0"), RCEC performs an internal reset upon transitioning from $D3_{hot}$ to $D0_{uninitialized}$ via software control of the Power State bits in the PCI_CFC_PCIPM_CTL_STAT register. Configuration Context is lost when performing the soft reset. Upon transition from the $D3_{hot}$ to the $D0_{uninitialized}$ state, full re-initialization sequence is needed to return the device to $D0_{active}$. Regardless of this bit, EC preserves the PME context when PME is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 —	Reserved
1-0 PWR_STATE	Power state This field is used to set and report the power state of a function as follows: 00b = D0 01b = D1 (not supported by EC) 10b = D2 (not supported by EC) 11b = D3 If, for any reason, the operating system software attempts to put a function into a power management state that the function does not support, the function should handle this gracefully and remain in whatever state it was in before the request. The PWR_STATE bits will reflect the current state of the function not the intended invalid state which was written. If INTx is asserted when D3 is requested, it will deassert. If MSI-X is supported, any actively pending transactions will be completed before D3 state is entered.

53.3.4.2.22 PCI PCI-PM capabilities data register (PCI_CFC_PCIPM_DATA)

Offset

Register	Offset
PCI_CFC_PCIPM_DATA	87h

Function

This is the PCI config capability PCI-PM data register. Not supported by RCEC since AUX power not supported in $D3_{cold}$.

Field	Function
31-20 NEXT_CAP_OFF	Next capability offset This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of capabilities.
19-16 CAP_VER	Capability version Must be 1h for this version of the specification.
15-0 PCIE_EXT_CAP_ID	The Extended Capability ID for the AER Extended Capability is 0001h.

53.3.4.2.24 PCIe AER root error command register (PCIE_CFC_AER_ROOT_ERR_CMD)

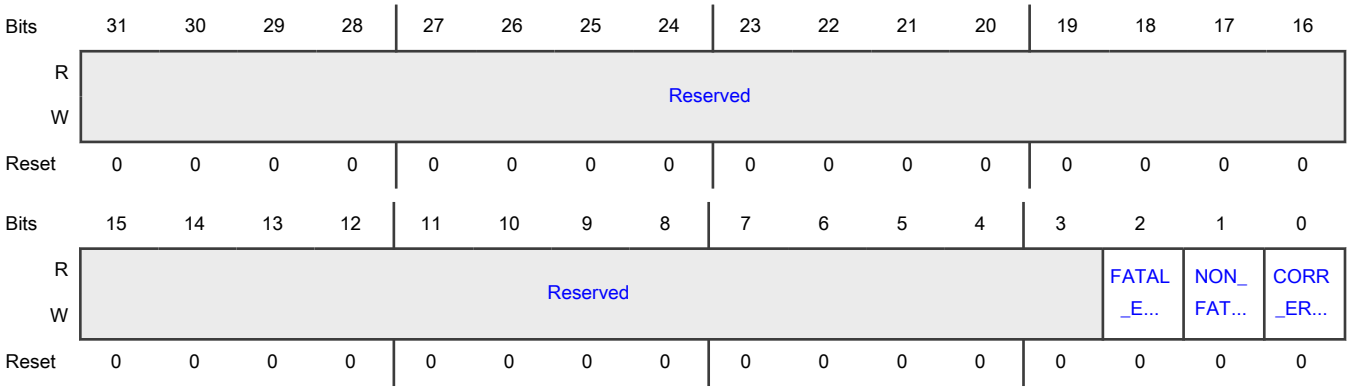
Offset

Register	Offset
PCIE_CFC_AER_ROOT_ERR_CMD	12Ch

Function

This is the PCIe config capability Advanced Error Reporting root error command register. The Root Error Command register allows further control of Root Complex Event Collector response to correctable, non-fatal, and fatal error messages reported by integrated Endpoints or the Event Collector itself.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 FATAL_ERR_RPT_EN	Fatal error reporting enable When set, this bit enables the generation of an interrupt when a fatal error is reported by any of the Integrated Endpoints (iEPs) or the Event Collector itself. Fatal uncorrectable errors for an iEP means it has been compromised and further operation is unreliable. Examples of this include multi-bit ECC errors in internal memory or other memories where the source cannot be isolated. To resume operation of the iEP, a device or function level reset is required.
1 NON_FATAL_ERR_RPT_EN	Non-fatal error reporting enable When set, this bit enables the generation of an interrupt when a non-fatal error is reported by any of the Integrated Endpoints (iEPs) or the Event Collector itself. Non-fatal uncorrectable errors require software intervention to resume operation and may need to reconfigure an iEP or a function therein. A function level reset of the iEP should not be required to continue operation.
0 CORR_ERR_RPT_EN	Correctable error reporting enable When set, this bit enables the generation of an interrupt when a correctable error is reported by any of the Integrated Endpoints (iEPs) or the Event Collector itself.

53.3.4.2.25 PCIe AER root error status register (PCIE_CFC_AER_ROOT_ERR_STAT)

Offset

Register	Offset
PCIE_CFC_AER_ROOT_ERR_STAT	130h

Function

This is the PCIe config capability Advanced Error Reporting root status command register. The Root Error Status register reports status of error messages (ERR_COR, ERR_NONFATAL, and ERR_FATAL) received by the Event Collector, and of errors detected by the Event Collector itself (which are treated conceptually as if the EC had sent an error message to itself). Each correctable and uncorrectable (Non-fatal and Fatal) error source has a first error bit and a next error bit associated with it respectively. When an error is received by the Event Collector, the respective first error bit is Set and the Requester ID is logged in the Error Source Identification register. A set individual error status bit indicates that a particular error category occurred; software may clear an error status by writing a 1b to the respective bit. If software does not clear the first reported error before another error message is received of the same category (correctable or uncorrectable), the corresponding next error status bit will be set but the Requester ID of the subsequent error Message is discarded. The next error status bits may be cleared by software by writing a 1b to the respective bit as well.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-7 —	Reserved
6 ERR_FATAL	Fatal error received Set when one or more fatal uncorrectable error messages have been received. **NOTE** This bit is "sticky" and is not cleared by PCI-PM power state change to uninitialized state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 ERR_NON_FATAL	Non-fatal error received Set when one or more non-fatal uncorrectable error messages have been received. **NOTE** This bit is "sticky" and is not cleared by PCI-PM power state change to uninitialized state.
4 FIRST_UCORR_FATAL	First uncorrectable error fatal Set when the first uncorrectable error message received is for a fatal error. **NOTE** This bit is "sticky" and is not cleared by PCI-PM power state change to uninitialized state.
3 MULT_ERR_FATAL_NON_FATAL	Multiple fatal/non-fatal errors received Set when either a fatal or a non-fatal error is received and ERR_FATAL_NON_FATAL received is already set. **NOTE** This bit is "sticky" and is not cleared by PCI-PM power state change to uninitialized state.
2 ERR_FATAL_NON_FATAL	Fatal/Non-fatal error received Set when either a fatal or a non-fatal error message is received and this bit is not already set. **NOTE** This bit is "sticky" and is not cleared by PCI-PM power state change to uninitialized state.
1 MULT_ERR_CORR	Multiple correctable errors received Set when a correctable error message is received and ERR_CORR received is already set. **NOTE** This bit is "sticky" and is not cleared by PCI-PM power state change to uninitialized state.
0 ERR_CORR	Correctable error received Set when a correctable error message is received and this bit is not already set. **NOTE** This bit is "sticky" and is not cleared by PCI-PM power state change to uninitialized state.

53.3.4.2.26 PCIe AER error source identification register (PCIE_CFC_AER_ERR_SRC_ID)

Offset

Register	Offset
PCIE_CFC_AER_ERR_SRC_ID	134h

Function

This is the PCIe config capability Advanced Error Reporting error source identification register. The Error Source Identification register identifies the source, i.e. Requester ID (see Routing/Requester ID (RID)), of first correctable and uncorrectable (Non-fatal/ Fatal) errors reported in the Root Error Status register.

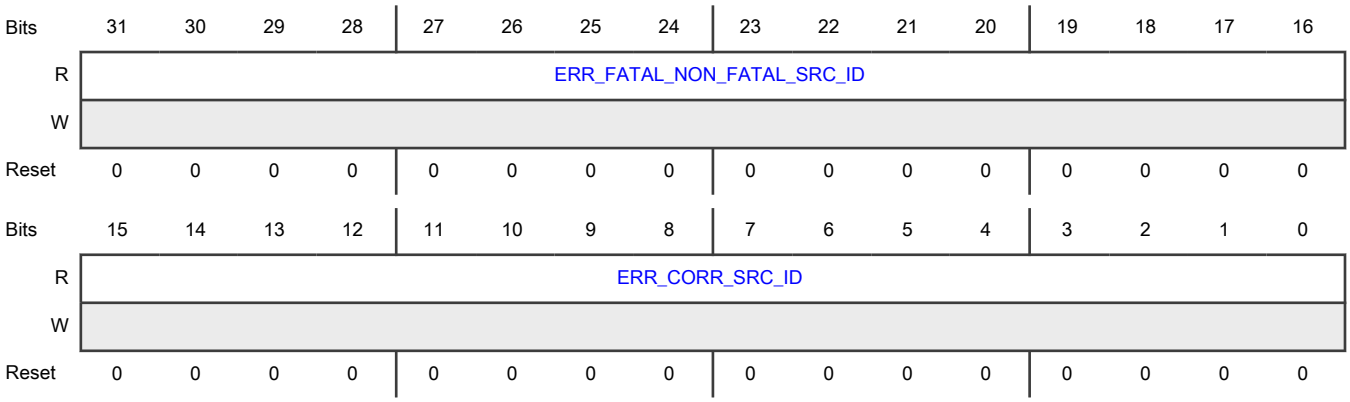
It should be noted that in the event of a global error reported by NETC, all functions will capture the error and report to RCEC, thus source ID may reflect the first function to report the error, but not necessarily the first function detecting the error.

This register is updated regardless of the settings of the Root Control register and the Root Error Command register.

NOTE

This register is "sticky" and is not cleared by PCI-PM power state change to uninitialized state.

Diagram



Fields

Field	Function
31-16 ERR_FATAL_NON_FATAL_SRC_ID	ERR_FATAL_NON_FATAL Source Identification Loaded with the Requester ID indicated in the received ERR_FATAL_NON_FATAL message when the ERR_FATAL_NON_FATAL received bit is not already set.
15-0 ERR_CORR_SRC_ID	ERR_CORR Source Identification Loaded with the Requester ID indicated in the received ERR_CORR message when the ERR_CORR received bit is not already set.

53.3.4.2.27 PCIe RCEC Endpoint association extended capability header (PCIE_CFC_RCEC_EPA_EXT_CAP_HDR)

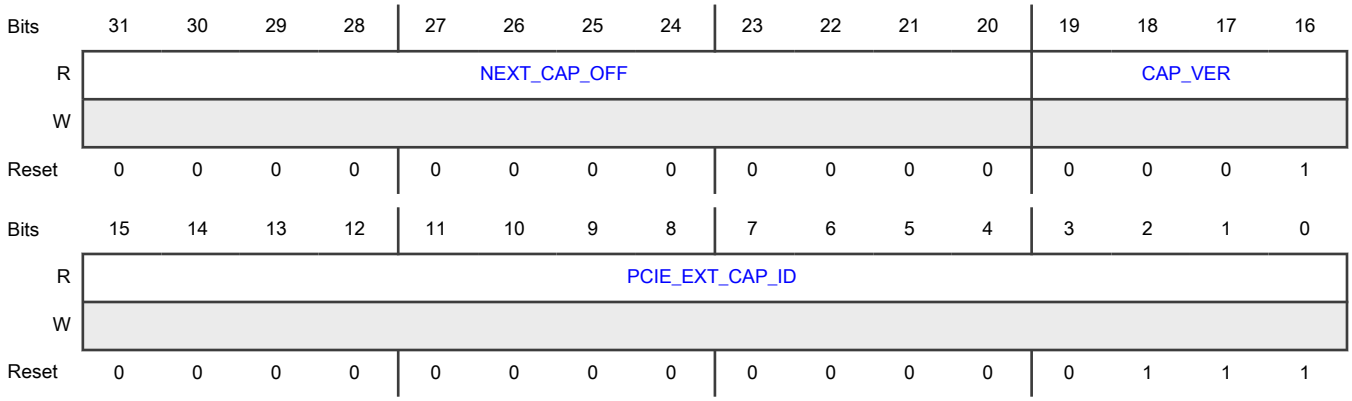
Offset

Register	Offset
PCIE_CFC_RCEC_EPA_EXT_CAP_HDR	138h

Function

This is the PCIe Root Complex Event Collector Endpoint association extended capability header register.

Diagram



Fields

Field	Function
31-20 NEXT_CAP_OFF	Next capability offset This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of capabilities.
19-16 CAP_VER	Capability version Must be 1h for this version of the specification.
15-0 PCIE_EXT_CAP_ID	The Extended Capability ID for the Event Collector Endpoint Association Capability is 0007h.

53.3.4.2.28 PCIe RCEC Endpoint association bitmap registerr (PCIE_CFC_RCEC_EPA_BITMAP)

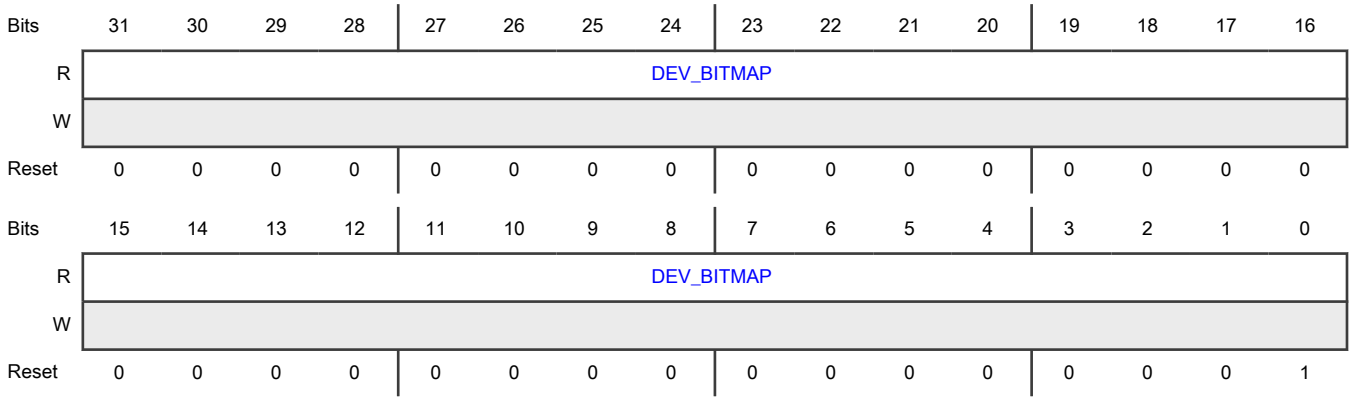
Offset

Register	Offset
PCIE_CFC_RCEC_EPA_BITMAP	13Ch

Function

This is the PCIe Root Complex Event Collector Endpoint association bitmap register. The Association Bitmap for Root Complex Integrated Endpoints is a read-only register that sets the bits corresponding to the Device Numbers of Root Complex Integrated Endpoints supported by the Root Complex Event Collector on the same Logical Bus as the Event Collector itself. The bit corresponding to the Device Number of the Root Complex Event Collector must always be set.

Diagram



Fields

Field	Function
31-0 DEV_BITMAP	Associated Endpoint device bitmap 31-0.

53.3.4.3 Event Collector Integrated Endpoint Register Block register descriptions

This section describes the Integrated Endpoint Register Block (iERB) registers. The iERB is a 64 KB size page containing registers that are used for pre-boot initialization, debug, and non-customer configuration.

The lower 32 KB of the iERB are reserved for architected registers required for Event Collector. The upper 32 KB are used for Event Collector specific resources.

53.3.4.3.1 IERB memory map

IERC_IERB base address: 6081_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Function 0 EC config header device ID and vendor ID register (F0_EC_CFH_DIDVID)	32	RW	E001_1957h
4h	Function 0 EC config header subsystem ID and subsystem vendor ID register (F0_EC_CFH_SIDSVID)	32	RW	E001_1957h

53.3.4.3.2 Function 0 EC config header device ID and vendor ID register (F0_EC_CFH_DIDVID)

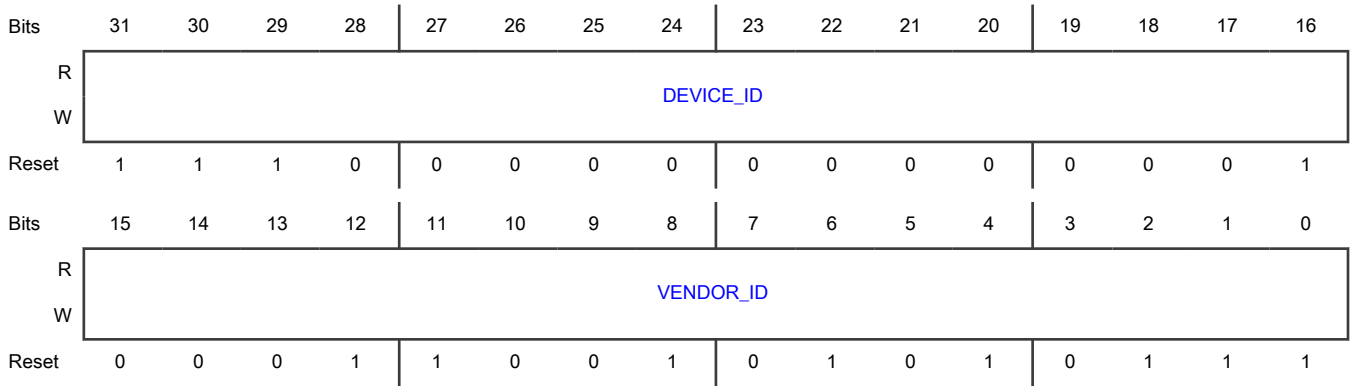
Offset

Register	Offset
F0_EC_CFH_DIDVID	0h

Function

This is the PCI Device and Vendor ID register. The values set here are reflected in the PCIe Type 0 header.

Diagram



Fields

Field	Function
31-16 DEVICE_ID	Device ID This field identifies the device ID of the device shown in the PCIe Device ID Register (02h). Default POR value is determined from the function's Device ID strap pins.
15-0 VENDOR_ID	Vendor ID This field identifies the manufacturer of the device as shown in the PCIe Vendor ID Register (00h). The default value will indicate Freescale (0x1957).

53.3.4.3.3 Function 0 EC config header subsystem ID and subsystem vendor ID register (F0_EC_CFH_SIDSVID)

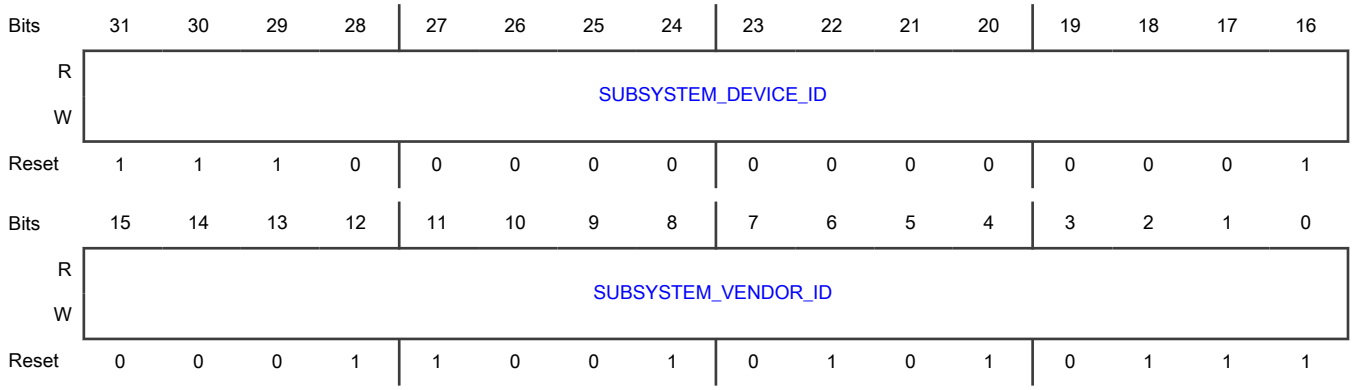
Offset

Register	Offset
F0_EC_CFH_SIDSVID	4h

Function

This is the PCI Subsystem ID and Subsystem Vendor ID register. The values set here are reflected in the PCIe Type 0 header.

Diagram



Fields

Field	Function
31-16 SUBSYSTEM_DEVICE_ID	Subsystem Device ID This field identifies the particular subsystem as shown in the PCIe Subsystem ID Register (2Eh). Default POR value is determined from the function's Device ID strap pins.
15-0 SUBSYSTEM_VENDOR_ID	Subsystem Vendor ID This field identifies the manufacturer of the subsystem as shown in the PCIe Subsystem Vendor ID Register (2Ch). The default value is the same as F0_EC_CFH_DIDVID[VENDOR_ID].

53.4 Ethernet Switch and Controller (NETC)

53.4.1 Overview

NETC is a TSN capable Ethernet IP which enables a comprehensive portfolio of Ethernet solutions. One of the major capabilities offered by NETC is the support of Time Sensitive Networking (TSN). TSN is a set of standards developed by IEEE that enables Ethernet to handle time sensitive traffic in addition to best effort traffic. TSN allows time sensitive traffic and best effort traffic to co-exist on the same network, makes Ethernet deterministic with bounded low latency, and with improved reliability and resiliency.

As shown in the NETC block diagram (see Block diagram), NETC provides a full range of Ethernet capabilities including Ethernet Controller / Network Interface Controller (NIC) and switching functionality.

NETC provides full 802.1Q Ethernet switch functionality, advanced QoS with 8 traffic classes and 4 discard resilience levels, and a full range of TSN standards capabilities.

The NIC functionality in NETC is known as ENETC (EtherNET Controller). ENETC supports virtualization/isolation based on PCIe Single Root IO Virtualization (SR-IOV), advanced QoS with 8 traffic classes and 4 discard resilience levels, and a full range of TSN standards and NIC offload capabilities. Switch CPU/host ENETC is fully integrated with the switch and does not require a back-to-back MAC, instead a light weight "pseudo MAC" provides the delineation between switch and Ethernet Controller. This translates to lower power (less logic and memory) and lower delay (as there is no serialization delay across this link).

NETC presents itself as a multi-function PCIe Root Complex Integrated Endpoint (RCiEP) for easy software discovery of peripheral functions. As such, it contains multiple PCIe functions. NETC also hosts PCIe functions for other related Ethernet functions, such as the Timer (IEEE 1588 and 802.1AS-2020) and MDIO (for managing external Ethernet PHY devices via an MDIO interface). PCIe RCiEP allows for easy software integration into OSes which support PCIe but can be easily integrated as a simple platform device for RTOSes or bare metal implementations which do not support it.

NETC connects to the Root Complex Event Collector to convey power management and error messages.

Software interacts with Ethernet through ENETC. It uses descriptor rings in memory managed by software external to NETC to transfer packets to and from ENETC. ENETC implements a DMA which is used to access these data structures and buffers.

Configuration and control of ENETC(s), as well as the switch, is implemented using a combination of registers and a command message interface implemented using descriptor rings in memory. Again, these are distinct, separate PCIe functions for ENETC(s) and the switch.

53.4.1.1 Block diagram

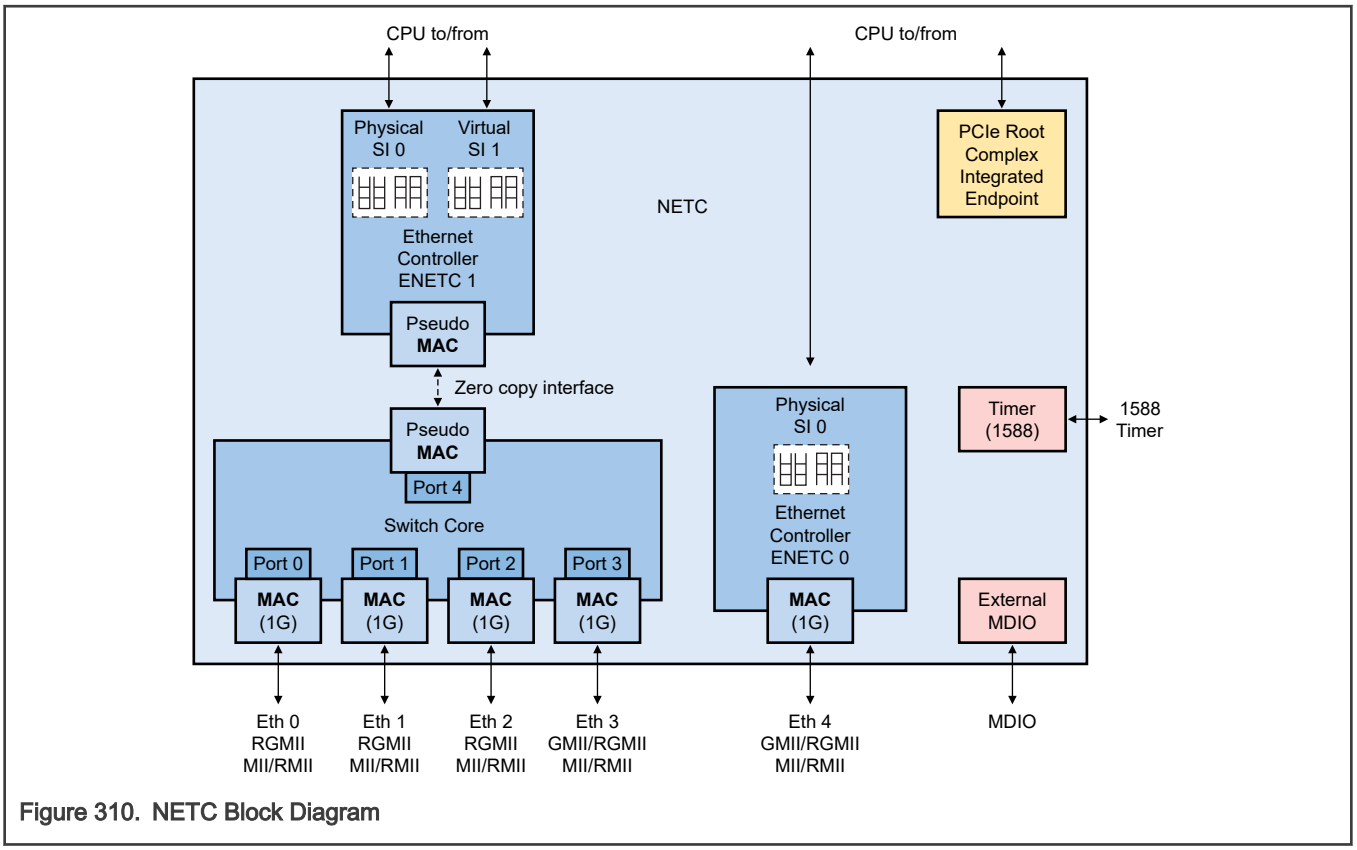


Figure 310. NETC Block Diagram

53.4.1.2 Features

Below is a list of features supported on NETC. Take note that not all of these features may be available on a SoC. See Table 351 for more details.

53.4.1.2.1 System features

- **Presents as a PCIe Root Complex Integrated End Point (RCiEP)** - For easy software discovery of peripheral Functions; leverage the infrastructure built into OSes and RTOS for PCIe.
- **Discoverable capabilities at a granular level** - Software can discover what features/capabilities exists; allow an easy upgrade path.
- **Power management** - Low power support based on PCIe Power Management. Includes wake-on-LAN on stand-alone ENETC.
- **Multifunction support per block** - Multiple functions as a single IP block using shared resources; reduced size and power.

53.4.1.2.2 802.1Q switch features

- **Wire-rate performance** - Non-blocking wire-rate switching from any port to any port at any Ethernet frame size (minimum 64 bytes) including multicast.

- **Optional cut-through for Ethernet ports** - Start transmitting frame out destination switch port before frame entirely received, to reduce latency.
- **MAC Filtering or Forwarding Database (FDB) table with guarantee minimum of entries** - Guarantee entries that can be added without table address conflict.
- **IP multicast Layer-2 forwarding** - Layer-2 forwarding based on IP multicast addresses.
- **IGMP/MLD snooping** - Capability to capture IGMP/MLD packets passing through, and have multicasting configured accordingly.
- **Hardware based address learning** - Hardware can add MAC addresses to the FDB autonomously with independent and shared VLAN learning.
- **Spanning Tree Protocols** - Spanning Tree and Multiple Spanning Tree Protocol (STP, MSTP) (and variants such as RTSP), provides basic interconnecting of multiple Ethernet switches with redundant paths, without forwarding loops.
- **Ingress filtering** - ACL style ternary match filtering on a wide set of protocol header fields (up to Layer-4) and user defined payload fields, to specify ingress packet treatments.
- **Stream identification** - Exact and ternary match stream identification. Ternary matching (implemented though ingress filtering) on a wide set of protocol header fields (up to Layer-4) and user defined payload fields. Exact matching on a wide set of Layer-2 protocol header fields and user defined payload fields.
- **Layer-2 header modification** - Comprehensive range of packet modifications: push/pop/translate of one VLAN (TPID, PCP, DEI, and VID) on ingress and/or on egress, sequence generation tag (R-TAG or HSR) modification.
- **Packet payload modification** - Layer-2 and Layer-3 payload modifications with arbitrary, dynamic content.
- **Ingress mirroring** - Ability to "mirror" or copy specific packets to another destination.
- **Copy/redirect to host** - Ability to copy or redirect specific packets to the host.
- **8 priorities (traffic classes) and 4 drop resilience levels** - Comprehensive internal QoS support with 8 priority egress queues per port scheduled using strict and/or weighted fair queuing.
- **802.1p Class of Service prioritization and tagging** - Flexible mapping of PCP on ingress and/or egress.
- **Storm control** - Controls for reducing replicated traffic of broadcast, multicast and flooded unicast/multicast traffic.
- **Time Capture** - Provides the ability to measure latency of a given frame through the switch.
- **TSN capabilities** - Full range of TSN standards, see TSN features .

53.4.1.2.3 Host interface (NIC) features

- **MAC and VLAN filtering** - Filtering for multiple MAC addresses and VLANs per port; steering to SIs (Station Interfaces) for VEPA support.
- **Virtualization** - Hardware supported isolation/virtualization through SR-IOV and Virtual Edge Port Aggregator (VEPA); support of multiple SIs (Station Interfaces) where there is one mandatory SI (SI 0) which is the Physical Station Interface (PSI) while the other optional SIs are VSI (Virtual Station Interface).
  - Hardware supported messaging between PSI and VSIs for resource and configuration requests and notifications.
  - Functional and recoverable error interrupt per SI.
  - Software controlled device, port (PF) and per interface (VF) reset capability; functionally equivalent to supported PCI function level reset (FLR)
- **Transmit and receive buffer descriptor rings to transfer packets to and from host** - Assignment of rings to any SI with isolation support. Buffer descriptor chaining support to allow frames to span multiple buffers.
- **Ingress filtering** - ACL style ternary match filtering on a wide set of protocol header fields (up to Layer-4) and user defined payload fields, to specify ingress packet treatments.

- **Stream identification** - Exact and ternary match stream identification. Ternary matching (implemented though ingress filtering) on a wide set of protocol header fields (up to Layer-4) and user defined payload fields. Exact matching on a wide set of Layer-2 protocol header fields and user defined payload fields.
- **VLAN tag extraction/insertion** - Insert predetermined tag on Tx and remove expected tag on Rx as seen by the SI. Note that this may be the second VLAN tag in the frame if the outer VLAN tag is the SI-based VLAN.
- **SI-Based VLAN** - Removal and addition of SI-based VLAN.
- **Checksum offload** - IP and TCP/UDP checksum offload for receive.
- **8 traffic classes and 4 drop resilience levels** - Comprehensive internal QoS support.
- **Interrupt coalescing control** - Interrupt coalescing can be set for each interrupt source.
- **CRC-32 generation** - CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per Transmit BD ring basis
- **TSN capabilities** - Full range of TSN standards, see TSN features .

53.4.1.2.4 Ethernet MAC features

- **10M/100M/GE port speeds** - Full range of standard 802.3 Ethernet speeds.
- **Half duplex support at 10M and 100M speeds** - Enables use of various low power PHYs.
- **EEE support** - Energy Efficient Ethernet.
- **Pause support** - Recognize and generate PAUSE frames with timing support for both receive and transmit.
- **One-step and two-step timestamping support for PTP/IEEE1588/IEEE802.1AS-2020** - One-step: update PTP Correction field based on current time and passed in timestamp value. Two-step: capture and report time of SFD.
- **if/ether/RMON MIB stats** - Comprehensive statistics support enables system management and debugging.

53.4.1.2.5 TSN features

- **802.1Qav-2009** - Forwarding and Queueing Enhancements for Time Sensitive Streams (FQTSS); provides credit-based shaper supports audio/video bridging (AVB).
- **802.1Qci-2017** - Per Stream Filtering and Policing (PSFP); receive side checking to ensure that the transmitter is following expected time schedule/rate profile.
- **802.1CBdb D0.5 (switch only)** - Frame Replication and Elimination for Reliability (FRER); packets are replicated at source and sent over redundant links with duplicates eliminated at destination. Often used in a loop with 2 port switches.
- **802.1Qbv-2015** - Enhancements for Scheduled Traffic (EST); time gated scheduling which provides time "slots" for specific classes of traffic in a manner similar to TDM. Host (beyond standard) can select time/time gate during which a packet will be sent; granular control by software of packet transmission.
- **802.1Qch-2017** - Cyclic Queuing and Forwarding (CQF); standardized forwarding in time slots across connected systems; Bucket brigade style forwarding provides TDM-like slots across multiple cascaded sub-systems to deliver deterministic latency.
- **802.1Qbu-2016/802.1br-2016** - Preemption; allows some traffic class(es) to interrupt the transmission of other classes.

53.4.1.2.6 Time Synchronization features

Supports IEEE 1588-2019 and PTP/802.1AS-2020

- Synchronized 64-bit nanosecond resolution time
- Common time base for all ports/switch
- Free running uncompensated time (in NETC clock ticks)
- Periodic pulse generation - Generate periodic (e.g. 1PPS) sync pulses.

- External input time capture - Capture time of 1PPS or similar pulses for sync with local systems.
- Non-periodic pulse generation at a specific future time
- Peer delay ratio support via software use of two-step timestamping

53.4.1.2.7 NETC SoC specific configurations

The table below provides a capability overview of the NETC.

Table 351. NETC SoC specific configurations

Feature	Configuration
PCIe Functions	
Timer Instances	1
EMDIO Instances	1
Switch Instances	1 (5 ports)
ENETC Instances	2
VSI Instances	1
Links	6
PCIe MSI-X Vectors	53
MACs	
Ethernet MAC	MAC 0/1/2/3/4
	10M, 100M, 1G operation
	MII/RMII/RGMII modes,
	supports half duplex,
	supports preemption
Pseudo MAC	MAC 5 - 1G pseudo MAC @ 240 MHz This figure includes the Ethernet Layer 1 overhead of 20 bytes per frame to reflect the total bits on a Ethernet physical wire.
Switch	
Aggregate bandwidth	5G at 240 MHz
Ports	5 ports - bound to links 0/1/2/3/5
ETM QOS	8
Buffer pools	8
Shared buffer pools	2
Cut-through supported	Yes
802.1Qci-2017 - Per Stream Filtering and Policing (PSFP)	Yes
802.1CBdb D0.5 - Frame Replication and Elimination for Reliability (FRER)	Yes

Table continues on the next page...

Table 351. NETC SoC specific configurations (continued)

Feature	Configuration
802.1Qav-2009 - Forwarding and Queueing Enhancements for Time Sensitive Streams (FQTSS)	Yes
802.1Qbv-2015 - Enhancements for Scheduled Traffic (EST)	Yes
802.1Qbu-2016/802.1br-2016 - Preemption	Yes
802.1Qch-2017 - Cyclic Queuing and Forwarding (CQF)	Yes
Guaranteed FDB entries	0
Egress Treatment table entries	384
Egress Count table entries	384
Egress Sequence Recovery table entries	384
Number of IPV	8
ENETC	
Ports	ENETC instance 0 - bound to link 4 (standalone)
	ENETC instance 1 - bound to link 5 (bound to switch)
Number VSI	ENETC instance 0 - 0
	ENETC instance 1 - 1
Number of Rx BD rings	14
Number of Tx BD rings	14
Number of command BD rings	5
ICM priorities	2
RSS (Receive Side Scaling) enabled	0
RFS (Receive Flow Steering) enabled	0
802.1Qci-2017 - Per Stream Filtering and Policing (PSFP)	Yes
LSO (Large Send Offload)	No
RSC (Receive Segment Coalesce)	No
Tx Checksum offload	No
Wake On LAN	Yes (ENETC instance 0 only)
802.1Qav-2009 - Forwarding and Queueing Enhancements for Time Sensitive Streams (FQTSS)	Yes
802.1Qbv-2015 - Enhancements for Scheduled Traffic (EST)	Yes
802.1Qbu-2016/802.1br-2016 - Preemption	Yes
Number of MAC Address Filter table entries	4 per ENETC
Number of VLAN Address Filter table entries	4 per ENETC
Number of RFS entries	0

Table continues on the next page...

Table 351. NETC SoC specific configurations (continued)

Feature	Configuration
Number of IPV	8
Shared between Switch, ENETC - TCAM	
Ingress Port Filter words (key can range from 2 to 14 words) - switch default	140
Ingress Port Filter words (key can range from 2 to 14 words) - ENETC 0 default	28
Ingress Port Filter words (key can range from 2 to 14 words) - ENETC 1 default	28
Shared between Switch, ENETC - common memory	
Rate Policer table entries - switch default	32
Rate Policer table entries - ENETC 0 default	2
Rate Policer table entries - ENETC 1 default	4
Ingress Stream table entries - switch default	384
Ingress Stream table entries - ENETC 0 default	8
Ingress Stream table entries - ENETC 1 default	16
Ingress Stream Count table entries - switch default	384
Ingress Stream Count table entries - ENETC 0 default	8
Ingress Stream Count table entries - ENETC 1 default	16
Ingress Sequence Generation table entries - switch default	384
Ingress Sequence Generation table entries - ENETC 0/1 default	N/A
Stream Gate Instance table entries - switch default	32
Stream Gate Instance table entries - ENETC 0 default	8
Stream Gate Instance table entries - ENETC 1 default	0
Stream Gate Control List entries per Stream Gate Instance - switch default	4 (2 admin + 2 operational)
Stream Gate Control List entries per Stream Gate Instance - ENETC 0 default	4 (2 admin + 2 operational)
Stream Gate Control List entries per Stream Gate Instance - ENETC 1 default	0
Frame Modification table entries - switch default	64
Frame Modification table entries - ENETC 0/1 default	N/A
Frame Modification Data table entries - switch default	256
Frame Modification Data table entries - ENETC 0/1 default	0

Table continues on the next page...

Table 351. NETC SoC specific configurations (continued)

Feature	Configuration
Exact match hash table entries - switch default; shared between FDB, L2 IPv4 Multicast filter, VLAN Filter, Ingress Stream Identification, Ingress Stream Filter tables	2448
Exact match hash table entries - ENETC 0 default; shared between Ingress Stream Identification, Ingress Stream Filter tables	8
Exact match hash table entries - ENETC 1 default; shared between Ingress Stream Identification, Ingress Stream Filter tables	16
Switch frame buffering - default	3138 words (20 bytes each) for total of 62,760 bytes
ENETC receive frame buffering - default	1490 words (20 bytes each) for total of 29,800 bytes
Shared between Switch, ENETC - Time Gate Scheduling memory	
Gate Control List entries - switch default	1280
Gate Control List entries - ENETC 0 default	256
Gate Control List entries - ENETC 1 default	256
Timer	
1722 enabled	No
1722 number of channels	0
Supports 802.1AS time	Yes
Number of alarms	2
Number of triggers	2
Number of fipers	3
MDIO	
Supports external emdioc (for PHYs)	Yes
Supports internal mdio (for RevMII or internal PCS)	Yes

The table below states the performance of NETC.

Table 352. NETC Performance - Throughput

Elements	Throughput
Switch - Non-blocking wire-rate switching from any port to any port at any Ethernet frame size (minimum 64 bytes) including multicast.	• 5 Gbit/s @ 240 MHz; 4 x 1 Gbit/s Ethernet port + 1 x 1 Gbit/s pseudo Ethernet port (see Note 1). Assumes standalone ENETC instance is not enabled/used. If the standalone ENETC instance is enabled (1G bit/s), wire-rate throughput (64 bytes frame size) on the Ethernet switch ports is achieved with a minimum frame size of 128 bytes on both ENETC instances.

Table continues on the next page...

Table 352. NETC Performance - Throughput (continued)

Elements	Throughput
ENETC port - Wire-rate termination at any Ethernet frame size (minimum 64 bytes).	• 2 Gbit/s @ 240 MHz; 1 x 1 Gbit/s Ethernet port + 1 x 1 Gbit/s pseudo Ethernet port (see Note 1). Assumes a 4 Gbit/s switch.
ENETC host interface - Aggregate maximum receive and transmit bit rate to/from host system memory. • Includes the Ethernet Layer 1 overhead of 20 bytes per frame to reflect the total bits on the Ethernet wire. • From a host interface perspective, each frame replicated by ENETC, is considered as a separate frame on the host Rx interface; for instance, a frame that is replicated twice, will therefore consume twice the bandwidth on the Rx host interface.	• 2 Gbit/s receive and 2 Gbit/s transmit @ 240 MHz (aggregate of 4 Gbit/s); across all ENETC instances.
ENETC host interface - Aggregate maximum receive and transmit frame rate to/from host system memory. • From a host interface perspective, each frame replicated by ENETC, is considered as a separate frame on the host Rx interface; for instance, a frame that is replicated twice, translates to 2 frames on the Rx host interface.	• 3 million frames per second receive and 3 million frames per second transmit @ 240 MHz (aggregate of 6 million frames per second); across all ENETC instances.

NOTE

Figures achievable under the conditions where all supported functions are performed, with the exception of the storm control function being disabled on the switch and the stream gating function being disabled on the ENETC instance that is attached to the switch. Pseudo link bandwidth figure includes the Ethernet Layer 1 overhead of 20 bytes per frame to reflect the total bits on an Ethernet wire.

53.4.2 Functional Description

53.4.2.1 Interface Modes of Operation

NETC has the following modes of operation.

- Interface Mode
  - MII mode
    - The port is configured for MII if PMCAPR[MII_PROT]=0b000. The MAC register IF_MODE[IFMODE] must be set to 0b001 for MII mode.
    - Link speed is controlled by IF_MODE[M10].
    - Duplex mode is controlled by IF_MODE[HD].
  - RMII mode
    - The port is configured for RMII if PMCAPR[MII_PROT]=0b001. The MAC register IF_MODE[IFMODE] must be set to 0b011 for RMII mode.
    - Link speed is controlled by IF_MODE[M10].
    - Duplex mode is controlled by IF_MODE[HD].
  - RGMII mode

- The port is configured for RGMII if PMCAPR[MII_PROT]=0b010. The MAC register IF_MODE[IFMODE] must be set to 0b100 for RGMII mode.
- Link speed is manually configured by IF_MODE[SSP].
- Note that for RGMII 10/100 Mbps modes (IF_MODE[SSP]=00 or 01), the device is dependent on receiving Rx clock (RXC) clock pulses in order to change TXC from the default 125 MHz to 25 or 2.5 MHz.
- Duplex mode for 10/100 Mbps speeds is manually configured by IF_MODE[SFD].

— GMII mode

- The port is configured for GMII if PMCAPR[MII_PROT]=0b011. The MAC register IF_MODE[IFMODE] must be set to 0b010 for GMII mode.
- Link speed mode for GMII is always 1 Gbps.
- Half duplex is not supported for GMII mode.

• Interface Options

— Half duplex

- Half duplex is supported for MII, RMII, and RGMII 10/100 Mbps
- Half duplex is not supported for speeds faster than 100 Mbps
- When half duplex is enabled with 1588 timestamping, only two-step timestamping is supported.

— Reverse Mode

- The port is configured for Reverse Mode if PIOCAPR[REVMII]=1. The MAC register IF_MODE[REVMII] must be set to 0b1 for reverse mode. When in reverse mode, the port acts as a PHY rather than as a MAC. See "Reverse Mode (RevMII) section" for details on Reverse Mode.
- Reverse mode is supported for all interface modes.

— Frame preemption

- Frame preemption is supported on a link if LaMCAPR[FP]=1
- Frame preemption is enabled on supported ports via MAC_MERGE_MMCSR[ME] = 1 or 2.
- When preemption is enabled, NETC uses both the express (0) and preemptable (1) MAC for operation.

— Internal Loopback

- The port is configured for internal loopback mode via PM_COMMAND_CONFIG[LOOP_ENA].

53.4.2.2 Common Resources

53.4.2.2.1 PCI Express Layer

NETC is operating as a multi-function RCiEP. The PCIe layer allows a PCIe device driver to discover and configure the device. NETC hosts multiple functions, including the EMDIO controller, one or more timers, one or more Ethernet controllers, zero or more switches and zero or more Virtual Station Interfaces (VSIs).

NETC connects to the Root Complex Event Collector to convey power management and error messages. It supports generation of MSI-X messages representing functional interrupts towards the system.

An ENETC that is assigned one or more VSIs operates as an SR-IOV capable physical function with one or more virtual functions.

The figure below shows a conceptual layout of the PCI functions hosted by NETC integrated endpoint.

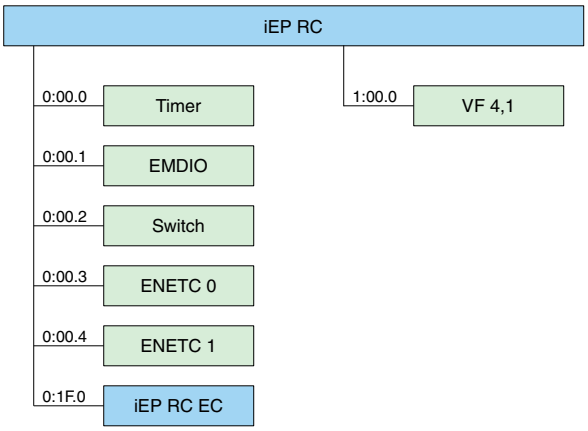

Figure 311. Root Complex Integrated Endpoint Block Diagram

53.4.2.2.1.1 Capability Discovery

NETC is discoverable as a PCIe device which has multiple PCIe functions. Each of these PCIe functions is either a physical port or a supporting function for NETC. Each physical port has one or more station interfaces associated with them. Both the port and station interfaces have capability registers to determine the overall supporting features, such as transmit/receive rings, traffic classes and offload functions.

The PCI Express device driver performs enumeration and discovers basic configuration as follows:

1. Determines available devices on the bus and number of supported functions by reading the Vendor ID field. NETC is a multi-function device.
2. Reads the Device ID from each PCIe function to determine type of function; eg. Ethernet port, IEEE 1588 etc.
3. Discovers the PCI and PCIe extended capabilities.
4. If the PCIe SR-IOV capability is present for an Ethernet port, this physical function (or physical station interface) may have additional virtual functions associated with it. Each virtual function represents a virtual station interface.
5. The PCIe Enhanced Allocation capability contains the base address of the device registers.
6. For each type of function, PCIe calls the appropriate device driver and passes the base address of the device registers.

The complete discovery sequence of physical and virtual functions for an SR-IOV multi-PF multi-function capable device is defined in PCI-SIG® Single Root I/O Virtualization and Sharing (SR-IOV) specification v1.2.

The following steps describe the basic discovery and configuration sequence by the NETC Ethernet port device driver:

1. Device driver receives the base address of the physical station interface, port and global registers.
2. Device driver receives the number of virtual station interfaces supported.
3. Device driver reads the port capability registers (PCAPRn). These registers will contain the following:
   - Support for offload functions and generic port capabilities
   - Number of transmit and receive buffer descriptor rings supported
   - Traffic classes supported
4. Device driver configures the capabilities of each virtual station interface.
   - Assign transmit and receive rings using PSI*a*CFGR0[NUM_TX_BDR] and PSI*a*CFGR0[NUM_RX_BDR].
   - Restrict transmit traffic classes using PSI*a*CFGR1[TC*b*_MAP].
   - Other capabilities may be available and can be configured as needed during run-time.

5. Software may configure the transmit and receive rings now or anytime later during run-time. See sections Transmit Buffer Descriptor Rings and Receive Buffer Descriptor Ring.
6. The port frame preemption register (MAC_MERGE_MMCSR[ME], PFPCR[FPE_TC*a*]) allow software to enable preemption as a result of further network discovery of link partners' capabilities.

53.4.2.2.1.2 PCI Express Root Complex Integrated Endpoint

NETC is operating as an SR-IOV multi-Function capable RCiEP. As such, it may span multiple devices and contain multiple functions, including the EMDIO controller, IEEE 1588 timer, one or more Ethernet host controllers, zero or more switches and zero or more Virtual Station Interfaces (VSIs). The PCIe layer allows a PCIe device driver to discover and configure the device.

It should be noted that a PCIe function that is not present will return a Vendor ID of 0xFFFF and 0's for all other register accesses within that function.

The table below shows all the functions of NETC operating as an integrated endpoint. Virtual functions are placed starting at bus 1 and are spaced 16 functions apart, allowing for a 64KB memory isolation per VSI.

Table 353. PCI Device and Function List

Bus Number	Device Number	Function Number	Description
0	0	0	**Timer** Base Class Code: 08h (Base System Peripheral) Sub-Class Code: 80h (System Peripheral) Device ID: 0xEE02
		1	**Central EMDIO** Base Class Code: 08h (Base System Peripheral) Sub-Class Code: 80h (System Peripheral) Device ID: 0xEE00
		2	**Ethernet Switch Config and Control (instance 0)** • 4 Ethernet ports (0-3) • 1 pseudo port (4) bound to ENETC instance 1 Base Class Code: 02h (Network Controller) Sub-Class Code: 00h (Ethernet Controller) Device ID: 0xEEF2
		3	**Ethernet host controller (ENETC - instance 0)** • 1 Ethernet port Base Class Code: 02h (Network Controller) Sub-Class Code: 00h (Ethernet Controller) Device ID: 0xE101
		4	**Ethernet host controller (ENETC - instance 1)** • 1 pseudo port bound to switch instance 0 - port 4. Base Class Code: 02h (Network Controller)

Table continues on the next page...

Table 353. PCI Device and Function List (continued)

Bus Number	Device Number	Function Number	Description
			Sub-Class Code: 00h (Ethernet Controller) Device ID: 0xE101
		5 - 7	Reserved
0	31	0	**Root Complex Event Collector** Base Class Code: 08h (Base System Peripheral) Sub-Class Code: 07h Device ID: 0xE001
1	0	0	VF 3,1 - VF1 for PF3 (VSI 0)

The table below lists capabilities associated with the (physical) functions that support SR-IOV.

Table 354. NETC SR-IOV PCIe Functions

Field	Physical Function 3	Description
Name	Ethernet Network Controller	Generic description
SR-IOV Cap Version	1	Corresponds to the Capability Version of SR-IOV Extended Capability Header.
Number of PF VFs	0	Corresponds to the Initial VFs (0Ch) and the Total VFs field (0Eh) of the SR-IOV capability structure. This number must be set to assign VFs to the PF.
Number of Initial VFs	0	Corresponds to the Num VFs (0Ch) of the SR-IOV capability structure. All VFs are initially visible.
PF Dependency Link	0	Corresponds to the Function Dependency Link (12h) of the SR-IOV capability structure. There is no dependency between PFs.
First VF Offset	253	Corresponds to First VF Offset field (14h). The field is fixed and cannot be modified.
VF Stride	16	VF Stride defines the Routing ID offset from one VF to the next.
VF Device ID	0xEF00	VF device ID is configured through IERB register PF*n*_IE_CFH_VFDID.
Supported Page Sizes	n/a	NETC uses PCI Enhanced Allocation with a page size of 64KB.

NETC supports the PCI Express Enhanced Configuration Mechanism (ECAM), which allows for a 4KB PCI Configuration space with a Type 0 header. The following PCI and PCI Express Extended capabilities are supported and their location within the ECAM is shown. The offset within ECAM shown in this table are for reference purposes only. Standard PCIe enumeration and discovery techniques should be used to find these structures.

Table 355. PCI and PCIe Capabilities Supported

Offset in Configuration Space	Type of Capability	PF/VF	Capability	Capability ID
0x40	PCI	Both	PCI Express Capability	10h
0x80	PCI	Both	Extended Message Signaled Interrupts (MSI-X)	05h
0x90	PCI	PF only	PCI Power Management Interface (PMI)	01h
0x9C	PCI	PF only	Enhanced Allocation (EA)	14h
0x100	PCI Express Extended	Both	Advanced Error Reporting (AER)	0001h
0x130	PCI Express Extended	Both	Access Control Services (ACS)	000Dh
0x140	PCI Express Extended	Both	Readiness Time Reporting (RTR)	0022h
0x150	PCI Express Extended	PF only	SR-IOV Capabilities	0010h

53.4.2.2.1.2.1 Enhanced Allocation

NETC does not support the standard PCI BARs (which are tied to 0). Instead the PCI Enhanced Allocation (EA) capability is used to fix the base addresses in the system. See the table below for the base addresses of the EA BEIs and the aperture size. Note that both the MSI-X table and Pending Bit Array (PBA) for a given function are located within a single 64KB page, see Message Signaled Interrupt (MSI-X) for more information about MSI-X. The offsets shown in this table are for reference only. Standard PCIe enumeration and discovery techniques should be used to determine these addresses from the EA Capability structures in the ECAM space.

Table 356. Enhanced Allocation Memory Map

F	EA BEI	Aperture Size (MaxOffset)	Offset	Description	Notes
0	0	128KB	0x0_0000	Timer base registers	Embedded function.
			0x1_0000	NETC global registers	
	2	64KB	0x0000	Timer MSI-X Table	
			0x0800	Timer MSI-X Pending Bit Array (PBA)	
1	0	128KB	0x0_0000	EMDIO base registers	Embedded function.
			0x1_0000	NETC global registers	
	2	64KB	0x0000	EMDIO MSI-X Table	
			0x0800	EMDIO MSI-X Pending Bit Array (PBA)	
2	0	1MB	0x0_0000	Switch base registers	Ethernet switch instance 0
			0x8_0000	NETC global registers	
	2	64KB	0x0000	Switch MSI-X Table	
			0x0800	Switch MSI-X Pending Bit Array (PBA)	
3	0	256KB	0x0_0000	ENETC physical station interface registers	Ethernet network controller instance 0
			0x1_0000	ENETC base registers	

Table continues on the next page...

Table 356. Enhanced Allocation Memory Map (continued)

F	EABEI	Aperture Size (MaxOffset)	Offset	Description	Notes
			0x2_0000	NETC global registers	
	2	64KB	0x0000	ENETC MSI-X Table	
			0x0800	ENETC MSI-X Pending Bit Array (PBA)	
	9	64KB	0x1_0800 x *n*	ENETC virtual station interface *n* registers, where n={0-0}, separated by aperture size bytes	
	11	64KB	0x1_0000 x *n*	ENETC virtual station interface *n* MSI-X Table, separated by aperture size bytes	
			0x1_0800 x *n*	ENETC virtual station interface *n* MSI-X Pending Bit Array (PBA), separated by aperture size bytes	
4	0	256KB	0x0_0000	ENETC physical station interface registers	Ethernet network controller instance 1
			0x1_0000	ENETC base registers	
			0x2_0000	NETC global registers	
	2	64KB	0x0000	ENETC MSI-X Table	
			0x0800	ENETC MSI-X Pending Bit Array (PBA)	

53.4.2.2.1.2.2 PCIe Function Number Assignment

The NETC PCIe device will allocate and assign PCIe function numbers starting at 0. The automatically assigned function number is shown in IERB binding register field T/EMDIO/S/E*a*BCR[FN]. Assignment is based on the following formula:

1. Only valid NETC instances, as defined by the IERB binding register field T/EMDIO/S/E*a*BCR[VALID], will be considered.
2. Valid instances will be assigned PCIe function numbers in increasing order, starting with function 0.
3. The NETC functions will be evaluated and assigned function numbers in the following order:
    a. Timer instances
    b. EMDIO instances
    c. Switch instances
    d. ENETC instances

53.4.2.2.2 NETC Table Management Protocol (NTMP)

Some NETC functionality is controlled using control messages sent to the hardware using BD ring interface with 32B descriptors similar to the packet Transmit BD ring used on ENETC. This BD ring interface is referred to as the command BD ring. This is used to configure functionality where the underlying resources may be shared between different entities or being too large to configure using direct registers (for example, lookup tables).

All of the functions (adding and removing table entries, installing schedules and so on) will be in effect by the time the command buffer descriptor is returned, assuming success except those which have a specified activation time, as noted in their description. If software is relying on a filter or rule being present or removed, it should wait for the buffer descriptor to return before taking any action based on it. Query of a function will return the state at the time it was processed by hardware. Different state may be reported if multiple requests are in-flight or manipulated by multiple entities concurrently. Ordering is guaranteed within a command BD ring that targets the same class of command (NTMP version 1.0), or the same table (NTMP version 2.0). Command BD ring selection amongst NETC functions is performed in a round robin manner.

A messaging protocol called the NETC Table Management Protocol (NTMP) is provided for exchanging configuration and management information between the software and the hardware using the command BD ring interface.

Two versions of the protocol are supported; NTMP version 1.0 and NTMP version 2.0. Following sections provide more details about the definitions of the message headers and the general message structures of each version of the messaging protocols.

53.4.2.2.2.1 NTMP Version 1.0

A command BD ring uses 32B descriptors and is similar in programming to the transmit ring operation. The generic format for the command descriptor is shown below. There is a short format where all information is provided (set command) or received (query command) within the command buffer descriptor. The long format is always accompanied by an address to a data buffer which provides (set command) or receives (query command) fields required to carry out the operation. Commands are identified by their 8-bit Class code and 8-bit Command code. Upon completion of a set command, the first 24 bytes of the set command CBD are not preserved. Upon completion of a query command, all fields in the first 24 bytes which are specific to the query command (ADDR for example) will not be preserved when the command returns; only query response specific field(s) are populated by the hardware.

A query command issued on an entry without a previous set command will have response returned with EN (enable bit) set to 0 but the rest of response fields will have undefined values. The EN field is located in the data portion of the command The format of the data portion depends on the class and command type.

Table 357. CBD Generic Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset
ADDR[31:0] / DATA[31:0]																																0x00
ADDR[63:32] / DATA[63:32]																																0x04
DATA[95:64]																																0x08
DATA[127:96]																																0x0C
DATA[159:128]																																0x10
DATA[191:160]																																0x14
LENGTH (SF=0) / Reserved (SF=1)																INDEX																0x18
SF	CI	STATUS							—							CLASS						CMD										0x1C

Table 358. CBD Field Descriptions

Bits	Name	Description
255	SF	Short format Determines if address field is present. 0 Long format. Address is used to indicate data buffer. 1 Short format. No data buffer, all information contained in the descriptor.
254	CI	Completion interrupt. 0 Disabled. 1 Enabled. When command BD completed for the ring, SICBDRIDR[CBDC] will be set and an interrupt will be generated if SICBDRIER[CBDCIE]=1.

Table continues on the next page...

Table 358. CBD Field Descriptions (continued)

<table>
<tr><th>Bits</th><th>Name</th><th>Description</th></tr>
<tr><td>253-248</td><td>STATUS</td><td>Status. Updated by NETC on completion of the configuration/query command. A non-zero value may indicate error or a class specific event. Note: if multiple errors are detected, only one bit in the STATUS field will be set. Unless specified, configuring reserved values of any kind, be it reserved field or reserved code point, results in undefined behavior.
<table>
<tr><th>Bits</th><th>Description</th></tr>
<tr><td>253</td><td>Reserved; set to 0</td></tr>
<tr><td>252</td><td>Integrity error
• The command did not execute due to a data integrity error (ECC on internal memory or AXI read/write error)</td></tr>
<tr><td>251</td><td>Class specific</td></tr>
<tr><td>250</td><td>Access violation error
• The entity is not allowed to perform the task requested</td></tr>
<tr><td>249</td><td>Size error
• Invalid table index, out of range.
• Table overflow, no additional entries available.</td></tr>
<tr><td>248</td><td>Format error
Buffer descriptor format is invalid, including:
• Illegal class or command.
• Invalid SF bit setting
• LENGTH is zero for long format.
• LENGTH is too small for buffer size.</td></tr>
</table></td></tr>
<tr><td>247-240</td><td>—</td><td>Reserved</td></tr>
<tr><td>239-232</td><td>CLASS</td><td>Class of command. See CMD field to determine operation.</td></tr>
<tr><td>231-224</td><td>CMD</td><td>Command. Used with class to determine operation. Setting a command value that is not supported, will result in undefined behavior.</td></tr>
<tr><td>223-208</td><td>LENGTH</td><td>Length((SF=0)
The length field specifies the effective number of bytes in the data buffer pointed to by ADDR field.</td></tr>
<tr><td>207-192</td><td>INDEX</td><td>Index
The index refers to an entry location within a table.</td></tr>
</table>

Table continues on the next page...

Table 358. CBD Field Descriptions (continued)

Bits	Name	Description
223-0	DATA[223:0]	Data. The content of this data depends on the class and command type.
63-0	ADDR	Address to data. The length of the data is defined by the LEN field. There is an alignment restrictions for the data address to be 16-byte aligned; hardware ignores the least significant 4 bits of the ADDR field.

53.4.2.2.2.2 NTMP Version 2.0

Note that the NETC IP block version used in this chip uses 32-byte long BD descriptors in the message control rings.

In the context of NTMP version 2.0 (thereafter referred to as NTMP only), a hardware table is the term used to refer to a hardware data structure, consisting of a set of similar entities, known as table entries, that share common characteristics. In other words, a table could be thought of as a set or a container of similar entries where each entry has the same structure as the other entries in the table. The figure below illustrates graphically the concept of a hardware table.

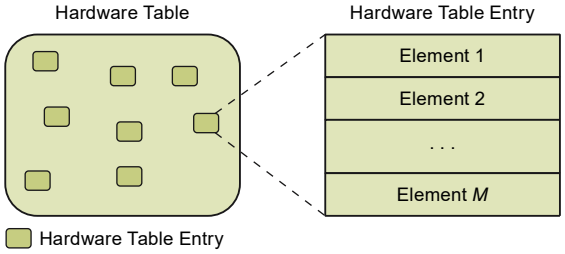

Figure 312. Hardware Tables, Entries and Elements

Because of practical considerations a table can accommodate a finite number of entries. As shown in the figure, the entries in the table do not have to be necessarily stored in a sequenced way.

Following are the ways to identify the location of an entry in a table:

- Index - an identifier that can be used to uniquely identify the location of an entry in the table in a direct manner. If a table is capable of storing up to N entries, the index value ranges from 0 to N - 1 where index 0 indicates the first entry in the table and index N - 1 indicates the last entry in the table. Accessing a table entry using an index is a fast and efficient operation.
- Opaque Entry ID - this is an implementation specific identifier, which is meaningful to the hardware but is of little or no significance to the external user of the table (that is, software). Because the value of the identifier has little or no meaning to the user, the user may not infer the location of the element in the table. An example of an opaque entry ID could be a pointer, an address or an offset identifying the location of the element in hardware managed memory. Accessing a table entry using an opaque entry ID is normally a fast and efficient operation. When an unassigned opaque entry ID is used to access an entry, hardware needs to process the command as if the entry were not found.
- Key - this is a set of attribute values stored in the entry that are used jointly to identify an entry in a table. Except in the case of ternary match tables, the NTMP protocol requires all the keys in a given table to be unique, that is, no two entries in the same table may have the same key.

NOTE

Depending on the table, the entries in the table could be accessed using more than one of the methods listed above.

In the next sections we will use the term Entry ID to identify either the index or the opaque entry ID identifiers and the term Key to identify the key entry identifier. Whenever necessary, it should be clear from the context if the Index or the Opaque Entry ID identifier is used.

Each hardware table entry contains one or many entry elements. The elements in an entry simply correspond to different parts of the data that must be stored and maintained to implement the required functionality.

53.4.2.2.2.2.1 Entry Elements

Entry elements store data needed by hardware and/or software to implement the required functionality.

The following three types of entry elements are supported:

- Key Elements - a key element contains the key data which, as explained before, is used to identify an entry in a table. Typical key data components are fields found in a frame and used to perform table lookups during frame processing, for example, MAC address, VLAN ID, and so on. Other key data components may be used to locate the key element in a table or to identify a table instance to use, for example, entry precedence or hardware resource identifier.

  Two types of Key Element exist within the NTMP protocol: the Ternary Match Key Element and the Exact Match Key Element:

  — Exact Match Key Element: used within the context of exact match tables. This key element can be used to perform any operation. When querying the Exact Match Key Element, the queried result will match exactly the data which was supplied when performing the add operation on the entry.

  — Ternary Match Key Element: used in the context of ternary match tables. Generally, this type of Key Element is composed of three pieces of information: a precedence, data and a data mask. The precedence portion of the Key Element will be used to determine the matching entry in the event that several entries' data/mask combinations match a lookup. This key element can be used to perform the add operation only. The precise data stored in the hardware will be compressed based on the mask portion of the Key Element. Thus, when querying the Ternary Match Key Element, the queried result will not match precisely the value of the Key Element which was supplied when adding the entry. When querying, the precedence portion of the key and the data mask portion of the key will always be returned as it was set by an add or update operation, The data portion, however, will be returned as an expansion of the masked data stored in the hardware; that is to say that any bit in the data whose corresponding data mask bit was a "don't care" will return as '0' when querying, regardless of the state of this bit in the original data portion of the key.

- Configuration Elements - a configuration element contains data that originates from the software control plane. The data stored in the configuration elements is used by the hardware to implement the required datapath processing.
- Status Elements - a status element contains data that typically originates from the hardware. The data stored in the status elements is used by the hardware to inform the software about the state of its resources. Software can read status elements from the hardware and in some cases software can update the element, however, hardware can change the value of the element at any time.

A table entry contains one or more elements. A typical entry will contain, likely no more than one configuration element and may contain zero, one or a number of status elements. The actual number and types of the elements present in an entry depend on the functionality supported by the given table.

53.4.2.2.2.2.2 Table Types

The following table types are supported by the NTMP protocol:

- Indexed table - linear arrays of homogeneous entries accessed using an index (0, 1, 2, ..., N-1) that uniquely identifies an entry within the arrays. The entries are typically stored in contiguous manner, meaning that entries are adjacent to one another in memory with no gaps between them. When accessing the table, the actual memory position of an entry is calculated by hardware from the index based on the size of the entry and the base memory address of the table. Given the index value of an entry, no processing or minimal processing of the index value is needed to access the table entry. Accessing an indexed table is a fast and efficient operation and, if the index value is not out of range for the table, it guarantees locating a unique entry in the table. Normally, there is no need to store the index value in the table entry. There are two types of indexed tables supported:

  — **Static bounded index table** - this table type is for the classic or traditional indexed table(s). Each of these tables has a well-defined, that is, bounded, size and memory is allocated for all the entries in the table. In these tables all the entries are pre-initialized by hardware and the entries can be accessed with the Update and Query operation at any time. The Add and Delete operations do not apply to these tables.

  — **Dynamic bounded index table** - this table type is for the tables that qualify the entries in the tables as present (or active) and absent (or inactive). Each of these tables has a well-defined, that is, bounded, size and memory is

allocated for all the entries in the table. In these tables all the entries are initially considered absent (or inactive). To add an entry to the table, the Add operation must be used. Once an entry is present in a table, it can be updated, queried, or deleted. The Delete operation removes the entry from the table. An attempt to update, query or delete an absent (or inactive) entry results in "entry not found" code being returned. Note that the word "dynamic" in the table name indicates that entries can be added to and deleted from the table in a dynamic fashion; it does not imply anything about the table memory management.

- Exact match table using hash function, also referred to as hash table - the search key must exactly match the key values stored in the table entry. All the key values must be unique. A hash function transforms the, possibly long, key into a shorter identifier which, like the index in an indexed table, is used as a direct index into the table. However, since there is the possibility of hash collisions, an additional mechanism is required to resolve the possible hash collisions. Once a new entry has been added to a hash table, a hardware-generated Entry ID (opaque entry ID) is provided to uniquely identify the location of an entry in a direct manner.
- Ternary match table using TCAM - all entry key matching fields are composed of pairs of data and mask values, to support a per-bit ternary match capability. To look for a match on a particular bit, set its mask bit to 1, and its corresponding data bit to the desired matching value, 0 or 1. A mask value of all 1's for a particular field means that field is required. To make a bit don't care, set its mask bit to 0. In a ternary match table, a single lookup key can be matched by multiple table entries, and thus, every entry must have a priority/precedent assigned by the software. When multiple entries match, the entry with the highest priority/precedence, is returned as the matching entry. Ternary match tables are typically implemented using a Ternary Content Addressable Memory (TCAM). TCAM provides deterministic and high-speed lookups. The following two types of ternary match tables are supported:
  - Hardware managed ternary match table – this table type is such that the precise location of an entry within the TCAM is managed by hardware. When adding an entry, software supplies the key and a specific precedence for this entry. The hardware will then find the correct location for the entry within the TCAM table and relocate existing entries if required based on the precedence of the newly added entry. Note that when adding multiple entries with the same Key Element, each entry will be added to the table with a new and unique Entry ID.
  - Software managed ternary match table – this table type is such that the precise location of an entry within the TCAM is managed by software. When adding an entry, software supplies the key and a specific location (Entry ID) where the entry is to be added. The hardware will then add the entry at the exact location specified by the software command. Entries at the lowest Entry ID take the highest precedence.

53.4.2.2.2.2.3 NTMP Request and Responses Messages

In the NTMP protocol, software sends request messages to hardware and receives response messages from hardware. Messages directed to hardware carry commands to be executed by hardware on a table entry or multiple entries and the responses carry the status information and response data if applicable.

53.4.2.2.2.2.3.1 Commands and Operation Types

Each NTMP command can perform one or a few of the following operations:

- Add Operation - this operation is used to add a single entry to a table. If an entry with the specified Entry ID or Key already exists in the table, that is, it has been added before, the add operation is not performed and the response message indicates that the entry has been found (NUM_MATCHED in Response Message Header is set to 1). There is one exception to this, and that is the case where an entry is added to a hardware managed ternary match table, which already exists in the table. When adding multiple entries with the same Key Element in a hardware managed ternary match table, each entry will be added to the table with a new and unique Entry ID.
- Query Operation - this operation is used to retrieve information from an existing entry or entries. If an entry with the specified Entry ID or Key does not exist in the table that is, no such entry has been added before or it has been deleted, the query operation is not performed, and the response message indicates that no entry has been found (NUM_MATCHED in Response Message Header is set to 0).
- Update Operation - this operation is used to modify an existing entry or entries. If an entry with the specified Entry ID or Key does not exist in the table, that is, no such entry has been added before or it has been deleted, the update operation is not performed, and the response message indicates that no entry has been found (NUM_MATCHED in Response Message Header is set to 0). Note that if a single update command targets multiple entries, all these entries are modified

using the same request message data. If a request message command specifies both the add and query operations, then NUM_MATCHED in the Response Message Header indicates the number of entries matched by the add operation. If NUM_MATCHED is set to 0 (no entry found), an add operation has been performed whereby if set to 1 (one entry found), the entry has been added before, and as a result, the add operation has not been performed. For the query operation in this combination command, it can be assumed that the query operation has been executed, as there will always be a match for the query operation unless an error is detected.

- Delete Operation - this operation is used to delete an existing entry or entries. If an entry with the specified Entry ID or Key does not exist in the table, that is, no such entry has been added before or has been already deleted, the delete operation is not performed, and the response message indicates that no entry has been found (NUM_MATCHED in Response Message Header is set to 0).

The NTMP protocol allows software to request multiple operation types in a single request message command. For example, the add and query operations could both be requested in one request message command to allow software to add a new entry using a key and query the Entry ID of the newly added entry. Not all the combinations of the operation types are supported in the NTMP command messages.

53.4.2.2.2.2.3.2 Operation Type Precedence

When multiple operation types are included in a request message they are always executed in the following order:

1. Add Operation first,
2. Query Operation next,
3. Update Operation next,
4. Delete Operation last.

53.4.2.2.2.2.3.3 Access Methods

Every NTMP protocol request message must specify the method to identify the table entry or entries to execute the command on. Four such access methods are supported:

- Entry ID Match - this access method uses the provided Entry ID, either an index or an opaque identifier, to identify the table entry. The Entry ID is used to access the entry in a direct way, for example, the Entry ID is used as an index or an offset in the table. In each request message, only a single entry in a table can be accessed with this access method. The Entry ID Match access method may be used on all the table types and with all the operation types except for the Add operations on tables whose Entry IDs are generated by hardware (such as exact match or ternary match tables).
- Exact Match Key Element Match - this access method uses the provided Exact Match Key Element to identify the table entry that matches the Key Element. This involves comparing the provided Key Element data with the Key Element stored in the entry. In each request message, only a single entry in a table can be accessed with this access method. When adding a new entry, the Key Element is used to calculate the unique entry ID of the entry within the table. The Exact Match Key Element Match access method may be used on Exact Match Tables.
- Ternary Match Key Element Match - this access method can only be used when performing add operations on ternary match tables. When adding a new entry using the Ternary Match Key Element, a unique entry ID for that entry is assigned by the hardware. That entry ID will remain assigned to that entry until it is deleted from the table and may be used for subsequent queries, deletion, or other table commands. The Ternary Match Key Element Match may be used on all ternary match tables, and as stated above, only the add operation is supported when using this access method.
- Search - this access method uses the provided search criteria data to identify and access the table entry or entries of interest. One or many entries in a table can be accessed with this access method, that is, all the entries that match the search criteria are accessed. The Search access method may be used on all the table types and with all the operation types except for the add operations.

53.4.2.2.2.2.3.4 Search Access Method

The Search access methods offers software a very flexible and powerful way to manage hardware. With a single search request message, software can issue a multi-operation command and execute such a command on all the entries in a given table that match flexibly defined search criteria.

The search access method has several characteristics:

- A single search message can be sent and executed on one table only. This is true for all access methods as an NTMP request message can be destined to a single table only.
- Some tables do not support the search access method.
- While executing a search operation, hardware needs to examine each entry present in the table. For each entry found, hardware checks if the search criteria match the data in the entry and, if so, performs the requested operation or operations on the entry.
- Software must allocate response data buffers that are large enough to store responses of at least one entry and, in cases of search commands, possibly multiple entries. Note that the search query operations tend to return more data than other operations and, therefore may require larger response buffers.
- For more optimal response buffer usage in search commands software can use response buffer sizes that accommodate an integral multiple of entry responses. For example, if an entry response occupies *K* bytes, the response buffer size could be set to (*F* + *n***K*) bytes, where *F* accounts for the possibly present fixed part of the response and *n* is the number of entries that can be returned in a single response.
- In each search response message hardware provides the resume entry ID which indicates if the search is finished or not. If a search is not finished, software is expected to send the provided resume entry ID back to hardware in the subsequent search continuation request message to let hardware know where in the table to resume the search.
- The, so called, NULL Entry ID is used in the request message to indicate the start of a new search. The same NULL Entry ID is used in the response message to indicate the end of a search.
- A table could be modified during a multi-message search, i.e., new entries could be added and/or existing entries could be deleted. However, depending on the table implementation, such modifications could result in duplicate table entries being found and returned to software and/or some entries not being found at all.

53.4.2.2.2.2.4 Entry ID Management

As explained at the beginning of NTMP Version 2.0, the tables rely on the Entry IDs to identify the entries in the tables. An Entry ID can be either an index or an opaque identifier. It is important to identify which entity in the system, namely software or hardware, manages the Entry IDs for each table. Entry ID management refers to allocating, de-allocating and, in general, keeping track of the availability and usage of entries in a table.

Whenever an index form of an Entry ID is required in an Add operation, software must allocate and supply the Entry ID value. Whenever an opaque Entry ID is returned in a query response, hardware must supply the Entry ID value. An entry ID is allocated through the Add operation and it is deallocated through the Delete operation.

53.4.2.2.2.2.5 NTMP Request Message Header Format

Table 359. Request Header Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset
ADDR																																0x0
ADDR																																0x4

																												ADD	QUERY	UPDATE	DELETE	
																																0x10
																																0x14
																																0x18
																NPF=1																0x1C

Table 360. Request Header Description

Bits	Width	Name	Description
63-0	64	ADDR	Address This field contains the address at which both the request and response data buffers are stored. Both buffers are stored at the same physical location which means that the same memory buffer is used for both of them. The memory buffer is first used as the request data buffer and then it is reused as the response data buffer. The address value stored in the ADDR field must be 16-byte aligned; hardware ignores the least significant 4 bits of the ADDR field.
83-64	20	RESPONSE_LENGTH	Response Buffer Length This field contains the length of the Response Data Buffer (data structure). Software must specify a Response Data Buffer length that is large enough to store the STATUS field if it is applicable and, in case of a query command, the response of at least one entry or, in cases of a query search command, possibly multiple entries. For more optimal memory buffer usage in search commands software can specify Response Data Buffer length that can accommodate an integral multiple of entry responses. For example, if an entry response occupies K bytes, the Response Data Buffer length could be set to (F + n*K) bytes, where F accounts for the possibly present fixed part of the response and n is the number of entries that can be returned in a single response. If this field is set to a value smaller than the size needed to store the minimum response, the command will fail with the error code “0x083” returned in the response message.

Table continues on the next page...

Table 360. Request Header Description (continued)

Bits	Width	Name	Description
			If this field is set to a value larger than the size of the allocated memory buffer used to store the Response Data Buffer, the command execution outcome is undefined. The maximum value of this field is 0xFFFF.
95-84	12	REQUEST_LENGTH	Request Buffer Length This field contains the length of the Request Data Buffer (data structure). The field must be set to the exact size of Request Data Buffer (data structure). If this field is set to a value smaller than the size of the Request Data Buffer, the command will fail with the error code “0x083” returned in the response message. If this field is set to a value larger than the size of the Request Data Buffer, the command execution outcome is undefined. The size of the allocated memory buffer that is used to store Request Data Buffer, can be larger than the REQUEST_LENGTH. For example, this can occur if the Response Data Buffer size is larger than the Request Data Buffer size, since the same memory buffer is used to store both buffers.
103-96	8	CMD	Command This field indicates the command to be issued to the hardware. A command may specify one or many operations to be executed in a well defined sequence. The supported operations are Add, Update, Delete and Query. The details of these operation are described below: Delete Operation: If the entry exists, it is deleted. If the entry does not exist, no table delete operation is performed. Update Operation: If the entry exists, the update actions specified in the UPDATE_ACTIONS field are performed and the table entry is updated with the data passed in the Request Data Buffer. If the entry does not exist, no table update operation is performed. Query Operation: If the entry exists, the table entry elements indicated by the QUERY_ACTIONS field in the request data buffer are returned in the response message. If the entry does not exist, no table query operation is performed. Add Operation: Add a new table entry if one does not exist already. If the entry already exists, no table add operation is performed. There is one exception to this, and that is the case where an entry is added to a hardware managed ternary match table, which already exists in the table. When adding multiple entries with the same Key Element in a hardware managed ternary match table, each entry will be added to the table with a new and unique Entry ID. Add is not supported when using the Search Access Method. Add is not supported when using

Table continues on the next page...

Table 360. Request Header Description (continued)

Bits	Width	Name	Description
			the Entry ID Access Method on tables whose Entry IDs are generated by hardware. 0x01 = Delete. The delete operation is performed. 0x02 = Update. The update operation is performed. 0x04 = Query. The query operation is performed. 0x05 = Query, followed by Delete. The query operation is performed first, followed by a delete operation. 0x06 = Query, followed by Update. The query operation is performed first, followed by an update operation. 0x08 = Add. The add operation is performed. 0x0A = Add or Update. If the entry exists, the Update operation is performed. If the entry does not exist, then the Add operation is performed instead. 0x0C = Add, followed by a Query. The Add operation is performed first, followed by a query operation. 0x0E = Add, followed by a Query, followed by an Update. The Add operation is performed. Then, the Query operation is performed. Then, if the entry existed prior to the Add operation of this command, the Update operation will be performed. All other field values are reserved and, if set, will result in an error code being returned in the response message.
107-104	4	--	Reserved
111-108	4	ACCESS_METHOD	Access Method This field specifies the format of the ACCESS_KEY field within the Request Data Buffer as one of the following: 0x0 = Entry ID Match. This access method indicates the Entry ID Match access method. ENTRY_ID is used as the ACCESS_KEY to access the table entry in a direct way. The Entry ID Match may be used on all tables for all operations except for the Add operations on exact match tables. 0x1 = Exact Match Key Element Match. This access method indicates the Exact Match Key Element Match access method. KEYE_DATA is used as the ACCESS_KEY and is matched against the Key Element stored in the exact match Table Entry. In general, the Exact Match Key Element Match access method may be used on all the applicable exact match tables and for all operations

Table continues on the next page...

Table 360. Request Header Description (continued)

Bits	Width	Name	Description
			0x2 = Search. This access method indicates the Search access method. The SEARCH_CRITERIA field is used as the ACCESS_KEY. The search criteria are a set of rules that are used to search for and identify all the entries that match these criteria. In general, the Search may be used on all tables for all operations except for: o Add operations 0x3 = Ternary Match Key Element Match. This access method indicates the Ternary Match Key Element Match. KEYE_DATA is used as the ACCESS_KEY. KEYE_DATA is the combination of a precedence, data, and mask value and is used when inserting entries into a Ternary Match Table. The Ternary Match Key Element Match is applicable only to ternary match tables, and is applicable only to the add operation. The NTMP protocol defines the following pieces of information for each table: - The length of the ENTRY_ID field, e.g., 16-bit or 32-bit or other and for which operations the Entry ID Match is supported. - Whether the Key Element Match access method is supported or not and if so, the specific format or formats of the Key Element for that Table ID and which operations may use the Key Element Match. Note that any reference to the Key Element Match will refer to the type of Key Element Match which is applicable to this table. For example, if a ternary match table indicates that Key Element Match is supported, it is referring to the support of the Ternary Match Key Element Match. - Whether the Search access method is supported or not and if so, the specific format of the SEARCH_CRITERIA field for that Table ID.
119-112	8	TABLE_ID	Table ID This field identifies to hardware which hardware table is the target of the request message.
125-120	6	HEADER_VERSION	Header Version This field specifies the format of the NTMP request message header 0x0 = Reserved. 0x1 = Reserved. 0x2 = version 2.0. 0x3-0x3F = Reserved.
126	1	CCI	Command Completion Interrupt

Table continues on the next page...

Table 360. Request Header Description (continued)

Bits	Width	Name	Description
			0x0 = Disabled. 0x1 = Enabled. When the processing of the request message has been completed the command completion interrupt can be generated. Whether the interrupt is generated or not depends on the settings of the message ring interrupt control register.
127	1	RR	Response Ready This flag must be set to zero by software in each request message and it is set to one by hardware in each response messages once hardware has finished processing the request message. This field is located in the same place in the request and response message headers.
238-128	111	--	Reserved
239	1	NPF	NTMP Protocol Format 0b = NTMP version 1.0 protocol is used 1b = NTMP version 2.0 or later protocol is used.
255-240	16	--	Reserved

53.4.2.2.2.2.6 NTMP Response Message Header Format

Table 361. Response Header Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset

Table continues on the next page...

Table 362. Response Header Description (continued)

Bits	Width	Name	Description
111-96	16	NUM_MATCHED	Number of Entries Matched This field indicates the number of entries that were matched and, if applicable returned, by the command. For example, in a search query response this field indicates the number of the matched entries returned in the response. Note also that an attempt to add an already existing entry results in this field being set to 1 which means that the entry already exists and the requested add operation was not performed. If more than 65535 matches were found then this field pegs at 0xFFFF.
123-112	12	ERROR	Error A zero value of this field indicates that the command has been executed successfully. A non-zero value of this field indicates that an error condition has occurred while executing the command and that no other fields in the response can be considered valid. Many error codes describe conditions triggered by malformed or unsupported commands. Receiving this kind of an error code means that the command has not been executed and that the hardware remains in a coherent state. These error conditions do not result in sending error notifications to the system-level error control unit. Some error codes, however, indicate more severe error conditions. Receiving this kind of an error code means that the command has not executed properly, the hardware may or may not be in a coherent state and that the system-level error control unit may have been notified about the error. When the system-level error control unit is notified about the error it also identifies the corrective action or actions to be taken. All the error codes that may result in error notifications being sent to the system-level error control unit are clearly identified as such. 0x000 = No error. 0x080 = Invalid table ID. 0x081 = Access method specified is not supported. 0x082 = Entry ID value is out of range. 0x083 = REQUEST_LENGTH or RESPONSE_LENGTH specified in the Request Header, is not sufficient. Note that in the case of a Response Data Buffer, this error code is returned only when the RESPONSE_LENGTH specified in the Request Header size is too small to accommodate the minimum response. 0x084 = Invalid command. 0x085 = Reserved.

Table continues on the next page...

Table 362. Response Header Description (continued)

Bits	Width	Name	Description
			0x086 = Multi-bit ECC or parity error observed during command processing. This error condition may trigger a notification to the system-level error control unit. 0x087 = Exceeded hash entry limit. 0x088 = Exceeded maximum hash collision chain limit and the CAM (guaranteed FDB entries) if present is full. 0x089 = Invalid ENTRY_ID for ENTRY_ID generated by hardware (hash, TCAM). 0x08B = Command for index table before OSR[ITM_STATE]=0. 0x08C = Query action specified is invalid. 0x08D = Invalid table access privilege. 0x08E = System Bus Read Error encountered while processing the command. This error condition may trigger a notification to the system-level error control unit. 0x08F = System Bus Write Error encountered while processing the command. This error condition may trigger a notification to the system-level error control unit. 0x090 = Client encountered a fault while processing the command. This error condition may trigger a notification to the system-level error control unit. 0x091 to 0x0FF = reserved. 0x100 to 0xFFF = Table specific error codes.

127	1	RR	Response Ready See Request Header Description - RR
255-128	128	--	Reserved

53.4.2.2.2.2.7 NTMP Request Message Data Buffer

Request and response data buffers contain information that is, generally table specific. However, the building blocks of the data buffers and how these blocks are incorporated into the data buffers are similar for all the tables.

In general, a request data buffer starts with some fields that are common for all the tables and are followed by the table specific entry element data blocks. The table below shows the structure of a typical request data buffer.

Table 363. Generic NTMP Request Data Buffer Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset
TABLE_VERSION				QUERY_ACTIONS				--								UPDATE_ACTIONS																		0x0
																--												zEU		yEU		xEU	
ACCESS_KEY																																0x4
...																																...
ACCESS_KEY																																...
xE_DATA																																...

Table continues on the next page...

Table 363. Generic NTMP Request Data Buffer Format (continued)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset
...																																...
xE_DATA																																...
zE_DATA																																...
...																																...
zE_DATA																																...

The three fields, namely the UPDATE_ACTIONS, QUERY_ACTIONS and ACCESS_KEY fields are always present, regardless of the type of the table. The TABLE_VERSION field is used to version the formats of the request/response data buffers on the table ID level. In other words, each table ID value may support different formats of the request/response data buffers and these formats can be versioned using this table version field. What follows are blocks of element data; in this example. there are two such blocks for elements with names X and Z.

The following table provides the descriptions of the fields present in the generic NTMP request data buffer format.

Table 364. Generic NTMP Request Data Buffer Description

Bits	Width	Name	Description
15-0	16	UPDATE_ACTIONS	Update Actions This field contains table specific update action code-points. See section Update Actions for more details.
27-24	4	QUERY_ACTIONS	Query Actions This field contains table specific query action code-points. See section Query Actions for more details.
31-28	4	TABLE_VERSION	Table Version This field specifies the table specific formats of the NTMP request and response data buffers. See section Table Version for more details.
variable -32	variable	ACCESS_KEY	Access Key This field contains table specific access key. See section Access Key for more details.
variable-variable	variable	xE_DATA, zE_DATA	Element Data Blocks These fields contain table specific element data blocks. See section Element Data Blocks for more details.

53.4.2.2.2.2.7.1 Update Actions

The UPDATE_ACTIONS field in the request data buffer contains a set of code-points. Each of the code-points is associated with a specific table entry element and it indicates what kind of operation is to be performed on that element. Each of the code-points

may also be associated with an element data block. In the example, the X Element Update (xEU) code-point is associated with the xE_DATA element data block and the z Element Update (zEU) code-point is associated with the zE_DATA element data block. Note that in this example the yEU code-point is not associated with any element data block which means that the yEU update action does not require any element data to perform the update.

The zero value in each of the UPDATE_ACTIONS code-points means that the specific update is not to be performed. A non-zero value means that an update is to be performed by hardware. Note that depending on the value of the code-point, a different operation may be performed on the same element. In our example, the xEU and zEU update actions are both 1-bit code-points which means that only one action can be performed on the x and z elements, as the zero value indicate that no action is performed. The yEU update is a two-bit code-point which indicates that up to 3 different actions could be performed on the y element in the entry. Note also, that the yEU update action does not require any data to perform the update and this is why there is no yE_DATA element data block present in the request message. In an actual system, the yEU-like update action could be suitable for updating a statistics element where there is no need for any element data and the update actions could be: reset statistics, pause collecting statistics and re-start collecting statistics.

It is important to know that regardless of the UPDATE_ACTIONS code-point values, all the element data blocks are always present. In other words, regardless if the code-point values are zero or not, all the defined element data blocks are always present in the request data buffer, even if they are not used.

The exact number and meaning of the update actions supported is table specific.

53.4.2.2.2.2.7.2 Query Actions

The QUERY_ACTIONS field in the request data buffer defines a set of code-points that are used to indicate which elements should be returned in the response to a query request. Each of the query action code-points defines a different set of elements to be returned in a query response message. This can be used to selectively query elements in a table entry or entries. If a query action code point indicates that an entry element or some elements are not to be queried, the data for these elements will not be present in the response message data buffer; the response message data buffer contains data only for the queried elements.

The exact number and meaning of the query action code-points is table specific.

53.4.2.2.2.2.7.3 Table Version

The TABLE_VERSION field in the request data buffer defines the pair of the request and response data buffer formats used by the table specified in the TABLE_ID field of the NTMP message header. The table version allows each supported NTMP table, and identified by the table ID, to have different versions of the request and response data buffer formats. This, in turn, facilitates adding new features or modifying existing features in NTMP tables while developing new versions of IP blocks. The table version field makes it easy to version a table without having to increment the NTMP header version or having to introduce a new table which could be identical in nature to an existing table and only differ in the supported feature set.

53.4.2.2.2.2.7.4 Access Key

The ACCESS_KEY field in the request data buffer is associated with the ACCESS_METHOD field in the request message header; the interpretation of the data stored in the ACCESS_KEY field depends on the value stored in ACCESS_METHOD field in the request header. In the add operation, the ACCESS_KEY data is used by hardware to determine where in the table to add the entry. In the update or query operations, the ACCESS_KEY data is used by hardware to determine which of the existing entry or entries the request message is destined for.

The exact meaning of the data stored in the ACCESS_KEY is table specific.

53.4.2.2.2.2.7.5 Element Data Blocks

The remaining fields in the request data buffer are the different element data blocks used in the add and update operations. Each element data block contains element specific data needed to perform the add operation or the update action requested in the corresponding codepoint of the UPDATE_ACTIONS field.

In our example there are two element data blocks: xE_DATA and zE_DATA. They contain data needed to perform the update actions that can be requested through the xEU and zEU code-points, respectively. Note that, as mentioned before, the yEU update action does not require any data and therefore does not have an element data block present in the data buffer.

An important characteristic of the request messages is that while they can act on multiple entries in the table, e.g., multiple entries could be updated in a single request operation, information from the same element data blocks is applied to all the entries addressed by the request message.

As mentioned before, regardless of the UPDATE_ACTIONS code-point values, all the element data blocks are always present. In other words, regardless if the code-point values are zero or not, all the defined element data blocks are always present in the request data buffer, even if they are not used.

The exact number of the element data blocks and the meaning of the fields within them are table specific.

The request data buffer format shown in Table 363 is generic and as such it does not apply exactly as shown to all the different operation types. The following section explains how the format changes for the different operation types.

53.4.2.2.2.2.7.6 Operation Specific Request Data Buffer Formats

The request data buffer format shown in Table 363 applies to the Add and Update operations. The Query and Delete operations use a slightly different data buffer format. This is because the Query and Delete operations do not require any element data to be present in the request. A generic request data buffer format used by the Query and Delete operations is shown in the table below.

Table 365. Generic NTMP Request Data Buffer Format for Query and Delete Operations

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset
TABLE_VERSION				QUERY_ACTIONS				--								UPDATE_ACTIONS																		0x0
																--													zEU	yEU	xEU	
ACCESS_KEY																																0x4
...																																...
ACCESS_KEY																																...

Note that the UPDATE_ACTIONS and QUERY_ACTIONS fields are present in the formats for all the operations, however, they are ignored by hardware if they do not apply. More accurately, the UPDATE_ACTIONS field is ignored in the Query operation and both of the fields are ignored in the Delete operation.

The comparison of the formats for the Add and Update operations (Table 363) and for the Query and Delete operations (Table 365) makes it clear that the Add/Update operation format is a superset of the Query/Delete operation format. Also, the UPDATE_ACTIONS, QUERY_ACTIONS and ACCESS_KEY fields are present in all the operation formats and are always at the same offsets in the request data buffer. This is illustrated graphically in the figure below.

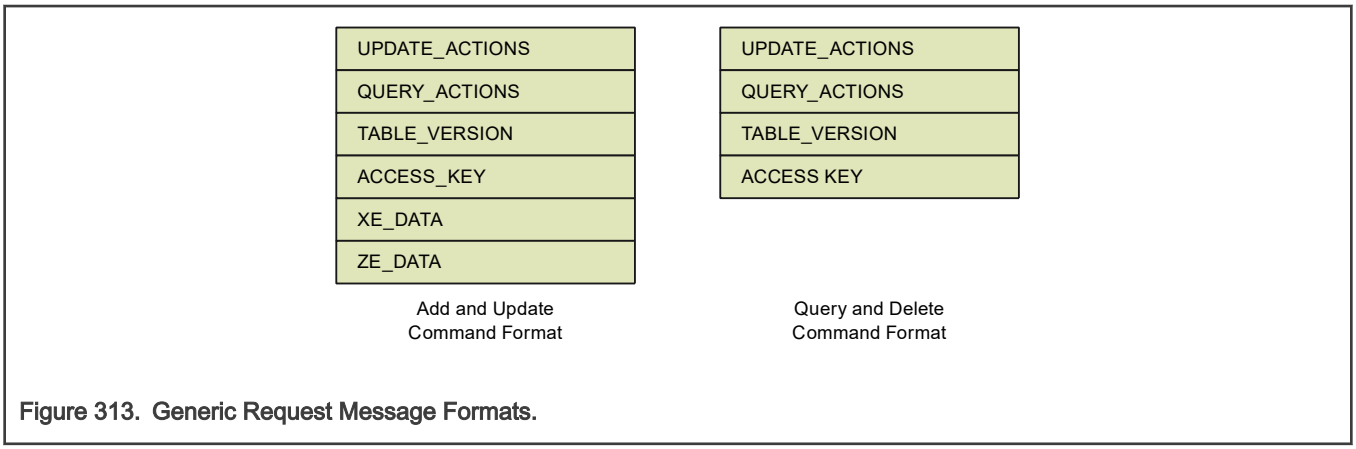

Figure 313. Generic Request Message Formats.

53.4.2.2.2.2.8 NTMP Response Message Data Buffer

Like with the request data buffer, the response data buffers use a common format. Consider Table below which shows the structure of a typical response data buffer.

Table 366. Generic NTMP Response Data Buffer Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset
STATUS																																0x0
...																																...
STATUS																																...
ENTRY_1_RESPONSE_ENTRY_ID																																...
ENTRY_1_RESPONSE_xE_DATA																																...
ENTRY_1_RESPONSE_yE_DATA																																...
ENTRY_1_RESPONSE_zE_DATA																																...
...																																...
ENTRY_*i*_RESPONSE_ENTRY_ID																																...
ENTRY_*i*_RESPONSE_xE_DATA																																...
ENTRY_*i*_RESPONSE_yE_DATA																																...
ENTRY_*i*_RESPONSE_zE_DATA																																...
...																																...
ENTRY_*N*_RESPONSE_ENTRY_ID																																...
ENTRY_*N*_RESPONSE_xE_DATA																																...
ENTRY_*N*_RESPONSE_yE_DATA																																...
ENTRY_*N*_RESPONSE_zE_DATA																																...
...																																...

The response data buffer contains the STATUS field followed by the response data for, in this example, N table entries.

53.4.2.2.2.2.8.1 Status

The presence or absence of the STATUS field in the response message depends on the table, i.e., some tables may have the STATUS field and others may not. The size and content of the STATUS field is also table specific. The response status field is intended to return status information that is not stored in hardware, i.e., it is not stored in any of the entry elements. Typically, the status information is available to hardware during the processing of a request message and once the response messages have been generated and sent to software the status information is no longer available to hardware. A good example of status data is the resume entry ID. Resume entry ID is used with the Search access method and it indicates to software at which entry in the table to resume the search.

In addition to being table specific, the status information may also be different for the different operation types. For example, the Add operation could return different status information than the Delete operation for the same table. In order to simplify the protocol, the amount of response data buffer space reserved for the STATUS field must be large enough to accommodate the largest status variant in a given table.

If a given table does not return any status-like information, the STATUS field is not present in the response data buffer for this table. However, all the tables that support the Search access method do return the resume entry ID and therefore have the STATUS field present in their responses.

53.4.2.2.2.8.2 Entry Response(s)

Entry responses are returned only in the case of the Query operation. They are not returned in the case of the Add, Update or Delete operations.

Generically, a response data buffer may contain responses for none, one or many entries. The number of entry responses depends on the number of matching entries found. If the access method used was not Search, there will be a maximum of one entry response returned, depending if the entry exists or not. If the access method used was Search, responses for many entries could be returned. The number of entry responses returned in the response data buffer is stored in the NUM_MATCHED field of the response header.

In the example in Table 366, N entry responses are returned, and each entry response contains an Entry ID as well as the data stored in the xE, yE and zE entry elements.

The response data buffer format shown in Table 366 is generic and as such it does not apply exactly as shown to all the different operation types. The following section explains how the format changes for the different operation types.

53.4.2.2.2.8.3 Operation Specific Response Data Buffer Formats

The response data buffer format shown in Table 366 applies to the Query operation only. The Add, Update and Delete operations use somewhat different data buffer format. This is because the Add, Update and Delete operations do not require any element data to be present in the response. A generic response data buffer format used by the Add, Update and Delete operations is shown in table below

Table 367. Generic NTMP Response Data Buffer Format for Add, Update and Delete Operations

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset
STATUS																																0x0
...																																...
STATUS																																...

The only field present in the response data buffer for the Add, Update and Delete operations is the STATUS field. Because, in general, the STATUS field may not apply to a specific table, it may not be present, meaning that response data buffer could contain no valid data.

The comparison of the formats for the query operation (Table 366) and for the Add, Update and Delete operations (Table 367) makes it clear that the Query operation format is a superset of the Add/Update/Delete format. This is illustrated graphically in the figure below.

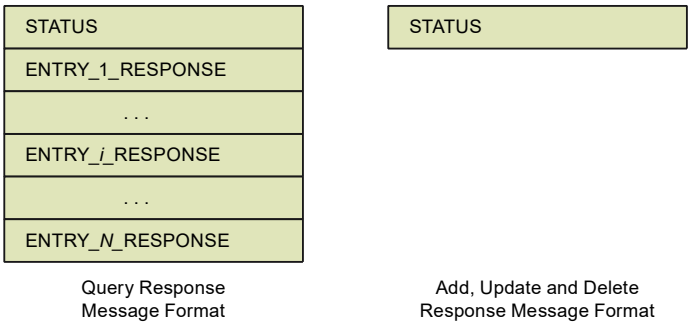

Figure 314. Generic Response Message Formats.

53.4.2.2.2.2.9 Data Buffer Alignment Considerations

In the NTMP protocol the alignment requirements specify the restrictions of the relative positions of the various data elements in the request and response data buffers. The following two alignment types are considered:

- Data component alignment.
- Entry response alignment.

Data Component Alignment

Data component alignment refers to the relative position of a data component in a request or response data buffer in relation to the preceding data components. NTMP data components are structures such as an access key, entry element, status, etc.

Some of the data components are always present in a data buffer while others may or may not be present depending on the command type. Different data components may have different alignment requirements.

The data component alignment for each data component in each NTMP table is well defined and documented. The specified data component alignments must be respected to ensure message format coherency.

Entry Response Alignment

An entry response is a collection of data components associated with a single table entry. NTMP commands utilizing the search access method may produce response data buffers containing multiple entry responses. Entry response alignment refers to the relative position of an entry response in the response data buffer in relation to the preceding data component or entry response.

The entry response alignment for each NTMP table is well defined and documented. The specified entry response alignments must be respected to ensure message format coherency.

Example

Consider the example shown in the figure below. The example shows a query response data buffer with two data components followed by *N* entry responses. "Data Component 2 Padding" is needed because of the required data component 2 alignment. All the entry response paddings are needed because of the required entry response alignment. Note that "Entry Response 1 Padding", may be of a different size than all the following entry response paddings. This is because "Data Component 2" may require a different padding than an entry response. Entry response paddings 2, ..., *N*-1 have the same size. The figure also shows *M* data components present in the entry response. Except for the first data component all others require a data component padding.

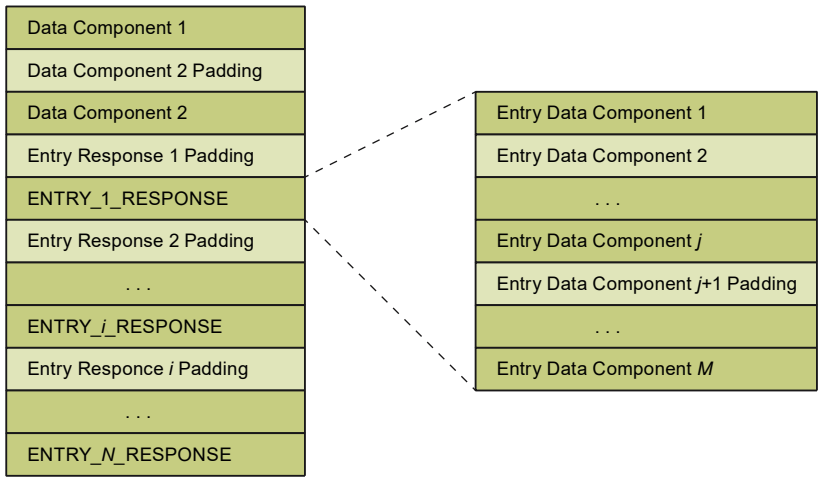

Figure 315. Data Buffer Alignment Considerations - Example.

53.4.2.2.3 Transmit and Receive Buffer Descriptor Format

53.4.2.2.3.1 Transmit Buffer Descriptor Format

This section describes the format of the buffer descriptors used by software to pass packets to hardware for transmission. The basic or standard descriptor is 16B and provides the ability to send a packet, possibly using multiple buffers, as well as optionally supporting one or two offloads. In addition, this descriptor can be extended by adding another 16B which supports more offloads. Since all transmit rings use 16B buffer descriptors, the extended version will always require a minimum of two chained BDs. The shaded fields in the descriptors indicate that the field is only applicable in the first BD. Reserved fields should be written with 0's.

The feature(s) supported by the (basic) descriptor format are:

- Time specific departure
- Switch management

Table 368. Transmit Buffer Descriptor Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset

Table 369. Transmit Buffer Descriptor Field Descriptions

Bits	Name	Description
127	F	Final Determines if this is the last buffer descriptor for the frame. This field is always valid. 0 Not final. Next buffer descriptor is part of a chain to create a list of buffers, or is an extension buffer descriptor.

Table continues on the next page...

Table 369. Transmit Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
		1 Final. This is the last buffer descriptor. Last buffer descriptor always needs to have the F bit set to 1 regardless of whether it is part of a chain or not, unless the next buffer descriptor is an extension buffer descriptor.
126	E	Extended Indicated that this descriptor is extended by the next descriptor in a chain. Valid only in the first descriptor in a chain. 0 Standard. 1 Extended. The next chained BD has the extended format.
125	FI	Frame interrupt. Valid only in the first descriptor in a chain. 0 Disabled. 1 Enabled. Transmit frame event for the ring, TB*a*IDR[TXF], will be set after completion of the frame and an interrupt will be generated if TB*a*IER[TXFIE]=1.
124-123	FL	Flags Indicate the presence of additional fields in bit offset 96-122. Valid only in the first descriptor in a chain 00b Definition depends on the Flags Qualifier (FLQ) setting. 01b Reserved 10b Indicates that the time specific departure fields are present 11b Reserved
121-120	FLQ	Flags Qualifier Indicates the presence of additional fields in bit offset 96-119. Valid only in the first descriptor in a chain. 00b No optional fields present, remaining bits at bit offset 96-119 are reserved (must be set to 0) 01b Reserved 10b Indicates that switch management sending options fields are present 11b Reserved
119	SMSO	Switch Management Sending Options This field specifies the sending options (optional) host originated switch management traffic. Applicable only if the *ENETC* port is connected internally to a switch port, designated as a switch management port. SMCAPR[SM] set to 1b indicates that ENETC is connected to a switch port designated as the switch management port. **0**: Switch Port Masquerading Host originated switch management traffic forwarded by the switch as it was received from another switch port. The switch port number is specified in the INGR_PORT field of the transmit BD.

Table continues on the next page...

Table 369. Transmit Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
		This option uses the regular ENETC transmit datapath processing and the switch ingress datapath processing, which in turn relies on the pseudo link to transfer frames between ENETC and the switch. **1**: Direct Switch Enqueue This option is used to direct host originated switch management traffic out a specific switch egress queue. It by-passes most of the ENETC transmit datapath processing and the switch ingress datapath processing. A dedicated transmit BD ring must be used for this option, and all frames put on that transmit BD ring will be directed to the specified switch egress queue, subject to the switch egress congestion management policy (possibility of having frames dropped if the egress queue is congested). Only SI 0 can make use of this option, with transmit BD ring number 0 permanently assigned to support this option. This transmit BD ring will not be assigned to a traffic class, meaning that this transmit BD ring will not be considered by the HTA transmit scheduling mechanism. For each frame put on this transmit BD ring, its transmit buffer descriptor (BD) must have the FL field set to 00b, the FLQ field set to 10b and the SMSO field set to 1b. If these fields are set otherwise, the frame is not transmitted and the STATUS field of the transmit BD is updated with the "Programming Error in Buffer Descriptor Used for Direct Switch Enqueue" code point. The output switch port and IPV need to be specified in the transmit BD (EGR_PORT and IPV fields respectively) in order for the switch to determine the switch egress queue. The DR needs also to be specified (in the DR field of transmit BD) for congestion management handling within the switch. The switch buffer pool ID will be determined by the switch using the IPV provided in transmit BD and the input switch port number to which the ENETC is internally connected. When sending the frame out from a specific NETC switch external port, there is the option to request timestamping of the frame using the one-step timestamping method or the two-step timestamping method (that is, returning the transmit timestamp to the host), or both. Request to perform one-step timestamping, is specified by setting the IEEE 1588 PTP one-step timestamp offload flag to 1 in the E_FLAGS field, and by writing to the TIMESTAMP field, the timestamp value to be used by the one-step timestamp function to calculate the residence time to be added to the Correction field of the frame being transmitted. Request to perform two-step timestamping, is specified by setting the Timestamp Reference Request (TSR) field to 1. If the frame is enqueued successfully onto the switch egress queue (no errors reported in the STATUS field), hardware writes back a timestamp identifier in the TXTSID field of the transmit buffer descriptor. This identifier is used by software to correlate the transmit timestamp response with the transmit frame.
118	TSR	Timestamp Reference Request Request to capture (and return to the host) the timestamp when the frame's SFD is transmitted by the switch's Ethernet MAC. After the switch dequeues and transmits the frame, it sends a transmit timestamp reference response message back to the host (as a Host Reason of 0x3) to the receive BD ring specified in the switch management host reason a receive BD ring mapping register (SMHR3BDRMR) with the receive buffer descriptor containing the TXTSID from the writeback, and the timestamp value returned from the switch Ethernet MAC.

Table continues on the next page...

Table 369. Transmit Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
		Valid if SMSO=1b
116-112	INGR_PORT	Ingress switch port number this frame is to be injected towards. Applicable only if the *ENETC* port is connected internally to a switch port, designated as a switch management port Valid values: 0..SCAPR0[NUM_PORT]-1 Valid if SMSO=0b
116-112	EGR_PORT	Egress switch port number this frame is to be transmitted. Applicable only if the *ENETC* port is connected internally to a switch port, designated as a switch management port Valid values: 0..SCAPR0[NUM_PORT]-1 Valid if SMSO=1b
110-108	IPV	Internal Priority Value Applicable only if the ENETC port is connected internally to a switch port, designated as a switch management port, and the frame is being transmitted with the Switch Management Sending Options (SMSO) set to 1 (directing a frame out a specific switch egress queue). The IPV specified in this field is be used by the switch to determine the switch egress queue and buffer pool. Valid if SMSO=1b
107-106	DR	Discard Resilience Applicable only if the ENETC port is connected internally to a switch port, designated as a switch management port, and the frame is being transmitted with the Switch Management Sending Options (SMSO) set to 1 (directing a frame out a specific switch egress queue). This field is used for congestion management handling within the switch. Valid if SMSO=1b
122	W	Written Used to determine if writeback occurred after completion of this frame. Must be initialized to 0b by software, hardware will change this to 1b if it writes back to the descriptor. Valid only in the first descriptor in a chain.
121	TSE	Transmit start enable Determines if the TX_START field is valid, and to be used for time specific departure. Valid only in the first descriptor in a chain. Present only if FL is 10b.
120-96	TX_START	Transmit start time Required start time for transmission of this frame that is time specific departure. This value is expressed as bit [29:5] of the IEEE 1588 synchronized nanosecond time. Since bit 31 and 30 are always 0, the time window is approximately 1 second and then wraps around. As a result, a departure time of up to approximately 0.5 s in the future from the current time, may be specified

Table continues on the next page...

Table 369. Transmit Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
		so that when hardware schedules the frame, it can determine whether the departure time is in the past or in the future. Note that the unit is 32 ns, since bit 0 to 4 are not included. Valid only in the first descriptor in a chain. Present only if FL is 10b.
95-80	FRM_LEN	Frame Length This field specifies the total effective frame length including data in the buffer referenced by this descriptor and those referenced by any chained descriptors. FRM_LEN must be same or less than all BUF_LEN combined. FRM_LEN is valid and required for both single and multi transmit buffer descriptors frames. Frames must not have a FRM_LEN that is less than 16 bytes. Frames of 0-15 bytes are not supported. The maximum recommended setting of FRM_LEN is 2000 bytes. If FRM_LEN exceeds 9600 bytes, the frame is not transmitted and the STATUS field of the transmit buffer descriptor is updated with the error code 0x00A (invalid frame/buffer/chain length).
79-64	BUF_LEN	Buffer Length The buffer length field specifies the effective number of bytes in the data buffer pointed to by ADDR field. This field must be a non-zero value. There must be no extra buffer descriptors (of any BUF_LEN value) beyond the one that contains the last byte of frame data. First descriptor in a chain must not have a BUFF_LEN that is less than 16 bytes.
63-0	ADDR	Address The memory address of a buffer containing the full or partial Ethernet packet. This address may be a virtual or a physical address as defined by software. When chaining is defined (F=0), multiple addresses are used to create the full packet.

The figure below shows the layout of the extension descriptor which can follow a standard descriptor and allows transmission of packets using more offloads than the standard descriptor alone. This descriptor serves as an extension of the standard transmit descriptor and is present if the E (“Extended”) bit of the standard descriptor is set (1b). Note that descriptor extensions can only follow the initial standard descriptor in a chain for a multi-buffer frame. The added offload features provided by the extended buffer descriptor format include:

- VLAN insert offload
- Timestamp offload

Table 370. Extension Transmit Buffer Descriptor Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset

PCP			DEI	VID												TPID		--														0x04
--																																0x08
F	--		FMT		--		E_FLAGS									--																0x0C

Table 371. Extension Transmit Buffer Descriptor Field Descriptions

Bits	Name	Description
127	F	Final Determines if this is the last buffer descriptor for the frame. This field is always valid. 0 Not final. Next buffer descriptor is part of a chain to create a list of buffers. 1 Final. This is the last buffer descriptor, Last buffer descriptor always needs to have the F bit set to 1 regardless of whether it is part of a chain or not.
126-125	--	Reserved
124-122	FMT	Format 000b The format described here All other values reserved
121-120	--	Reserved
119-112	E_FLAGS	Extension flags Indicates what offloads are enabled for this frame, see table below.

Bits	Description
119-115	Reserved
114	IEEE 1588 PTP two-step timestamp offload When set, timestamp information is updated in TIMESTAMP field after successful transmit.
113	IEEE 1588 PTP one-step timestamp offload The hardware subtracts the timestamp value provided in the TIMESTAMP field from the timestamp value captured when the frame transmission started. The hardware then adds the results of the subtraction (also referred to as the residence time) “on-the-fly” to the Correction field of the frame being transmitted. The Correction field location in the frame is specified in the register PMa_SINGLE_STEP[OFFSET]. **NOTE** The one-step timestamp offload is not supported on the pseudo MAC.
112	VLAN insert offload When set, indicates that the packet is a VLAN packet and hardware must add the VLAN tag header to the packet on transmit. The VLAN tag to be inserted by hardware is specified in the extension transmit buffer descriptor fields TPID, PCP, DEI and VID.

63-61	PCP	Priority code point

Table continues on the next page...

Table 371. Extension Transmit Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
		This field contains the PCP value of the VLAN tag to be inserted in the packet during transmission.
60	DEI	Drop eligible indicator This field contains the DEI value of the VLAN tag to be inserted in the packet during transmission.
59-48	VID	VLAN identifier This field contains the VLAN identifier of the VLAN tag to be inserted in the packet during transmission.
47-46	TPID	Tag protocol identifier This field contains the TPID of the VLAN tag to be inserted in the packet during transmission. The TPID is specified as a 2-bit code value. 2 standard and 2 custom tag identifiers are supported. 00b Standard C-VLAN 0x8100 01b Standard S-VLAN 0x88A8 10b Custom C-VLAN as defined by CVLANR1[ETYPE] 11b Custom S-VLAN as defined by CVLANR2[ETYPE]
45-32	--	Reserved
31-0	TIMESTAMP	Timestamp The timestamp value provided in this field is subtracted from the SFD transmit time of the frame. The result of the subtraction (also referred as to the residence time) is then added to the value read in the Correction field of the frame. Finally, the result of the addition is writing back to the Correction field of the frame. The timestamp value is expressed in units of nanoseconds, with the upper 2 bits of the timestamp value (bits 31-30) not being used. The value of this field is in the range 0 to 0x3FFFFFFF. This field is valid when IEEE 1588 PTP one-step timestamp offload flag is set.

Following transmission hardware may write data back into the transmit descriptor, depending on the requested offloads and whether any errors occurred in transmit processing. To allow a blind write instead of a read-modify-write the fields of the descriptor are overwritten. The figure below shows the descriptor format.

Writeback always occurs if a direct switch enqueue is requested. Otherwise writeback only occurs if required either due to a requested offload or an error. The W (Written) bit at bit position 122 in the transmit descriptor must be initialized to a 0 by software when the descriptor is passed to hardware and is written with a 1 during writeback to allow detection of the writeback. Writeback only occurs in the first descriptor of a chain of descriptors for a frame.

Table 373. Transmit Buffer Writeback Descriptor Field Descriptions

Bits	Name	Description	
120-112	STATUS	Status	
		Code Points	Description
		0x001:	Programming error An error exists in either the Tx BD, the Tx ring registers, or some combination of these which meant that this frame could not be transmitted.
		0x002:	Time specific departure drop The time defined in TX_START expired before frame could be processed for transmission.
		0x008:	Frame size error One of the following conditions occurred: • Frame length exceeds PTCaTMSDUR[MAXSDU] (where a is the traffic class number) for a non-segmented frame. • Frame has exceeded 63 chained BDs in length. Frames provided in chained BDs must not exceed 63 BDs. • FRM_LEN is larger than (combined) buffer lengths in a multi-BD frame.
		0x009:	Null address A null address 0xFFFF_FFFF_FFFF_FFFF detected in the transmit buffer descriptor, or entire transmit descriptor is read in as 0s, or an all 0s BD is encountered in the middle of a mulit-BD frame.
		0x00A:	Invalid frame/buffer/chain length • A frame length of less than 16 bytes is detected in the transmit buffer descriptor. • A buffer length of less than 16 bytes is detected in the first descriptor of a chain. • A single-BD frame's FRM_LEN value exceeds the BUF_LEN. Note that this condition occurring in a multi-BD frame is reported as a frame size error. • A FRM_LEN exceeding 9600 bytes has been provided. • The W bit in a provided BD is not 0. • A single-BD frame (FRM_LEN <= BUF_LEN) does not have F=1 in the BD or its extension.

Table continues on the next page...

Table 373. Transmit Buffer Writeback Descriptor Field Descriptions (continued)

Bits	Name	Description	
		0x010:	Source MAC address spoofing detected An attempt was made to transmit a frame with a source MAC address not matching that of the SI's primary MAC address when PSI*a*CFGR0[ASE]=1.
		0x020:	Frame dropped due to port reset. Timestamp value is not valid if this bit is set to 1.
		0x021:	Frame dropped due to port disabled. Frame not transmitted (dropped) due to port disabled (POR[TXDIS]= 0b1).
		0x040:	VLAN TPID not allowed Frame not transmitted (dropped) because the TPID in it's VLAN tag (either in the frame itself or through the transmit BD) is not allowed.
		0x060:	Programming error in buffer descriptor used for direct switch enqueue Buffer descriptor in the transmit BD ring for direct switch enqueue, doesn't have the FLQ field set to 10b and the SMSO field set to 1, or a buffer descriptor has the FLQ field set to 10b and the SMSO field set to 1, in a non "direct switch enqueue" transmit BD ring. This error code is also returned if a direct switch enqueue is attempted within a transmit BD ring assigned to an ENETC which is not designated as a switch management ENETC.
		0x080:	Frame too large for time gating window The frame was determined to be too large to transmit during the open phase of the traffic class transmit gate. Adjust the window size or the frame size.
		0x090:	AXI read error Frame not transmitted (dropped) due to an AXI read error detected.
		0x091:	AXI write error Frame not transmitted (dropped) due to an AXI write error detected.
		0x0A0:	Multi-bit ECC error Frame not transmitted (dropped) due to a multi-bit ECC error detected.
		0x0F0:	Parity error Frame not transmitted (dropped) due to a parity write error detected.
		0x100:	Frame dropped due to switch congestion Frame drops due to congestion on the switch buffer pool or class queue, in the case where the option to direct a frame out a specific switch egress queue is used.
111-96	--	Reserved	

Table continues on the next page...

Table 373. Transmit Buffer Writeback Descriptor Field Descriptions (continued)

Bits	Name	Description
31-0	TIMESTAMP	Timestamp Timestamp value represents the transmission time of the frame. The timestamp reported in this field can be either a synchronized timestamp or a free running timestamp. For the Ethernet MAC, the PMa_COMMAND_CONFIG[TS_MODE] register determines which of the two clock sources (synchronized clock or free running clock) is used for sampling the timestamp. For the pseudo MAC, the PCR[TIMER_CS] register determines which of the two clock sources (synchronized or free running) is used for sampling the timestamp. If a synchronized timestamp is reported, the timestamp in this field is the lower 32 bits of the 64-bit synchronized timestamp. The value in this field is in units of nanoseconds with the range 0 to 0xFFFFFFFF. To reconstruct the 64-bit synchronized timestamp, perform the following steps: 1. Get the current 64-bit synchronized time. It can be obtained from the following registers: • **ENETC SI register address space** - Read to the SICTR0 register followed immediately by a read to the SICTR1 register. • **Timer register space** - Read to the TMR_FRT_L register, followed immediately by a read to the TMR_SRT_L register and to the TMR_SRT_H register. TMR_SRT_L/H indicates the current synchronized time. 2. Check if the lower 32-bits of the current synchronized time has wrapped around since the timestamp was captured, by comparing it to the timestamp value reported in this field. If the reported timestamp value in this field is higher than the lower 32-bits of the current synchronized time, the time has wrapped around resulting the need to adjust the upper 32-bits of the current synchronized time by subtracting 0x00000001 from it. This value is then used to set the upper 32 bits of the synchronized timestamp. If the time has not wrapped around, the upper 32 bits of the current synchronized time read from the register, is used to set the upper 32 bits of the synchronized timestamp. 3. The upper 32 bits value determined in step 2, and the lower 32 bits reported in this field are combined to create the 64-bit synchronized timestamp. If a free-running timestamp is reported, the timestamp in this field is the lower 32 bits of the 64-bit free running timestamp. The value in this field is in units of NETC clock ticks with the range 0 to 0xFFFFFFFF. To reconstruct the 64-bit free running timestamp, perform the following steps: 1. Get the current free-running time by issuing a read to the TMR_FRT_L register followed immediately by a read to the TMR_FRT_H register. 2. Check if the lower 32-bits of the current free-running time has wrapped around since the timestamp was captured, by comparing it to the timestamp value reported in this field. If the timestamp value reported in this field is higher than the lower 32-bits of the current free-running time, the time has wrapped around resulting the need to adjust the upper 32-bits of the current free-running time by subtracting 0x00000001 from it. This value is then used to set the upper 32 bits of the free-running timestamp. If the time has not wrapped around, the upper 32 bits of the current running time read from the register, is used to set the upper 32 bits of the free-running timestamp. 3. The upper 32 bits value determined in step 2, and the lower 32 bits reported in this field are combined to create the 64-bit free running timestamp. This field is updated after successful transmission when IEEE 1588 PTP two-step timestamp offload is enabled for the frame transmitted.

Table continues on the next page...

Table 373. Transmit Buffer Writeback Descriptor Field Descriptions (continued)

Bits	Name	Description
15-0	TXTSID	Transmit Timestamp Identifier This field contains an incrementing value that is updated with every writeback. It is only meaningful when the transmit buffer descriptor has specified that a timestamp be captured (and be returned to the host) when the frame's SFD is transmitted by the switch's Ethernet MAC. This timestamp request is specified by setting the Timestamp Request Reference (TSR) field to 1, in the transmit buffer descriptor. When TSR is set 1, the TXTSID value from the writeback must be used to associate the received TSR response with the transmit frame.

The figure below illustrates the four possible ways to represent a frame in memory using the 16B standard and extended BD formats.

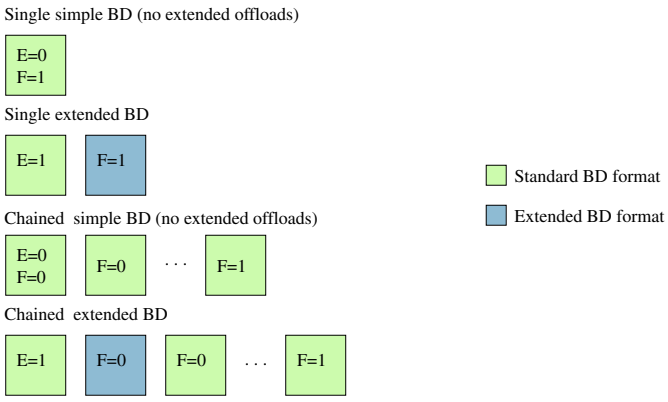

Figure 316. BD Frame Representation

Transmit Frame Restrictions and Limitations

This section describes unsupported transmit frame configurations and limitations on supported configurations. Software must ensure that frames which violate the following conditions are not given to the ENETC for processing. Erroneous hardware behavior will result; i.e. frames with error, dropped frames.

1. Frames must not have a FRM_LEN that is less than 16 bytes. Frames of 0-15 bytes are not supported.
2. Chained transmit frames must not contain any BDs beyond the number required to hold the transmitted frame; i.e. the F=1 BD must contain the final frame byte. One or more "empty" BDs of any BUF_LEN >=0 must not be present following the BD(s) that contain frame data.
3. Chained transmit frames must not contain any BDs that have BUF_LEN = 0. This restriction is already stated in the definition of the BUF_LEN field.
4. Chained transmit frames must not have a FRM_LEN which is greater than the sum of its BDs BUF_LEN fields.

53.4.2.2.3.2 Receive Buffer Descriptor Format

The BD formats for receive rings which operate with standard 16B descriptors are shown below. Software includes the buffer address to NETC in the provided BD. NETC overwrites the address with information extracted from the received frame. The shaded fields in the descriptors indicate that the field is only applicable for unchained BDs or the first descriptor in a chain.

The BD formats for receive rings which operate with extended 32B descriptors are shown below. Additional fields support:

- Timestamping for PTP (IEEE 1588) and gPTP (802.1AS-2020).

Software must configure the BD rings and the steering of frames accordingly. Software includes the buffer address to NETC in the provided BD. NETC overwrites the address field from the provided BD with information extracted from the received frame. The shaded fields in the descriptors indicate that the field is only applicable for unchained BDs or the first descriptor in a chain.

Rx Buffer Descriptors containing transmit timestamp reference response messages are formatted as follows. These buffer descriptors are received in response to a successfully processed Tx buffer descriptor which had a set TSR bit (Timestamp Reference Request). Received transmit timestamp reference response BDs are identified by their Host Reason code (0x3 Timestamp Response), which is unique to these messages and is used to determine which Rx ring within the designated switch management ENETC they are received in. Mapping of Host Reason to receive BD ring is via the receive BD ring mapping register SMHRaBDRMR.

No DMA operation is performed when NETC produces transmit timestamp reference response messages. So, if a BD ring is used exclusively for handling these messages it is not necessary for software to provide a valid ADDR in the ring entries.

The standard ERROR code field is present but only provides an indication of internal logic parity or SRAM ECC mismatch for transmit timestamp reference response message BD entries.

Table 379. Software Provided Receive Buffer Descriptor Field Descriptions

Bits	Name	Description
255-128	--	Reserved (32B format only)
127-64	--	Reserved

Table continues on the next page...

Table 379. Software Provided Receive Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
63-0	ADDR	Address Memory address of a buffer containing the full or partial Ethernet packet. NETC will ignore bits 5-0 of the address field. May be a virtual or a physical address as defined by software. When chaining is defined (F=0), multiple addresses are used to create the full packet. Minimum buffer size is 128 bytes. For better performance, it is recommended not to use a buffer size smaller than 256 bytes. The memory address of the buffers must be 64B aligned. If the SBCR[WBS] register is configured for 128B maximum burst size (WBS=3) then the memory address of the receive buffers must be 128B aligned. WBS=2 is the recommended setting (default; 64B maximum burst size).

Table 380. Receive Writeback Buffer Descriptor Field Descriptions

Bits	Name	Description
255-168	--	Reserved (extended format only)
159-128	TIMESTAMP	Timestamp (extended format only) Timestamp value that was applied by MAC at time of ingress . For the Ethernet MAC, the timestamp is captured when the MAC detects the one-octet start frame delimiter (SFD) of the frame. For the pseudo MAC, the timestamp is captured at the time the frame was transferred across the pseudo link, as there is no frame serialization or copy across a pseudo link. Valid when timestamp flag is set. The timestamp reported in this field can be either the synchronized timestamp or the free running timestamp. The PCR[TIMER_CS] register determines which of the two timestamps (synchronized or free running) is reported. If the synchronized timestamp is reported, the timestamp in this field is the lower 32 bits of the 64-bit synchronized timestamp. The value in this field is in units of nanoseconds with the range 0 to 0xFFFFFFFF. To reconstruct the 64-bit synchronized timestamp, perform the following steps: 1. Get the current 64-bit synchronized time. It can be obtained from the following registers: • **ENETC SI register address space** - Read to the SICTR0 register followed immediately by a read to the SICTR1 register. • **Timer register space** - Read to the TMR_FRT_L register, followed immediately by a read to the TMR_SRT_L register and to the TMR_SRT_H register. TMR_SRT_L/H indicates the current synchronized time. 2. Check if the lower 32-bits of the current synchronized time has wrapped around since the timestamp was captured, by comparing it to the timestamp value reported in this field. If the reported timestamp value in this field is higher than the lower 32-bits of the current synchronized time, the time has wrapped around resulting the need to adjust the upper 32-bits of the current synchronized time by subtracting 0x00000001 from it. This value is then used to set the upper 32 bits of the synchronized timestamp. If the time has

Table continues on the next page...

Table 380. Receive Writeback Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
		not wrapped around, the upper 32 bits of the current synchronized time read from the register, is used to set the upper 32 bits of the synchronized timestamp. 3. The upper 32 bits value determined in step 2, and the lower 32 bits reported in this field are combined to create the 64-bit synchronized timestamp. If the free-running timestamp is reported, the timestamp in this field is the lower 32 bits of the 64-bit free running timestamp. The value in this field is in units of NETC clock ticks with the range 0 to 0xFFFFFFFF. To reconstruct the 64-bit free running timestamp, perform the following steps: 1. Get the current free-running time by issuing a read to the TMR_FRT_L register followed immediately by a read to the TMR_FRT_H register. 2. Check if the lower 32-bits of the current free-running time has wrapped around since the timestamp was captured, by comparing it to the timestamp value reported in this field. If the timestamp value reported in this field is higher than the lower 32-bits of the current free-running time, the time has wrapped around resulting the need to adjust the upper 32-bits of the current free-running time by subtracting 0x00000001 from it. This value is then used to set the upper 32 bits of the free-running timestamp. If the time has not wrapped around, the upper 32 bits of the current running time read from the register, is used to set the upper 32 bits of the free-running timestamp. 3. The upper 32 bits value determined in step 2, and the lower 32 bits reported in this field are combined to create the 64-bit free running timestamp. When the extended 32B descriptors are used, every received frame, has its captured timestamp reported in this field. If the ENETC port is connected internally to a switch port, designated as a switch management port, and the Host Reason is set to a non-zero value, this field contains the Rx timestamp captured at the switch port where the frame was received.
127	F	Final Determines if multiple descriptors are chained to form a list of buffer addresses. 0 Not final. Next buffer descriptor is part of a chain to create a list of buffers. 1 Final. This is the last buffer descriptor in a chain.
126	R	Ready Indicates that the BD has been written. If the ready bit is set for the first BD, it also indicates the entire chain of BDs is complete. NETC will not set the ready bit for the first BD in a chain unless all other BDs associated with it are also complete. Note that although software can use the R bit as an efficient means to qualify the BD contents and also read frame data from the associated buffers (i.e. avoid the need to poll ring PI), it is still necessary to check the ring's RBaPIR[BDR_INDEX] prior to incrementing RBaCIR[BDR_INDEX]. Set R bits will appear in the ring ahead of the corresponding RBaPIR update. Software must not advance the ring consumer index before hardware has updated the ring producer index.
125-120	--	Reserved

Table 380. Receive Writeback Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
119-112	ERROR	Error status code for the received frame. The listed codes indicate the presence of a detected error condition or event. **Bits** / **Description** 119-112 / 0x00: No error detected. 0x40: L3 (IPv4) Header Checksum validation failed. 0x41: L4 (TCP or UDP) Checksum validation failed. 0x80: Internal logic parity or SRAM (ECC) mismatch detected. 0x88: System Bus Read Error detected during processing of the frame. 0x89: System Bus Write Error detected during processing of the frame. All unlisted code points are reserved and will not appear.
111-104	FLAGS	Flags for receive information. **Bits** / **Description** 111-109 / Reserved 108 / L4 (TCP or UDP) Checksum was validated and found to be correct. 107 / L3 (IPv4) Header Checksum was validated and found to be correct. 106 / Timestamp received When set, timestamp information is available in TIMESTAMP field. 105 / VLAN header extracted When set, VLAN header information is available in TPID, PCP,DEI and VID fields. 104 / RSSV - RSS hash valid 0 = RSS_HASH/RSS_HASH_P field is not valid 1 = RSS_HASH/RSS_HASH_P field is valid The value in the RSS_HASH/RSS_HASH_P field is not valid if RSS is not supported, RSS is disabled, or no RSS rules were matched.
103-102	--	Reserved
101-98	HR	Host Reason 0: Regular forwarded frame 1: Ingress mirroring 2: MAC learning

Table continues on the next page...

Table 380. Receive Writeback Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
		3: Timestamp Response 4-7: Reserved 8-15: Software defined Host Reason
97-96	TPID	Extracted VLAN tag protocol identifier. A 2-bit TPID value identifying which known value matched. Valid if VLAN Extracted flag (bit 105) is set to 1. 00 0x8100 01 0x88A8 10 Custom tag 1 (as defined in CVLANR1[ETYPE]) 11 Custom tag 2 (as defined in CVLANR2[ETYPE])
95-93	PCP	Priority code point A 3-bit field which refers to the IEEE 802.1p class of service and maps to the frame priority level. Valid if VLAN Extracted flag (bit 105) is set to 1.
92	DEI	Drop eligible indicator May be used separately or in conjunction with PCP to indicate frames eligible to be dropped in the presence of congestion. Valid if VLAN Extracted flag (bit 105) is set to 1.
91-80	VID	VLAN identifier The VLAN identifier is a 12-bit field specifying the VLAN to which the frame belongs. Valid if VLAN Extracted flag (bit 105) is set to 1.
79-64	BUF_LEN	Buffer length The length field specifies the effective number of bytes in the data buffer pointed to by ADDR field. It does not include any size adjustments done by NETC for alignment purposes to the head or tail end BD.
63-32	RSS_HASH	Receive side scaling 32-bit hash value. Valid only if the RSSV bit is set to 1.
63-40	RSS_HASH_P	Receive side scaling 24-bit hash value. Valid only if the RSSV bit is set to 1, and the ENETC port is connected internally to a switch port, designated as a switch management port.
36-32	SRC_PORT	Switch Port ID of received frame. Valid only if the ENETC port is connected internally to a switch port, designated as a switch management port.
31-16	PARSER_SUMMARY	Parser summary, see Parse Summary.
15-0	INET_CSUM	Internet checksum. Calculated over the L2 payload, i.e. does not include the L2 header (first 14 bytes consisting of DMAC, SMAC and EtherType) nor FCS. The Internet checksum is used in various Internet protocols to check for data corruption in headers.

Table 381. Transmit Timestamp Reference Response Writeback Buffer Descriptor Field Descriptions

97-96	--	Reserved
95-80	--	Reserved
79-64	TXTSID	Transmit Timestamp Identifier Transmit timestamp identifier (or correlation identifier) that was written back by hardware in the TXTSID field of the transmit buffer descriptor, in response to a successfully processed transmit buffer descriptor which had a set TSR bit (Timestamp Reference Request). The transmit timestamp identifier is used by software to correlate the transmit timestamp reference response with the request (or transmit frame).
63-32	--	Reserved
31-0	TIMESTAMP	Timestamp Timestamp value represents the transmission time of the frame on a switch port.

Table continues on the next page...

Table 381. Transmit Timestamp Reference Response Writeback Buffer Descriptor Field Descriptions (continued)

Bits	Name	Description
		The transmit timestamp can be either a synchronized timestamp or a free running timestamp. The PMa_COMMAND_CONFIG[TS_MODE] register determines which of the two clock sources (synchronized clock or free running clock) is used for sampling the timestamp. If the synchronized timestamp is reported, the timestamp in this field is the lower 32 bits of the 64-bit synchronized timestamp. The value in this field is in units of nanoseconds with the range 0 to 0xFFFFFFFF. To reconstruct the 64-bit synchronized timestamp, perform the following steps: 1. Get the current 64-bit synchronized time. It can be obtained from the following registers: • **ENETC SI register address space** - Read to the SICTR0 register followed immediately by a read to the SICTR1 register. • **Timer register space** - Read to the TMR_FRT_L register, followed immediately by a read to the TMR_SRT_L register and to the TMR_SRT_H register. TMR_SRT_L/H indicates the current synchronized time. 2. Check if the lower 32-bits of the current synchronized time has wrapped around since the timestamp was captured, by comparing it to the timestamp value reported in this field. If the reported timestamp value in this field is higher than the lower 32-bits of the current synchronized time, the time has wrapped around resulting the need to adjust the upper 32-bits of the current synchronized time by subtracting 0x00000001 from it. This value is then used to set the upper 32 bits of the synchronized timestamp. If the time has not wrapped around, the upper 32 bits of the current synchronized time read from the register, is used to set the upper 32 bits of the synchronized timestamp. 3. The upper 32 bits value determined in step 2, and the lower 32 bits reported in this field are combined to create the 64-bit synchronized timestamp. If the free-running timestamp is reported, the timestamp in this field is the lower 32 bits of the 64-bit free running timestamp. The value in this field is in units of NETC clock ticks with the range 0 to 0xFFFFFFFF. To reconstruct the 64-bit free running timestamp, perform the following steps: 1. Get the current free-running by issuing a read to the TMR_FRT_L register followed immediately by a read to the TMR_FRT_H register. 2. Check if the lower 32-bits of the current free-running time has wrapped around since the timestamp was captured, by comparing it to the timestamp value reported in this field. If the timestamp value reported in this field is higher than the lower 32-bits of the current free-running time, the time has wrapped around resulting the need to adjust the upper 32-bits of the current free-running time by subtracting 0x00000001 from it. This value is then used to set the upper 32 bits of the free-running timestamp. If the time has not wrapped around, the upper 32 bits of the current running time read from the register, is used to set the upper 32 bits of the free-running timestamp. 3. The upper 32 bits value determined in step 2, and the lower 32 bits reported in this field are combined to create the 64-bit free running timestamp.

53.4.2.2.4 MAC Layer

53.4.2.2.4.1 Ethernet MAC

Following are the major functions provided by the Ethernet MAC:

- Full MAC layer implementation compliant with IEEE802.3 specification.
- 10M/100M/GE port speeds.
- Half duplex support at 10M and 100M speeds.
- EEE (Energy Efficient Ethernet).
- CRC-32 checking with forwarding of the FCS field to upper layer processing functions.
- CRC-32 generation and append on transmit or forwarding of provided FCS.
- Ethernet PAUSE frame (802.3 Annex 31B) termination.
- One-step and two-step timestamping support for PTP/IEEE1588/IEEE802.1AS-2020.
- 802.3 basic and mandatory managed Objects statistic counters and IETF Management Information Database. (MIB) package (RFC2665) and Remote Network Monitoring (RMON) counters.
- IEEE 802.3 physical-layer fields encapsulation and decapsulation such as the Preamble, Start of Frame Delimiter and Inter-Frame Gap. The Preamble must be an integral number of octets (octet-aligned).

53.4.2.2.4.1.1 MAC Flow Control

The Ethernet MAC supports one mode of flow control:

- Link Pause Flow Control: This is the standard IEEE 802.3 defined PAUSE frame to allow pausing the remote device connected to the link (link local pause). Upon reception (if enabled by configuration) the transmitter is paused for the time received in the PAUSE frame.

If a frame of another mode is received it is treated as a regular command frame. Depending on PM*a*_COMMAND_CONFIG[CNT_FRM_EN], it is either discarded or forwarded to the user application but has no effect within the MAC. See PM*a*_COMMAND_CONFIG register for configuration options.

53.4.2.2.4.1.1.1 MAC Transmit Pause

In transmit direction, MAC receives flow control requests from upper layer processing functions, and determines based on the request and current state whether to schedule transmitting a link PAUSE control frame. The following conditions trigger the transmission of a link PAUSE control frame:

- A Tx pause is not in progress and there is a request for pausing the transmission of the other end of the link – the MAC schedules transmitting a new link PAUSE control frame with the programmed quanta value (PMn_PAUSE_QUANTA[PQNT]), enters 'Tx pause in progress' state, and starts counting down the quanta threshold (PM1_PAUSE_THRESH[QTH]).
- A Tx pause is already in progress, but the upper layer function dropped the pause request (request link partner resume transmission) – the MAC schedules transmitting a new link PAUSE control frame with QUANTA = 0, stops the quanta threshold countdown, and exits 'Tx pause in progress' state
- A Tx pause is already in progress, the request is still outstanding, and the quanta threshold countdown counter expires – the MAC schedules transmitting a refresh link PAUSE control frame with QUANTA=PQNT, stays in 'Tx pause in progress' state, and restarts counting down the quanta threshold with the counter reset to QTH.

The MAC completes transmitting any application frame that has already started transmission before it schedules transmitting a new link PAUSE control frame. Transmit of link PAUSE control frames takes priority over pending application frames that have not started transmission.

When preemption is enabled, upper layer processing functions must be configured in such a way that they won't generate requests to generate PAUSE frame. See Preemption for more details.

53.4.2.2.4.1.1.2 MAC Receive Pause Operation

PAUSE frames are processed in the MAC receive engine if PM*a*_COMMAND_CONFIG[PAUSE_IGN] is set to 0. In that case, the quanta is extracted from the terminated PAUSE frame and sent to the MAC transmit control. The quanta extracted is loaded into an internal timer to pause the transmitter. The transmitter continues to complete any ongoing frame transmission and then enters a pause state where it does not read any frames from the transmit FIFO. When the transmitter has reached its pause state, the timer starts to decrement. When the timer reaches 0 the transmitter resumes to normal transmission of frames.

If a CRC or a length error is detected, the quanta is ignored. If the PM*a*_COMMAND_CONFIG[PAUSE_IGN] is set to 1, the quanta is not extracted from the received PAUSE frame. In either case, transmit continues normal transmission without interruption.

PAUSE frames are also optionally forwarded to the MAC Client if PM*a*_COMMAND_CONFIG[PAUSE_FWD] is set to 1.

Table 382. PAUSE Frame Processing Options

PAUSE_IGN	PAUSE_FWD	Description
0	0	• PAUSE frames terminated • Quanta extracted and sent to MAC transmit path • PAUSE frames not transferred to MAC FIFO interface
0	1	• PAUSE frames terminated • Quanta extracted and sent to MAC transmit path • PAUSE frames transferred to MAC FIFO interface
1	0	• PAUSE frames not terminated • Quanta not extracted and not sent to MAC transmit path • PAUSE frames not transferred to MAC FIFO interface
1	1	• PAUSE frames not terminated • Quanta not extracted and not sent to MAC transmit path • PAUSE frames transferred to MAC FIFO interface

A PAUSE frame is valid only if all of the following conditions are true:

- Ethertype is set to 0x8808
- Opcode immediately following Ethertype is 0x0001
- Destination MAC address matches configured primary MAC address (registers PM*a*_MAC_ADDR_0/1) or the control frame multicast address 01-80-C2-00-00-01
- Valid CRC
- Length of 64 bytes
- Received by the express MAC

When a PAUSE frame is received, the statistics counter aRxPAUSEMACCtrlFrames is always incremented.

53.4.2.2.4.1.2 Preemption

NETC supports IEEE 802.1Qbu preemption. A physical port which supports preemption contains two MACs; i.e. MAC 0 and 1. When frame preemption is enabled, MAC 0 handles express traffic, and MAC 1 handles preemptive traffic. Preemption is enabled on a per port basis by setting MAC_MERGE_MMCSR[ME] to 1 or 2. The two MACs are merged on one port as defined in 802.3 Clause 99.When frame preemption is disabled, all traffic goes through MAC 0. The ability to designate one or more priorities as express (and the remaining priorities as preemptable) means that, when an express frame is ready for transmission and a preemptable frame is already in the process of being transmitted, the delay before the express frame transmission starts is at worst

the sum of the minimum final (64B) and non-final (MAC_MERGE_MMCSR[RAFS]) fragment sizes minus four octet times and will often be 64 octet times or less.

The traffic class assignment to either the express MAC or the preemptable MAC is specified by setting PFPCR[FPE_TCa] (where a corresponds to the traffic class number). By default all traffic classes are assigned to the express MAC. Preemption, is therefore a useful tool for reducing the jitter experienced by time-sensitive frames. These frames could be transmitted using any of the available transmission selection algorithms, but the likely choice would be an algorithm that is intended for use with time sensitive data, such as the time-gating, time specific departure scheduling, or credit-based shaping. In common use cases, it would be expected that express traffic would have a higher priority than preemptable traffic.

When preemption is enabled, generation of PAUSE frames must be disabled, as stated in the IEEE 802.3 standard.

When preemption is disabled, PAUSE frames can be transmitted and received on the express MAC only.

When preemption is enabled on a port, IEEE 1588 PTP one-step timestamping is not supported.

For statistics related to preemption, see section Ethernet MAC Statistics Counters.

53.4.2.2.4.1.3 Ethernet MAC Statistics Counters

NETC offers a set of statistics counters required in IEEE 802.3 basic, mandatory and recommended management information packages. In addition, these counters can be used to generate applicable objects of the Management Information Base (MIB, MIB-II) according to IETF RFC2665 for SNMP managed environments. For monitoring applications, RMON counters are available according to IETF RFC2819.

In NETC, a physical port which supports preemption will contain two MACs - MAC 0 and 1. When frame preemption is enabled, MAC 0 handles express traffic, and MAC 1 handles preemptive traffic. As a result, the user needs to read the counters from both MACs and add them together to get the correct count values. Preemption Verify and Respond mPackets are not included in MAC statistics. When frame preemption is disabled, all traffic goes through MAC 0. In this case, the user only needs to look at the counters in MAC 0.

Following tables list the available Ethernet MAC statistics counters.

Table 383. Ethernet MAC Traffic Statistics Counters

Direction	Counter	Description
Rx	PM*a*_REOCTn	Received Ethernet octets counter (etherStatsOctets); good and errored
Rx	PM*a*_ROCTn	Received octets counter (ifInOctets); good
Rx	PM*a*_RXPFn	Received valid PAUSE frames counter
Rx	PM*a*_RFRMn	Received frames counter; good
Rx	PM*a*_RVLANn	Received VLAN tagged frames counter; good
Rx	PM*a*_RUCAn	Received unicast frames counter; good
Rx	PM*a*_RMCAn	Received multicast frames counter; good
Rx	PM*a*_RBCAn	Received broadcast frames counter; good
Rx	PM*a*_RPKTn	Received packets counter (etherStatsPkts); good and errored
Rx	PM*a*_RMIN63n	Received Min to 63-octet packets counter; good only
Rx	PM*a*_R64n	Received 64-octet packets counter (etherStatsPkts64Octets); good and errored
Rx	PM*a*_R127n	Received 65 to 127-octet packets counter (etherStatsPkts65to127Octets); good and errored

Table continues on the next page...

Table 383. Ethernet MAC Traffic Statistics Counters (continued)

Direction	Counter	Description
Rx	PM*a*_R255n	Received 128 to 255-octet packets counter (etherStatsPkts128to255Octets); good and errored
Rx	PM*a*_R511n	Received 256 to 511-octet packets counter (etherStatsPkts256to511Octets); good and errored
Rx	PM*a*_R1023n	Received 512 to 1023-octet packets counter (etherStatsPkts512to1023Octets); good and errored
Rx	PM*a*_R1522n	Received 1024 to 1522-octet packets counter (etherStatsPkts1024to1522Octets); good and errored
Rx	PM*a*_R1523Xn	Received 1523 to Max-octet packets counter (etherStatsPkts1523toMaxOctets); good and errored
Rx	PM*a*_RCNPn	Received control packets counter (type 0x8808 but not PASUE packets)
Rx	MAC_MERGE_MMFAOCR	Received valid reassembled frames counter
Rx	MAC_MERGE_MMFCRXR	Received additional mPackets counter
Tx	PM*a*_TEOCTn	Transmitted Ethernet octets counter (etherStatsOctets); good and errored
Tx	PM*a*_TOCTn	Transmitted octets counter (ifOutOctets); good
Tx	PM*a*_TXPFn	Transmitted valid PAUSE frames counter
Tx	PM*a*_TFRMn	Transmitted frames counter; good
Tx	PM*a*_TVLANn	Transmitted VLAN tagged frames counter; good
Tx	PM*a*_TUCAn	Transmitted unicast frames counter; good
Tx	PM*a*_TMCAn	Transmitted multicast frames counter; good
Tx	PM*a*_TBCAn	Transmitted broadcast frames counter; good
Tx	PM*a*_TPKTn	Transmitted packets counter (etherStatsPkts); good and errored
Tx	PM*a*_T64n	Transmitted 64-octet packets counter (etherStatsPkts64Octets); good and errored
Tx	PM*a*_T127n	Transmitted 65 to 127-octet packets counter (etherStatsPkts65to127Octets); good and errored
Tx	PM*a*_T255n	Transmitted 128 to 255-octet packets counter (etherStatsPkts128to255Octets); good and errored
Tx	PM*a*_T511n	Transmitted 256 to 511-octet packets counter (etherStatsPkts256to511Octets); good and errored
Tx	PM*a*_T1023n	Transmitted 512 to 1023-octet packets counter (etherStatsPkts512to1023Octets); good and errored
Tx	PM*a*_T1522n	Transmitted 1024 to 1522-octet packets counter (etherStatsPkts1024to1522Octets); good and errored

Table continues on the next page...

Table 383. Ethernet MAC Traffic Statistics Counters (continued)

Direction	Counter	Description
Tx	PM*a*_T1523Xn	Transmitted 1523 to Max-octet packets counter (etherStatsPkts1523toMaxOctets); good and errored
Tx	PM*a*_TCNPn	Transmitted control packets counter (type 0x8808 but not PAUSE packets)
Tx	MAC_MERGE_MMFCTXR	Transmitted additional mPackets counter
Tx	MAC_MERGE_MMHCR	Hold transitions from false to true counter

Table 384. Ethernet MAC Frame Drops/Errors Counters

Direction	Scope	Counter	Description
Rx	MAC	PM*a*_RERRn	MAC received frame error counter; incremented for each frame received with an error (except for undersized frames)
Rx	MAC	PM*a*_RUNDn	MAC received undersized frames counter
Rx	MAC	PM*a*_ROVRn	MAC received oversized frames counter
Rx	MAC	PM*a*_RFCSn	MAC received frame check sequence (FCS) error counter
Rx	MAC	PM*a*_RFRGn	MAC received undersized frames with FCS error counter
Rx	MAC	PM*a*_RJBRn	MAC received oversized frames with FCS error counter
Rx	MAC	PM*a*_RDRPn	MAC received frame drops counter; full or truncated frames dropped due to receive FIFO overflows
Rx	MAC	PM*a*_RDRNTPn	MAC received non-truncated frame drops count; full frame dropped due to receive FIFO overflows
Rx	MAC	PM*a*_RFRGn	Receive fragment packet counter; incremented for each packet which is shorter than the length programmed in PM*a*_MINFRM register received with a bad CRC.
Rx	MAC	PM*a*_RJBRn	Receive jabber packet counter; incremented for each packet which is larger than the maximum frame length specified in register PM*a*_MAXFRM[MAXFRM] register received with a bad CRC.
Rx	MAC Merge	MAC_MERGE_MMFAECR	MAC Merge frame reassembly error counter
Rx	MAC Merge	MAC_MERGE_MMFSECR	MAC Merge frame SMD error counter
Tx	MAC	PM*a*_TERRn	MAC transmitted frames error counter
Tx	MAC	PM*a*_TUNDn	MAC transmitted frames counter less than 64B with good FCS
Tx	MAC	PM*a*_TDFRn	MAC transmitted frames counter with deferral (half duplex only)
Tx	MAC	PM*a*_TSCOLn	MAC transmitted frames counter with single collision (half duplex only)
Tx	MAC	PM*a*_TMCOLn	MAC transmitted frames counter with multiple collisions (half duplex only)

Table continues on the next page...

Table 384. Ethernet MAC Frame Drops/Errors Counters (continued)

Direction	Scope	Counter	Description
Tx	MAC	PM*a*_TECOLn	MAC dropped frames counter with excess collisions (half duplex only)
Tx	MAC	PM*a*_TLCOLn	MAC dropped frames counter with late collision (half duplex only)

53.4.2.2.4.1.4 Ethernet MAC Graceful Stop

In order to stop receive:

1. Write PM1_COMMAND_CONFIG[RX_EN]=0b; this step is required only if frame preemption is enabled.
2. Wait for PM1_IEVENT[RX_EMPTY] to be set; this step is required only if frame preemption is enabled.
3. Write PM0_COMMAND_CONFIG[RX_EN]=0b.
4. Wait for PM0_IEVENT[RX_EMPTY] to be set.
5. Wait for PSR[RX_BUSY] to clear.
6. Stop the upper layer functions from receiving any frames by setting POR[RXDIS] to 1b.

In order to stop transmit:

1. Perform the graceful stop of traffic from upper layer processing functions; set POR[TXDIS] to 1b, for the upper layer processing functions to stop enqueuing frames for transmission and to flush any internal Tx queues.
2. Wait for PM0_IEVENT[TX_EMPTY] to be set. If frame preemption is enabled, wait for TX_EMPTY from both PM0_IEVENT and PM1_IEVENT registers.
3. Wait 64 byte time for Tx packet transmission to complete.
4. Write PM0_COMMAND_CONFIG[TX_EN]=0b.
5. Write PM1_COMMAND_CONFIG[TX_EN]=0b; this step is required only if frame preemption is enabled.

53.4.2.2.4.2 Pseudo MAC

A switch port connects internally to an ENETC port using a pseudo link. Pseudo MACs are used at both ends of a pseudo link to transfer frames across a pseudo link.

Functions provided by the pseudo MAC are:

- **Frame transfer across a pseudo link** - Main tasks are:
  - Pseudo links are implemented without a physical transmission medium, and thus frames are not encapsulated with IEEE 802.3 physical-layer fields such as the Preamble, Start of Frame Delimiter and Inter-Frame Gap, when transferred across a pseudo link. However when scheduling a frame, the PTXSDUOR register can be configured with the appropriate per frame overhead; overhead (number of bytes) to be added to the actual length of each frame, to reflect the PPDU (Physical Layer PDU) frame length on a physical Ethernet link.
  - Only frame descriptors are transferred across a pseudo link; actual frames continue to remain in the same memory location as they are transferred across the pseudo link. Thus there is no need to store or copy these frames as they have already been stored in the shared internal buffer memory.
  - Out of band metadata to carry switch management port related info (source port, Host Reason). There is also an annotated frame header carried along with the frame when performing frame modifications (only added on transmit, by the switch).
  - Rate limiting function if 802.1Qbv operation is not configured. The rate limiting function is achieved by enabling time gate scheduling (PTGSCR[TGE] set to 1) with no administrative gate control list configured, and for ENETC with EaTGSLR[ZERO_LOOKAHEAD] set to 1. There is no equivalent "ZERO_LOOKAHEAD" field for the switch as there is no need to compensate for any DMA delay; default value for the S0TGSLR[MIN_LOOKAHEAD] field is suitable

to rate limit a switch port bound to pseudo MAC. The bit rate is specified in PCR[PSPEED]. This also requires the timer function to be configured and enabled. Either the default nanosecond timer or the 1588 timer can be used to generate the required nanosecond resolution time. The default nanosecond timer is configured and enabled by default out of reset. The pseudo MAC for both ENETC and the switch will have this rate limiting function configured and enabled by default.

- **Statistics** - Subset of RMON counters provided, no frame length related counts provided.
- **Timestamp** - Support consists of:
  - Receive (switch and ENETC): Two timestamps (one sampling the synchronized clock whereby the other sampling the free running clock) at the time the frame was transferred across the pseudo link.
  - Transmit (ENETC only): On any given transmit frame, the pseudo MAC returns the timestamp at the moment where the frame was transferred across the pseudo link. The Ethernet Tx I/F returns this value to HTA which in turn uses this as the indication that the corresponding transmit BD descriptors have been transmitted, and if the IEEE 1588 PTP two-step timestamp offload is enabled, writes back the returned timestamp in the metadata of the host transmit descriptor. Note that IEEE 1588 PTP one-step timestamp offload is not supported on the pseudo MAC.
- **Pseudo link control and configuration.**
  - Transmit link speed configuration (specified in PCR[PSPEED]); used by the egress port scheduler to determine the transmit link speed on a port.
  - Padding configuration; indicates whether padding is to be applied; only used by HTA Transmit to determine if a frame needs to be padded to a minimum frame length of 64 bytes.
  - Pseudo MAC enable/disable (POR[TXDIS/RXDIS]).
- **Flow control** - Flow control on per port basis to mimic Ethernet PAUSE functionality (no Pause frame generation).
  - Internal flow control signals are carried across the pseudo link in both directions, to request the other end of the link to pause transmission for all traffic classes.
  - These flow control signals are directly connected to the respective pseudo link end point transmit scheduler. When these flow control signals are asserted, the transmit scheduler enters a pause state where it stops scheduling frames for all traffic classes.
- **FCS** - The pseudo MAC does not remove the FCS(s). The FCS(s) are carried in the frame, and remain as the frame is processed by the ENETC receive datapath. No FCS checking is performed on receive as no transmission of bits occurs on pseudo link.
- **Preemption** - Not applicable.

No minimum and maximum frame length checking is performed on both receive and transmit.

The only frame drop that can occur is, if there is no available internal memory for creating the annotated frame header when performing frame modifications (on transmit, and only applicable to the switch). These frame discards are counted against the port's Tx discard count register (PTXDCR) along with the setting of the Shared Memory Resource Exhaustion Discard Reason (SMREDR) flag to 1 in the port's Tx discard count reason register 0 (PTXDCRR0).

53.4.2.2.4.2.1 Pseudo MAC Statistics Counters

Following table lists the available pseudo MAC statistics counters.

Table 385. Pseudo MAC Traffic Statistics Counters

Direction	Counter	Description
Rx	PPMROCR0/1	Received octets counter (ifInOctets)
Rx	PPMRUFCR0/1	Received unicast frames counter
Rx	PPMRMFCR0/1	Received multicast frames counter

Table continues on the next page...

Table 385. Pseudo MAC Traffic Statistics Counters (continued)

Direction	Counter	Description
Rx	PPMRBFCR0/1	Received broadcast frames counter
Tx	PPMTOCR0/1	Transmitted octets counter (ifOutOctets)
Tx	PPMTUFCR0/1	Transmitted unicast frames counter
Tx	PPMTMFCR0/1	Transmitted multicast frames counter
Tx	PPMTBFCR0/1	Transmitted broadcast frames counter

NOTE

Pseudo MAC statistics counters are not updated for frames sent towards the switch management port with a Host Reason set to a codepoint other than 0 (not regular forwarded frame).

53.4.2.2.5 Common Internal Memory

The common internal memory (also referred in the document as "common memory") is used by NETC functions for frame buffering and for the storage of exact match lookup tables. The common internal memory is divided into a set of fixed (static) non-overlapping memory partitions, namely:

- Shared memory partition.
- NETC function partitions used for the storage of indexed tables; one partition for each of the NETC functions.
- Hash table bucket array partition. The hash table bucket array partition is a global hash table bucket array memory that is shared by all hash tables from the switch and ENETC functions.
- Guaranteed hash table entry partition. Each entry in this memory partition is currently used to store the content of a switch FDB entry, when the FDB table entry is added as a Content-Addressable-Memory (CAM) entry, as opposed to an hash entry (hash space), due to collision chain length having reached its maximum length.

The layout of the common internal memory is shown in the figure below:

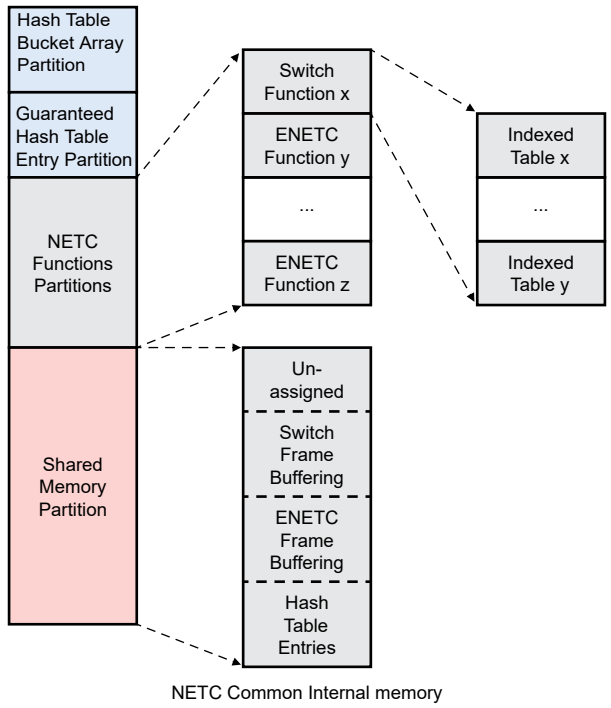

Figure 317. NETC Common Internal Memory Layout

Common internal memory allocation for the above memory partitions is performed at pre-boot initialization based on the setting of Integrated Endpoint Register Block (IERB) registers with the exception of the guaranteed hash table entry partition whose allocation is fixed (or "hardwired"). The number of guaranteed hash table entries is indicated in the Guaranteed hash table entry memory capability register (GHTEMCAPR).

- Hash table bucket array partition allocation is set to the value configured in the Hash bucket table memory allocation register (HBTMAR).
- Switch function indexed table partition is set to the value configured in the Switch 0 index table memory allocation register (S0ITMAR).
- Size of each ENETC function indexed table partition is set to the value configured in a corresponding ENETC index table memory allocation register (EaITMAR).
- Shared memory partition is set the total size of the common internal memory (CMCAPR) minus the values in HBTMAR, GHTEMCAPR, S0ITMAR and EaITMAR(s).

The allocation is performed in a contiguous fashion, allocating first the common internal memory for the hash table bucket array partition followed by the guaranteed hash table entry partition, by the switch function indexed table partition and ENETC function indexed table partition(s), with the remaining space allocated to the shared memory partition.

Shared memory partition

The shared memory partition is managed using a single free list of fixed equal size units of memory. The shared memory partition is used for the following storage functions:

- Frame buffering for the switch; this is referred to as the switch shared internal buffer memory
- Receive frame buffering for all ENETC ports; this is referred to as the ENETC receive shared internal buffer memory
- Storage for table lookup entries; allocation/deallocation of those entries to tables is managed by the hardware

An allotment is configured at pre-boot initialization time for each of the above storage functions, by configuring the following IERB registers:

- Switch 0 shared memory buffer allotment register (S0SMBAR) for the switch shared internal buffer memory.

- ENETC receive shared memory buffer allotment register (ERSMBAR) for the ENETC receive shared internal buffer memory.
- Switch 0 hash table memory allotment register (S0HTMAR) for the hash table lookup entries used by the switch.
- ENETC hash table memory allotment register (EaHTMAR) for the hash table lookup entries used by ENETC, where a represents an ENETC function.

The sum of all of individual allotments must not exceed the total size of the shared common memory region minus the amount of memory required by the switch and ENETC functions for buffering frames that haven't been assigned to a specific memory allotment (frames in flight). The latter is referred to as the "unassigned" frame buffering memory (memory acquired but not assigned to a memory allotment). The amount of unassigned buffering memory is determined by adding the following memory amounts (20 bytes of frame buffering per memory word/unit):

- Sum of all physical ports usage (switch and ENETC) for storing frames being received from the MAC but not yet accounted against the switch frame buffering or ENETC frame buffering. For a given port, this amount corresponds to the maximum frame size that can be received from the express MAC plus the maximum frame size that can be received from the preemptable MAC (the later applies only if preemption is enabled/used).
- Sum of all ENETC instances usage for transmit frame buffering. For a given ENETC instance, the recommended amount is 2 times the maximum frame size for the express MAC or the pseudo MAC plus 2 times the maximum frame size for the preemptable MAC (the later applies only if preemption is enabled/used).
- One additional maximum frame size for the switch, as the switch frame buffering usage can go over by one maximum frame size above the amount of the switch buffering memory configured in S0SMBAR.
- 64 memory words/units of 24 bytes for internal hardware usage.

Free memory units from the free list are available to be dynamically allocated to any storage function subject to the allotment constraint of that function.

When the amount of free memory units falls below the threshold indicated in SMDTR[THRESH], a depletion indication is asserted internally, which may trigger "intelligent drop" of frames from the ingress queues in the ENETC Ingress Congestion Manager (ICM).

NETC function partitions

NETC function partitions are used for storing specific switch and ENETC indexed tables. Specifically, there is one partition for the switch function and one partition for each ENETC function, where each partition may hold one or more indexed tables. These tables are implemented as linear arrays of words, stored in contiguous manner, meaning that words are adjacent to one another in memory with no gaps between them. Indexed table entries can occupy one or more words, and within a given table, entries can be either of fixed size or variable size.

In the case of fixed size entries, the table is accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the table. When accessing a table with fixed size entries, the actual memory position of an entry is calculated by hardware by multiplying the entry index by the number of words occupied by an entry, and then adding the result to the base memory address of the table. The base memory addresses of the indexed tables in the common internal memory, are determined by hardware when the sizes of the indexed tables are configured.

In the case of variable size entries, the table is accessed using an index (0, 1, 2, ..., n) expressed in units of words relative to the start of the table, that points to the first word of the entry to be accessed.

Note that not all indexed tables are stored in common memory. Some of the indexed tables are stored in dedicated internal memories, and thus there sizes cannot be changed. Switch and ENETC indexed tables that are stored in the common internal memory are listed respectively in Table 386 and Table 387.

Within each function (switch and ENETC(s)), memory allocation is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers. These allocations can also be changed when the functions are initialized through their respective base function registers. The IERB and function base registers used to configure the size of each indexed table, are shown below.

Table 386. Switch Indexed Tables Allocation Registers

Table Name	IERB Registers	Switch Base Registers
Rate Policer table	S0RPITMAR[NUM_WORDS]	RPITMAR[NUM_WORDS]
Ingress Stream Count table	S0ISCITMAR[NUM_WORDS]	ISCITMAR[NUM_WORDS]
Ingress Stream table	S0ISITMAR[NUM_WORDS]	ISITMAR[NUM_WORDS]
Ingress Sequence Generation table	S0ISQGITMAR[NUM_WORDS]	ISQGITMAR[NUM_WORDS]
Stream Gate Instance table	S0SGIITMAR[NUM_WORDS]	SGIITMAR[NUM_WORDS]
Stream Gate Control List table	S0SGCLITMAR[NUM_WORDS]	SGCLITMAR[NUM_WORDS]
Frame Modification table	S0FMITMAR[NUM_WORDS]	FMITMAR[NUM_WORDS]
Frame Modification Data table	S0FMDITMAR[NUM_WORDS]	FMDITMAR[NUM_WORDS]

Table 387. ENETC Indexed Tables Allocation Registers

Table Name	IERB Registers	ENETC a Base Registers
Rate Policer table	EaRPITMAR[NUM_WORDS]	RPITMAR[NUM_WORDS]
Ingress Stream Count table	EaISCITMAR[NUM_WORDS]	ISCITMAR[NUM_WORDS]
Ingress Stream table	EaISITMAR[NUM_WORDS]	ISITMAR[NUM_WORDS]
Stream Gate Instance table	EaSGIITMAR[NUM_WORDS]	SGIITMAR[NUM_WORDS]
Stream Gate Control List table	EaSGCLITMAR[NUM_WORDS]	SGCLITMAR[NUM_WORDS]

The sum of all of the table sizes within a NETC function must not exceed the size of the NETC function memory partition. Within a function, the memory allocation is performed in a contiguous fashion, assigning in the order listed in the table above; starting first with the Rate Policer table, followed by the Ingress Stream Count table, and so on.

53.4.2.2.6 Time Gate Scheduling Memory

The Time Gate Scheduling internal memory is used to store all of the administrative gate control lists and the operational gate control lists information, for time gate scheduling. The memory is shared between the switch and all of the ENETC instances supporting time gate scheduling. Each gate control list is comprised of a sequence of gate operation entries where each entry occupies one word of memory. The total number of words in the Time Gate Scheduling internal memory is indicated in TGSMCAPR[NUM_WORDS].

The allocation to the switch and the ENETC instances, is based on the setting of the IERB registers S0TGSTAR[NUM_WORDS] and E*a*TGSTAR[NUM_WORDS], respectively. The sum of all of the individual allocations must not exceed the total size of the Time Gate Scheduling internal memory. The values configured in the IERB registers S0TGSTAR[NUM_WORDS] and E*a*TGSTAR[NUM_WORDS], are then reflected in the respective switch and ENETC instance registers TGSTCAPR[NUM_WORDS].

53.4.2.2.7 Ingress Port Filter TCAM

The Ingress Port Filter Ternary-Content-Addressable Memory (TCAM) is used to implement the Ingress Port Filter tables for the switch and for each ENETC instance. The total number of TCAM words/lines available to all NETC functions, is indicated in IPFTCAPR[NUM_WORDS]. Each TCAM word (or line) is 48-bit wide.

The allocation to the switch and the ENETC instances, is based on the setting of the IERB registers S0IPFTMAR[ALLLOC] and E*a*IPFTMAR[ALLOC], respectively. The sum of all of the individual allocations must not exceed the total size of the Ingress Port Filter TCAM. The values configured in the IERB registers S0IPFTMAR[ALLLOC] and E*a*IPFTMAR[ALLOC], are then reflected in the respective switch and ENETC instance registers IPFTCAPR[NUM_WORDS].

53.4.2.2.8 Error Management

NETC supports three different types of errors which are capable of generating an interrupt through a process described in Error Reporting. The following error categories exist:

- Correctable errors

  Correctable errors include those error conditions where hardware can recover without any loss of information. Hardware corrects these errors and software intervention is not required. Examples of correctable errors include:

  — single-bit ECC errors

- Uncorrectable errors.

  Uncorrectable errors may impact the functionality of the interface. Depending on the severity and type of error, software intervention may be required. The detection of an uncorrectable fatal error will result in the device/function entering a safe state, see Error Reaction.

  — Non-fatal errors

    Non-fatal uncorrectable errors can be global or per function. To resume operation software may be required to reconfigure the entire function or part of it. A Function Level Reset (FLR) should not be required to continue operation.

  — Fatal errors

    Fatal uncorrectable errors can be global or per function. When an uncorrectable fatal error occurs it means NETC or a function has been compromised and is unable to perform a hardware task. Examples of this include multi-bit ECC errors in internal memory or other memories where the source cannot be isolated and stop operation (safe state reaction). To resume operation, a soft reset of NETC for global events or an FLR for function level events is required.

53.4.2.2.8.1 Error Reporting

NETC reports errors to the SoC using the INTA pin, see Wired Interrupt. For this to occur the PCIe layer must be properly configured.

Hardware detects an error and reports it directly to a device error register. There may be additional information captured at the device level depending on the error type. Once the device error has been detected it can be reported to the PCIe iEP function's Advanced Error Reporting capability structure. This is done by clearing the associated device Report Disable bit, see Error Detection and Handling for a full description of the involved device registers.

A device error reported to the PCIe function will set either of the bits:

- PCIE_CFC_AER_CORR_ERR_STAT[CORR_INT_ERR]
- PCIE_CFC_AER_UCORR_ERR_STAT[UCORR_INT_ERR]

For INTA to be asserted, the function must report the PCIe error to the Root Complex Event Collector. This is accomplished by clearing the appropriate function mask bit:

- PCIE_CFC_AER_CORR_ERR_MASK[CORR_INT_MASK]=b0
- PCIE_CFC_AER_UCORR_ERR_MASK[UCORR_INT_ERR_MASK]=b0.

It should be noted that the distinction between the fatal and non-fatal (severity) uncorrectable error is defined in the PCIe AER uncorrectable error severity register, PCIE_CFC_AER_UCORR_ERR_SEV[UCORR_INT_SEV]. It cannot be set on a per event basis for a function. Software may have to rely on the device registers to determine what action.

The Event Collector receiving an error from one of the associated functions, as defined by PCIE_CFC_RCEC_EPA_BITMAP[DEV_BITMAP], will set one of the following detect bits:

- PCIE_CFC_AER_ROOT_ERR_STAT[ERR_FATAL]
- PCIE_CFC_AER_ROOT_ERR_STAT[ERR_NON_FATAL]
- PCIE_CFC_AER_ROOT_ERR_STAT[ERR_CORR]

For the Event Collector to assert INTA for a reported error, it must enable the reporting of the error and clear the interrupt disable bit:

- PCIE_CFC_AER_ROOT_ERR_CMD[FATAL_ERR_RPT_EN]=b1
- PCIE_CFC_AER_ROOT_ERR_CMD[NON_FATAL_ERR_RPT_EN]=b1
- PCIE_CFC_AER_ROOT_ERR_CMD[CORR_ERR_RPT_EN]=b1
- PCI_CFH_CMD[INTR_DISABLE]=b0

53.4.2.2.8.2 Error Detection and Handling

The figure below shows a simplified flow diagram to determine which device error registers to read based on what has been reported in the PCIe Event Collector by one or more functions. Here it is assumed that the most critical error is handled first. Omitted from the flow is clearing of errors and repeating the process if additional errors are pending.

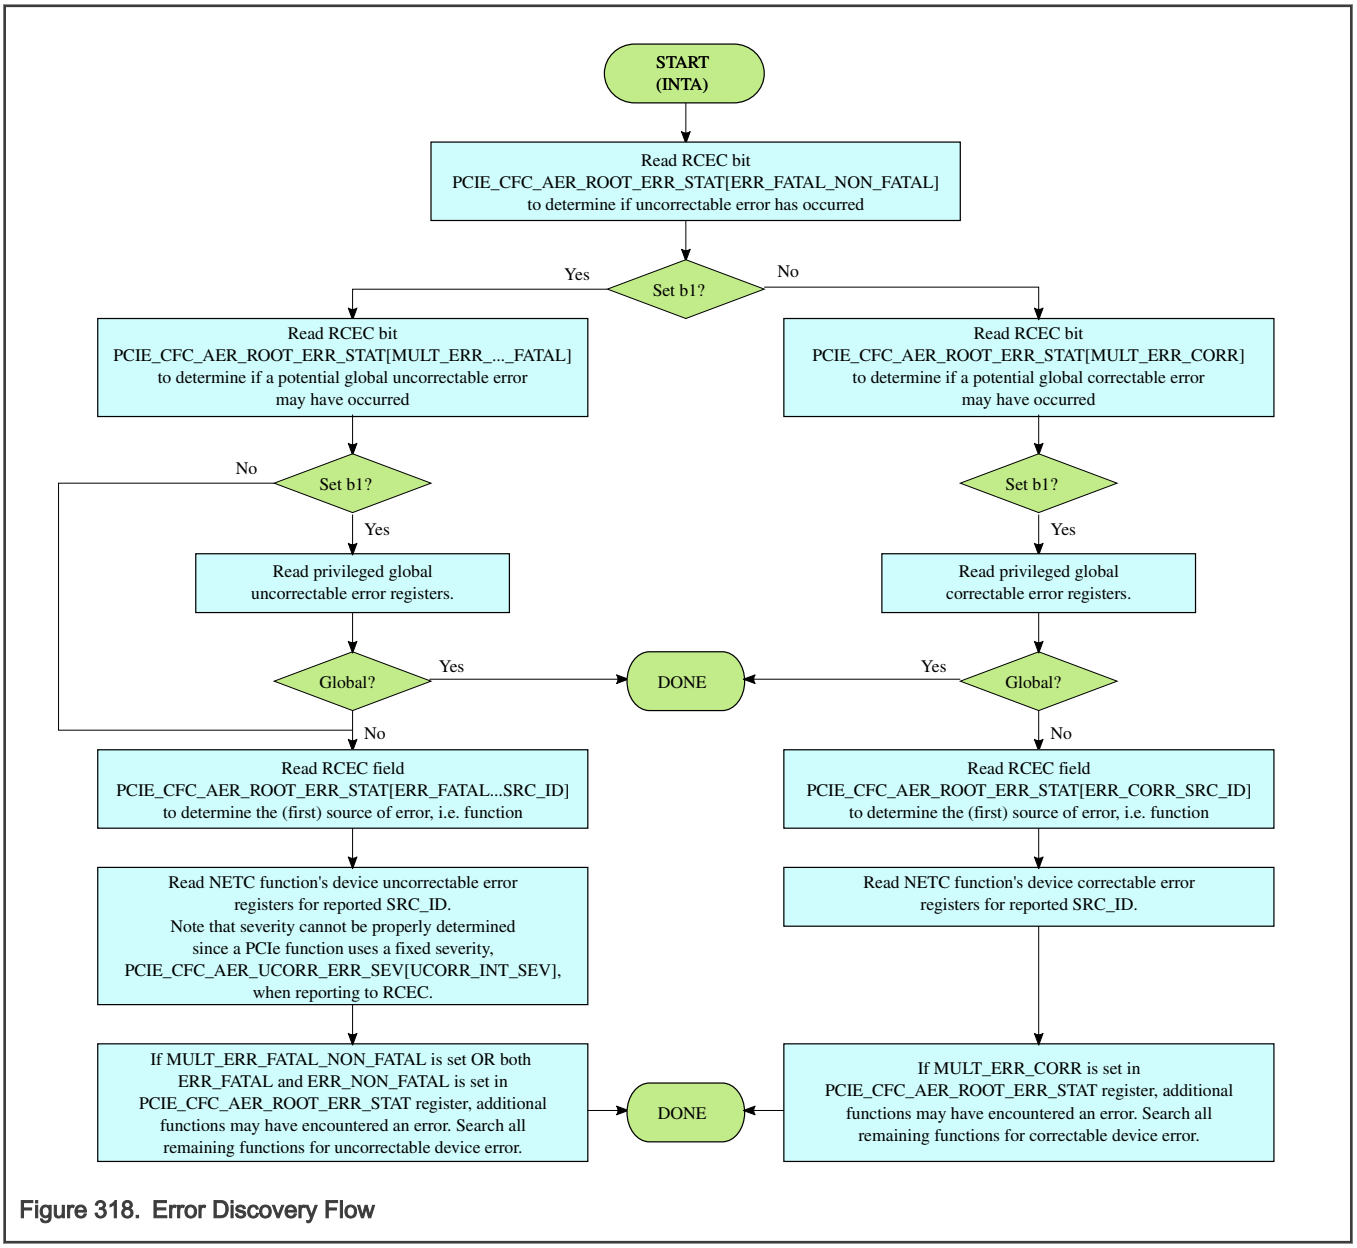

Figure 318. Error Discovery Flow

The tables below describe error handling in more detail; how each error is detected, enabled and where additional error capture information can be found.

Table 388. Uncorrectable Non-Fatal Software Errors

Error Description	Error Handling	
Received frame steered to a disabled station interface.	**Device Error Detect**[1]	SIUPESR[PE], SIUPESR[DROP_SI_EN]
	PCIe Error Report Disable	SIUPECR[RD]
	Error Capture[2]	SIUPESR[M] , SIUPECTR[COUNT]
	Target Function(s)	ENETC PF (SI0), ENETC VF (SI1+)
	Comments Programming error. The station interface is not enabled. The frame has been dropped.	
Received frame steered to a BD ring which has not been enabled by the SI.	**Device Error Detect**[1]	SIUPESR[PE], SIUPESR[DROP_RING_EN]
	PCIe Error Report Disable	SIUPECR[RD]
	Error Capture[2]	SIUPESR[M], SIUPECTR[COUNT]
	Target Function(s)	ENETC PF (SI0), ENETC VF (SI1+)
	Comments Programming error. The default receive BD ring 0 is not enabled or a ring is targeted by RFS/RSS that has not been enabled. The frame has been dropped and counted.	
Receive frame steered to a non existing ring (within a group) that results in a ring number outside the total number of rings assigned.	**Device Error Detect**[1]	SIUPESR[PE], SIUPESR[DROP_RING_SEL]
	PCIe Error Report Disable	SIUPECR[RD]
	Error Capture[2]	SIUPESR[M], SIUPECTR[COUNT]
	Target Function(s)	ENETC PF (SI0), ENETC VF (SI1+)
	Comments Programming error. If a selected BD ring is outside the range of rings assigned for a group, a ring for a higher numbered group may be selected and no error reported. In the case the ring (number) selected exceeds the total number of rings assigned to the SI, an error will occur. The frame has been dropped and counted.	
Illegal receive BD ring mapping (e.g. IPV to BDR, RFS BD ring selection out of range, no receive rings mapped).	**Device Error Detect**[1]	SIUPESR[PE], SIUPESR[DROP_RING_SEL]
	PCIe Error Enable/Disable	SIUPECR[RD]
	Error Capture[2]	SIUPESR[M], SIUPECTR[COUNT]
	Target Function(s)	ENETC PF (SI0), ENETC VF (SI1+)
	Comments Programming error. There is an illegal mapping from Internal Priority Value to BD ring number. The BD ring number exceeds the assigned number of rings for the station interface. The frame has been dropped and counted.	
Switch / ENETC misconfiguration.	**Device Error Detect**[1]	n/a
	PCIe Error Enable/Disable	n/a

Table continues on the next page...

Table 388. Uncorrectable Non-Fatal Software Errors (continued)

Error Description	Error Handling	
	Error Capture[2]	ENETC: PRXDCRR0[ITEDR] Switch: PRXDCRR0[ITEDR/FMMEDR], PTXDCRR0[ITEDR/FMMDR]
	Target Function(s)	Switch, ENETC
	Comments These Switch and ENETC programming errors do not have the capability to generate interrupt or faults to the FCCU. Software must read these bits to check the configuration for correctness.	

Table 389. Correctable Hardware Errors

Error Description	Error Handling	
Internal memory single bit ECC error	**Device Error Detect**[1]	Switch/ENETC: CMESR[SBEE] SI: SICMESR[SBEE] Global: CMESR[SBEE]
	PCIe Error Report Disable/Threshold	Switch/ENETC: CMECR[THRESHOLD] SI: SICMECR[THRESHOLD] Global: CMECR[THRESHOLD]
	Error Capture[2]	Switch/ENETC: CMESR[MEM_ID] SI: SICMESR[MEM_ID] Global: CMESR[MEM_ID]
	Target Function(s)	Switch, ENETC, ENETC PF (SI0), ENETC VF (SI1+), Global
	Comments Single bit ECC errors are flagged internally by NETC and are detected at a function or global level, see Table 392. This type of error is correctable by hardware.	

Table 390. Uncorrectable Non-Fatal Hardware Errors

Error Description	Error Handling	
Switch system bus error.	**Device Error Detect**[1]	UNSBESR[SBE], CBDR*a*SR[SBE]
	PCIe Error Report Disable	UNSBECR[THRESHOLD]
	Error Capture[2]	UNSBESR[SB_ID], UNSBECTR[COUNT]
	Target Function(s)	Switch
	Comments See Table 394 for more information.	
ENETC station interface receive system bus error.	**Device Error Detect**[1]	SIUNSBESR[SBE], RB*a*SR[SBE]

Table continues on the next page...

Table 390. Uncorrectable Non-Fatal Hardware Errors (continued)

Error Description	Error Handling	
	PCIe Error Report Disable	SIUNSBECR[THRESHOLD]
	Error Capture[2]	SIUNSBESR[SB_ID], SIUNSBECTR[COUNT]
	Target Function(s)	ENETC PF (SI0), VF (SI1+)
	Comments See Table 394 for more information.	
ENETC station interface transmit system bus error.	**Device Error Detect**[1]	SIUNSBESR[SBE], TB*a*SR[SBE]
	PCIe Error Report Disable	SIUNSBECR[THRESHOLD]
	Error Capture[2]	SIUNSBESR[SB_ID], SIUNSBECTR[COUNT], TB*a*CIR[BDR_INDEX]
	Target Function(s)	ENETC PF (SI0), VF (SI1+)
	Comments See Table 394 for more information.	
Ethernet MAC error.	**Device Error Detect**[1]	UNMACESR[PORT*n*], PM*a*_IEVENT[LOC_FAULT, REM_FAULT, LI_FAULT, TX_OVFL, TX_UNFL, RX_OVFL, MGR_SERR, MGR_AERR]

Table 394. System Bus ID (SB_ID)

Source ID	Agent	Scope and Severity	Description
0	Prefetcher (SI)	Function Fatal	A system bus error occurred during prefetch of a receive BD for the station interface. Frame BD prefetching for the station interface ring is stalled. The frame BD producer index will indicate the last successfully updated BD. Function reset is required.
1	Prefetcher (SI)	Function Fatal	A system bus error occurred during prefetch of a transmit BD for the station interface. Frame BD prefetching for the station interface ring is stalled. The frame BD producer index will indicate the last successfully updated BD. Function reset is required.
2	Prefetcher (SI)	Function Fatal	A system bus error occurred during prefetch of a command BD for the station interface. All command BD prefetching for the station interface is stalled. Function reset is required.
3	HTA receive/ transmit	Function Non-Fatal	A system bus error occurred during a data access (read or write) as a result of processing a command BD for the station interface. Ring writeback status code indicates the nature of the error. Software should clear the error detect events from the relevant error status register (e.g. SIUNSBESR) prior to re-using the command BD ring.
4	HTA receive/ transmit	Function Non-Fatal	A system bus error occurred while writing status information to command BD in memory. The RR bit in the response message indicates the presence of a response command BD entry in the ring. Software should disable the ring and clear the error detect events from the relevant error status register (e.g. SIUNSBESR) prior to re-enabling the command BD ring. This error is primarily useful as a debug aid when the location provided to NETC for the command BD ring is not writeable by the HTA; i.e. expected responses are not received in the ring.
5	HTA receive	Function Non-Fatal	A system bus error occurred while writing status information to receive frame BD in memory. Frame BD prefetching for the station interface ring is stalled until the BD ring is re-enabled. The ring producer index and R bit in the receive writeback BD indicate the presence of a writeback response. RBSR[SBE] is also set and identifies the affected ring. Software should disable the ring and clear the error detect events from the relevant error status register (e.g. SIUNSBESR) prior to re-enabling the BD ring. This error is primarily useful as a debug aid when the location provided to NETC for the receive BD ring is not writeable by the HTA; i.e. expected responses are not received in the ring. This code is returned for the first BD of a frame only. Due to transaction pipelining, write errors on accesses to non-first BDs within a multiple-BD frame are reported as Source ID 6.
6	HTA receive	Function Non-Fatal	A system bus error occurred while writing receive frame data in memory. Frame BD prefetching for the station interface ring will be stalled until the BD ring is re-enabled. RBSR[SBE] is set and identifies the affected ring. The frame BD ring producer index will indicate the last successfully updated BD. BD status code indicates the affected entry. Data for the affected frame is not reliable. Software should disable the ring and clear the error detect events from the relevant error status register (e.g. SIUNSBESR) prior to re-enabling the BD ring. Due to transaction pipelining, write errors on accesses to non-first BDs within a multiple-BD frame will also be reported as Source ID 6.
7	HTA receive	Function Fatal	A system bus error occurred while processing the VSI to PSI message partition copy. The message failed and must be retried by the virtual station interface. Function reset is required.

Table continues on the next page...

Table 394. System Bus ID (SB_ID) (continued)

Source ID	Agent	Scope and Severity	Description
8	HTA transmit	Function Non-Fatal	A system bus error occurred while writing status information to transmit frame BD in memory. The ring consumer index and W bit in the transmit writeback BD indicate the presence of a writeback response. TBSR[SBE] is set and identifies the affected ring. Software should disable the ring and clear the error detect events from the relevant error status register (e.g. SIUNSBESR) prior to re-enabling the BD ring. This error is primarily useful as a debug aid when the location provided to NETC for the transmit BD ring is not writeable by the HTA; i.e. expected responses are not received in the ring.
9	HTA transmit	Function Non-Fatal	A system bus error occurred while reading frame data from memory. Current frame was not transmitted, BD writeback status code identifies the affected frame. TBSR[SBE] is set and identifies the affected ring.
10	Prefetcher (Switch)	Function Fatal	A system bus error occurred during prefetch of a command BD for the switch. All command BD prefetching for the switch is stalled. Function reset is required.
11	Switch	Function Non-Fatal	A system bus error occurred during a data access (read or write) as a result of processing a command/query BD for the switch. Ring writeback status code indicates the nature of the error. Software should clear the error detect events from the relevant error status register (e.g. SIUNSBESR) prior to re-using the command BD ring.
12	Switch	Function Non-Fatal	A system bus error occurred while writing status information to command BD in memory. The RR bit in the response message indicates the presence of a response command BD entry in the ring. Software should disable the ring and clear the error detect events from the relevant error status register (e.g. SIUNSBESR) prior to re-enabling the command BD ring. This error is primarily useful as a debug aid when the location provided to NETC for the command BD ring is not writeable by the Switch; i.e. expected responses are not received in the ring.
13	MSI-X	Function Fatal	A system bus error occurred while writing message signaled interrupt to interrupt controller. Messaged failed to be delivered and interrupt is lost. Function reset is not required, but MSI-X table address(es) may have to be reconfigured.

53.4.2.2.8.3 Error Reaction

Following are the possible error reactions in NETC:

- Correctable errors (ECC) will correct any single event, count the event, and continue processing normally on all functions.
- Uncorrectable non-fatal errors on a frame context will cause the frame to be discarded or aborted (cut-through) and an event count to be updated. Processing continues normally on all functions.
- Uncorrectable fatal errors in a specific function (timer, EMDIO, ENETC, switch) will cause that function to stop processing. The function itself will be disabled, while processing continues normally on all other functions.
  - **Timer fault**
    - PCIe bus master enabled cleared (PCIe PCI_CFH_CMD[BUS_MASTER_EN]=0b) for the PCIe function.
  - **EMDIO fault**
    - PCIe bus master enabled cleared (PCIe PCI_CFH_CMD[BUS_MASTER_EN]=0b) for the PCIe function.
  - **Switch fault**
    - PCIe bus master enabled cleared (PCIe PCI_CFH_CMD[BUS_MASTER_EN]=0b) for the PCIe function.

- Ethernet MAC ports disabled (PM0_COMMAND_CONFIG[RX_EN/TX_EN]=0b).
- Pseudo MAC ports disabled (POR[TXDIS/RXDIS]=1b).

— **ENETC/PSI fault**

- PCIe bus master enabled cleared (PCIe PCI_CFH_CMD[BUS_MASTER_EN]=0b) for the PCIe function. All VSIs bound to the instance are also affected in the same way.
- PSI disabled (SIMR[EN]=0b). All VSIs bound to the instance are also affected in the same way.
- Ethernet/Pseudo MAC port disabled (PM0_COMMAND_CONFIG[RX_EN/TX_EN]=0b / POR[TXDIS/RXDIS]=1b).

— **VSI fault**

- PCIe bus master enabled cleared (PCIe PCI_CFH_CMD[BUS_MASTER_EN]=0b) for the PCIe function.
- VSI disabled (SIMR[EN]=0b).

- Global uncorrectable non-fatal error is most commonly reported by a service block (e.g. Multi-target Arbiter, AXI resources, Prefetcher). These service blocks may return an error indication back to the client who has issued the command, so the client may enter the appropriate safe state. See the description of the safety mechanism for more information. NETC processing continues without interruption.
- Global uncorrectable fatal error on a common structure will cause NETC processing to stop, and all of the NETC functions to enter safe state as described above for each individual function. Processing will come to a stop implying that the error does not get propagated, that processing thread stops in its tracks, but other threads may limp along if not negatively hindered. The disabling of functions will ensure this skid comes to a full stop.

Software must monitor the single bit error recoverable error counts or frame discards/bad frames due to error counts in order to detect errors of a more permanent nature.

53.4.2.2.9 Address Alignment

NETC supports byte alignment for transmit buffer descriptor addresses and 64B alignment for receive buffer descriptor addresses. Transmit and receive buffer descriptor rings need to be 128B aligned. PSI-VSI messages needs to be 64B aligned. Data buffers and messages that cross a 4KB page boundaries may incur a small performance penalty. Apart from these restrictions it is generally recommended to align buffers to 64B whenever possible, to improve performance.

The receive ring mode register, RB*a*MR, provides an additional field for alignment of the frame header in the 1st frame descriptor buffer.

- Setting RB*a*MR[AL]=1 allows for a +2B data (0s) alignment which is written by NETC

The last buffer used will align the tail end of data written to a 64B alignment. The figure below shows the alignment of a frame using the settings described above. Included is an example of how a 60B frame can be made into an optimal 64B aligned data transfer to memory.

NOTE

Additional data written for alignment or extension to optimize the memory write to 64B should not be assumed to be 0 or any other value.

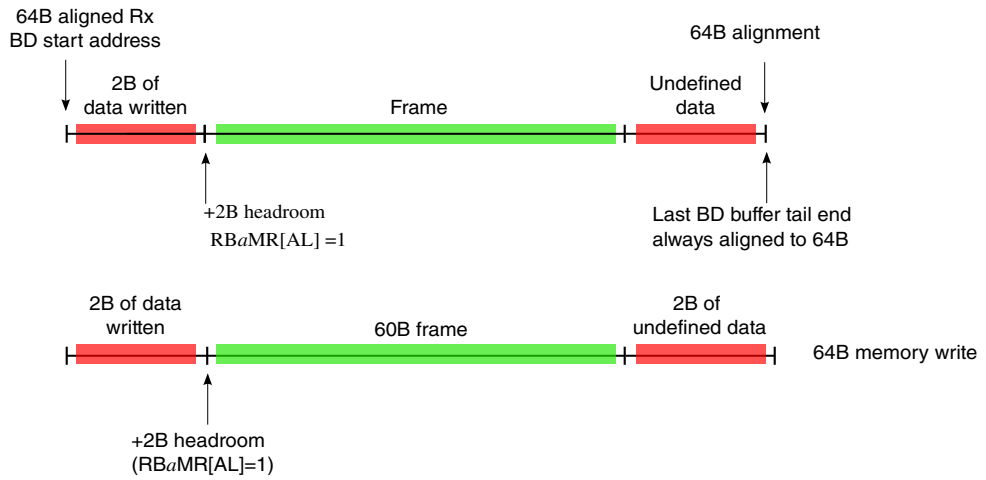

Figure 319. Frame alignment in receive buffer

53.4.2.3 ENETC

53.4.2.3.1 ENETC Datapath

The ENETC datapath consists of the receive datapath blocks, the transmit datapath blocks and a shared internal buffer memory used for internal receive and transmit frame buffering.

Figure 320 shows the functional block diagram of an externally accessible ENETC port (stand-alone ENETC) configuration.

When NETC includes the switch function, ENETC connects to the switch without the need of a back-to-back MAC connection. Instead a light weight back-to-back "pseudo MAC connection" provides the delineation between the switch and ENETC. The back-to-back connection is referred to as a pseudo link. Only frame descriptors are transferred across a pseudo link, resulting in no serialization delay. There is no need to store or copy frames received on a pseudo MAC as they have already been stored in the shared internal buffer memory by the switch. Similarly, there is no need to retrieve or copy frames when sending frames to pseudo MAC. Figure 321 shows the functional block diagram of an ENETC port connected internally to the switch.

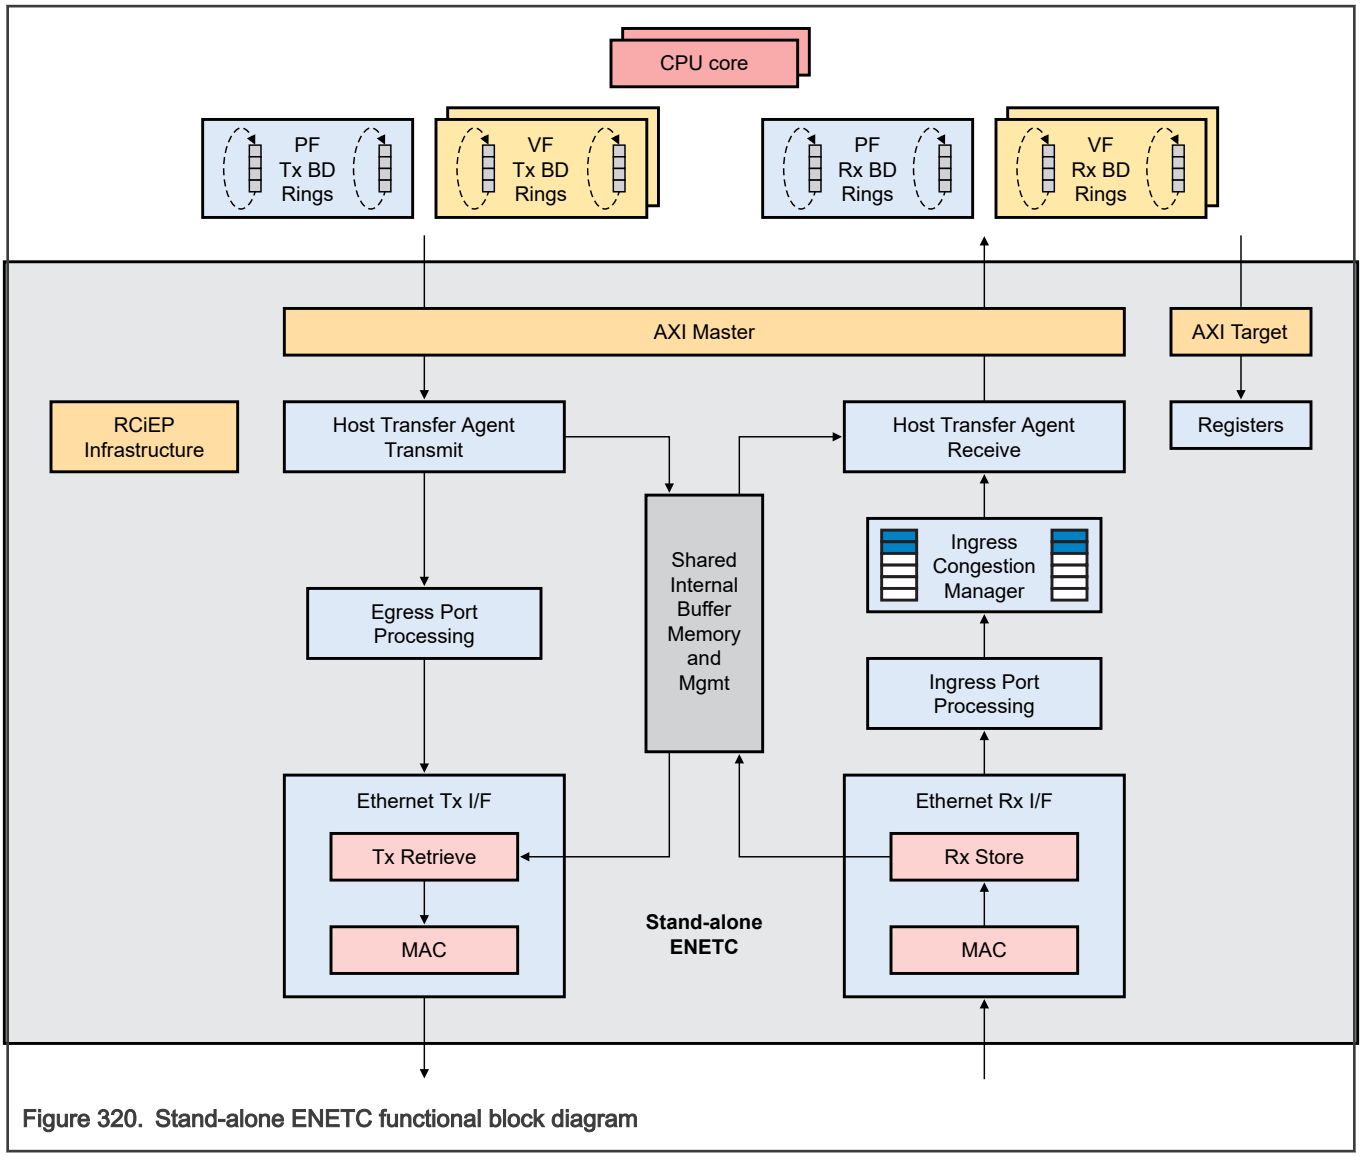

Figure 320. Stand-alone ENETC functional block diagram

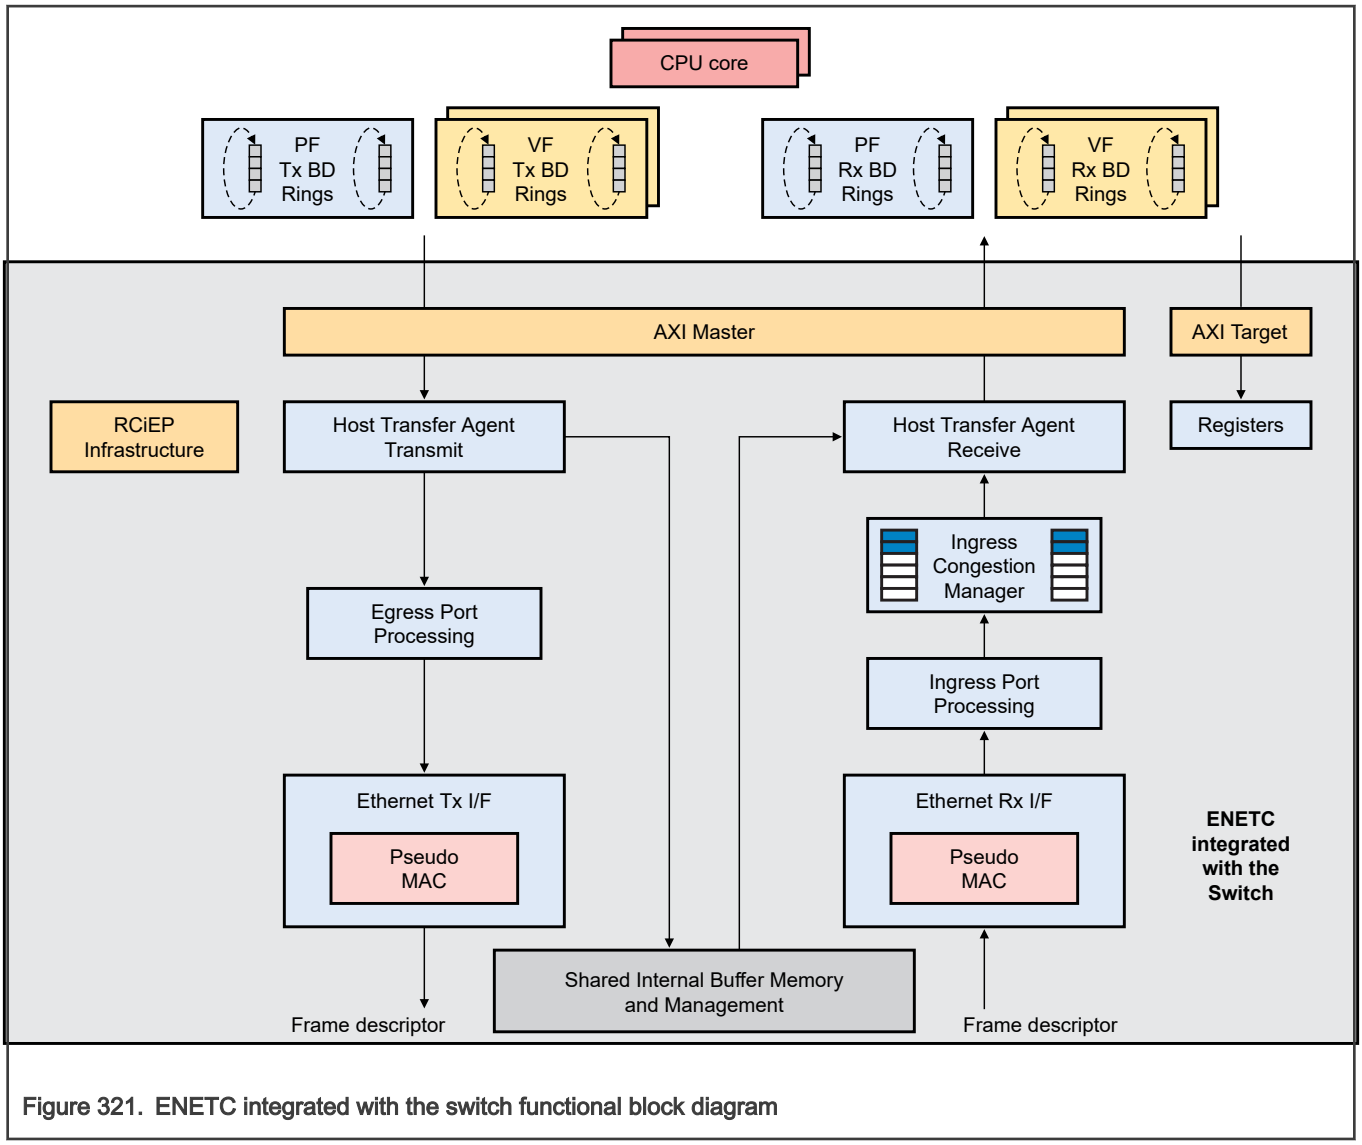

Figure 321. ENETC integrated with the switch functional block diagram

The receive datapath is implemented as a series of functional processing blocks pipelined together. This includes the Ethernet Rx I/F, Ingress Port Processing, Ingress Congestion Manager and the Host Transfer Agent (Receive).

The Ingress Port Processing block implements the ingress parsing, classification (ingress table lookups) and policing functions.

The Ingress Congestion Manager is responsible for implementing the ingress congestion management policies (e.g. drop decisions or back-pressure) when received frames are starting to consume too much of the shared internal buffer memory as a result of downstream resources congestion; e.g. system memory access congestion at the Host Transfer Agent when transferring a frame to the host.

The Host Transfer Agent (receive) implements the receive interface functionality to the host. It includes the necessary DMA engines to efficiently transfer frames from the shared internal buffer memory to host system memory. It also provides multi-receive BD rings support towards the host, for load spreading, virtualization support and QoS.

The transmit datapath is implemented as a series of functional processing blocks pipelined together. This includes the Host Transfer Agent (transmit), Egress Port Processing, and Ethernet Tx I/F.

The Host Transfer Agent (transmit) implements the transmit interface functionality from the host. This includes determining which frame (transmit buffer descriptor(s)) from the transmit BD rings assigned to a port to send next when bandwidth on the outgoing port is available. Once a frame has been selected for transmission, it is loaded from the host system memory into the shared internal buffer memory. The device transmits the frame only after it has completely loaded all frame data from host memory and has performed the required header modifications (i.e. insertion of up to 2 VLAN tags). Note that there is no memory copy when

transferring a frame across a pseudo link (ENETC port connected internally to the switch). Instead a frame descriptor (which includes a pointer to the frame), is passed to the other end of the link (i.e. in this case the switch) when sending a frame across a pseudo link.

The Egress Port Processing block implements the internal transmit queues. The internal transmit queues are used as short staging queues to provide a place to hold frames ready to be transmitted.

ENETC supports multiple Station Interfaces (SIs) for PCIe SR-IOV support (I/O isolation/virtualization) where each SI can be assigned a programmable number of transmit and receive buffer descriptor rings (BD Rings). The SI 0 interface is called the Physical Station Interface (PSI), while SI 1, 2, ...n interface is called Virtual Station Interface n (VSIn). A PSI per port is always present. VSIs are present only if I/O virtualization is supported on the port. A PSI is mapped to a PCIe SR-IOV Physical Function (PF) whereby a VSI is mapped to a PCIe SR-IOV Virtual Function (VF).

A single 64-bit ACE-Lite compliant master interface is used is to move data between ENETC and host system memory. The maximum number of bytes to transfer in a read transaction and an in a write transaction is user configurable. See register SBCR, for more details.

53.4.2.3.1.1 Shared Internal Buffer Memory

As frames are received from the Ethernet MACs, they are stored immediately in the shared internal buffer memory, and remain stored in this memory as they move through the ENETC receive frame processing pipeline up to the point where frames are ready to be transferred into receive data buffers in the host system memory. For frames received from the pseudo MACs, they are already stored in the shared internal buffer memory by the switch and remain stored in the same memory location as they move through the ENETC receive frame processing pipeline; there is no memory copy when receiving a frame from a pseudo MAC. When received on ENETC, non-replicated frames are no longer accounted against switch shared internal buffer memory allotment (and buffer pool), instead their usage then gets accounted against the ENETC receive shared internal buffer memory allotment. For replicated frames, they remain accounted in the switch shared internal buffer memory allotment till the last copy of the frame is transmitted out the switch. There may be frame copies still in ENETC at that point, in which case the buffers of those frames are still in use and still accounted in ENETC (and thus not released), but these buffers are no longer accounted in the switch (buffer pool and switch shared internal buffer memory allotment). Note that from an ENETC congestion management accounting perspective, each replicated frame received from the switch (pseudo MAC), is considered as a separate frame, meaning that the amount of ENETC buffering consumed by each frame reference is equivalent to hold the entire frame.

For transmit frame buffering, a port-per-HTA Transmit priority (2 priorities) byte credit-based flow control mechanism is used to control the amount of internal memory used for transmit buffering. There is a separate byte credit count maintained for each of the two priority tiers within a given port. The ENETC *a* transmit high priority tier byte credit register (E*a*TXHPTBCR) is used to configure the maximum number of byte credits for the high priority tier whereby the ENETC *a* transmit low priority tier byte credit register (E*a*TXLPTBCR) is used to configure the maximum number of byte credits for the low priority tier. Here, *a* indicates the ENETC instance number. The high priority tier is used for traffic directed to the express MAC or pseudo MAC. The low priority tier only applies when IEEE 802.1Qbu frame preemption is enabled, and specifically used for traffic directed to the preemptable MAC. For more details on frame preemption, see Preemption. Note that there are no frame drops when credits are exhausted, instead back-pressure is applied by stopping scheduling host transmit frames.

Once a transmit BD ring is selected for transmission, the frame at the head of the transmit BD ring is loaded from the host system memory into the shared internal buffer memory, and the frame remains stored in the internal memory until it has been transmitted to the Ethernet MAC. For ENETC ports connected internally to the switch, the frame continues to remain in the same memory location as it is transferred to the switch across the pseudo link. Once the frame is received by the switch, its frame buffer usage gets accounted against the switch shared internal buffer memory allotment.

The ENETC shared internal buffer memory partitioning is shown in the following figure:

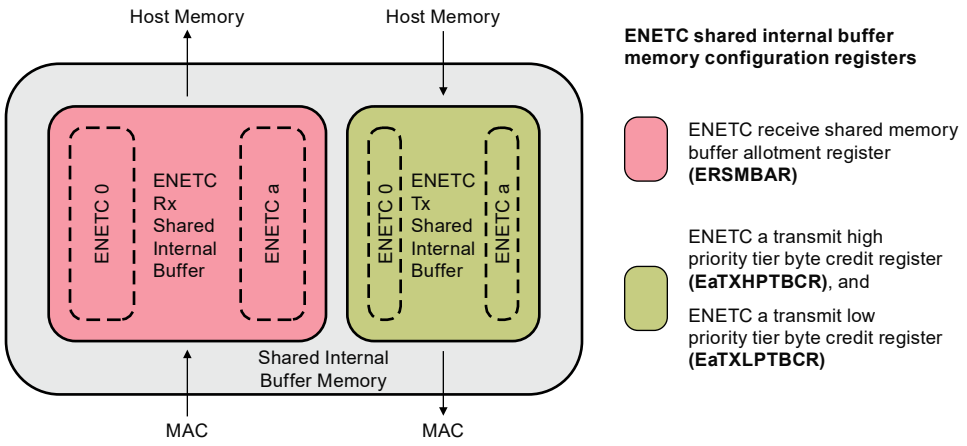

Figure 322. ENETC shared internal buffer memory

53.4.2.3.1.2 Transmit Datapath

The transmit datapath is implemented as a series of functional processing blocks pipelined together. This includes the Host Transfer Agent (transmit), Egress Port Processing, and Ethernet Tx I/F. Details of these functional blocks are given in the following sections.

53.4.2.3.1.2.1 Host Transfer Agent Transmit

The figure below shows the processing through the Host Transfer Agent Transmit.

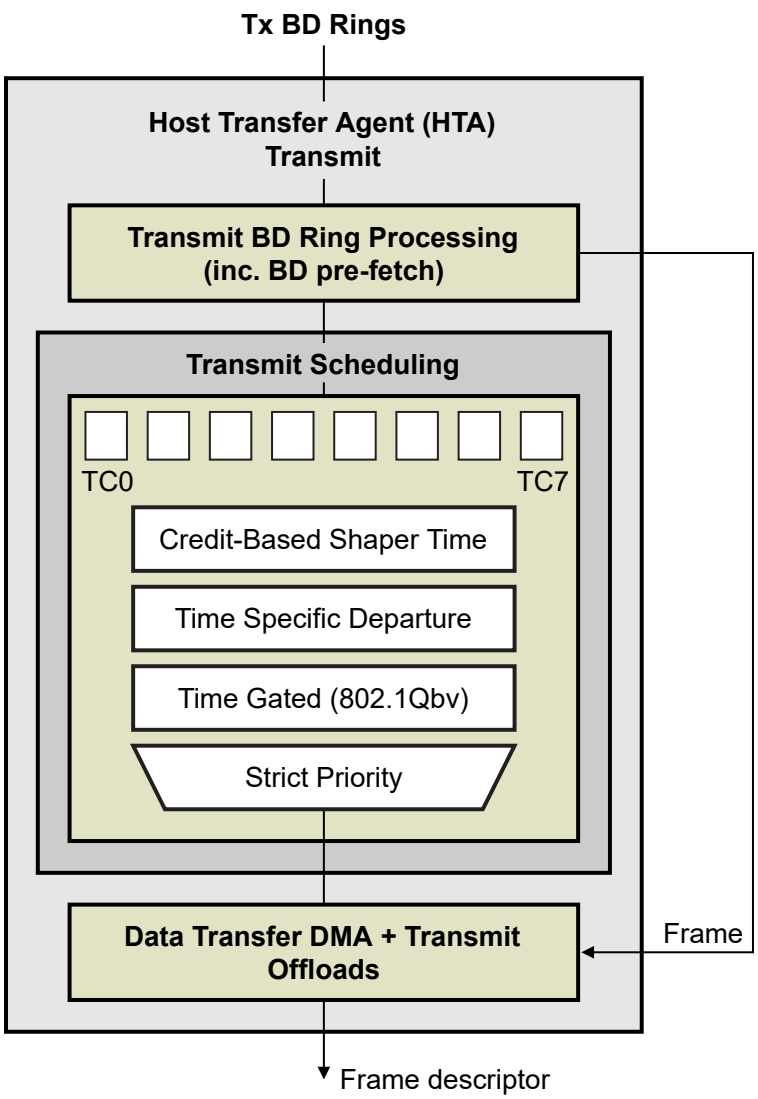

Figure 323. Host Transfer Agent Transmit processing diagram

The Host Transfer Agent (HTA) Transmit block implements the transmit interface functionality from the host. This includes selecting a transmit BD ring from which a frame (transmit buffer descriptor(s)) is to be transmitted when bandwidth on the outgoing port is available. Once a transmit BD ring has been selected, the frame from the head of this transmit BD ring is loaded from the host system memory into the shared internal buffer memory, which in turn serves as a staging memory for getting the frame ready for transmission to the outgoing port.

A Station Interface (SI) will normally be assigned one or more transmit buffer descriptor rings (BDRs) during initialization, these will be numbered 0, 1, 2, …, n, in the SI address map.

The number of transmit rings used per SI depends on the priorities and number of cores that need to be supported. It is allowed to have multiple transmit rings with the same priority if for example an SI services multiple cores. Same priority rings may have different weights.

53.4.2.3.1.2.1.1 Transmit Buffer Descriptor Rings

A Station Interface (SI) will normally be assigned one or more transmit buffer descriptor rings (BDRs) during configuration, see PSI*a*CFGR0[NUM_TX_BDR], these will be numbered 0-*n* in the SI address map. When the SI has been assigned transmit rings, each ring is configured as follows:

1. Configure the transmit ring base address registers TB*a*BAR0/1. The address must be 128 byte aligned.

2. Configure the transmit ring producer index register TB*a*PIR. Software should initialize the index value at this address to 0 to reflect an empty ring. Optionally if the ring is pre-initialized with BDs the index values should reflect the number of BDs added.
3. Configure the transmit ring consumer index register TB*a*CIR. This index value indicates the next BD to be processed by HTA Transmit. When the ring is re-initialized this register should be set to 0. The consumer index is later updated by HTA Transmit during processing of the ring.
4. Configure the transmit ring size TB*a*LENR[LENGTH] to indicate how many 16B entries, are allowed in the ring. Note that when the BD extension bit is set (BD[E]=1), each frame uses two or more entries in the ring. There is no wrap bit to indicate full/empty; one entry is used to differentiate between full and empty. When producer index + 1 equals consumer index, the ring is considered full. When the producer/consumer indices match, the ring is always considered empty.
5. Configure the priority value of a transmit ring via the register TB*a*MR[PRIO]. Also configure the mapping of priority value to traffic class. PRIO2TCMR0 register is used to define the mapping of internal priority value to traffic class. Register PSI*a*CFGR1 (where *a* is the VSI number) is used to remap a VSI traffic class to a different transmit traffic class to restrict use.
6. For an ENETC port connected internally to a switch port, designated as a switch management port, there is the option to direct a frame out a specific switch egress queue. To support this option, a dedicated transmit BD ring must be used, and all frames put on that transmit BD ring will be directed to the specified switch egress queue, subject to the switch egress congestion management policy (possibility of having frames dropped if the egress queue is congested). Only SI 0 can make use of this option, with transmit BD ring number 0 permanently assigned to support this option. This transmit BD ring will not be assigned to a traffic class, meaning that this transmit BD ring will not be considered by the HTA transmit scheduling mechanism. For each frame put on this transmit BD ring, its transmit buffer descriptor (BD) must have the FLQ field set to 10b and the SMSO field set to 1. The output switch port and IPV need also to be specified (in the transmit BD) in order for the switch to derive the switch egress queue. The DR needs also to be specified (in the transmit BD) for congestion management handling within the switch. The switch buffer pool ID will be derived by the switch using the IPV and the switch port number to which the ENETC is internally connected. If the frame is enqueued successfully onto the switch egress queue, hardware may write back a timestamp identifier in the metadata of the transmit buffer descriptor if the transmission time of the frame on the switch port has been requested to be returned to the host. If the frame enqueue is rejected by the switch (due to congestion), an error is reported in the transmit buffer descriptor, indicating that frame wasn't transmitted out the specified switch egress queue due to congestion.
7. Enable the transmit ring TB*a*MR[EN]=1.

53.4.2.3.1.2.1.1.1 Operation of the Transmit Buffer Descriptor Ring

To add one or more buffer descriptors to an enabled transmit ring, follow the procedure below.

1. Software checks to make sure the ring is not full by examining the consumer index (CI) register, TB*a*CIR. Note that maximum number of BDs allowed on a ring is one less than ring size.
2. Software adds one or more BDs to the ring. A memory barrier must be used to guarantee update to memory. If software requires an interrupt when a BD has been transmitted, set BD[FI]=1 and enable the interrupt through TB*a*IER[TXFIE]
3. Software updates producer index register TB*a*PIR to match number of BDs added to the ring. The size of the BD ring index depends on the BD ring size. For 64K-1 entries a 16-bit index value is used.
4. When TB*a*CIR[BDR_INDEX] match TB*a*PIR[BDR_INDEX], the ring is empty. After one or more BDs have been transmitted, the consumer index will be updated by HTA Transmit. The status information is updated in memory for each transmitted BD if required, e.g. timestamp or error information. TB*a*CIR[STAT_ID] is incremented by HTA Transmit if one or more transmitted BDs encountered an error in the last batch of BDs processed. Reading TB*a*CIR[STAT_ID] will reset the field to 0. If software reads a non-zero value for TB*a*CIR[STAT_ID], errors were encountered in the last batch of processed BDs, which can be useful to avoid memory reads with the intent to only examine the status of the transfer.

Table 395. Consumer Index Register (TB*a*CIR)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
STAT_ID																BDR_INDEX															

5. After one or more BDs have been transmitted, the consumer index as defined by registers TB*a*CIR, will be updated by the device.
    a. Status information is updated in memory for each transmitted BD if required, e.g. timestamp or error information.

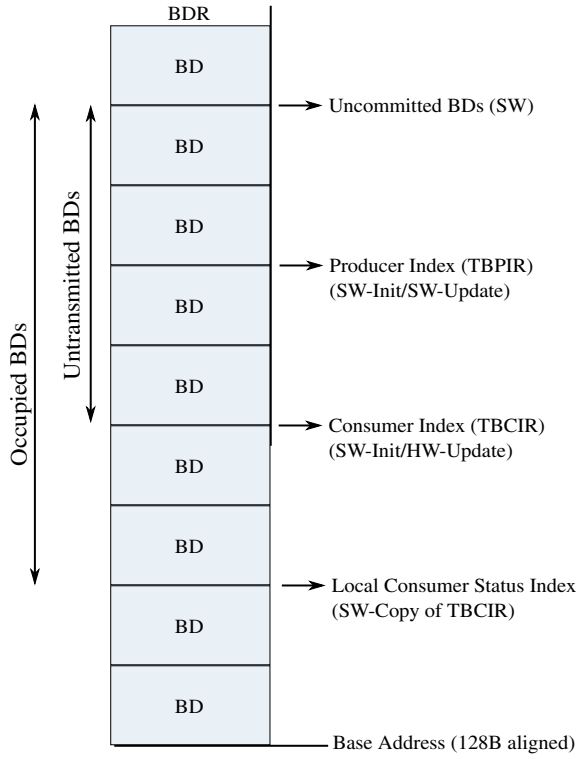

Figure 324. BDR Transmit Components

53.4.2.3.1.2.1.1.2 Transmit Buffer Descriptor Fetching

A pre-fetch mechanism is used to load buffer descriptors from the transmit BD rings in host memory (e.g. DDR) to a cache internal to the pre-fetcher. As BDs are loaded into the internal memory, they are put onto an internal BD queue that is associated with the transmit BD ring from which the BDs were fetched. There is one queue for each possible transmit BD ring. Each internal BD queue can hold up to 8 transmit BDs. When an internal BD queue has 3 or less transmit BDs, a fetch is initiated as soon as there are any transmit BDs ready for transmission in the corresponding transmit BD ring. When an internal BD queue has 4 transmit BDs, the pre-fetch mechanism waits until there are at least 4 transmit BDs in the corresponding transmit ring before loading the next BDs. This results in fetching BDs aligned on a cache line boundary. Transmit BD ring selection for the purpose of fetching BDs is performed in a round robin manner. The BD transfers have higher priority than the frame data transfers on the system memory interface.

53.4.2.3.1.2.1.1.2 Transmit Scheduling

Traffic can be prioritized into a number of traffic classes (up to a maximum of 8). The number of available traffic classes is SoC specific, see Capability Discovery. Traffic classes are numbered from zero to N-1, where N is the number of traffic classes. Numerically higher traffic classes have higher priority. Each transmit buffer descriptor ring (BDR) is assigned a priority, which maps to one of the available traffic classes using register PRIO2TCMR0.

The PSI has the option to remap a VSI traffic class to another traffic class for transmission using register PSI*a*CFGR1 (for a = 1 to 2). This could be a case of restricting the use of certain traffic classes.

As a result, a traffic class may have multiple transmit BD rings assigned to it, where each transmit BD ring either attached to the same SI or different SIs.

Transmit scheduling refers to the procedures used to determine from which of the transmit BD rings assigned to a port to send next when an outgoing port is free.

Each port contains a 3-level hierarchical scheduler.

At the root node (port level), the scheduler selects traffic based on traffic classes according to the following scheduling algorithms:

- Time specific departure (TSD) - Enables the user to specify the time when a frame is to be transmitted. When this capability is enabled, the port will delay the transmission of the frame so that it can be transmitted at the precisely specified time.
- IEEE 802.1Qav - Credit-based shaping (CBS), also referred to as Forwarding and Queueing Enhancements for Time Sensitive Streams (FQTSS). A maximum of 7 traffic classes is supported with credit-based shaping (CBS) enabled. CBS should be enabled on numerically highest traffic class(es).
- IEEE 802.1Qbv - Enhancements for Scheduled Traffic (EST), provides time "slots" for specific classes of traffic in a manner similar to time division multiplexing. EST is also referred in the document as to 'time gate scheduling'.
- Strict priority - Strict priority scheduling amongst eligible traffic classes; i.e. traffic classes with one or more frames available for transmission.

The above algorithms/mechanisms can be used together. Time specific departure and CBS require that IEEE 802.1Qbv be enabled, with or without a gate control list configured.

When preemption is enabled, the express traffic classes tier and the preemptable traffic classes tier are scheduled independently based on the next transmission opportunity from their respective link tier.

When the port is attached to a pseudo MAC, the internal flow control signals from the pseudo link are connected directly to the scheduler. When asserted, the scheduler enters a pause state where it stops scheduling frames for all traffic classes. When de-asserted, the scheduler resumes to normal transmission of frames.

At the next level of the hierarchy, traffic is selected on the basis of SIs where a proprietary weighted fair scheduling algorithm named Weighted Bandwidth Fair Scheduling (WBFS) is used. WBFS provides work conserving fair bandwidth allocation among SIs. The WBFS algorithm is described in Weighted Bandwidth Fair Scheduling (WBFS) Algorithm. Only SIs which have an available frame that map to the selected TC are considered. Weight value for an SI is configured via the PSIaCFGR0[SIBW] register. A higher weight number indicates less bandwidth. SIs assigned with a weight of 0 are treated as strict priority and serviced ahead of SIs assigned with a non-zero weight. SIs assigned with the same weight, are serviced using the WBFS algorithm in which the bandwidth to those SIs is equally shared among them.

At the last level, called leaves, the scheduler selects a transmit BD ring from which a frame (transmit buffer descriptor(s)) is to be transmitted using a combination of strict priority and frame-based weighted round robin algorithms. Only BDRs which have an available frame that map to the selected SI and whose IPV maps to the selected TC, are considered. Transmit BD rings with larger numeric priority value are treated as strict priority and are serviced ahead of transmit BD rings with a smaller numeric priority value. Transmit BD rings with the same priority value are scheduled using a frame-based weighted round robin algorithm. The weight of each transmit BD ring is configured via the TBaMR[WRR] register. The weight corresponds to how many times a transmit BD ring will be selected consecutively. For example, if a transmit BD ring has a weight of 5 it will be selected 5 times before the next transmit BD ring.

IEEE 802.1Qbv and time specific departure (TSD) require that a traffic class to be transmitted at a precisely specific time. For ENETC, transmit scheduling must be performed in advance to ensure there is sufficient time to load the frame from host memory to the shared internal buffer memory prior to the frame departure time (in the case of TSD) or prior to the frame open time gate window (in the case of IEEE 802.1Qbv). For IEEE 802.1Qbv, the dequeue rate is performed at the rate of the link speed (rate configured

on the Ethernet MAC or pseudo MAC (PCR[PSPEED])) instead of pushing data as fast as possible to the Egress Port Processing block until it applies back pressure.

In order to support 802.1Qbv, the scheduling structure supports the concept of ‘transmission gates’. A transmission gate is a construct that connects or disconnects the scheduler (or the transmission selection function) from a traffic class (or Tx BD ring(s)), allowing or preventing the scheduler from selecting frames from that traffic class. A transmission gate has two states: open and closed. Only frames in a traffic class with an open transmission gate are eligible for scheduling.

When 802.1Qbv is disabled (or enabled but no gate control list is operational), the states of the transmission gates are set according to the state values configured in PDGSR[DGS_TC*n*], where ‘*n*’ is the traffic class number. The power-on-reset settings for PDGSR[DGS_TC*n*], are gate open. The PDGSR[DGS_TC*n*] settings can be written at any time and take effect immediately if no gate control list is operational or if 802.1Qbv is disabled.

The figure below shows the HTA transmit scheduling structure when time gate scheduling is enabled, and with 2 traffic classes configured with CBS and TC0 and TC7 configured with multiple SIs and multiple BDRs at the same IPV for each SI.

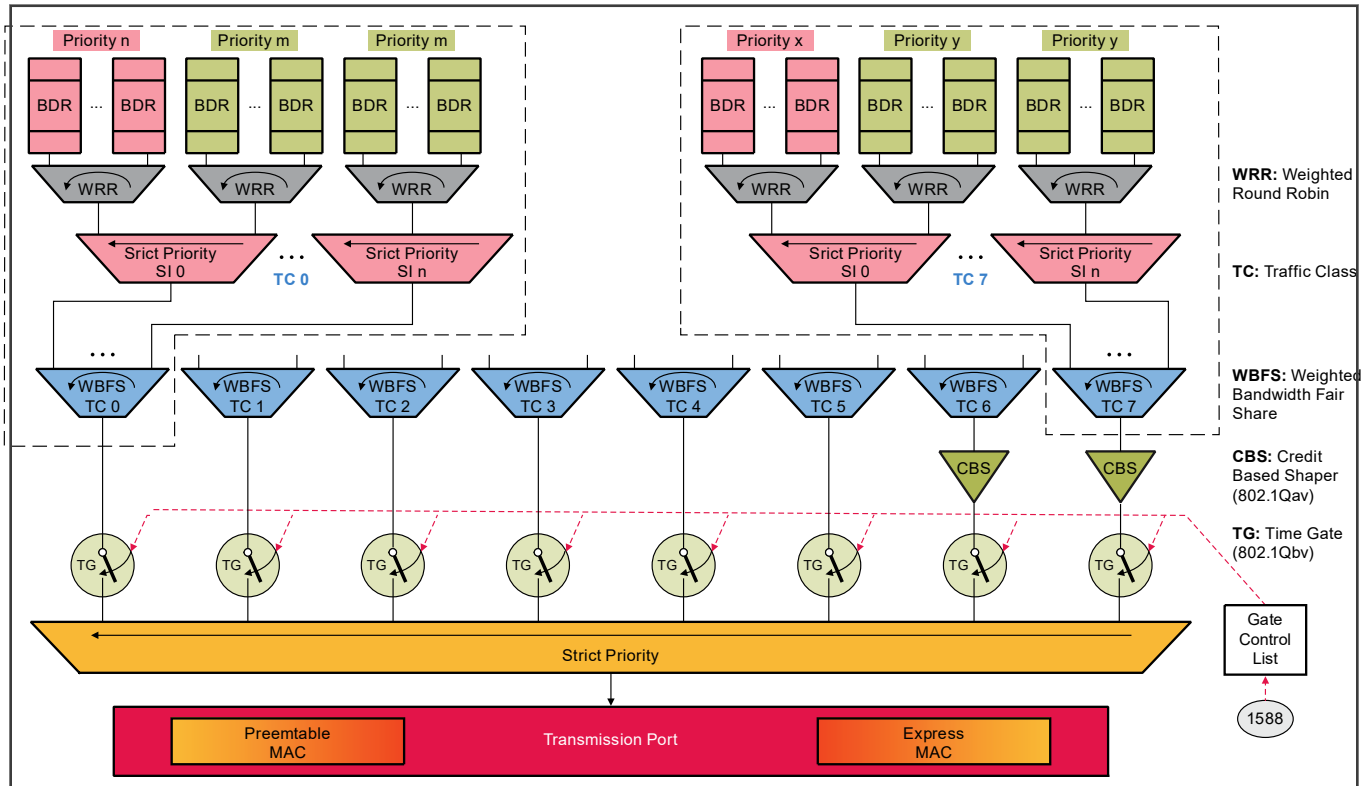

Figure 325. HTA transmit scheduling structure with time gate scheduling enabled

The figure below shows the HTA transmit scheduling structure when time specific departure is enabled.

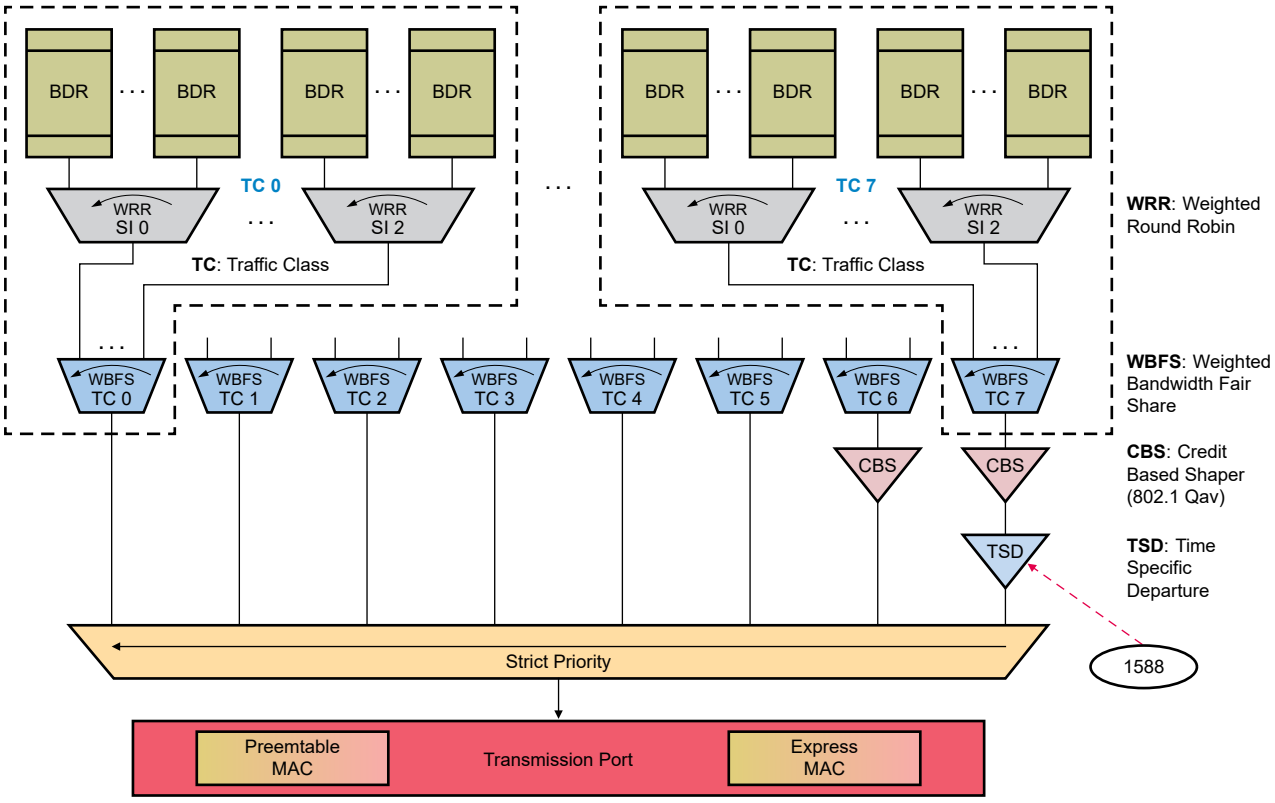

Figure 326. HTA transmit scheduling structure with time specific departure

An HTA transmit thread is dispatched to load the frame from the host memory to the shared internal buffer memory along with executing any required transmit offloads (e.g. MAC anti spoofing, VLAN insert). These transmit threads are executed on the HTA multi-threaded hardware engine(s) which are shared engine(s) between HTA Receive and HTA Transmit for executing hardware threads. Each engine implements a finite state machine (FSM) which operates on a plurality of receive and transmit threads with each thread handling a single frame. One or more engines is instantiated inside the HTA hardware block depending on the requirements e.g. number of ports, port speeds. Multiple transmit threads can be dispatched for a port. More threads can be dispatched than the total number of possible active threads (i.e. the threads currently being handled by the engines) since some threads may need to suspend (e.g. to wait for an earlier larger frame directed to the same internal queue to finish). These in-active or suspended threads therefore do not occupy a thread in an engine.

Once all frame data from host memory has been loaded into the internal memory with all required transmit offloads completed, the frame is sent towards the Egress Port Processing block where it will be queued internally waiting to be transmitted to the MAC.

53.4.2.3.1.2.1.2.1 Credit-Based Shaper - IEEE 802.1Qav

A credit-based shaper is implemented, as per IEEE 802.1Qav (Forwarding and Queueing Enhancements for Time Sensitive Streams (FQTSS)), which is needed for applications requiring bandwidth allocation. The credit-based shaper acts independently, per traffic class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. In order for the credit-based shaper algorithm to operate as intended, it is necessary for all traffic classes that support the algorithm to be numerically higher than any traffic classes that support the strict priority algorithm.

The Audio Video Bridging (AVB) profile specification (IEEE 802.1BA) states that the sum of AVB Class A and Class B traffic may not exceed 75% of the port transmit rate. The following example uses 70% for AVB frames and 30% for non-AVB frames. AVB class A and B uses one credit-based shaper each, while non AVB classes do not use any credit-based shapers.

Table 396. Bandwidth allocation example for AVB

Class	Percent Bandwidth (total 100%)
AVB Class A	50%
AVB Class B	20%
Non-AVB classes	30%

The following bandwidth availability parameters exist for each port, and for each traffic class that supports the credit-based shaper algorithm.

- *idleSlope*

  The actual bandwidth that is currently reserved for use by the queue(s) associated with a traffic class. Once the frame transmission is complete, *credit* increases back to zero at the rate of *idleSlope*, at which point, a further frame can be selected for transmission. Credits also increase at the rate of idleSlope up to *hiCredit* when there are frames available to send waiting for conflicting traffic to complete. If there is an operational gate control list that is active, then credits are accumulated only while the gate for the credit-based shaper traffic class, is open.

- *sendSlope*

  Credit consumption (per byte) while traffic class is transmitting is calculated as: sendSlope = idleSlope - portTxRate. If a class had 100% bandwidth, sendSlope would be 0, allowing for continuous transfers.

- *hiCredit*

  hiCredit is the maximum number of credits that can be accumulated by the credit-based shaper. The hiCredit is dependent on the maximum interference time for the traffic class.

  For the AVB Class A (highest priority), hiCredit is calculated as follows:

  hiCredit = maxSizedFrame * (idleSlope/portTxRate)

  For the AVB Class B (second highest priority), the maximum interference size is equal to the maximum burst size for the AVB Class A plus the maximum interference size for SR class A (which is equal to the maximum frame size for the port). Maximum burst size for the AVB Class A is calculated as follows:

  maxAVBClassABurst = (RA * M0)/(R0 - RA) + MA (equation (L-16) in IEEE Std 802.1Q-2018), where

  - RA: idleSlope for AVB Class A
  - R0: port transmit rate (specified in PCR[PSPEED])
  - M0: maximum sized frame for the port
  - MA: maximum sized frame for AVB Class A

  hiCredit = (maxAVBClassABurst + maxSizedFrame) * (idleSlope/portTxRate)

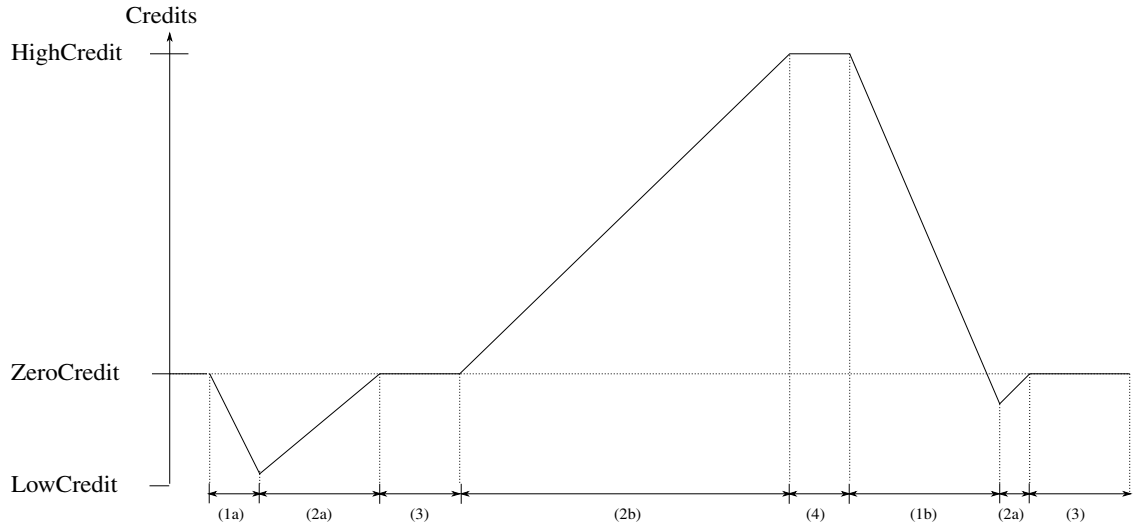
  The maximum sized frame for a traffic class is determines by PTCaTMSDUR[MAXSDU] (where a is the traffic class number)

- *loCredit*

  loCredit is the minimum number of credits that can be accumulated by the credit-based shaper. The loCredit is computed by hardware as follows:

  loCredit = (idleSlope - portTxRate) * maxSizedFrame/portTxRate

The figure below shows the different stages of credit changes for a traffic class as it transmits, waits or is idle.



1a) Send slope. Credits decrement for each byte transmitted assuming BW<100%.
1b) Send slope. Multiple frames may be sent when credits>=0. Bursting would allows class to catch up if conflict occurs.
2a) Idle slope. Increment back to zero credits at the rate of allocated bandwidth for each byte sent.
2b) Idle slope. Class has packet ready for transmit while there are conflicting frames using the port. Allows for >0 credits.
3) No frame ready for transmit.
4) High credit watermark. AVB cannot accumulate more credits.

Figure 327. Stages of credit changes for shaper

To program the credit-based shaper for a class, follow these steps:

1. Enable time gate scheduling for the port by setting PTGSCR[TGE] to 1. An administrative gate control list does not need to be configured, for the credit-based shaper to operate. This also requires the timer function to be configured and enabled. Either the default nanosecond timer or the 1588 timer can be used to generate the required nanosecond resolution time.
2. Enable credit-based shaper for the port traffic class *a* by setting PTC*a*CBSR0[CBSE]=1.
3. Determine *hiCredit* from the formula described above and set PTC*a*CBSR1[HI_CREDIT].
4. Set the allocated bandwidth for the traffic class credit-based shaper which ranges from 1-100 (%), in register PTC*a*CBSR0[BW]. The total bandwidth for all enabled shapers must not exceed 100% or the allotted bandwidth.
5. Set PTXSDUOR register with the appropriate per frame overhead; that is number of bytes to be added to the actual length of each frame, to determine the Physical Layer PDU (PPDU) frame length on the link.

53.4.2.3.1.2.1.2.2 Time Specific Departure

A time specific departure capability is implemented, which enables the user to specify when a frame can be transmitted. When this capability is enabled, the device will delay the transmission of the frame so that it can be transmitted at the precisely specified time.

Time specific departure operations is enabled by performing the following steps:

1. Enable time gate scheduling for the port by setting PTGSCR[TGE] set to 1. An administrative gate control list does not need to be configured, for time specific departure to operate.
2. Enable time specific departure on the traffic class(es) that are to support time specific departure operations, by setting PTC*a*TSDR[TSDE] to 1, where *a* corresponds to the traffic class number.

NOTE

The 1588 timer must be initialized and configured before enabling time specific departure on any traffic class. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer is in normal operation, any change to the 1588 timer configuration (for example, in TMROFF_H/L), except for TMR_ADD updates, requires that time specific departure be disabled on all traffic classes (PTCaTSDR[TSDE]=0).

The departure time of a frame is specified in the transmit BD[TX_START] field. The value of this field is expressed as bit [29:5] of the 1588 synchronized nanosecond time. Since bit 31 and 30 are always 0, the time window is approximately 1 s and then wraps around. As a result, a departure time of up to approximately 0.5 s in the future from the current time, may be specified so that when hardware schedules the frame, it can determine whether the departure time is in the past or in the future. Note that the unit is 32 ns, since bit 0 to 4 are not included. If the departure time in the transmit BD has not yet been reached, based on the current time, the packet will not be transmitted. To indicate the presence of a departure time in the transmit BD, the BD[FL] must be set to b10.

Transmit BD rings transmission selection process is performed in advance to ensure there is sufficient time to load the frame from host memory to internal buffer prior to the departure time of the frame. The time specific departure function relies on the use of the time gate scheduler for executing the transmission selection process ahead of time; that is, 1588 time + look ahead time where the look ahead time is equal to the sum of the time values in the registers EaTGSLR[MIN_LOOKAHEAD] and PTGSATOR[ADV_TIME_OFFSET]. A time specific departure frame becomes available for scheduling when the 1588 time + look ahead time reaches the frame scheduled departure time. See Time Gate Scheduling - IEEE 802.1Qbv, for more details on the operation of the time gate scheduler. Note that the time gate scheduler can operate with or without an administrative gate control list.

Software must guarantee that frames with a departure time in a transmit ring are in increasing order or additional delay may be imposed upon a frame. Packets in the ring are processed in order and the packet at the head of the ring can delay sending of packets later in the ring. Any frame with no departure (or start) time information will be considered eligible to be scheduled, according to its traffic class transmission selection algorithm. To reduce the packet delay variation due to interference from non-time scheduled traffic, consider the following:

1. Time specific departure operation should only be used on the highest priority traffic class. All traffic on that traffic class should use time specific departure operation. Note that within a traffic class, any subsequent frames with or without a departure time, will be held behind if the frame ahead has a departure time that has not been reached.
2. The traffic class being used for time specific departure operation, can use frame preemption by setting MAC_MERGE_MMCSR[ME] to 1 or 2, to enable frame preemption on the port and by assigning the time sensitive traffic class (used for time specific departure) to the express MAC (PFPCR[FPE_TCa] set to 0 (where a corresponds to the traffic class number)) and non time sensitive traffic classes to the preemptable MAC (PFPCR[FPE_TCa] set to 1 (where a corresponds to the traffic class number)). Frame preemption allows interrupt transmission of an ongoing frame. Worst case scenario is the time scheduled frame transfer being delayed by at worst the sum of the minimum final (64B) and non-final (MAC_MERGE_MMCSR[RAFS]) fragment sizes minus four octet times, which cannot be preempted.

53.4.2.3.1.2.1.2.3 Time Gate Scheduling - IEEE 802.1Qbv

IEEE 802.1Qbv, also referred in this document as time gate scheduling, introduces a time based transmission mechanism operating on a global (offline) configured periodic schedule called the gate control list. IEEE 802.1Qbv amendment has been incorporated in the IEEE standard 802.1Q 2018; the mechanism itself is referred in the standard as "enhancements for scheduled traffic."

The mechanism is shown in the diagram below.

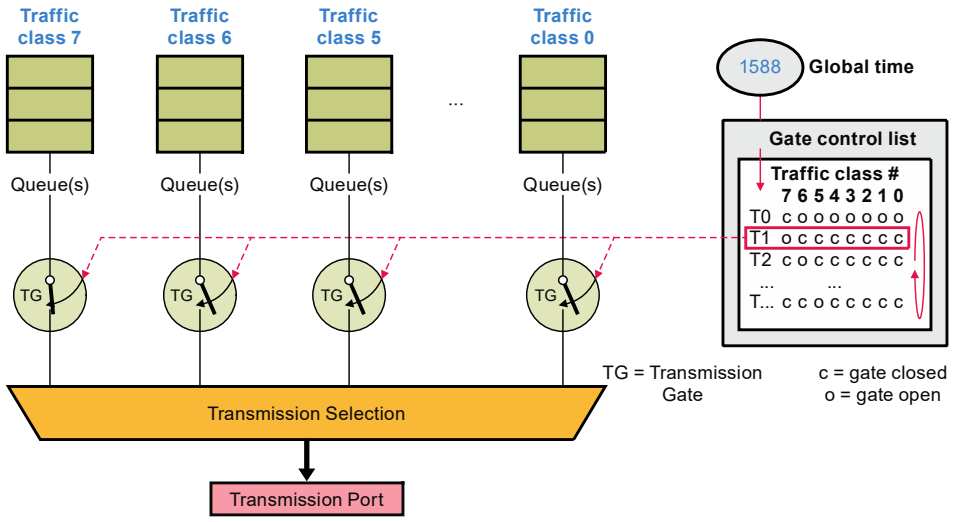


Figure 328. Time Gate Scheduling - IEEE 802.1Qbv

Each traffic class has a gate, which controls if the traffic class is open or closed. Only frames in traffic classes with open gate are eligible for transmission. For the switch, each traffic class has a single queue, and for ENETC, it is possible that a traffic class may have more than one queue (or Tx BD ring). In this case, all queues (or Tx BD rings) in a traffic class have/shared the same gate state.

The gate state in each traffic class is controlled by the gate control list. A gate control list consists of an ordered list of gate control entries, where each entry specifies an 8 bit gate state vector where each bit (one per gate), indicates whether the gate is open or closed. The gate control entry also specifies the time duration for the states.

The gate control lists are typically generated offline, and then timely configured on each network device. To support no-downtime gate control list configuration changes, the standard requires that a network device supports two sets of gate control lists:

- **Operational gate control list** – Represents the currently active gate control list.
- **Administrative gate control list** - Provides a means of configuring a new gate control list prior to its installation in a running system.

The hardware executes the (operational) gate control list cyclically based on a global time. The hardware starts executing the gate control list from the head, and then goes through the gate control entries as time goes on, and after the cycle time is passed, the hardware jumps back to the head of the gate control list.

The transmission selection process (or the scheduler) which executes at the port level, may only select frames from traffic classes that have their gates in the open state. The transmission selection uses a strict priority algorithm to select the next frame for transmission by querying/checking the open traffic classes in descending order from the highest priority traffic class to the lowest priority traffic class. If the open traffic class being queried has one or more frames waiting to be transmitted, then the scheduler determines if the frame at the head of the queue can be transmitted entirely before its traffic class gate closes. If it is determined that there is insufficient time available to transmit the entirety of that frame (transmission of the frame does not fit in the current open window), that frame will remain queued, and an attempt to schedule it will be made in the next open window associated with the frame traffic class. The transmission selection process then moves to the next lowest priority traffic class that has its gate open.

To set up time gate scheduling, follow these steps:

1. The 1588 timer must be initialized and configured before enabling time gate scheduling. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer is in normal operation, any change to the 1588 timer configuration (for example, in TMROFF_H/L), except for TMR_ADD updates, requires that time gate scheduling be disabled ((PTGSCR[TGE]=0). The state of each gate while time gate scheduling is disabled, can be controlled via register PDGSR[DGS_TCn], where n is the traffic class number.
2. Enable time gate scheduling for the port by setting PTGSCR[TGE] to 1.

3. The initial state of each gate, when no gate control list is operational, is determined by the setting in PDGSR[DGS_TCn], where n is the traffic class number. The power-on-reset setting for PDGSR[DGS_TCn] is gate open. The initial state of each gate can be changed by configuring PDGSR[DGS_TCn]. Note that the PDGSR[DGS_TCn] settings can be written at any time and take effect immediately if no gate control list is operational or if time gate scheduling is disabled. Thus, it may be required to re-configure PDGSR[DGS_TCn], before disabling time gate scheduling, if the state of the gates when time gate scheduling is disabled, differ from their initial state when time gate scheduling is enabled.
4. Set the maximum frame size for each traffic class in PTC*a*TMSDUR[MAXSDU]. Frames that exceed the limit are discarded.
5. Configure the (administrative) gate control list through the use of the Time Gate Scheduling table; for more details, see Time Gate Scheduling Table for the ENETC and Time Gate Scheduling Table for the switch. The Time Gate Scheduling table contains time gate scheduling configuration and operational information for a given NETC function. There is one Time Gate Scheduling table for each ENETC instance and one Time Gate Scheduling table for the entire switch. For the switch, there is one entry for each switch port, whereby for an ENETC instance, there is a single entry for the entire ENETC instance. Each entry includes both an administrative gate control list and an operational gate control list, along with the related configuration and status parameters. The gate control list includes the following parameters:
   - Size of the gate control list.
   - Base time (start time) of the schedule. Base time is expressed in units of nanoseconds.
   - Cycle time of gate control list. Cycle time is expressed in units of nanoseconds. The cycle time cannot be shorter than the sum of all gate control list entry durations.
   - Cycle extension time of gate control list. Cycle extension time is expressed in units of nanoseconds.
   - Gate control list.
6. When hardware processes a Time Gate Scheduling table command to configure a new (administrative) gate control list, it calculates the time at which the administrative gate control list is to become active (config change time), based upon the values of the base time and cycle time of the administrative gate control list. When the config change time of the administrative gate control list is reached, the hardware installs the gate control list (the gate control list becomes operational) and starts the execution of the gate control list. This function is performed in advance by having its time reference set to the 1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET], to adjust for latency encountered in the transmit processing pipeline. Register PTGSATOR[ADV_TIME_OFFSET] is used to specify the latency across the MAC plus if needed, delays outside of NETC (for example, PHY delay). Register E*a*TGSLR[MIN_LOOKAHEAD] is used only for ENETC, to specify the latency encountered for scheduling, dequeuing, and loading frames from the host memory to NETC internal memory. Register S0TGSLR[MIN_LOOKAHEAD] is used only for the switch, to specify the latency encountered for scheduling and dequeuing frames. Note that E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] are IERB registers, and thus can only be setup at pre-boot initialization time.
7. Similarly, time gate scheduling of all frames is also done in the future to adjust for latency encountered in the transmit processing pipeline. As in the previous step, this is achieved by advancing the 1588 time reference by the amount of time (*LookAheadTime*) configured in E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET].
8. Set PTXSDUOR register with the appropriate per frame overhead; that is number of bytes to be added to the actual length of each frame, to determine the PPDU (Physical Layer PDU) frame length on the link.

Time Gate Scheduling Operation

The setting of the transmission gate state for the gate associated with each of the port's traffic classes and the execution of transmission selection function are performed in advance to mitigate against any long latency (e.g. DMA latency in the case of ENETC) and latency variation encountered in the transmit processing pipeline. This in turn leads to better timing accuracy and reduction in jitter. The time used to perform these function, is set to the 1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]. Since the transmission selection function is performed in advance, it no longer relies on the MAC/link being idle for the indication that there is a transmission opportunity to transmit a frame. Instead the link is modeled by the transmission selection function to determine when frames are selected for transmission. Once the transmit transmission function selects a frame for transmission, next transmission opportunity provided by the link model, will occur after the time interval corresponding to the transmission time of the current selected frame at the rate configured in PCR[SPEED], with physical frame

overhead (IFG, preamble, SFD) accounted. The frame overhead is specified in PTXSDUOR. Time remaining for the transmission of a frame is tracked on every clock cycle. Note that the modeling of link also models the preemption function if enabled (such as stopping transmission of preemptible frame with added overhead of non-final fragments (mCRC, IFG, preamble, SFD) being accounted for, in the link model).

Each frame selected for transmission is tagged with a timestamp corresponding to the advance time that the time gate scheduler is operating on (1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]). The timestamp of a frame determines its departure time, that is the time at which the frame should be transmitted to the link. Then at the point where frames are transferred to the MAC, a timestamp-based shaper is implemented where the frames are released only when their transmission time (timestamp) is reached. The timestamp-based shaper function can also be performed in advance by having the time used to perform this function advanced by the amount of time specified in PTGSATOR[ADV_TIME_OFFSET], to adjust for the latency encountered through the Ethernet interface logic (MAC + physical layer latency).

Time gate scheduling proceeds as follows when there is transmission opportunity on the link to transmit a frame. It first selects the highest priority traffic class for which there is a frame waiting to be transmitted at the head of the traffic class. It then determines if that frame can be transmitted. A frame for a given traffic class can only be transmitted if the transmission gate associated with that traffic class is open and there is sufficient time for the entire frame (length of the frame is known) to be transmitted before the next gate-closed operation associated with that gate is executed. If both conditions are not met, then the next highest priority traffic class for which there is a frame waiting to be transmitted at the head of the traffic class, is selected to determine if that frame can be transmitted based on the criteria described above.

To determine if a frame can be transmitted, the scheduler first checks if there is sufficient time left in the current gate control entry interval, to transmit the entirety of the frame. If there is insufficient time, then the pre-processed gate control list data is accessed to extract how many bytes (up to the maximum SDU length) that can be transmitted in the next gate operations for this traffic class. This gate control list pre-processing, which is performed when the gate control list is configured, consists of performing the following computation for each entry in the gate control list.

- For each traffic class that has its gate open, the next gate operations in the gate control list (next gate control entries) are inspected to accumulate the number of bytes that can be transmitted in each gate control entry, until the accumulated number of bytes reaches the configured maximum SDU frame size, or a gate-closed operation is found.
- If the end of the gate control list is reached and the gate control cycle time is longer than the total execution time of the sequence of gate operations, the last gate control entry is extended to the end of the gate control list cycle. Once the end of the gate control list cycle is reached (no gate-closed operation found), and the accumulated the number of bytes that can be transmitted has not reached the size of a maximum SDU frame, inspection continues from the beginning of the same gate control list.
- This accumulated number of bytes that can be transmitted, is then stored in the gate control list entry, to be used later by the scheduler to determine for a given traffic class, how many bytes that can be transmitted in the next gate operations. This pre-processed data avoids having the scheduler at run-time, examining the next entries in the gate control list.

If it is determined that there is insufficient time available to transmit the entirety of that frame (transmission of the frame does not fit in the current open window), that frame will remain queued, and an attempt to schedule it will be made in the next open window associated with the frame traffic class.

In the case where the existing gate control list cycle is extended so that it ends at the base time of the new gate control list to be installed, any inspection from previous gate control entries will not continue into this extension time interval. Frame scheduling during the extension time internal is permitted with the gate states set to the values of the last gate control entry of the existing gate control list.

If there is a new gate control list scheduled to be installed in the next gate control list cycle, the scheduler cannot take into consideration the new configuration as the scheduler is using pre-processed gate control list data to determine how many bytes that can be transmitted in the next gate operations. Furthermore, any of the next gate operations accumulated byte fields in the current operational gate control list, that resulted from inspecting back to the beginning of the gate control list, are no longer accurate. As a result, all of the next gate operations accumulated byte fields in the last cycle are overwritten to 0.

Note that once the time gate scheduler has cycled through the entire operational gate control list and has detected a condition where a frame at the head of a traffic class will never be able to be transmitted, that frame will be discarded in the case of switch. These frame discards are counted against the port's Tx discard count register (PTXDCR) along with the setting of the Time Gate Scheduling Frame Too Large Discard Reason (TGSFTLDR) flag to 1 in the port's Tx discard count reason register 0 (PTXDCRR0).

In the case of ENETC, the frame is not transmitted and the STATUS field of the transmit buffer descriptor is updated with the error code 0x080 (frame too large for time gating window). The conditions where a frame at the head of a traffic class will never be able to be transmitted are:

- A frame at the head of a traffic class, although shorter than the value configured in PTC*a*TMSDUR[MAXSDU] (where *a* is the traffic class number), cannot be transmitted because there is no time interval between any gate-open event and a subsequent gate-close event, sufficient, long enough to transmit the entirety of the frame.
- There are no gate-open events for that traffic class in the entire operational gate control list; its gate is closed in every entry of the operational gate control list.

In the absence of any gate control list configuration, the time gate scheduler if enabled, still executes the transmission selection function ahead of time based on the setting of E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD], E*a*TGSLR[ZERO_LOOKAHEAD] and PTGSATOR[ADV_TIME_OFFSET].

Gate Control List Installation

The time when a new gate control list takes affect is calculated based on the rules described below (where *LookAheadTime* = E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET])

If the operational gate control list is not active, PTGAGLSR[TG]=0, the time (i.e. *ConfigChangeTime*) at which the next gate control list configuration change is scheduled to occur is determined as follows (where *CurrentTime* is at the 1588 time reference):

- if *AdminBaseTime* >= *CurrentTime* + *LookAheadTime*, then *ConfigChangeTime* = *AdminBaseTime*
- if *AdminBaseTime* < *CurrentTime* + *LookAheadTime*, then *ConfigChangeTime* = (*AdminBaseTime* + N**AdminCycleTime*) where N is the smallest integer for which the relation (*ConfigChangeTime* >= *CurrentTime* + *LookAheadTime*) would be TRUE.

If the operational gate control list is active, PTGAGLSR[TG]=1, the time (i.e. *ConfigChangeTime*) at which the next gate control list configuration change is scheduled to occur is determined as follows (where the end of the current operational cycle (*EndCurrentCycle*), is the absolute end time of the currently operational cycle without the cycle extension time, at the time reference of 1588 time + EaTGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]):

- if *AdminBaseTime* < *EndCurrentCycle* + *OperCycleTime*, then *ConfigChangeTime* = *AdminBaseTime* + N**AdminCycleTime*) where N is the smallest integer for which the relation (*ConfigChangeTime* >= *EndCurrentCycle* + *OperCycleTime*) would be TRUE.
- if *AdminBaseTime* >= *EndCurrentCycle* + *OperCycleTime*, then *ConfigChangeTime* = *AdminBaseTime*

The *ConfigChangeTime* can be retrieved by issuing a query command against the Time Gate Scheduling table entry associated with the port.

When the administrative gate control is about to be installed, and operational gate control list is not active, PTGAGLSR[TG]=0, then *CycleStartTime* is set to *ConfigChangeTime*. If the operational gate control list is active, PTGAGLSR[TG]=1, *CycleStartTime*, is determined according to the following rules:

- If *ConfigChangeTime* > *EndCurrentCycle* + *OperCycleTimeExtension*, then *CycleStartTime* = *EndCurrentCycle*
- If *ConfigChangeTime* <= *EndCurrentCycle* + *OperCycleTimeExtension*, then *CycleStartTime* = *ConfigChangeTime*

If a new gate control list configuration is installed and starts to execute in the current cycle, the current cycle is truncated in order to start the first new cycle and any inspection in the old cycle would not continue into the new cycle in order to start the first new cycle. This could result for the time interval of the last entry of the old gate control list to be very short. This is turn could cause overrunning the next gate-close event, or cause not being able to transmit a frame because the time interval was shortened, and that frame could then get discarded if it had been waiting to be transmitted for a full cycle interval.

Time Gate Scheduling Example

Time gating may be better understood with an example gate control list showing how scheduling will be performed. The example below, Table 397, shows a non-overlapping open gate case, where two traffic classes are never allowed to transmit at the same time. The interval normally defines a multiple of time ticks, in this example assume that the interval and number of bytes allowed to be transferred are the same. The number of bytes per interval would normally be calculated based on the interval length, transmit rate, and time tick granularity.

The total length of the gate control list is 3000B when adding up each individual time interval. The (admin) cycle time provided must be 3000B or greater. If the cycle time is 3000B, then when entry 15 completes, entry 0 would start immediately. Additional time added to the cycle time will extend the entry 15 interval. Assume here that the cycle time is set to 3100.

Table 397. Example: Non-Overlapping Gate Control List

Entry	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Interval (bytes)	100	200	100	300	100	200	100	300	500	100	200	200	300	100	100	100
TC 0	0	0	**1**	**1**	0	0	0	0	**1**	**1**	0	0	0	0	0	0
TC 3	0	0	0	0	0	**1**	0	0	0	0	0	**1**	0	0	0	0
TC 7	**1**	**1**	0	0	0	0	**1**	**1**	0	0	0	0	**1**	**1**	**1**	**1**

In this example, traffic class 7 gate has an open window (gate in the open state) of 1000 bytes starting at the beginning of the 4th last entry and ending at the end of the 2nd entry of the next cycle (if no new gate control list is to be installed).

Lets look at a first scheduling example where two frames are about to be scheduled. Both frames are available at least *LookAheadTime* before they are required to be transmitted in the open time gate window (Interval 1). This time is needed for the device to fetch the frame from memory and prepare it for transmission.

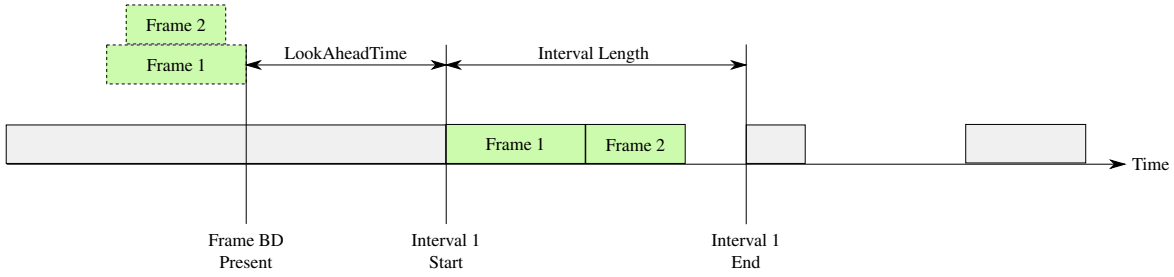

Figure 329. Scheduling of Frames

In this next example, consider the case where a best-effort first frame arrives "late" for scheduling within the next open gate window. Since the scheduler is always looking at LookAheadTime in the future it will calculate the amount of time left in a window at LookAheadTime from the current time to the end of the window. If the frame can still fit it will be scheduled for that window.

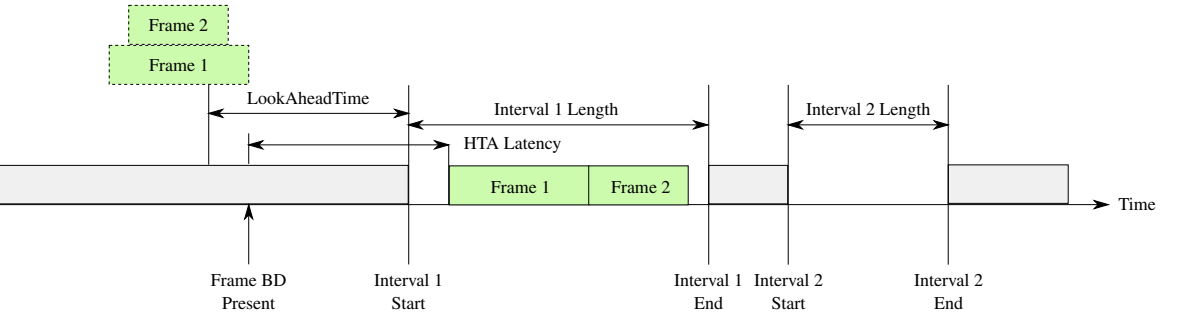

Figure 330. Scheduling of Frames - Late Arrival

Time Gate Scheduling in Combination with Preemption

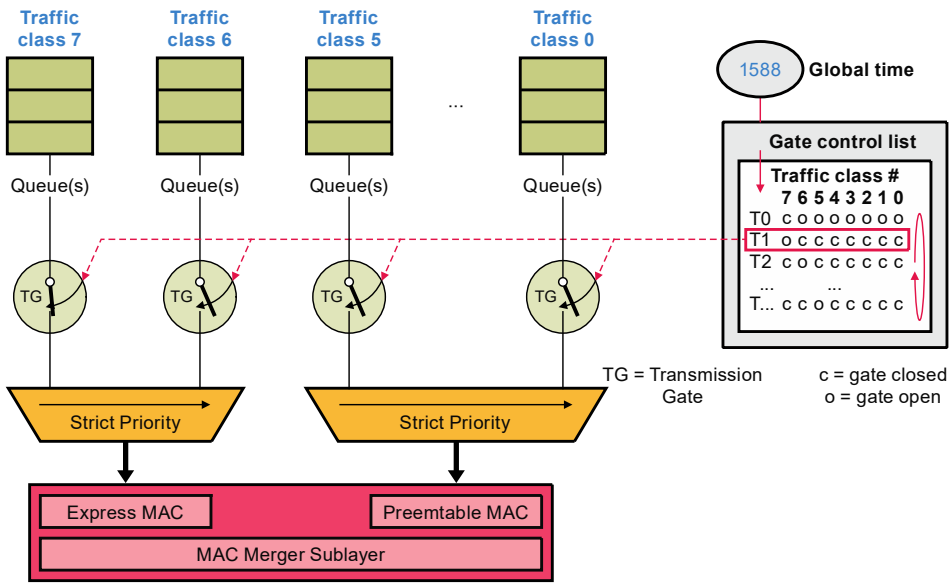

Figure 331. Time gate scheduling in combination with frame preemption

When time gate scheduling is used in combination with frame preemption, the "Hold and Release" mechanism can be used to protect the express traffic class window from interference from preemptable traffic, while at the same time minimizing the impact of the protected window on the amount of bandwidth that is available to preemptable traffic. The "Set-And-Hold-MAC" and "Set-And-Release-MAC" gate operations are used to specify the start and the end of a protected window.

When the time gate scheduler is processing a "Set-And-Hold-MAC" gate operation, asserting the Hold signal to the MAC merge sublayer is not always performed. Specifically, at the point of time where an Hold signal needs to be asserted (start of the hold advance interval), the time gate scheduler will not assert an Hold signal to the MAC merge sublayer under the following conditions:

- The preemptible frame transmission will complete its transmission before the Set-And-Hold-MAC time slot begins.
- There is no preemptible frame transmission.

The time gate scheduler will not schedule a preemptible frame during the Set-And-Hold-MAC time slot, regardless of whether or not an Hold signal was asserted. Furthermore, the time gate scheduler will not schedule a preemptible frame during the hold advance interval, if the preemptible frame transmission would continue into the Set-And-Hold-MAC time slot.

Delaying the scheduling of preemptable traffic classes to the start of the "Set-And-Release-MAC" time slot, has the benefit of selecting a newly arrived higher-priority preemptible frame, instead of the lower priority preemptible frames that were hold off by the scheduler prior and during the "Set-And-Hold-MAC" time slot. Note that once the time gate scheduling decides to not schedule a preemptible frame, any subsequent preemptible frames received will not be scheduled till the "Set-And-Release-MAC" time slot begins even if they there were of higher-priority.

In all other cases, the time gate scheduler will assert the Hold signal, in advance to the Set-And-Hold-MAC time slot by the time interval corresponding to the transmission of the worst case (longest) fragment length that cannot be preempted plus associated physical layer overheads. IEEE Std 802.3-2018 Clause 99 defines a minimum final fragment size of 64 bytes and allows the minimum non-final fragment size to be 64, 128, 192, or 256 bytes. For example, with a non-final fragment size of 64 bytes, a fragment that is 123 or fewer bytes in length cannot be preempted, because the non-final fragment would be less than 64 bytes (60 bytes + 4 bytes for mCRC). The minimum non-final fragment size is configured in MAC_MERGE_MMCSR[RAFS].

Note that time gate scheduler operates at the time reference of 1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET] and assumes that there is no delay from asserting the Hold/Release signal to the MAC merge

sublayer and the MAC merge sublayer ceasing/resuming to transmit any preemptible frame. Since it operates in advance, instead of immediately asserting the Hold/Release signal, an Hold/Release message is generated, and tagged with a timestamp set to the advance time (1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]), at which the Hold/Release signal must be asserted assuming no internal pipeline delay from the point where frames are transferred to the MAC to the point where frame preemption occurs. Then at the point where frames are transferred to the MAC, a timestamp-based shaper is implemented where the Hold/Release messages are released, which trigger immediate assertion of the Hold/Release signal to the MAC merge sublayer when their time (timestamp) is reached. This timestamp-based shaper function is performed in advance by the amount of time specified in PTGSHCR [HOLD_SKEW] (that is, 1588 time + PTGSHCR [HOLD_SKEW]), to adjust for the Hold/Release latency encountered through the Ethernet interface logic (Hold Release delay to the MAC merge sublayer + any external delay (for example, PHY delay)).

Take for example, where MAC_MERGE_MMCSR[RAFS] is set to 64 bytes, meaning that the minimum fragment size that can be preempted is 124 bytes. If the time gate schedule determines that the Hold must be asserted, the time for asserting the hold would be set to 163 bytes transmission time prior to the start of the Set-And-Hold-MAC time slot; 20 bytes (IFG, preamble, SFD) + 123 bytes + 20 bytes (IFG, preamble, SFD).

An increased IFG length and any other overhead increases in frame transmission time are accounted for by setting the PTXSDUOR register appropriately.

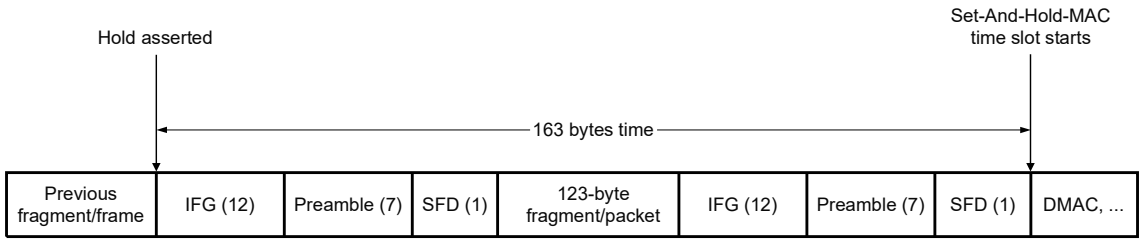

Figure 332. Hold Assertion Timing

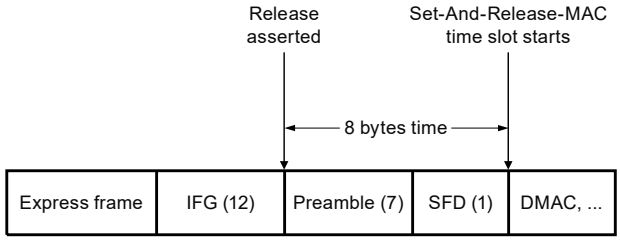

Figure 333. Release Assertion Timing

In the case where the "Hold and Release" mechanism is not used to protect the express traffic class window, and a preemptible frame has been scheduled and its transmission cannot be stopped by the time the express traffic gate opens, the scheduling of the express traffic class is delayed up to the point where the transmission of the preemptible frame has ceased.

If the schedule that applies to the preemptible traffic classes is constructed to disallow preemptible traffic to be transmitted at certain time (that is, there are "gate close" events for the preemptible traffic classes), then there is no way of telling in advance how many times a given frame will be preempted before its transmission is complete, and thus this configuration may result in overrunning the next gate-close event for the preemptible traffic classes concerned.

Note that the when gate control list preprocessing is inspecting the next gate operations in the gate control list (next gate control entries) for a preemptible traffic class, and encounters a gate control list entry that contains an express traffic class with its gate open, the accumulated number of bytes that can be transmitted is set to the configured maximum SDU frame size for the preemptible traffic class being inspected.

Time Gate Scheduling in Combination with Half Duplex Transmission

When time gate scheduling (802.1Qbv) is used in combination with half duplex transmission, the time gate scheduler compensates for deferred transmissions. Accurate transmission scheduling (that is, transmitting only within open gate time intervals) will be recovered for future frames in the event that one or more scheduled frame transmissions are deferred. These deferred frame(s) may violate their classes' open gate times as a result of the deferral, but it will not create a frame scheduling backlog that results in persistent gate violations once the deferred transmission has completed.

The time gate scheduler does not compensate for transmission back off delays due to collisions. A back off delay that follows a collision event may result in gate violations by the re-transmitted frames. In addition, collision back off delays will result in persistently late frame transmissions (potential gate violations) so long as there are transmit frames available for selection by the time gate scheduler; that is as long as transmit traffic is continuously flowing.

The time gate scheduler will recover accurate transmission scheduling during any idle time periods when there are no transmit frames available for selection. Once the sum of the idle time periods equals the total collision delays encountered, accurate transmission scheduling is reestablished.

53.4.2.3.1.2.1.2.4 Transmit Scheduling Timing

The figure below shows the moments in time related to current time a frame has been scheduled for IEEE 802.1Qbv. This is to emphasize the role of EaTGSLR[MIN_LOOKAHEAD], PTGSATOR[ADV_TIME_OFFSET] and PTGSHCR[HOLD_SKEW] values.

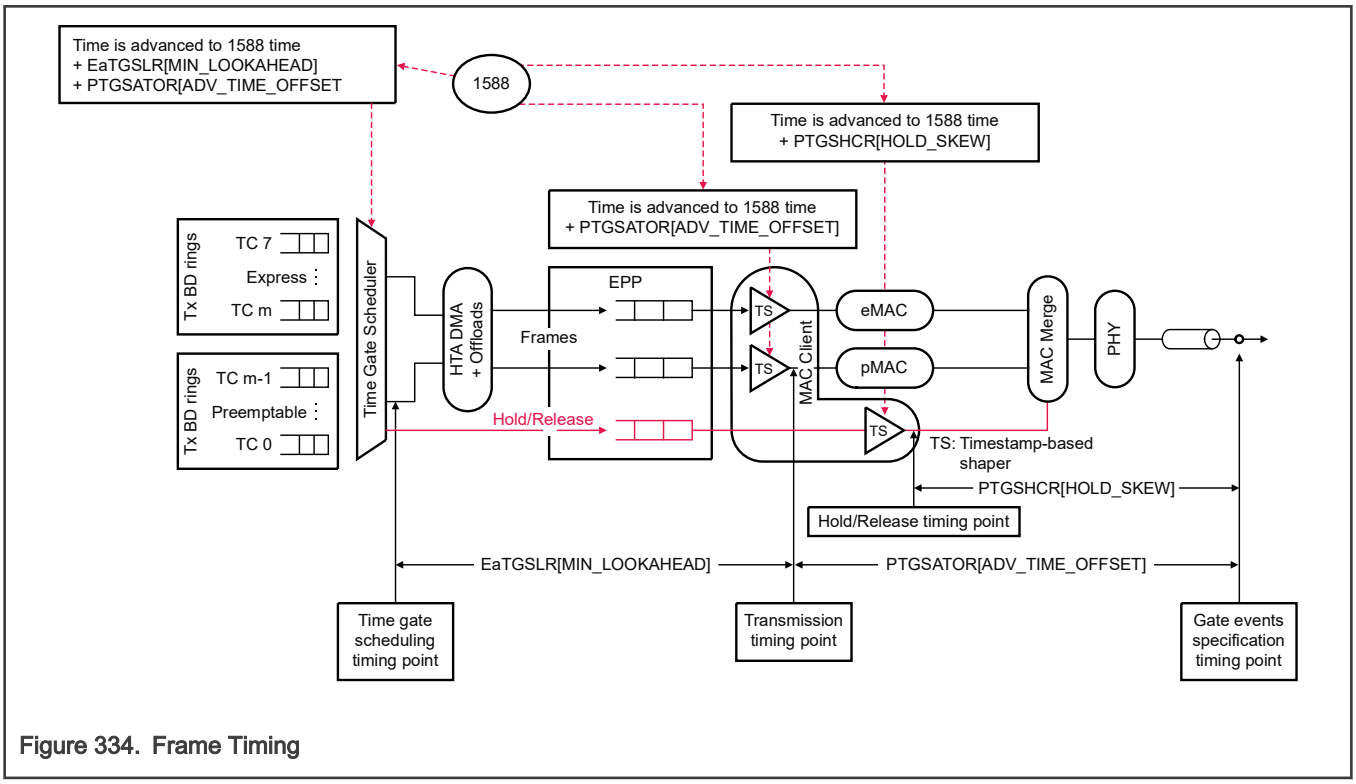

Figure 334. Frame Timing

For time gate scheduling, a frame that appears at the time gate schedule timing point (reference point at which the time of the gate events are specified (gate control list), would have been scheduled at 1588 time - EaTGSLR[MIN_LOOKAHEAD] - PTGSATOR[ADV_TIME_OFFSET] inside the HTA. After which the frame would then have been assigned a departure time and DMA'd to the Egress Port Processing (EPP). The EPP will then have forwarded the frame to the MAC client which in turn will sent to the MAC at 1588 time - PTGSATOR[ADV_TIME_OFFSET] . The added latency through the MAC will have caused the frame to be sent out of ENETC at 1588 time. For example, with a EaTGSLR[MIN_LOOKAHEAD] time of 800 ns, PTGSATOR[ADV_TIME_OFFSET] of 200 ns, and a gate opening of 50000 ns the HTA will schedule the first frame of the gate at 49000 ns. The frame will then be forwarded to the MAC at 49800 ns and will appear on the output (time gate schedule timing point) at the gate opening of 50000 ns.

53.4.2.3.1.2.1.3 VLAN Insert

The device supports the offloading of VLAN tag insertion. VLAN tag can be inserted in the following ways:

- **SI-Based VLAN insertion** – The PF driver through the PSI can request that hardware inserts the SI-based VLAN into the outgoing frame. This is inserted “outside” of any software tag i.e. this tag is inserted closest to the Ethernet header with its Ethertype immediately following the SMAC address. SI-based VLAN insertion is enabled by setting PSI*a*CFGR0[SIVIE] to 1 and PSI*a*VLANR[E] to 1 along with the appropriate VLAN tag configuration. (i.e. VLAN ID, PCP, DEI and TPID settings in the PSI*a*VLANR register).
- **Descriptor-based VLAN insertion** – Software can request hardware to insert a VLAN tag by putting the VLAN tag to be inserted in the transmit BD ring. TB*a*MR[VIH] is set to 1 to indicate that software intends to use descriptor-based VLAN insertion offload. When this flag is set, calculations performed by hardware in the transmit scheduler involving the size of the frame (e.g. credit-based shaper) will account for the extra 4 bytes of VLAN information in their calculations regardless of whether descriptor-based VLAN insertion offload is used or not used.

The following processing is applied to each frame as it is taken from a transmit BD ring for transmit:

1. Firstly, if the frame from the host has a VLAN tag (either in the frame itself or in the BD descriptor (descriptor-based VLAN insertion), a check is made to determine if the Ethertype of the VLAN tag is "acceptable". If no descriptor-based insertion is requested then the outer Ethertype in the frame (16b immediately following the SMAC address) is compared against the VLAN Ethertypes (0x8100, 0x88A8, CustTag1 (CVLANR1[ETYPE] if valid), CustTag2 (CVLANR2[ETYPE] if valid)) in order and matching stops on the first match found , and a 2-bit TPID value is assigned identifying which known value matched (00: 0x8100, 01: 0x88A8, 10: CustTag1, 11: CustTag2). If a match is found, the 2-bit TPID is checked against the 4-bit map of allowed VLAN types for this SI (PSI*a*CFGR0[SIVC]). By using the 2-bit TPID value as an index into the SIVC bitmap. If the corresponding bit is set then the VLAN tag has an "acceptable" Ethertype. If the corresponding bit is not set, then this VLAN tag not allowed and the frame is not transmitted and an appropriate error is reported in the BD. If no match is found when the outer Ethertype in the frame is compared against the VLAN Ethertypes, the frame is considered untagged, and thus accepted for transmission.
2. If a VLAN is provided in the Tx BD then the 2-bit TPID of the VLAN tag to be inserted (taken from the Tx BD) is checked to determine if the Ethertype of the VLAN tag is "acceptable". If the Ethertype to be used to construct the VLAN tag is a custom VLAN Ethertype (i.e. CVLANR1/CVLANR2[ETYPE]), the CVLANR1/CVLANR2[V] field is checked to see if it is set to 1 (i.e. valid). If set to 0, the VLAN Ethertype specified in the BD to be inserted is not valid, and as a result the frame is not transmitted and an appropriate error is reported in the BD. If set to 1, the 2-bit TPID is then checked against the 4-bit map of allowed VLAN types for this SI (PSI*a*CFGR0[SIVC]) by using the 2-bit TPID as an index into the SIVC bitmap. If the corresponding bit is set then the VLAN tag has an "acceptable" Ethertype. If the corresponding bit is not set, then this VLAN tag is not allowed and the frame is not transmitted and an appropriate error is reported in the BD.
3. Hardware VLAN insertion is implemented as required. Logically this can be described as:
   - Any BD supplied VLAN is inserted in the outer position immediately following the SMAC address.
   - If configured the SI-based VLAN is inserted in the outer position immediately following the SMAC address. If both descriptor-based VLAN insertion and Si-based VLAN are enabled, the SI-based VLAN tag will appear as the outer most tag inserted, immediately after the Ethernet header (i.e. immediately following the SMAC address) and the descriptor-based VLAN tag will appear as the second outermost VLAN tag in the frame. Note that there is no checking needed for the SI based VLAN insertion. That is controlled by the PSI and, if enabled, is performed unknown to the driver on the SI itself and is inherently allowed.
4. Any bandwidth calculations used in transmit will account for the extra 4/8 bytes of VLAN information in their calculations.

53.4.2.3.1.2.1.4 Source MAC anti spoofing

The hardware supports anti spoofing functionality. This feature ensures that software is sending frames with a source MAC address that is associated with the SI.

If anti spoofing is enabled for an SI (PSI*a*CFGR0[ASE] set to 1), the source MAC address of each frame being sent by this SI is compared against its SI Primary MAC address register PSI*a*PMAR0/1 (where a is the SI number). If it matches, then the frame is allowed to be transmitted. Otherwise, a lookup of the source MAC address is performed in the exact match MAC address table. If this does not result in a match with the SI’s bit set in the result bitmap then the frame is not transmitted.

The Source MAC anti spoofing feature is not applicable to frames that are enqueue directly to egress switch ports using the direct switch enqueue capability (SMSO=1).

53.4.2.3.1.2.2 Egress Port Processing (EPP)

The Egress Port Processing block acts as a staging resource to mediate the transfer of transmit data to the MACs. Two priority queues per port are used to hold frames waiting for transmission to the MAC.

A physical port supporting IEEE 802.1Qbu frame preemption contains two MACs; i.e. MAC 0 and MAC 1. MAC 0 is called the express MAC and is used to handle the express traffic, whereby MAC 1 is called the preemptable MAC and is used to handle the preemptive traffic. Within the Egress Port Processing block, there is an internal queue for holding frames waiting to be transmitted on the express MAC and another internal queue for holding frames waiting to be transmitted on the preemptable MAC. If preemption is disabled, only MAC 0 (express MAC) is used. MAC 1 (preemptable MAC) and its corresponding internal queue are not used. The traffic class assignment to either the express MAC or the preemptable MAC is specified by setting PFPCR[FPE_TCa] (where a corresponds to the traffic class number). For more details on frame preemption, see Preemption.

A physical port that doesn't support IEEE 802.1Qbu frame preemption contains one MAC and one internal queue within the Egress Port Processing block. Similarly, a port attached to a pseudo MAC contains one internal queue within the Egress Port Processing block.

A port-per-HTA Transmit priority byte credit-based flow control mechanism is used to limit the amount of frame bytes in the ENETC transmit datapath that have been scheduled for transmission but not yet transferred to a given port and MAC ((express MAC or preemptable MAC (physical port), or pseudo MAC). There is a separate byte credit count maintained for each MAC, each initialized to the value configured in the ENETC *a* transmit high priority tier byte credit register (E*a*TXHPTBCR) for the express MAC or pseudo MAC and in the ENETC *a* transmit low priority tier byte credit register (E*a*TXLPTBCR) for the preemptable MAC. Here *a* is the ENETC instance number.

Credits are decremented when a frame is scheduled by HTA Transmit and incremented as the frame is being sent to the MAC. HTA is allowed to schedule a frame as long as credits are greater than 0. This will limit the number of frame bytes in the ENETC transmit path to "E*a*TXHPTBCR[BYTE_CREDIT] + maximum frame size" for traffic destined to the express MAC or pseudo MAC and to "E*a*TXLPTBCR[BYTE_CREDIT] + maximum frame size" for traffic destined to the preemptable MAC.

When IEEE 802.1Qbv or time specific departure (TSD) is enabled, the HTA transmit scheduler will indicate the departure time at which the frame is to be transmitted to MAC.

53.4.2.3.1.2.3 Ethernet Tx I/F

The Ethernet Tx I/F block integrates the Tx MAC functionality and implements the interface functions specific to the MAC from the transmit path.

53.4.2.3.1.2.3.1 Ethernet MAC

In the case where frames are transmitted to an Ethernet MAC, the Ethernet Tx I/F retrieves the frame from the shared internal buffer memory and transfers it to the Ethernet MAC.

If the FCS is not being provided by software, then it is calculated by HTA Transmit as it is performing frame modifications if any, and loading the frame from host memory to the shared internal buffer memory. Whether or not software provides the FCS, is specified through the register TB*a*MR[CRC], where a is the BD ring number. Once the frame has been loaded into the shared internal buffer memory, the calculated 4 bytes FCS is appended to the frame. If the port is configured to pad a frame to the minimum length of 64 bytes (see PMa_COMMAND_CONFIG[TXP] register for more details), HTA transmit will pad the frame with 0s to extend the frame to 60 bytes after performing frame modifications, if any. It will then append the calculated 4 bytes FCS to the frame.

The Ethernet MAC transmit function manages inter-packet gap and generates preamble and SFD or SMD.

The MAC supports configurable minimum frame size from 18 to 64B, and configurable maximum frame size up to 2000B. See Port MAC a Minimum Frame Length Register (PM0_MINFRM - PM1_MINFRM) and Port MAC a Maximum Frame Length Register (PM0_MAXFRM - PM1_MAXFRM) registers for more details.

After a frame has been sent to the Ethernet MAC, the Ethernet Tx I/F performs the following actions:

- For any given transmit frame, the Ethernet MAC returns the timestamp at the moment where the one-octet start frame delimiter (SFD) of the frame was transmitted. PMa_COMMAND_CONFIG[TS_MODE] determines which clock source

(synchronized 1588 clock or 802.1AS free running clock) is used for sampling the timestamp. The Ethernet Tx I/F returns this value to HTA which in turn uses this as the indication that the corresponding transmit BD descriptors have been transmitted, and if the IEEE 1588 PTP two-step timestamp offload is enabled, writes back the returned timestamp in the metadata of the host transmit descriptor.

- IEEE 1588 PTP one-step timestamp offload is also supported. When set, the Ethernet MAC is instructed to insert the timestamp information into the frame when transmitting the frame.
- Ethernet Tx I/F increments in chunks of 72 bytes, the high priority byte credit count for the port-per-HTA Transmit priority (2 priorities) byte credit-based flow control mechanism, for traffic directed to the express MAC. Similarly, it increments in chunks of 72 bytes, the low priority byte credit count for the port-per-HTA Transmit priority (2 priorities) byte credit-based flow control mechanism, for traffic directed to the preemptable MAC.
- Internal buffers holding the frame are released.

For any uncorrectable errors detected (such as multi-bit ECC errors), the frame is discarded if the frame transfer to the MAC has not started, and an appropriate error is reported in the transmit buffer descriptor. If the frame transmission has started, the frame can no longer be discarded at this point. Instead the MAC is instructed to set the frame FCS field to a bad CRC value to ensure that the next hop identifies the frame as being bad. The error (no longer a frame discard) is counted against the port's MAC FCS counters (PMa_TERRn and PMa_TFCSn).

53.4.2.3.1.2.3.2 Pseudo MAC

For frames transmitted to a pseudo MAC, there is no need to retrieve or copy these frames, as only a frame descriptor is being transferred across that interface.

Note that IEEE 1588 PTP one-step timestamp offload is not supported on the pseudo MAC.

If the FCS is not being provided by software, then it is calculated by HTA Transmit as it is loading the frame from host memory to the shared internal buffer memory. Whether or not software provides the FCS, is specified through the register TB*a*MR[CRC], where a is the BD ring number. Once the frame has been loaded into the shared internal buffer memory, the calculated 4 bytes FCS is appended to the frame. If the port is configured to pad a frame to the minimum length of 64 bytes (see PPMCR[TXPAD], for more details), HTA transmit will pad the frame with 0s to extend the frame to 60 bytes after performing frame modifications. It will then append the calculated 4 bytes FCS to the frame.

After a frame has been passed to the pseudo MAC, the Ethernet Tx I/F performs the following actions:

- Increments in chunks of 72 bytes, the high priority byte credit count for the port-per-HTA Transmit priority (2 priorities) byte credit-based flow control mechanism.
- For any given transmit frame, the pseudo MAC returns the timestamp at the moment where the frame was transferred across the pseudo link. PCR[TIMER_CS] determines which clock source (synchronized clock or free running clock) is used for sampling the timestamp. The Ethernet Tx I/F returns this value to HTA which in turn uses this as the indication that the corresponding transmit BD descriptors have been transmitted, and if the IEEE 1588 PTP two-step timestamp offload is enabled, writes back the returned timestamp in the metadata of the host transmit descriptor.

If the ENETC port is connected internally to a switch port, designated as a switch management port, an out of band metadata indicating whether to forward as it was received from the switch management port itself or from another switch port, is passed along with the frame to the pseudo MAC. This out of band metadata is taken from the host transmit descriptor of the frame.

53.4.2.3.1.3 Receive Datapath

The receive data path is implemented as a series of functional processing blocks pipelined together. This includes the Ethernet Rx I/F, Ingress Port Processing, Ingress Congestion Manager, and the Host Transfer Agent (receive). Details of these blocks are given in the following sections.

53.4.2.3.1.3.1 Ethernet Rx I/F

The Ethernet Rx I/F block integrates the Rx MAC functionality and implements the interface functions specific from the MAC to the ENETC receive path.

53.4.2.3.1.3.1.1 Ethernet MAC

In the case where frames are received from an Ethernet MAC, the Ethernet Rx I/F stores them immediately in the shared internal buffer memory.

The Ethernet MAC detects the SFD or SMD, receives the frame, and checks for layer 2 data integrity (FCS errors) while forwarding data to MAC client. All frames >= 18B with valid SFD are forwarded to MAC client.

The last 4 bytes of the frame which represents the frame check sequence (FCS), are also stored in the shared internal buffer memory. The Ethernet MAC does not remove the FCS from the frame. The FCS carried in the frame remains as the frame is processed by the ENETC receive datapath. The FCS is not updated if frame modifications are performed on the frame by the ENETC receive datapath (i.e. VLAN removal offloads). When frames are transferred into receive data buffers in the host system memory, there is the option to preserve or remove the FCS. Whether to preserve or remove the FCS is specified through the register RB*a*MR[CRC], where *a* is the BD ring number.

For any internal error detected, the ERROR field of the receive descriptor for the frame is updated to indicate that the frame is bad (internal fault code point (0x80) set).

The first 144 bytes of the received frame in addition of being stored in the shared internal buffer memory, are also stored in a frame header memory which is accessed by the Ingress Port Processing (IPP) for processing the received frame. Once the first 24 bytes of data is received and presented to the IPP, it starts parsing the frame header (first 24 bytes). If the end of the parse graph has not been reached while parsing the first 24 bytes of the frame, the IPP waits for the next 24 bytes to be received so that it can resume parsing, and so on up to 144 bytes. Once parsing is completed and although the entire frame may not have been entirely received, the IPP proceeds with executing the required lookup-ups and resulting packet processing actions that aren't dependent on at the end of frame status (good/bad) and/or frame length. The IPP will then wait for the entire frame to be received before executing actions that are dependent on the end of frame status and/or frame length (for example, policing, byte counters updates).

No drops are expected when delivering frames from the Ethernet Rx I/F to the Ingress Port Processing (IPP) as the IPP is engineered to operate at wire-rate (assuming a minimum frame length of 64 bytes); no back-pressure is expected from the IPP. If an unforeseen overload condition of the IPP is detected, received frames from the MAC will be discarded. These frame discards are counted against the port's Rx discard count register (PRXDCR) along with the setting of the Pre-Classification Discard Reason (PCDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).

The following metadata is passed along with the frame:

- Two timestamps (one sampling the synchronized clock and the other sampling the free running clock); for all receive frames, the timestamps are captured when MAC detects the one-octet start frame delimiter (SFD) of the frame. The receive timestamp is reported in the receive BD ring descriptor if the receive BD ring is configured with the extended 32B buffer descriptor format. PCR[TIMER_CS] determines which of the two timestamps (synchronized or free running) is to be reported.
- Indication that the frame was received from an Ethernet MAC (not a pseudo MAC) along with the indication whether it was received from the Express MAC or the Preemptable MAC.
- ENETC instance number; acquired from the register LaBCR[SW_PORT_ENETC_INST], where a corresponds to the link number from which the frame was received.
- Frame length; calculated by the Ethernet RX I/F as it transfers the frame from the MAC Rx FIFO to internal memory.
- Indicator if MAC detected an error (for example, CRC error, invalid frame length, and so on). Errored frames are passed to the Ingress Port Processing where they will be discarded.
- Indicator of whether the received frame is a magic packet. On ports supporting the power management Wake-on-LAN feature, every frame is scanned by the MAC for occurrences of 6 bytes of 0xFF, followed by sixteen repetitions of the endpoint MAC address. The MAC address in the magic packet pattern, must match the MAC address configured in the PM*a*_MAC_ADDR_0/1 registers. No check is performed beyond the magic packet pattern; e.g. destination MAC address in the Ethernet header of a magic packet can be a broadcast, multicast, or unicast MAC address.
- Indicator that the received frame was truncated due to the lack of free shared internal buffer memory available to store the entire frame. These frame are passed to the Ingress Packet Processing where they will be discarded. These frame discards are counted against the port's Rx discard count register (PRXDCR) along with the setting of the Shared Memory Resource Exhaustion Discard Reason (SMREDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).

For ports supporting IEEE 802.1Qbu frame preemption, there are two MACs used per port (express MAC and preemptable MAC). In this case, the Ethernet RX I/F implements the interface functions to both MACs.

53.4.2.3.1.3.1.2 Pseudo MAC

For frames received from a pseudo MAC, only frame descriptors are transferred across a pseudo link. There is no need to store or copy these frames as they have already been stored in the shared internal buffer memory by the switch. Frame descriptors received on a pseudo link from a switch port include references to the original frame (including FCS) and annotated frame header if present as a result of the switch having to perform frame modifications. This annotated frame header represents the first n bytes of the frame, along with an indication of how many bytes from the start of the original frame are no longer valid. There is an FCS covering the annotated frame header, which is distinct from the FCS covering the entire original frame.

The pseudo MAC doesn't remove the FCS(s). The FCS or two FCSs carried in the frame remain as the frame is processed by the ENETC receive datapath. The FCS(s) are not updated if frame modifications are performed on the frame by ENETC receive datapath (i.e. VLAN removal offloads).

When a frame is received, the first 144 bytes of the received frame are stored in a frame header memory which is accessed by the Ingress Port Processing (IPP) for processing the received frame.

No drops are expected when delivering frames from the Ethernet Rx I/F to the IPP as the IPP is engineered to operate at wire-rate (assuming a minimum frame length of 64 bytes); no back-pressure is expected from the IPP. If an unforeseen overload condition of the IPP is detected, received frames from the pseudo MAC are no longer accepted; frames are not dropped, instead back-pressure is applied towards the switch.

The following metadata is passed along with the frame:

- Two timestamps (one sampling the synchronized clock and the other sampling the free running clock) at the time the frame was transferred across the pseudo link. For the receive timestamp reported in the receive BD ring descriptor (receive BD ring must be configured with the extended 32B buffer descriptor format), PCR[TIMER_CS] determines which of the two timestamps (synchronized or free running) is to be reported.
- Indication that the frame was received from a pseudo MAC.
- ENETC instance number; derived from the register LaBCR[SW_PORT_ENETC_INST]
- Frame length.
- If the ENETC port is connected internally to a switch port, designated as a switch management port, an indication of the source port ID from which the frame was received is provided along with the reason why this frame was forwarded to the switch management port. Once the frame has been transferred to the host system memory, the source port ID and reason to forward to the switch management port, are placed in the metadata of the receive descriptor for the frame. Only frames with the Host Reason set to "regular forwarded frame" can be received from a pseudo MAC. Frames with a Host Reason set to a codepoint other than a "regular forwarded frame" do not go through a pseudo link, instead they are sent directly from the switch to the ENETC Ingress Congestion Manager (ICM), where they will be queued based on internal QoS set by the switch, for delivery to the HTA receive; note that all of the Ingress Port Processing (IPP) functions are by-passed with bit 0 of the SI bitmap set to 1 (indicates to HTA that the frame is to be delivered to SI numbered 0).

No errors are expected; FCS is not checked as there are no transmission of bits on pseudo link interface as only a frame descriptor is being transferred across that interface.

53.4.2.3.1.3.2 Ingress Port Processing (IPP)

The figure below shows the processing through the Ingress Port Processing.

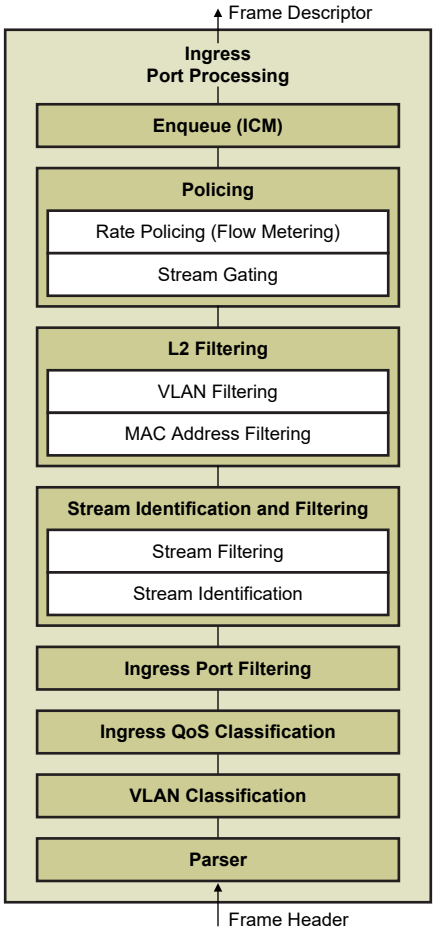

Figure 335. Ingress Port Processing diagram

The Ingress Port Processing block responsibilities are to parse the frame headers and to do the necessary table lookups (or classification) to determine the internal QoS attributes (Internal Priority Value/IPV and Discard Resiliency/DR), to decide whether to accept the frame and to determine the set of Station Interfaces (SIs) where to forward the frame next.

After it is determined that a frame can be delivered to a least one SI, a policing function may be applied. Policing involves determining whether a frame is in or out of some defined time window and bandwidth profile. If out of profile, the DR is marked down (more discardable) or the frame is dropped as per profile. Frames rejected by the prior classification stage are not policed.

The Ingress Port Processing block performs the following ingress port processing functions in a pipeline manner:

- **Parser** - Parses the frames and identifies the locations of the required packet header fields in preparation for classification. Supports major protocols such as Ethernet, IPv4, IPv6, TCP and UDP.
- **VLAN classification** - Determine what VLAN tag data will be passed with the frame for later ingress processing. This includes optional assignment of configured port tag data if the frame is untagged.
- **Ingress QoS classification** - Provides internal identification of the QoS attributes that are used for subsequent QoS processing as frames go through the device. As an example, the IPV and DR can be set based on the pbits and DE bit in a VLAN tag. Internal QoS attributes indicate the given QoS (queueing priority and discard resiliency) as the frame moves through the device. At any queuing point, frames can be placed in the appropriate queue based on the internal queuing priority and can be dropped based on the internal drop priority.
- **Ingress port filtering** - Can deny or allow a frame. It may also override internal QoS attributes associated with the frame and set the stream ID or rate policer instance ID. It can also forward a frame to a particular set of SIs.

- **Stream identification and filtering** - Implements stream identification and filtering as per IEEE 802.1Qci (Per-Stream Filtering and Policing).
- **L2 filtering** - Performs a series of lookups based on SMAC, DMAC and VLAN, to decide whether to accept the frame and to provide the set of Station Interfaces (SIs) eligible to receive the frame.
- **Policing** - Implements traffic policing as per IEEE 802.1Qci (Per-Stream Filtering and Policing) to protect against time window and bandwidth violations.
- **Enqueue** - Sends frames towards the HTA block by passing the frames to the Ingress Congestion Manager (ICM) where they will be queued internally (inside ICM); i.e. frames are placed in the appropriate ICM queue based on their incoming port and internal Priority Value (IPV). There are 2 priority queues per port. Within a port the IPV is used to select one of the priority queues based on the configured IPV to ICM receive port priority queue mapping (IPV2ICMPMR0) register. There is no drop at this point (i.e. no enqueue reject) as ICM ensures that an arriving frame is always accepted by having the ability to drop some already stored and enqueued frames, in the case where the ENETC receive shared internal buffer memory becomes full.

Frames received from the Ethernet Rx I/F with the indication that an error was detected are dropped. No drop count is incremented at this point as the appropriate error count has already been incremented by the Ethernet Rx I/F.

53.4.2.3.1.3.3 Parser

The Parser parses up to L4 protocol headers in up to the first 144 bytes of the frame. Extracted field values and locations of relevant L2, L3 and L4 headers values are then used to perform the various table lookups and hash functions in subsequent processing stages of the IPP.

During parsing, the parser examines and validates headers.

The parsing process can be expressed as a directed graph with nodes representing header types and edges (arrows) representing the sequence of headers. Parsing starts at the root node then walks from node to node using the next-header field values. Specifically, each node works within a protocol layer presuming a certain type of header, confirms the validity of the header, identifies boundaries of the header, extracts attributes and offsets, and determines the next header to examine beyond the current header.

Figure below shows the parse graph supported in the IPP. The parse graph is structured by layers (L2, L3, and L4), with the details per each layer provided in the next sections.

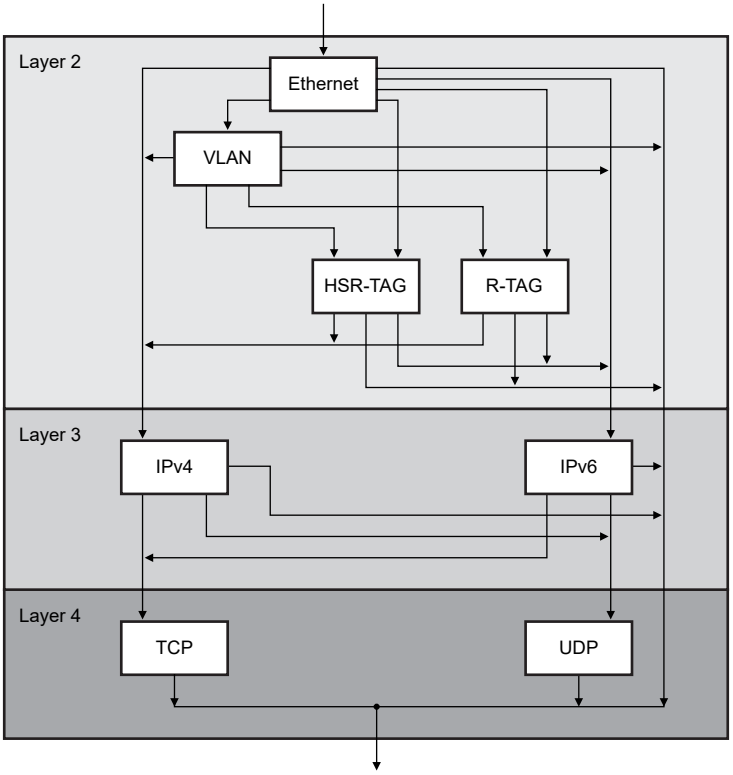

Figure 336. IPP Parse Graph

By default, the parser will parse and extract fields from each layer. There is the option to configure the parser to end parsing at L2 or L3 regardless of the content of the frame (for more details, see the port parser configuration register (PPCR)). The parser will also extract the payload (up to 24 bytes by default) of the last layer parsed (L2, L3 or L4). The maximum amount of payload to extract is configurable for each layer via the port parser configuration register (PPCR).

Parsing is terminated via one of the following:

- Upon reaching the natural end of a branch in the parse graph
- Upon reaching a layer (L3 or L4) for which the parser has been configured not to parse.
- A parsing error is encountered; note that parse information from headers that have been successfully parsed is still used by table lookups and hash functions in subsequent processing stages of the IPP.

53.4.2.3.1.3.3.1 Layer 2 Headers

As the first header in a frame, the parser supports Ethernet frames of the IEEE 802.3 (Ethernet II) format. IEEE 802.3 (Ethernet II) frames may be tagged with the IEEE 802.1Q VLAN tagging method. The 4-byte IEEE 802.1Q VLAN tag has two 2-byte components: Tag Protocol Identifier (TPID, residing within the type/length field) and the Tag Control Information (TCI). The following 4 TPID values are recognized as VLAN tags:

- The standard types 0x8100 and 0x88A8
- Two optional user programmable EtherType values known as CustTag1 and CustTag2; configured through CVLANR1 and CVLANR2 registers.

The TCI includes the following fields:

- PCP - Priority Code Point, the first three bits of the TCI define user priority.
- DEI - Drop Eligibility/ (single-bit field)
- VID - The 12-bit VLAN ID (VID) field identifies the VLAN the frame belongs to. The 12 bits allow for 4096 different VLANs. Out of the 4096 VLANs, the VID of zero is used to identify priority tagged frames and the value of 4095 is reserved.

Parser can parse frames with up to 2 VLAN tags. VLAN tags are named based on their position in the frame relative to other VLAN tags and the beginning of the frame i.e. the 802.3/Ethernet header consisting of Destination followed by Source MAC addresses.

The VLAN tag or header nearest the 802.3/Ethernet header is called the outer (or first) tag. The VLAN tag which is next closest to the 802.3 header is the inner (or second) tag. VLAN tags are expected to be contiguous, following one after the other, with no intervening non-VLAN tags.

Note that any VLAN tags which are within encapsulated frames and after any Upper Layer Protocol (ULP) header are not recognized. If only one VLAN tag is present in the frame, the inner VLAN tag is considered not present.

The outer and inner VLAN tag data (PCP, DEI and VID), if present, are extracted from the frame. The TPID from each VLAN tag is matched against the 4 known VLAN EtherTypes (2 standard, up to 2 custom) and a 2-bit TPID value is assigned identifying which known value matched (00: 0x8100, 01: 0x88A8, 10: CustTag1, 11: CustTag2). Matching is done against the list {0x8100, 0x88A8, CustTag1, CustTag2} in order and matching stops on the first match found. A 4-bit vector where each bit represents a TPID code point (bit 0 -> 00, bit 1 -> 01, bit 2 -> 10 and Bit 3 -> 11) is used by subsequent processing stages within the IPP to perform non-contiguous masked matching operation against the TPID.

The information found in the next EtherType field (after VLAN parsing) is used to determine the next ULP header to parse. The EtherType field is located following the Source MAC address field if no VLAN tag present, or following the last VLAN tag. The ULP header is determined according to the “Ethernet - EtherType to Next ULP” mapping described in the table below.

EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends. If parsing reached end of frame, while more octets are expected to extract the 2-byte EtherType, the extracted EtherType is set to 0.

Table 398. Ethernet - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0800	IPv4	IPv4
x86DD	IPv6	IPv6
x892F	HSR Tag	HSR Tag
xF1C1	IEEE 802.1CB R-TAG	Redundancy tag
Pre-standard R-TAG EtherType register	IEEE 802.1CB draft 2.0 R-TAG	Redundancy tag

For High Availability Seamless Redundancy (HSR) tag, the parser locates the EtherType field following the 6-byte HSR tag. The next ULP header is determined according to the “HSR tag - EtherType to Next ULP” mapping described in the table below. If the EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 399. HSR tag - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0800	IPv4	IPv4
x86DD	IPv6	IPv6

For the 802.1CB R-tag, the parser locates the EtherType field following the 6-byte CB Redundancy tag. The next ULP header is determined according to the “CB Redundancy tag - EtherType to Next ULP” mapping described in the table below. If the EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

The 4-byte pre-standard (802.1CB draft 2.0) R-TAG is also supported, The format of this tag is 2 bytes for the EtherType followed by 2 bytes for the sequence number. The recognized value for the Ethertype value of the pre-standard R-TAG is configured through the pre-standard R-TAG Ethertype register (PSRTAGETR). For the 4-byte pre-standard R-TAG, the parser locates the EtherType field following the 4-byte pre-standard R-TAG. The next ULP header is determined according to the "Redundancy tag -

EtherType to Next ULP" mapping described in the table below. If the EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 400. CB Redundancy tag - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0800	IPv4	IPv4
x86DD	IPv6	IPv6

Following information is provided along with the frame, by the parser for subsequent processing within the IPP:

- Source and Destination MAC addresses are extracted.
- Indication of whether the outer VLAN tag header is present. If the header is present and valid (no parsing error), extracted VLAN tag data along with a 2-bit code identifying the TPID is also provided.
- Indication of whether the inner VLAN tag header is present. If the header is present and valid (no parsing error), extracted VLAN tag data along with a 2-bit code identifying the TPID is also provided. If only one VLAN tag is present in the frame, the inner VLAN tag is considered not present.
- Whether destination MAC address is unicast, multicast or broadcast.
- A 3-bit redundancy tag type codepoint
  000b = No redundancy tag present
  001b = 802.1CB draft 2.0 R-TAG.
  010b = 802.1CB R-TAG.
  011b = HSR Tag
  100b ... 111b = Reserved.
- The sequence number is extracted if a redundancy tag is present and valid (no parsing error)
- The last parsed EtherType is extracted; i.e. 2 bytes immediately after source MAC address or VLAN tag(s)/R-TAG/HSR (if any). If the EtherType wasn't parsed successfully (e.g. missing one byte due to frame too short), the EtherType is set to all 0s.
- Extracting up to 24 bytes located immediately after payload EtherType. The payload EtherType is located immediately after the source MAC address or VLAN tag(s)/R-TAG/HSR (if any) if parsing is ending at this layer. The maximum amount of payload to extract is configurable via the port parser configuration register (PPCR).

Possible parsing errors for L2 headers are:

- Frame parsing reached end of frame while parsing a VLAN tag or R-TAG/HSR that expects more data. Frames shorter than 14 bytes excluding 4-byte FCS will never reach the parser as they will be discarded by the Ethernet Rx I/F.

There are no validation checks performed on the Source and Destination MAC addresses, and EtherType fields.

Note that if an L2 header parsing error is detected, the frame is not discarded. Instead, only successfully parsed L2 header fields are extracted, but no payload data is extracted. The parse information is then passed along with the frame for subsequent processing within the IPP(e.g. table lookups and hash functions).

Note that any sequence tag information extracted by the parser for usage by subsequent processing stages, is overwritten if FRER sequence generation is enabled for the frame. NETC only supports ONE CB redundancy tag, one added as part of sequence generation if enabled, or a parsed redundancy tag if present.

53.4.2.3.1.3.3.2 Layer 3 Headers

The parser supports parsing of both IPv4 and IPv6 packets. Only the first IPv4 or IPv6 header encountered in a packet is parsed.

IPv4 options are not parsed. They are also not skipped meaning that the next ULP header will not be parsed if the packet has IPv4 options.

If a non-fragmented IPv4 packet (Fragment Offset is set to zero and the More Fragments flag is set to zero) or an initial fragment packet ((Fragment Offset is set to zero and the More Fragments flag is set to one) is parsed, then the parser uses the information stored in the Protocol field to determine the next ULP header to be parsed.

For IPv4 header, the next ULP header is determined according to the "IPv4 - Protocol to Next ULP" mapping described in the table below. If the Protocol field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 401. IPv4 - Protocol to Next ULP Mapping

Protocol (decimal)	Recognized Protocol	Next ULP to be parsed
6	TCP	TCP
17	UDP	UDP

For IPv6 header, the IPv6 main header may be followed by an arbitrary number (0, 1 or multiple) of extension headers chained together through the Next Header field. IPv6 extension headers are not parsed. They are also not skipped meaning that the next ULP header will not be parsed if the packet has extension headers.

The parser uses the information stored in the Next Header field of the IPv6 main header to determine the next ULP header. The next ULP header is determined according to the “IPv6 – Next Header to Next ULP” mapping described in the table below. If the Next Header is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 402. IPv6 - Next Header to Next ULP Mapping

Next Header (decimal)	Recognized Protocol	Next ULP to be parsed
6	TCP	TCP
17	UDP	UDP

Following information is provided along with the frame, by the parser for subsequent processing within the IPP:

- Indication of whether the outer IP header is present and valid (no parsing error). If the header is present and valid, indication of whether IP header is v6 or v4, is also provided.
- Indication of whether IPv4 options / IPv6 extensions are present. Note that value 59 (No Next Header) in the Next Header field of the IPv6 main header, is not considered an IPv6 extension header. See table below for the recognized IPv6 extension headers.
- IP source address , IP destination address, DSCP and Protocol fields are extracted.
- Extracting up to 24 bytes located immediately after the IP header if parsing is ending at this layer. The maximum amount of payload to extract is configurable via the port parser configuration register (PPCR). Note that if IPv4 options or IPv6 extensions are present, payload extraction starts at the beginning of the IPv4 Options/IPv6 Extensions header.

Possible parsing errors for L3 headers are:

- Frame parsing reached end of frame while parsing a L3 header that expects more data.
- For each IPv4 header parsed, if any of the following conditions is detected:
  - Version number in IPv4 header is not equal to 4.
  - IPv4 Header Length field value is less than 20 bytes, or exceeds the received packet length (excludes L2 header), or exceeds the IPv4 header Total Packet Length field value
- For each IPv6 header parsed, if any of the following conditions is detected:
  - Version number in IPv6 header packet is not equal to 6,

Note that if an L3 header parsing error is detected, the frame is not discarded. Instead, the L3 header is considered not present, and parsing ends. The parse information from the L2 headers (including L2 payload if extracted) is passed along with the frame for subsequent processing within the IPP (e.g. table lookups and hash functions).

Table 403. IPv6 extension headers

Protocol Number (decimal)	Description
0	IPv6 Hop-by-Hop Option
43	Routing Header for IPv6
44	Fragment Header for IPv6
50	Encapsulating Security Payload
51	Authentication Header
60	Destination Options for IPv6
135	Mobility Header
139	Host Identity Protocol
140	Shim6 Protocol
253	Use for experimentation and testing
254	Use for experimentation and testing

53.4.2.3.1.3.3.3 Layer 4 Headers

The parser supports parsing of both TCP and UDP packets. Only the first TCP or UDP header encountered in a packet is parsed.

The TCP header may have options but these aren't examined.

Following information is provided along with the frame, by the parser for subsequent processing within the IPP:

- If the L4 header parsed is TCP, an indication that TCP is present (L4 codepoint set 01b).
- If the L4 header parsed is UDP, an indication that UDP is present (L4 codepoint set 10b).
- Source and destination port numbers are extracted.
- If no TCP nor UDP header is detected, an indication that other L4 is present (L4 codepoint set 00b).
- Extracting up to 24-bytes located immediately after the first 4 bytes of the TCP/UDP header. The maximum amount of bytes to extract is configurable via the port parser configuration register (PPCR).

Possible parsing errors for L4 headers are:

- Frame parsing reached end of frame while extracting source and destination port numbers (L4 header shorter than 4 bytes).

Note that if an L4 header parsing error is detected, the frame is not discarded. Instead, the L4 header is considered other L4, and parsing ends. The parse information from the L3 headers (including L3 payload if extracted) is passed along with the frame for subsequent processing within the IPP (e.g. table lookups and hash functions).

53.4.2.3.1.3.4 VLAN classification

VLAN classification processing stage determines what VLAN tag data will be passed with the frame for later ingress processing.

Following VLAN tag metadata provided by the parser is used by VLAN classification:

- Indication of whether the outer VLAN tag header is present (no parsing error)
- Indication of whether the inner VLAN tag header is present (no parsing error)

- Extracted outer VLAN tag data from frame
  - PCP, DEI, VID
  - TPID expressed as 2-bit code point
- Extracted inner VLAN tag data from frame
  - PCP, DEI, VID
  - TPID expressed as 2-bit code point

Output of the VLAN classification is:

- VLAN tag attribute indicators
  - Indication of whether the frame is untagged
  - Indication of whether outer VLAN tag is valid, if valid then the following attributes further qualifies it
    - VLAN tag data taken from port outer VLAN configuration register
    - VID is set 0 in the frame outer VLAN tag; i.e. priority tag
  - Indication of whether inner VLAN tag is valid, if valid then the following attributes further qualifies it
    - VLAN tag data taken from port inner VLAN configuration register
    - VID is set to 0 in the frame inner VLAN tag; i.e. priority tag
- Outer VLAN tag data (PCP, DEI, VID) if outer VLAN tag is valid
- Inner VLAN tag data (PCP, DEI, VID) if inner VLAN tag is valid

The setting of the above VLAN classification output attribute indicators (along with appropriate VLAN tag data) is provided in the following steps:

1. All VLAN classification output indicators are cleared at the start of VLAN classification processing except for the outer/inner tag presence indicators which are taken from the parser. Outer/inner tag data and 2-bit TPID code point are also taken from the parser
2. If no tags are present then frame metadata is marked as untagged.
3. If only the outer tag is present (i. e. there is only one VLAN tag recognized in the frame) and the setting requires that it be treated as the inner tag (PVCLCTR[OAI] bit set to 1) then the outer tag data is used as the inner tag data for further processing. The outer tag is deemed not present and the inner tag is deemed present.
4. For each of the inner/outer tags which are (deemed) present the appropriate acceptance bitmap (PTAR[IVTPIDL/OVTPIDL]) is checked. If the tag's TPID's bit is set then the tag is acceptable otherwise it is deemed not present.
5. For each of the inner/outer tags which are (deemed) present if the tag has a 0 VID and port VLAN VID 0 usage is enabled (PINVLANR/PONVLANR[VZE] bit is set to 1) then insert the port VLAN VID (PINVLANR/PONVLANR[VID]) into the frame's metadata VLAN tag data. Frame metadata is marked as having VID 0 in that tag for upstream use.
6. For each of the inner/outer tags which are (deemed) not present if the port VLAN is enabled (PINVLANR/PONVLANR[PNE] bit is set) then the appropriate configured (inner/outer) port VLAN tag data ((PINVLANR/PONVLANR[PCP], (PINVLANR/PONVLANR[DEI] and PINVLANR/PONVLANR[VID]) is used as the VLAN tag data in the frame metadata. The tag is now deemed present. Frame metadata is marked as using port VLAN data in that tag for upstream use.
7. For each of the inner/outer tags if the tag is (deemed) present then frame metadata is marked as tag data being valid.

The resulting VLAN tag data and attribute indicators are passed along for upstream use.

53.4.2.3.1.3.5 QoS classification

QoS classification involves setting the internal QoS. The internal QoS indicates the given QoS (Internal Priority Value and Drop Resilience) as the frame moves through the device, and encounters resource contention and possibly be conditioned (e.g.

policing). Internally at any queuing point, frames can be placed in the appropriate queue based on the Internal Priority Value and can be dropped based on the Drop Resilience.

Internal Priority Value (IPV) is a 3-bit attribute assigned to a frame which is used for certain scheduling decisions in subsequent receive processing stages. A higher IPV value generally indicates higher priority, assuming strict priority scheduling is applied. The lowest priority is 0 and the highest is 7.

Drop Resilience (DR) is a 2-bit attribute assigned to a frame which is used to determine the likelihood of dropping the frame if there is congestion. A higher DR value generally indicates being more discardable. For example:

- Drop resilience 0

  Committed frames. With proper allocation of buffer and bandwidth resources within the network, it is possible to guarantee a lossless and timely delivery of a committed frames. In a "colored" mapping scheme such as IEEE 802.1Qci flow metering, this corresponds to Green.

- Drop resilience 1

  Normal frames. In a "colored" mapping scheme such as IEEE 802.1Qci flow metering, this corresponds to Green.

- Drop resilience 2

  Non-committed frames. At sign of congestion, these frames can be dropped but should otherwise be delivered. In a "colored" mapping scheme such as IEEE 802.1Qci flow metering, this corresponds to Yellow.

- Drop resilience 3

  Violating frames. These frames are delivered on a "best effort" basis. In a "colored" mapping scheme such as IEEE 802.1Qci flow metering, this corresponds to Red.

Received frames are initially assigned an IPV and DR based on the setting for the port (PQOSMR[DIPV] and PQOSMR[DDR]).

The PCP and DEI from one of the sets of VLAN tag data may be used to override the default settings. This is achieved by setting PQOSMR[VE] to 1 to enable the use of VLAN tag data to determine IPV and DR and configuring PQOSMR[VS] to determine which VLAN tag (inner/outer) to be used.

If the selected VLAN tag is valid (VLAN classification output), the PCP and DEI from the selected VLAN tag data are used to determine IPV and DR based on the configured per port mapping VLANIPVMP*a*R0/1 and VLANDRMP*a*R, where *a* identifies a mapping profile. The profile to use (i.e *a*) is specified in PQOSMR[VQMP].

IPV and DR values for the frame may also be changed by subsequent processing stages.

53.4.2.3.1.3.6 Ingress Port Filtering

This stage implements the ingress port filtering functions. There are two functions being performed; denial of service checks function and the ingress port filtering lookup function.

The denial of service (DOS) checks function is first executed to determine whether admit or drop incoming frames. The denial of service checks to be performed are specified in DoS L2 configuration register (DOSL2CR). Whether to perform the L2 DOS checks is specified in register PCR[L2DOSE].

If the frame hasn't been discarded by the previous function, the ingress port filtering lookup function is then executed by examining the frame header information to determine on whether to deny or allow a frame. It may also be used to override internal QoS attributes associated with the frame and set parameters (e.g. Rate Policer Entry ID, stream ID, SI bitmap) for the subsequent frame processing functions.

The ingress port filtering lookup function must be enabled to be executed (i.e. PIPFCR[EN] set to 1). If the ingress port filtering lookup function is disabled, the ingress port filtering lookup function is by-passed, and frames are passed to the next frame processing function.

The ingress port filtering lookup function involves performing a lookup against the ingress port filter table. The ingress port filter table is defined as a ternary match table. In a ternary match table, all entry key matching fields are composed of pairs of data and mask values, to support a per-bit ternary match capability. For each {data, mask} bit pair, the following combinations are supported:

- 00 = always match (X)
- 01 = match on 0
- 11 = match on 1
- 10 = always match (X); note that the table management query operation will always be returning 0 for any data bits which have their corresponding mask bit set to 0, regardless of whether they are set to 0 or 1 by the table management add or update operations.

In other words, to look for a match on a particular bit, set its mask bit to 1, and its corresponding data bit to the desired matching value, 0 or 1. A mask value of all 1's for a particular field means that field is required. To make a bit don't care, set its mask bit to 0.

In a ternary match table, a single lookup key can be matched by multiple table entries, and thus every entry must have a priority (or precedence) assigned by the software. When multiple entries match, the entry with the highest priority, is returned as the matching entry.

If no entry matches the frame, the frame is allowed in, and passed to the next frame processing function.

The ingress port filter table is implemented using a Ternary Content Addressable Memory (TCAM).

For programming of the table entries, see Ingress Port Filter Table

The ingress port filter table entry includes the following matching key fields (each field is bit-wise maskable):

- Source and destination MAC address
- Outer VLAN tag PCP, DEI and VID
- Inner VLAN tag PCP, DEI and VID
- Payload EtherType, located immediately after the source MAC address or VLAN tag(s)/R-TAG/HSR (if any).
- IPv4 source address and destination IPv4 address
- IPv6 source address and destination IPv6 address
- Protocol field present; for IPv6 packets the Protocol key (called the "Next Header" in IPv6) is not extracted if the packet has IPv6 extension headers.
- Protocol
- IP DSCP
- TCP/UDP header source and destination port
- Payload (up to 24-bytes)
  - When no IP header is present, the payload is matched against the frame bytes located immediately after the payload EtherType. The payload EtherType is located immediately after the source MAC address or VLAN tag(s)/R-TAG/HSR (if any).
  - When IP header is present and no TCP or UDP header is present, the payload is matched against the frame bytes located immediately after the IP header except when IPv4 options or IPv6 extensions are present. For the latter, payload matching starts at the beginning of the IPv4 Options/IPv6 Extensions header.
  - When TCP or UDP header is present, the payload is matched against the frame bytes located immediately after the first 4 bytes of the TCP/UDP header.
- Frame attributes fields
  - o Outer VLAN tag present
  - o Inner VLAN tag present
  - o IP header present
  - o Indication of whether IP header is v6 or v4
  - o TCP header present

- UDP header present
- Other L4 present (not TCP or UDP)
- IPv4 option / IPv6 extension present
- Sequence Tag present
- Magic packet

Note that when hardware constructs a table lookup key for a frame header field for which the frame header is not present in the frame, it sets the key field to zero. If zero corresponds to a valid value in a frame header field, this could lead to a false positive match. To avoid these false positive matches, the present frame header (or field) 1-bit key matching fields are defined in the table entry to explicitly specify whether the presence of a frame header (or field) must be present or not present in a frame header, for an entry to match.

Following are the possible actions when an ingress port filter entry is matched:

- Filtering action, one of the following:
  - Discard
  - Permit
- Modifying internal QoS attributes (IPV and DR)
- Indicating that the frame should be treated as a Wake-on-LAN frame (valid if IPFCAPR[WOL]=1)
- Setting internal parameter, one of the following
  - Enabling policing with a specified Rate Policer Entry ID
  - Specifying a Ingress Stream Entry ID along with lookup precedence
  - Setting a pre L2 filtering SI bitmap that will be used by the L2 filtering function to determine the final SI bitmap.

53.4.2.3.1.3.7 Stream Identification and Filtering

This stage implements the stream identification and filtering functions. Steam identification mainly involves classifying incoming traffic into a locally-significant identifier (global to the device), that identifies a stream within the device. This identifier is referred to as the Ingress Stream Entry ID (IS_EID). The stream identification function is implemented as per IEEE 802.1CB (Frame Replication and Elimination for Reliability (FREF)). Note that IEEE 802.1Qci (Per-Stream Filtering and Policing) exploits the stream identification functions specified in IEEE 802.1CB. The stream filtering function identifies the actions/functions to be applied to frames belonging to the identified stream. Namely, the main actions/functions are:

- Whether a frame is accepted or discarded.
- Maximum service data unit size defined for the stream as per IEEE 802.1Qci (Per-Stream Filtering and Policing).
- Stream gate instance and rate policer instance to be used to police the stream as per IEEE 802.1Qci (Per-Stream Filtering and Policing). The stream gating and rate policer functions are applied later in the ingress processing pipeline after it has been determined where to forward the frame.
- FREF (IEEE 802.1CB) sequence generation function. This function applies only to the switch.
- Stream forwarding function; the port(s) to which the frame should be output are provided in the stream context along with the egress packet processing actions to be applied to packets for each of the outgoing port(s); when the stream forwarding function is selected, the 802.1Q bridge forwarding function is by-passed. This function applies only to the switch.
- Ingress frame modifications such as ingress VLAN translation and IEEE 802.1CB active stream identification (replacing DMAC and/or VLAN). This function applies only to the switch.
- The Ingress Stream Counter ID that indicates the Ingress Stream Count table entry to be used to count matched frames and count discarded frames.

53.4.2.3.1.3.7.1 Stream Identification

Stream identification function mainly involves performing a series of table lookups to determine the Ingress Stream Entry ID (IS_EID), which in turn is used to access the Ingress Stream table to retrieve the action(s) to be applied to the frame. A default IS_EID, can be specified on a per port basis in PISIDCR register. Following are the lookup tables that can yield the IS_EID.

- **Ingress Port Filter table** - IS_EID can be specified in an Ingress Port Filter entry along with its relative precedent resolution value. Specifying IS_EID in ingress port filter entry is optional. If specified, its relative precedent resolution value determines if further lookups are required for stream identification.
- **Ingress Stream Identification table** - The Ingress Port Filter table lookup (prior stage) is followed up by a series of up to 2 hash based exact match table lookups into the Ingress Stream Identification table. The key used for stream identification exact match lookup is specified through a "key construction rule". A key construction rule specifies how the lookup key should be constructed. Specifically, it specifies metadata, specific frame header fields, and payload data that should be concatenated to form a key for the table lookup. A key construction rule is specified through a set of registers. For the switch, there are 4 key construction rules available for the entire switch, and are identified by the decimal number (0-3). For ENETC, there are 2 key construction rules per ENETC instance, and are identified by the decimal number (0-1). Note that the key construction register names imbeds the ID of the key construction rule that they are associated with. For example, ISIDKCaCR0, "a" represents the rule ID (decimal) that the register is associated with. Assignment of key construct rules to Ingress Stream Identification table lookups is achieved through key construction rule profiles. A key construction rule profile contains 2 construction key rules (one for the first exact match lookup and one for the second exact match lookup). Key construction rule profiles are derived through a static hard-wired assignment; profile 0 includes rules ID 0 and 1, profile 1 includes rules ID 2 and 3, and so on if it needs to be expanded in the future. For the switch, which of the two key construction rule profiles to use, is configurable on per switch port basis (register PISIDCR[KCPAIR]). For ENETC, key construction rule profile 0 is always used.

The following details the sequence of table lookups for determining the IS_EID (also illustrated in Figure 337).

1. If the Ingress Port Filtering function has yield an IS_EID and its relative precedent resolution value indicates that it has the highest precedence level (set to 0), then this IS_EID is selected, else go to step #2.
2. The first of the two hash based exact match lookups is performed (if enabled (PISIDCR[KC0EN]=1)) based on the key construction rule specified for this lookup. If a matching entry is found, the IS_EID specified in the entry is then selected. If this lookup is not enabled or a matching entry is not found and if the Ingress Port Filtering function has yield an IS_EID with a relative precedent resolution value falling between first and second exact match lookup (i.e. value set to 1), then this IS_EID is selected. Otherwise go to step #3.
3. The second of the two hash based exact match lookups is performed (if enabled (PISIDCR[KC1EN]=1)) based on the key construction rule specified for this lookup. If a matching entry is found then the IS_EID specified in the entry is selected. If this lookup is not enabled or a matching entry is not found and the Ingress Port Filtering function had yield an IS_EID then this IS_EID is selected. Else the default IS_EID is selected.

Note that if the selected IS_EID is NULL, the ingress stream frame processing will not be performed and the frame is passed on to the next stage of processing.

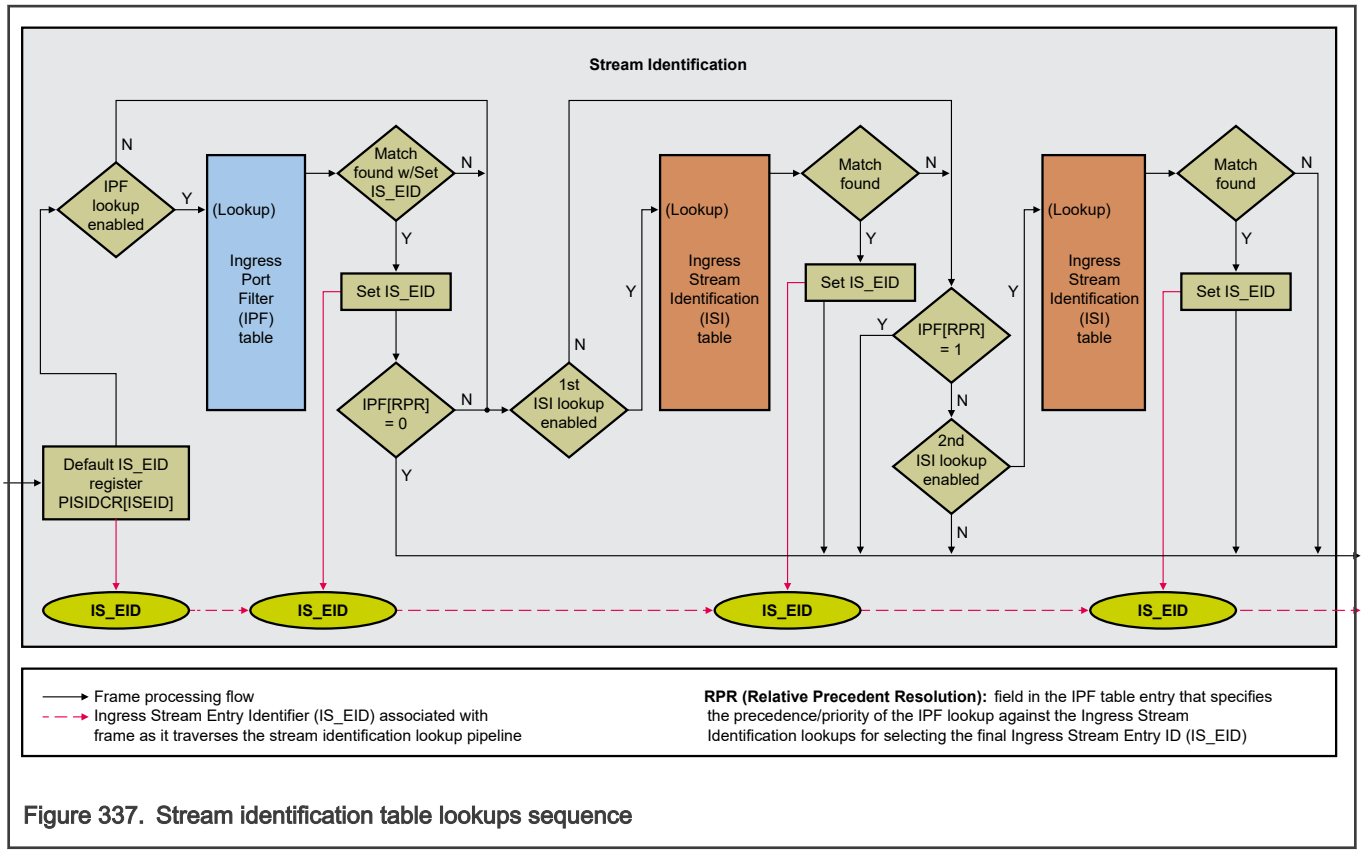

Figure 337. Stream identification table lookups sequence

Following registers are associated with lookups in the Ingress Stream Identification table.

- Ingress Stream Identification Capability Register (ISIDCAPR); indicates number of key construction rules, maximum key size, and so on.
- Ingress Stream Identification Hash Table Capability Register (ISIDHTCAPR); indicates which configuration access methods are supported.
- Switch registers for ingress stream identification key construction rules are noted below.
  - Ingress Stream Identification Key Construction a Operational register (ISIDKC*a*OR); indicates the number of entries in the Ingress Stream Identification table for particular key construction rule, where *a* =0..3 represents the key construction rule ID.
  - Ingress Stream Identification Key Construction Configuration Register 0 (ISIDKC*a*CR0) , where *a*=(0..3) represents the key construction rule ID.
  - Ingress Stream Identification Key Construction a Payload Field 0 Configuration Register (ISIDKC*a*PF0CR), where *a*=(0..3) represents the key construction rule ID.
  - Ingress Stream Identification Key Construction a Payload Field 1 Configuration Register (ISIDKC*a*PF1CR), where *a*=(0..3) represents the key construction rule ID.
  - Ingress Stream Identification Key Construction a Payload Field 2 Configuration Register (ISIDKC*a*PF2CR), where *a*=(0..3) represents the key construction rule ID.
  - Ingress Stream Identification Key Construction a Payload Field 3 Configuration Register (ISIDKC*a*PF3CR), where *a*=(0..3) represents the key construction rule ID.
  - Port Ingress Stream Identification Configuration Register (PISIDCR); used to enable/disable exact match ingress stream identification lookups and to specify which key construction rule profile to use.
- ENETC registers for ingress stream identification key construction are noted below.

- Ingress Stream Identification Key Construction a Operational register (ISIDKC*a*OR); indicates the number of entries in the Ingress Stream Identification table for particular key construction rule, where *a* =0..1 represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Configuration Register 0 (ISIDKC*a*CR0), where *a*=(0..1) represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Payload Field 0 Configuration Register (ISIDKC*a*PF0CR), where *a*=(0..1) represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Payload Field 1 Configuration Register (ISIDKC*a*PF1CR), where *a*=(0..1) represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Payload Field 2 Configuration Register (ISIDKC*a*PF2CR), where *a*=(0..1) represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Payload Field 3 Configuration Register (ISIDKC*a*PF3CR), where *a*=(0..1) represents the key construction rule ID.
- Port Ingress Stream Identification Configuration Register (PISIDCR); used to enable/disable exact match ingress stream identification lookups.

The Ingress Stream Identification table is managed using command messages. See Ingress Stream Identification Table for the switch and Ingress Stream Identification Table for ENETC.The Ingress Stream Identification table entry includes the following matching key fields:

- Key construction rule ID (referred to as KEY_TYPE in the Ingress Stream Identification table)
- Source port ID; applicable to the switch only
- Source Port Masquerading (SPM); applicable to the switch only
- Frame portion of the key (up to 16 bytes) frame header key construction is specified in ISIDKC*a*CR0 and frame payload key construction is specified in ISIDKC*a*PF*b*CR , where *a* represents the rule ID and *b* represents the payload field.

The frame portion of the key format (frame key) is specified by the aforementioned key construction rule registers. The frame key entered in the Ingress Stream Identification table entry has to be in packed form in the order they appear in the frame with each field formatted in big endian format (order they are received from the link). If the constructed key is less than 16 bytes then the frame key entered in the Ingress Stream Identification table entry, must be padded with zeros for the rest of the bytes.

Protocol header data or payload data has to be added to the key in the Ingress Stream Identification entry if indicated as 'present' in key construction register. Format of protocol header data or payload data in 16 byte key (referred to as Key) is specified below.

- Source port and SPM are included in the key if respective 'present' bit is set in the key construction register. These values are part of the reserved area in the hash key and do not add bytes to the frame portion of the key.
- Following are the options for the Ethernet header:
  - If SMAC or DMAC is present in key construction register then each of these adds 6 bytes of data to the key. If both are present then DMAC has to follow SMAC.
  - If VID or PCP are indicated as present in key construction register then the following is added to the key: VID only, PCP only, VID and PCP, or 'no VLAN tag present in the frame'. VID and PCP can be specified for both inner and outer VLANs.
  - A one-byte frame attribute code point is included in the key indicating whether there is no 802.1CB R-TAG/HSR tag, 802.1CB draft 2.0 R-TAG present, 802.1CB R-TAG present or HSR tag present.
  - If EtherType is present in key construction register then an EtherType is added to the key. The EtherType extracted is located immediately after source MAC address or VLAN tag(s)/R-TAG/HSR (if any).
  - ISIDKCaPFbCR registers specify the key format for the payload data (where 'a' indicates the key construction rule used for the exact match lookups and 'b' indicates the payload field). The key format is big endian (network byte order).

53.4.2.3.1.3.7.2 Per-Stream Filtering

Based on the selected IS_EID, the Ingress Stream table entry is read from Ingress Stream table to obtain the actions to be performed for the received frame:

- Forwarding options for switch function - Discard frame, redirect/copy frame to switch management port, use 802.1Q bridge forwarding function or use stream forwarding which by-passes the 802.1Q bridge forwarding function.
- Forwarding options for ENETC function - Discard frame, forward with SI bitmap or forward without SI bitmap set.
- Specify whether to perform the maximum Service Data Unit (SDU) check. See Maximum SDU Check for more details.
- Override IPV, DR
- The frame is to be mirrored to the mirror destination specified in the IMDCR0 register (applicable to the switch only).
- Enable timestamp capture if not already enabled (applicable to the switch only).
- Enable/disable Ingress Sequence Generation (applicable to the switch only).
- Enable/disable Ingress Stream Gating operation. If enable, the stream gate instance identifier is provided to indicate the stream gate instance to be used.
- Option to override Rate Policer Entry ID.
- Option to disable cut through frame transfer on a specific destination port or on all destination ports (applicable to the switch only).
- Specify egress packet processing actions (applicable to the switch only)
- Specify the Ingress Stream Counter ID to count matched frames and count discarded frames. Discard counts are maintained for maximum SDU drops, Stream Gating frame drops and Rate Policing frame drops. If Ingress Stream Counter ID is set to NULL, no Ingress Stream Counter table entry is updated. If the entry referred to by the Ingress Stream Count ID is not found in the Ingress Stream Count table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).
- Option to specify performing an Ingress Stream Filter table lookup; to support a PSFP (IEEE 802.1Qci) stream filtering function that uses the 3-bit PCP value (priority) of the received frame and the stream handle (i.e. Ingress Stream Entry ID) to select a stream filter. Note that the Ingress Stream table is used to support stream filters that require an exact match only on the stream Id (PCP is wild-carded). Note that to support stream filters that requires exact match only on the PCP (stream Id is wild-carded), multiple Ingress Stream table entries must be created for a given stream, one for each of the PCP value that requires matching. For the latter, the PCP must be included as one of the parameter/key field to determine the Ingress Stream Entry ID (IS_EID).
- Option to specify Ingress Frame Modification Entry ID (IFM_EID) to perform ingress frame modification operation (applicable to the switch only).

If a frame is discarded, in addition to updating the relevant discard counts in the Ingress Stream Count table, discard count and discard reasons are updated in PRXDCR, PRXDCRRR and in PRXDCRR0/1 registers.

The Ingress Stream table is an index table. There is a single instance of this table for the switch and an instance per ENETC function. The IS_EID is used as the index to this table. For more details, see Ingress Stream Table for the switch and Ingress Stream Table for ENETC. Ingress stream table capabilities and configuration are specified in following registers:

- Ingress Stream Index Table Capability Register (ISITCAPR)
- Ingress Stream Index Table Memory Allocation Register (ISITMAR)
- Ingress Stream Index Table Operational Register (ISITOR)

If the entry referred to by the selected IS_EID (non-NULL value) is not found in the Ingress Stream table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). If the selected IS_EID is the default IS_EID specified in PISIDCR[ISEID], and is set to a value which indexes outside of the available Ingress Stream table entries, the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along

with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). Note that IS_EIDs configured in tables (Ingress Port Filter table, Ingress Stream Identification table), are checked at configuration time to ensure that the ID falls within the range of valid indexes. If the IS_EID is out of range and is not set to NULL, the table configuration operation is not performed. If the IS_EID is set to NULL, the stream filtering function is by-passed.

53.4.2.3.1.3.7.3 Per-Stream, Per-Priority Filtering

To support a PSFP (IEEE 802.1Qci) stream filtering function that uses the 3-bit PCP value (priority) of the received frame and the stream handle (i.e. Ingress Stream Entry ID) to select a stream filter, an additional lookup (i.e. against the Ingress Stream Filter table) must be performed to obtain the PSFP (IEEE 802.1Qci) filtering and policing actions. If a lookup is performed against the Ingress Stream Filter table, the PSFP (IEEE 802.1Qci) filtering and policing actions from the Ingress Stream table entry are overridden by the actions from the matched Ingress Stream Filter table entry. If no match is found in the Ingress Stream Filter table, processing moves on with the actions from the matched Ingress Stream table entry.

As stated earlier on, in the case where the stream handle (i.e. Ingress Stream Entry ID) is used to select a stream filter, the Ingress Stream table entry contains the PSFP (IEEE 802.1Qci) filtering and policing actions that are to be applied to frames received on this stream. Furthermore to support stream filters that requires exact match only on the PCP (stream Id is wild-carded), multiple Ingress Stream table entries must be created for a given stream, one for each of the PCP that requires matching. Additionally, the PCP must be included as one of the parameter/key field to determine the Ingress Stream Entry ID (IS_EID).

The Ingress Stream Filter table is a hash table accessed using the IS_EID specified in the Ingress Stream table entry and PCP in the VLAN tag of the received frame. For more details, see Ingress Stream Filter Table for the switch and Ingress Stream Filter Table for ENETC.

If a match is found, the following actions can be specified:

- Options to override IPV, DR.
- Option to mirror frame to the mirror destination specified in the IMDCR0 register (applicable to the switch only).
- Option to disable cut through forwarding of frame if not already disabled (applicable to the switch only).
- Enable timestamp capture if not already enabled (applicable to the switch only).
- Option to enable/disable Ingress Stream Gating. If enable, the stream gate instance identifier is provided to indicate the stream gate instance to be used.
- Option to override Rate Policer Entry ID.
- Specify the Ingress Stream Counter ID to count matched frames and count discarded frames. Discard counts are maintained for maximum SDU drops, Stream Gating frame drops and Rate Policing frame drops. If Ingress Stream Counter ID is set to NULL, no Ingress Stream Counter table entry is updated. This field overrides the Ingress Stream Counter ID field specified in the previous matched Ingress Stream table entry. If the entry referred to by the Ingress Stream Count ID is not found in the Ingress Stream Count table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).
- Specify the maximum SDU check. See the following section for more details.

If a frame is discarded, in addition to updating the relevant discard counts in the Ingress Stream Count table, discard count and discard reasons are updated in PRXDCR, PRXDCRRR and in PRXDCRR0/1 registers.

53.4.2.3.1.3.7.4 Maximum SDU Check

Maximum SDU check is performed prior to policing where frame will be dropped if frame size exceeds maximum SDU. Note that the maximum SDU check is not performed, if the frame is being forwarded in the cut-through mode of operation, to at least one egress port. This means that the maximum SDU check is not performed for a frame that is replicated, where some copies are forwarded as cut-through frames while others are forwarded as store-and-forward frames. A value of zero disables the maximum SDU check.

53.4.2.3.1.3.8 L2 filtering

L2 filtering consists of performing a series of lookups based on SMAC, DMAC and VLAN, to decide whether to accept the frame and to provide the set of Station Interfaces (SIs) eligible to receive the frame.

L2 filtering is performed in two stages:

1. MAC Address filtering
2. VLAN filtering

Each received frame is associated with an SI bitmap which is used to provide to HTA the set of Station Interfaces (SIs) eligible to receive the frame within a port. Each bit of the bitmap corresponds to an SI on a given port. Least significant bit of the bitmap corresponds to the smallest SI number; i.e. bit offset 0 of the bitmap corresponds to SI numbered 0, bit offset 1 to SI numbered 1, and so on. The SIs to which the frame is to be delivered, are identified by having their corresponding bit set to 1 in the bitmap. The SI bitmap is initially set to 0 and updated while the frame is processed by the various L2 filters.

When operating in the Wake-on-LAN (WoL) mode, all frames are first filtered according to its WoL frame type. The MAC Address filtering and VLAN filtering stages are by-passed. See L2 Filtering with Wake-on-LAN, for more details.

53.4.2.3.1.3.8.1 MAC address filtering

Following registers and lookup tables are used in MAC address filtering:

- **SI Primary MAC Address registers (per SI)**

  Each SI has a primary MAC address configured in registers PSI*a*PMAR0/PSI*a*PMAR1 (where a is the SI number).

- **Exact Match MAC address table (per port)**

  An exact match table that is shared between SIs. Each table entry includes a MAC address that may be unicast or multicast and a result containing an SI bitmap identifying the associated SI(s) with the MAC address. If more than one entry are present with the same MAC address, the matched entry with the lowest table index is returned.

  This table is configured using command messages (see MAC Address Filter Table). Take note that the Primary MAC addresses don't need to be added into this table.

- **Unicast MAC hash table (per SI)**

  A 64 entry (1-bit wide entry) hash table used to match against the hashed unicast MAC addresses.

  The unicast MAC address to be matched is hashed into a 6-bit index which in turn is used to access a bit in the unicast MAC hash table. If the corresponding bit is set to one, then this is considered a successful match.

  The unicast MAC hash table is defined on per SI basis, via PSI*a*UMHFR0/1 registers, where a is the SI number.

- **Multicast MAC hash table (per SI)**

  A 64 entry (1-bit wide entry) hash table used to match against the hashed multicast MAC addresses.

  The multicast MAC address to be matched is hashed into a 6-bit index which in turn is used to access a bit in the multicast MAC hash table. If the corresponding bit is set to one, then this is considered a successful match.

  The multicast MAC hash table is defined on per SI basis via the PSI*a*MMHFR0/1 registers, where a is the SI number.

For the hash tables, as there is no subsequent match against the key used to generate the (hash) index into the table these are “imperfect” filters and have false positives. Software drivers relying on these filters must be aware of this and do further filtering to ensure that only frames of interest are accepted. This filtering is an assist only provided to improve performance.

Software which configures these hash tables, inserting and removing entries, must track the actual addresses or IDs that are inserted so that removals can be handled properly. Multiple addresses or IDs may require the same bit to be set in the table. On removal of an address/ID the corresponding bit should be cleared only if no other address/ID requires that bit to be set.

See Hash Functions for Imperfect Match (“hash”) Filtering for more details on the hash functions.

L2 filtering is performed according to the following steps:

1. **Initialization** - The frame metadata SI bitmap is initially set to 0 and updated while the frame is processed by the various L2 filters.

2. **Destination unicast or multicast MAC address exact match lookup** – Destination MAC address extracted from the frame is matched against each SI Primary MAC address register PSI*a*PMAR0/PSI*a*PMAR1 (where a is the SI number). If a match is found, the corresponding bit in the SI bitmap attribute of the frame metadata is set. In parallel, an exact match lookup is performed on the Exact Match MAC address table using the Destination MAC address (unicast or multicast) extracted from the frame. If a match is found, then for every bit set in the SI bitmap of the matched entry result, corresponding bit in the SI bitmap attribute of the frame metadata is set
3. **Broadcast** - If the frame is a broadcast frame then the frame metadata SI bitmap is updated with the bits set for each SI that does not have broadcast receipt disabled (broadcast receipt is disabled if SIMR[RNBM] bit set to 1).
4. **Destination unicast MAC address hash match lookup** – If the frame is a unicast frame and the prior steps yielded no SIs, for every SI, the Destination unicast MAC address extracted from the frame is hashed into an index to access the per SI Unicast MAC hash table ([PSI*a*UMHFR0/1] registers). If the accessed bit is set to 1, then the corresponding bit in the SI bitmap attribute of the frame metadata is set to 1.
5. **Destination multicast MAC address hash match lookup** – If the frame is a multicast frame and the prior steps yielded no SIs, for every SI, the Destination multicast MAC address extracted from the frame is hashed into an index to access the per SI Multicast MAC hash table ([PSI*a*MMHFR0/1] registers). If the accessed bit is set to 1, then the corresponding bit in the SI bitmap attribute of the frame metadata is set to 1.
6. **Unicast Promiscuous** - If the frame is a unicast frame then the frame metadata SI bitmap is updated with the bits set for each SI that has unicast promiscuous enabled (PSIPMMR[SI*a*_MAC_UP] bit is set to 1).
7. **Multicast promiscuous** - If the frame is a multicast frame then the frame metadata SI bitmap is updated with the bits set for each SI that has multicast promiscuous enabled (PSIPMMR[SI*a*_MAC_MP] bit is set to 1).
8. **Source MAC address pruning** - Source MAC address pruning is used to discard frames that originated from an SI and got forwarded back to this device by an external switch. Source MAC address extracted from the frame is matched against each SI Primary MAC address register PSI*a*PMAR0/PSI*a*PMAR1 (where a is the SI number). If a match is found the corresponding bit in the SI bitmap attribute of the frame metadata is set to 0. In parallel, an exact match lookup is performed on the Exact Match MAC address table using the Source MAC address. If a match is found, then for every bit set in the SI bitmap of the matched entry result, corresponding bit in the SI bitmap attribute of the frame metadata is set to 0. Source MAC address pruning is enabled by setting the PSI*a*CFGR0[SPE] bit to 1 (where a is the SI number).
9. **Unicast MAC address reject** – If the frame is a unicast frame then the frame metadata SI bitmap is updated with the bits reset for each SI that does have unicast receipt disabled (unicast receipt is disabled if SIMR[RNUM] bit set to 1).
10. **Multicast MAC address reject** - If the frame is a multicast frame then the frame metadata SI bitmap is updated with the bits reset for each SI that does have multicast receipt disabled (multicast receipt is disabled if SIMR[RNMM] bit set to 1).
11. **Next Stage - VLAN filtering** - The frame is passed to the next filtering stage (VLAN).

53.4.2.3.1.3.8.2 VLAN filtering

Following lookup tables are used in VLAN filtering:

- **Exact Match VLAN table (per port)**

  An exact match VLAN table shared between SIs. Each table entry includes a VLAN ID and 2-bit TPID, and a result containing an SI bitmap identifying the associated SI(s) with that VLAN (VLAN ID and TPID).

  This table is configured using command messages (see VLAN Address Filter Table) with some entries intended to be used for entries matching the SI-based VLANs. For VLAN removal and insertion, the SI-based VLANs are configured through register PSIaVLANR (where a is the SI number). For VLAN filtering, the SI-based VLANs must be explicitly inserted in the exact match VLAN table. If more than one entry are present with the same VLAN ID, the matched entry with the lowest table index is returned.

  Software is responsible for inserting entries for the SI-based VLANs in the exact match VLAN table. Hardware does not automatically insert these entries. Entries must be reserved for the SI-based VLANs for the various SIs but hardware does

not restrict the use of the table or enforce these "reservations". Software is responsible for ensuring the entries are available if required.

- **VLAN hash table (per SI)**

  A 64 entry (1-bit wide entry) hash table used to match against hashed VLAN ID.

  The VLAN ID to be matched is hashed into a 6-bit index which in turn is used to access a bit in the VLAN hash table. If the corresponding bit is set to one, then this is considered a successful match.

  The VLAN hash table is defined on per SI basis via PSI*a*VHFR0/1 registers, where a is the SI number.

  For the hash table, as there is no subsequent match against the key used to generate the (hash) index into the table these are "imperfect" filters and have false positives. Software drivers relying on these filters must be aware of this and do further filtering to ensure that only frames of interest are accepted. This filtering is an assist only provided to improve performance.

  Software which configures these hash tables, inserting and removing entries, must track the actual addresses or IDs that are inserted so that removals can be handled properly. Multiple addresses or IDs may require the same bit to be set in the table. On removal of an address/ID the corresponding bit should be cleared only if no other address/ID requires that bit to be set.

  See Hash Functions for Imperfect Match (“hash”) Filtering for more details on the hash functions.

VLAN filtering is performed according to the following steps:

1. **Initialization** - The frame metadata SI bit mask is initially set to all 0s. Each bit of the bit mask corresponds to an SI on a given port. Least significant bit of the bit mask corresponds to the smallest SI number; i.e. bit offset 0 of the bit mask corresponds to SI numbered 0, bit offset 1 to SI numbered 1, and so on. VLAN filtering is always on.
2. **VLAN selection** - There is a per port setting (PSIVLANFMR[VS]) selecting inner or outer VLAN tag data derived by the VLAN classification. If the selected VLAN tag (out of VLAN classification) is not valid, then steps 3, 4 and 5 are skipped.
3. **VLAN exact match lookup** - An exact match lookup is performed on the Exact Match VLAN table using the VLAN ID and TPID from the VLAN tag selected in step 1. If a match is found, then for every bit set in the SI bitmap of the matched entry result, corresponding bit in the SI bit mask attribute of the frame metadata is set.
4. **VLAN hash match lookup** - If the prior step yielded no SIs, for each SI, the VLAN ID from the VLAN tag selected in step 1 is hashed into an index to access the per SI VLAN hash table (PSI*a*VHFR0/1 registers). If the bit is set, then the corresponding bit in the SI bit mask attribute of the frame metadata is set.
5. **VLAN Promiscuous** - The frame metadata SI bit mask is updated with the bits set for each SI that has VLAN promiscuous enabled (PSIPVMR[SI*a*_VLAN_P] bit enabled).
6. **Untagged** - If the frame metadata untagged indicator is set or if the selected VLAN tag (out of VLAN classification) is not valid then the frame metadata SI bit mask is updated with the bits set for each SI that does have untagged enabled (PSIPVMR[SI*a*_VLAN_UTA] set to 1).

Result from MAC address filtering (frame metadata SI bitmap) is masked (bitwise "AND" operation) with the result from VLAN filtering (frame metadata SI bit mask).

The resulting frame metadata SI bitmap is "ORed" (bitwise OR operation) with the pre L2 filtering bitmap set by an Ingress Port Filtering table lookup match or an Ingress Stream table lookup match. If the resulting frame metadata SI bitmap is non-zero, the frame is passed to HTA, otherwise the frame is discarded.

53.4.2.3.1.3.8.3 L2 Filtering with Wake-on-LAN

When operating in the Wake-on-LAN (WoL) mode, all frames are first filtered based on whether the frame has been identified as a WoL trigger frame. Any frame not matching the supported WoL frame types is discarded. These frame discards are counted against the port's Rx discard count register (PRXDCR) along with the setting of the Station Interface Filter Discard Reason (SIFDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).

WoL trigger frames are identified though the Ingress Port Filtering function by adding one or more Ingress Port Filter entries with the "Wake-on-LAN Trigger" action set to "enabled". The Ingress Port Filtering function can match WoL trigger frames based on a mix of L2, L3, and L4 header fields including arbitrary fields (e.g. fields not identified by parsing). It can also match frames that have been identified by the MAC, as "magic packets".

If a WoL trigger frame is detected, a WoL event is generated followed by sending the WoL trigger frame towards HTA by having it queued internally (inside ICM) with the SI bitmap set to the pre L2 filtering bitmap stored in the Ingress Port Filter entry that matched the WoL trigger frame. Subsequent frames resume normal L2 filtering processing.

53.4.2.3.1.3.8.4 Hash Functions for Imperfect Match (“hash”) Filtering

There are 2 different types of imperfect match filtering performed: MAC address filtering and VLAN ID filtering. Both of these will use a simple and relatively small 64 entry tables to determine a “match”. In hardware, these entries will be single bit essentially indicating (potential) match or not. As there is no subsequent match against the key used to generate the (hash) index into the table these are “imperfect” filters and may generate false positive matches.

53.4.2.3.1.3.8.4.1 MAC Address Hash Functions

The figure below shows the format of the Ethernet MAC address. On the wire, transmission order for Ethernet is from the most significant byte to the least significant byte and within a byte the transmission order is from the least significant bit to the most significant bit. The MAC address bits are labeled as they appear on the wire, with bit 0 identifying the first bit of the MAC address on the wire and bit 47 identifying the last bit of the MAC address on the wire.

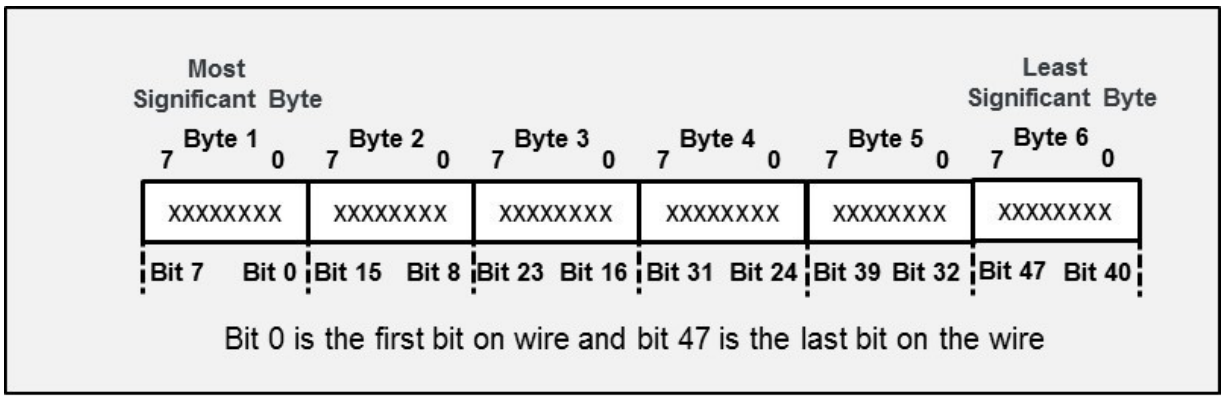

Figure 338. Ethernet MAC Address Format

The upper 24 bits of all MAC addresses (except the broadcast address) consist of an Organizationally Unique Identifier (OUI). The lower 24 bits are then assigned by that organization.

For unicast addresses, these are often assigned sequentially, or near sequentially, to systems such as switches or network adapters as they are manufactured. It is common to see a network with unicast MAC addresses with a small number of OUIs and in some case with changes only in the lower 8 or 16 bits for some addresses if the systems were purchased at or near the same time.

A similar situation can exist for multicast addresses. The OUIs commonly seen include those used for L2 management traffic, IPv6 management traffic, and IPv4 multicast. In some cases, the lower 24 bits are used to represent small numbers (i.e. the upper bits of the 24b are 0). In others, the lower 24b may actually be derived from the unicast MAC address (e.g. for some IPv6 addresses) and thus have the same characteristics as the unicast MAC addresses.

Given the relatively small distribution of “entropy” in these addresses it is important to not include too much input into a single bit of the hash result from a single byte or set of contiguous bits in the address.

The hash function used for imperfect MAC address filtering will use the exclusive-or (XOR) of every 6th bit in the 48b address to generate one bit of the required 6-bit (hash) index. If we number the bits in the MAC address b0 .. b47 then our 6b hash index (h) is:

h0 = b0 XOR b6 … XOR b42

h1 = b1 XOR b7 … XOR b43

h2 = b2 XOR b8 … XOR b44

h3 = b3 XOR b9 … XOR b45

h4 = b4 XOR b10 … XOR b46

h5 = b5 XOR b11 … XOR b47

The hash index h0 is the least significant bit of the index, h5 is the most significant bit of the index.

53.4.2.3.1.3.8.4.2 VLAN ID Hash Function

VLAN IDs are often assigned with relatively small values and over a relatively small portion of the 12b space.

The hash function used for imperfect VLAN ID filtering will XOR every 6th bit in the 12b VLAN ID to generate 1 bit of the required 6 bit hash result. If a VLAN ID is b11 .. b0 where bit 11 is the most significant bit and bit 0 is the least significant bit. Then the hash result (h) is:

h0 = b0 XOR b6

h1 = b1 XOR b7

h2 = b2 XOR b8

h3 = b3 XOR b9

h4 = b4 XOR b10

h5 = b5 XOR b11

The hash index h0 is the least significant bit of the index, h5 is the most significant bit of the index.

53.4.2.3.1.3.9 Policing

This function implements traffic policing as per IEEE 802.1Qci (Per-Stream Filtering and Policing) to protect against time window (stream gating) and bandwidth violations (rate policing).

53.4.2.3.1.3.9.1 Stream Gating

Whether to perform stream gating is determined earlier by the stream identification and filtering function. If stream gating is to be performed, a Stream Gate Instance Entry ID (SGI_EID) is provided to access the Stream Gate Instance table.

The Stream Gate Instance table contains the stream gate configuration and operational information for the switch or an ENETC instance. Each entry contains a set of parameters that defines a single stream gate instance. A stream gate instance includes a gate control list, which specifies the time gates or time slots during which incoming frames from one or more streams will be accepted.

The gate control lists are typically generated offline, and then timely configured on each network device. To support no-downtime gate control list configuration changes, the standard requires that a network device supports two sets of gate control lists:

- **Operational gate control list** – Represents the currently active gate control list.
- **Administrative gate control list** - Provides a means of configuring a new gate control list prior to its installation in a running system. An administrative gate control list becomes operational at Config Change Time as defined in the IEEE 802.1 Qci specification and remains operational till another administrative stream gate control list is installed.

The hardware executes the gate control list cyclically based on a global time. The hardware starts executing the gate control list from the head, and then goes through the gate control entries as time goes on, and after the cycle time is passed, the hardware jumps back to the head of the gate control list.

A stream gate in a gate control list entry can be in one of the two states:

- **Open**: Frames pass through the gate
- **Closed**: Frames do not pass through the gate; frames are discarded.

There are two "Open Gate Check" modes (PSGCR[OGC]) available for determining if a frame can pass through an open gate:

- Only the start of frame needs to be within the open gate interval.
- Both the start and end of the frame need to be within the open gate interval.

For more details on managing this table, see Stream Gate Instance Table for ENETC and switch. If the entry referred to by SGI_EID is not found in the Stream Gate Instance table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). If the SGI_EID is set to NULL, the stream gating function is by-passed.

Note that a Stream Gate Instance has to be associated with streams received from the same port. Streams received from different ports cannot use the same Stream Gate Instance. This is not enforced by hardware; considered a software configuration error.

The actual stream gate control lists are stored in separate table called the Stream Gate Control List table, with their entry ID being specified in the Stream Gate Instance table. For a given Stream Gate Instance, only two stream gate control lists may be allocated to the instance. It is recommended that the entry ID for each of these two stream gate control lists be predetermined and fixed by software, and persist till the Gate Stream Instance is no longer in use.

Each Stream Gate Control List entry is of variable size, and is used to hold one stream gate control list. One or up to 256 gates can be specified for a gate control list. A list consists of one configuration 24-byte word plus a variable number of words to configure stream gates. Up to two stream gates can be specified in a word. The Stream Gate Control Entry ID (SGCL_EID) has to be specified in units of words such that it points to the first word in a stream gate control list.

The configuration word and the gate configurations for a gate control list has to be in consecutive words in Stream Gate Control List table. For example, if a gate control list starts at address offset 0x100 in SGCL table and has 9 gates specified, then, the gate list SGCL_EID is 0x100 and the stream gate control list configuration will be at address offset 0x100, configuration for gates 0 and 1 will be in 0x101, configuration for gates 2 and 3 are in 0x102, and so on, and configuration for gate 8 is in 0x105. Hence the gate control list starts at address offset 0x100 and ends at offset 0x105. As such the next gate control list can start at address offset 0x106.

For more details on managing the SGCL table, see Stream Gate Control List for ENETC and the switch.

For stream gating, frame reception timestamp can be aligned to an earlier reference timing point (e.g. at the remote port's transmit timing point). This is achieved by having the frame reception timestamp(s) adjusted by subtracting the delay specified in PSGCR[PDELAY], from the Start of Frame receive timestamp and from the End of Frame receive timestamp (in the case where PSGCR[OGC] is set to 1).

A stream gate control list contains an ordered list of gate operations. Each gate operation specifies the following:

- Gate state (open/close) that determines whether a frame is allowed to pass through the gate or not.
- Internal priority value (IPV).
- Time interval in nanoseconds.
- Interval maximum number of PDU/SDU (Protocol/Service Data Unit) bytes. An optional feature to limit the number of frame bytes that can pass an open gate during its time interval.
- Option to disable cut-through forwarding of frame if not already disabled (applicable to the switch only).

If the frame is being forwarded in the cut-through mode of operation, to at least one port, the initial segment size of the frame is used for checking interval maximum number of bytes. Frame is accepted if the accumulated interval byte count in a gate plus the number of bytes received in the first segment of the frame is less than or equal to the interval maximum number of PDU/SDU bytes, else the frame is discarded. If frame is accepted, accumulated interval byte count gets updated later when the entire frame is received. Note that in cut-through operation, it is possible that the interval maximum number of PDU/SDU bytes can be exceeded (at most by an PDU/SDU size minus the initial segment size).

If the frame is being forwarded in the store-and-forward mode of operation, to all ports identified as the destination for the frame, the frame is accepted if accumulated interval byte count in a gate plus the frame size is less than or equal to the interval maximum number of PDU/SDU bytes. Accumulated interval byte count in a gate is not updated if frame is discarded.

Statistics for stream gating related frame drops are kept in the Ingress Stream Count table.

Gate control list installation is carried on, as defined by IEEE 802.1Qci (Per-Stream Filtering and Policing)

NOTE

The 1588 timer must be initialized and configured before adding any administrative gate control list to a Stream Gate Instance. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer is in normal operation, any change to the 1588 timer configuration (for example, TMROFF_H/L), except for TMR_ADD updates, requires that all Stream Gate Instances with an operation gate control list be deleted, and for Stream Gate Instances that have no operation gate control list, that the administrative gate control list if present, be removed from the Stream Gate instance.

IERB registers:

- Stream Gating Lag Time For Timestamp Refresh Register (SGLTTR). Common for both ENETC and switch. Lag time is in units of nanoseconds. The refresh timestamp timer is used to trigger the hardware to traverse the stream gate control list up to the entry corresponding to the current time minus a lag time (value in SGLTTR) when there is no traffic being received on the port.
- Switch Stream Gate Instance Index Table Memory Allocation Register (S0SGIITMAR)
- Switch Stream Gate Control List Index Table Memory Allocation Register (S0SGCLITMAR)
- ENETC a Stream Gate Instance Index Table Memory Allocation Register (EaSGIITMAR)
- ENETC a Stream Gate Control List Index Table Memory Allocation Register (EaSGCLITMAR)

Switch / ENETC function registers:

- Stream Gate Capability Register (SGCAPR)
- Stream Gate Instance Index Table Capability Register (SGIITCAPR)
- Stream Gate Instance Index Table Memory Allocation Register (SGIITMAR)
- Stream Gate Instance Index Table Operational Register (SGIITOR)
- Stream Gate Control List Index Table Capability Register (SGCLITCAPR)
- Stream Gate Control List Index Table Memory Allocation Register (SGCLITMAR)
- Stream Gate Control List Table Memory Operational Register (SGCLTMOR) Port Rx Discard Count related Registers (PRXDCR, PRXDCRR0/1). When a discard is due to stream gate function the discard count will be updated in this register and following reasons will be specified.
  - [SGCDR] - Stream Gate Closed discard reason.
  - [MSDUEDR] Maximum SDU Exceed discard reason

53.4.2.3.1.3.9.2 Rate Policing

Whether to perform rate policing is determined in prior ingress processing functions. A rate policer instance (or more specifically a Rate Policer Entry ID (RP_EID)) can be specified in the Ingress Port Filter table, Ingress Stream table, and/or Ingress Stream Filter table. When more than one source specifies a rate policer instance, only one instance can be applied to a frame with the following precedent (with 1 having higher precedence):

1. Ingress Stream Filter table
2. Ingress Stream table
3. Ingress Port Filter table

By default (prior to any lookups), the RP_EID is set to NULL, meaning that no rate policing is to be applied to the frame.

Rate policing (or flow metering) is compliant to IEEE 802.1Qci specification.

If rate policing is to be performed, the Rate Policer Entry ID (RP_EID) specified by one of the above table lookups, is used to access the Rate Policer Instance table. For more details on managing this table , see Rate Policer Table for ENETC and Rate Policer Table for the switch. If the entry referred to by RP_EID (non-NULL value) is not found in the Rate Policer table (entry has not been

added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). If the RP_EID is set to NULL, the rate policing function is by-passed.

The Rate Policer table contains the rate policer configuration and operational information for the entire function (switch or an ENETC function). Each entry contains a set of parameters that defines a single rate policer instance. A rate policer instance controls the amount of traffic (or bytes) that is allowed to go through for a particular received flow of frames.

The MEF (Metro Ethernet Forum) 10.3 technical specification "bandwidth profile algorithm for one flow per envelope processing without token sharing", is used.

When the rate policer instance is configured to operate in the color-aware mode, the incoming frame "color" is indicated through the Drop Resilience (DR) associated with the frame. When the rate policer instance is configured to operate in the color-blind mode, the incoming frame is assumed to always be green for the rate policer. The figure below shows the default decision making process. Some of the default decisions can be modified by configuration, for example setting MR, DOY or NDOR in a rate policer instance will change the default packet marking and drop decisions. Dropped frames by a rate policer instance are counted in against the port's Rx discard count register (PRXDCR), the Rate Policer table entry drop counter and the Ingress Stream Count table entry counter.

If the frame is being forwarded in the cut-through mode of operation (switch only), to at least one port, the initial segment size of the cut-through frame is used by the rate policer for making the decision to declare an arriving frame as Green, Yellow, or Red and then based on the color assigned to the frame, whether the frame is dropped or marked (overwriting the Drop Resilience (DR) assigned to the frame). If the frame is accepted, the rate policer byte credits get updated as data is received (cut-through segment transfers). If the total frame length turns out to be greater than the number of tokens in the bucket that was used to declare the color of the frame, then the bucket token count will go negative (effectively borrowing future tokens). This has a side effect of increasing the effective committed or excess burst size by up to a maximum frame size minus the size of the initial cut-through frame segment.

NOTE

The timer function must be configured and enabled before any rate policer instance is enabled (see Rate Policer table entry Functional Enable Element Data). Either the default nanosecond timer or the 1588 timer can be used to generate the required nanosecond resolution time. The default nanosecond timer is configured and enabled by default out of reset. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer is in normal operation, any change to the 1588 timer configuration (for example, TMROFF_H/L), except for TMR_ADD updates, requires that all rate policer instances be disabled (see Rate Policer table entry Functional Enable Element Data).

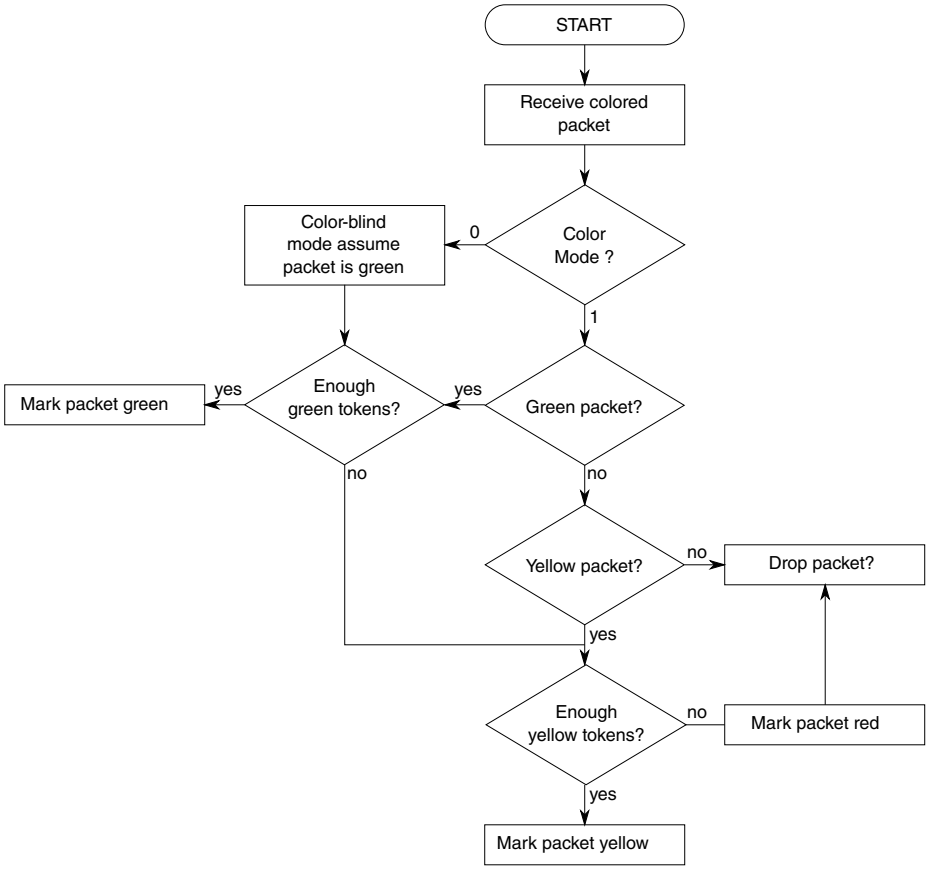

Figure 339. Bandwidth Profile Coloring Flow Diagram

53.4.2.3.1.3.10 Ingress Congestion Manager (ICM)

The Ingress Congestion Manager (ICM) block provides the main buffering/queuing for frames waiting to be scheduled for processing by the HTA Receive. ICM is also responsible for implementing drop decisions and when to start pausing the other end of link when received frames are starting to consume too much of the ENETC receive shared internal buffer memory due to downstream congestion, for example endpoint traffic encountering congestion at the Host Transfer Agent due to slow host system memory access.

The congestion control discipline employed by the ICM is to drop a received frame already queued inside ICM so that when a frame arrives from the MAC, it is always accepted (that is never dropped). This approach provides optimal usage/efficiency of the ENETC receive shared internal buffer memory where no memory space is ever held idle. Ports that need to use more shared internal buffer memory for receive can use more than their minimal allocation, borrowing from other quiet ports. When the ENETC receive shared internal buffer memory consumed by a port is reaching its maximum port usage level or that the ENETC receive shared internal buffer memory is becoming full, internal memory is reclaimed by dropping frames already queued based on the port receive internal memory usage and congestion resiliency.

By default, the amount of internal memory available for all ports is equally shared between all ports. There is an option to explicitly configure a guaranteed amount of internal memory for receive buffering on per port basis. This is achieved by specifying a receive entitlement for each port via the IERB ENETC *a* receive memory buffer entitlement register (E*a*RXMBER). The value configured in E*a*RXMBER is reflected in the ENETC instance base port receive memory buffer entitlement register (PRXMBER). To ensure that no drop occurs when port usage is below its receive entitlement, the sum of all receive entitlements must not exceed the total size of the ENETC receive shared internal buffer

memory is configured via the IERB ENETC receive shared memory buffer allotment register (ERSMBAR). The value configured in ERSMBAR is reflected in the NETC global ENETC shared memory ENETC receive buffer capability register (SMERBCAPR).

When a port exceeds its configured receive entitlement, it becomes eligible for dropping when the ENETC receive shared internal buffer memory becomes full. The ENETC received shared internal buffer memory usage is indicated in the shared memory ENETC receive buffer operational register 0 (SMERBOR0). Note that if there is no receive entitlement configured for a port, then this port is always considered eligible for dropping. Reclaimed memory is obtained by dropping frames first from the port that exceeds the most its receive entitlement. Within a port, frames with a lower congestion resiliency are dropped first. If more than one scheduling priority queue within a port have frames at the same lower congestion resiliency, frames are dropped from the lower scheduling priority queue first. When the port receive usage exceeds its configured limit, frames are dropped from the port till its usage is no longer exceeding its configured limit. Frames with a lower congestion resiliency are dropped first. If more than one scheduling priority queue have frames at the same lower congestion resiliency, frames are dropped from the lower scheduling priority queue first. This limit is configured via the IERB ENETC a receive memory buffer limit register (E*a*RXMBLR). The value configured in E*a*RXMBLR is reflected in the ENETC instance base port receive memory buffer limit register (PRXMBLR). This limit defines an upper-bound limit for a given port receive internal memory usage. The ENETC port received shared internal buffer memory usage is indicated in the ENETC instance base port receive buffer count register (PRXBCR).

Dequeue operations are performed by ICM when the downstream (i.e. HTA receive) indicates its readiness to accept incoming frames.

Dequeue scheduling first selects which port to service next. Scheduling among ports is performed using a byte-based weighted fair scheduling algorithm. A proprietary algorithm, Weighted Bandwidth Fair Scheduling (WBFS) is used to implement the weighted fair scheduling function. The WBFS algorithm is described in Weighted Bandwidth Fair Scheduling (WBFS) Algorithm. Once a port is selected, queue selection within a port is performed using a strict priority algorithm. There are 2 priority queues per port. The higher priority queue is selected for dequeue if it is not empty otherwise the lower priority queue will be selected. As long as there are frames in the higher priority queue, no frames from the lower priority queue will be serviced. A single frame is dequeued from the selected queue

A byte credit-based flow control mechanism on a per priority tier (2 tiers) basis is provided to control the rate at which the consumer (i.e. HTA receive) can accept data from ICM. A byte credit counter is maintained for each priority tier, for all ENETC instances. This credit counter represents the number of bytes that can be in flight inside the HTA for a given priority tier. The byte credit counter must be non-zero for a priority to be considered eligible by the dequeue scheduling mechanism. A priority is no longer eligible for dequeues when its byte credit counter has reached a value 0 or lower (negative); after a dequeue it is possible that the byte credit count becomes a negative value if the accumulated byte credit count value was lower than the actual dequeued frame size. HTA 0 high priority configuration register (HTA0HPCR) is used to configure the maximum number of byte credits for the high priority tier whereby the HTA 0 low priority configuration register (HTA0LPCR) is used to configure the maximum number of byte credits for the low priority tier.

ICM can request the MAC to signal the other end of the link, to pause its data transmission on the link, based on shared internal receive buffer memory consumption. For each port, ICM monitors the amount of data accumulated in the shared internal receive buffer memory and if this amount exceeds the Pause ON threshold (PPAUONTR register), it then sends a request to the MAC to signal the other end of the link, to pause its data transmission on the link. The pausing of the other end of the link is stopped when the amount of data accumulated in the internal receive buffer goes below the Pause OFF threshold (PPAUOFFTR register).

53.4.2.3.1.3.11 Host Transfer Agent (HTA) Receive

The figure below shows the processing through the Host Transfer Agent Receive.

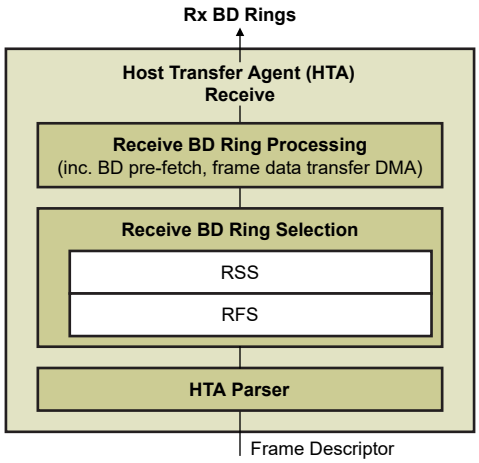

Figure 340. Host Transfer Agent Receive processing diagram

The HTA Receive block implements the receive interface functionality to the host. It includes the necessary DMA engines to efficiently transfer received frames to the host. It also provides multi-queue (buffer descriptor ring) support towards the host, for load spreading, virtualization support and QoS.

A Station Interface (SI) will normally be assigned one or more receive buffer descriptor rings (BDRs) during initialization, these will be numbered 0, 1, 2, …, n, in the SI address map.

Once receive BD rings have been assigned to an SI, they can further be assigned to a group within a SI. A group is an abstract entity (e.g. representing a core for the purpose of distribution), which will resolve into a specific receive BD ring that is a member of that group based on a configurable Internal Priority Value (IPV) to Receive BD ring mapping. This mapping allows each IPV (or set of IPV's) to be mapped to a specific receive ring for QoS distinction. The grouping should be done evenly within a SI for IPV to map to an existing ring. Note that there are at most 8 IPV values so there should not be more than eight receive rings per group.

ICM can push one frame per scheduling opportunity per input port towards HTA Receive. Associated with each frame, is the following metadata:

- SI bitmap; provides the set of Station Interfaces (SIs) to receive the frame
- IPV and DR
- IPV qualifier indicator; whether IPV was set as a result of match in the following tables: Ingress Port Filter, Ingress Stream, ingress Stream Filter or in Stream Gate Instance tables.
- If the ENETC port is connected internally to a switch port, designated as a switch management port, an indication of the source port ID from which the frame was received is provided along with the reason why this frame was forwarded to the switch management port.

The HTA Transmit functional block and the HTA Receive functional block are realized by the HTA hardware block which for the for the most part, is implemented using multi-threaded hardware engine(s) where each engine implements a finite state machine (FSM) which operates on a plurality of receive and transmit threads with each thread handling a single frame. One or more engines is instantiated depending on the requirements e.g. number of ports, port speeds. Multiple threads can be dispatched for a port. More threads can be dispatched than the total number of possible active threads (i.e. the threads currently being handled by the engines) since some threads may need to suspend (e.g. to wait for an earlier larger frame directed to the same BD ring to finish). These in-active or suspended threads therefore do not occupy a thread in an engine.

For a given frame for each of the SIs marked as eligible to receive that frame, HTA dispatches a hardware receive thread to deliver the frame to the SI. When a frame is to be delivered to more than one SI, a single copy of the frame is kept in internal memory with multiple copies written to system memory (i.e. one copy per SI). Once the processing on the last SI is completed, the internal memory that was used to store the frame is released.

Each receive thread performs the following processing:

- **Parsing** - Parses the frames and identifies the locations of the required packet header fields in preparation for classification. Supports major protocols such as Ethernet, IPv4, IPv6, TCP, UDP. It also implements the receive IP, TCP and UDP checksum offloads.
- **Receive BD ring selection** - Within an SI, determines which receive BD ring is used for the frame received. Receive BD ring selection is based on QoS and Receive Flow Steering (RFS).
- **VLAN removal** - If configured, removes VLAN tag(s) from the frame and optionally reports it in the receive BD ring descriptor.
- **Receive BD processing** - Interface functionality to the hosts including transferring frame from internal memory into buffers in system memory.

53.4.2.3.1.3.12 HTA Parser

The Parser parses up to L4 protocol headers in up to the first 256 bytes of the frame. It identifies the locations of the required packet header fields for processing by subsequent receive stages of the device. For VLAN headers, the actual field values extraction is performed by the parser. Extracted VLAN header field values and locations of relevant L2, L3 and L4 headers values are then used to perform the various table lookups and hash functions in subsequent receive stages of the device. The parser also generates a 16-bit Parse Summary of the header types identified. This summary is returned in the meta data of the receive descriptor for the frame.

During parsing, the parser examines and validates headers and validates the Internet Checksum for IPv4, TCP, and UDP. The parser is invoked with the frame fully received from the MAC and stored in internal memory.

The parsing process can be expressed as a directed graph with nodes representing header types and edges (arrows) representing the sequence of headers. Parsing starts at the root node then walks from node to node using the next-header field values. Specifically, each node works within a protocol layer presuming a certain type of header, confirms the validity of the header, identifies boundaries of the header, extracts attributes and offsets, and determines the next header to examine beyond the current header.

Figure below shows the parse graph supported by the device. The parse graph is structured by layers (L2, L3, and L4), with the details per each layer provided in the next sections. Parsing normally progresses from the lower layer to the upper layers. In the case where a node is to be re-entered, the previous parse data from that node is typically overwritten. Exceptions are stacked protocols. Special provisions are made for these protocols and will be discussed in the section pertaining to those headers.

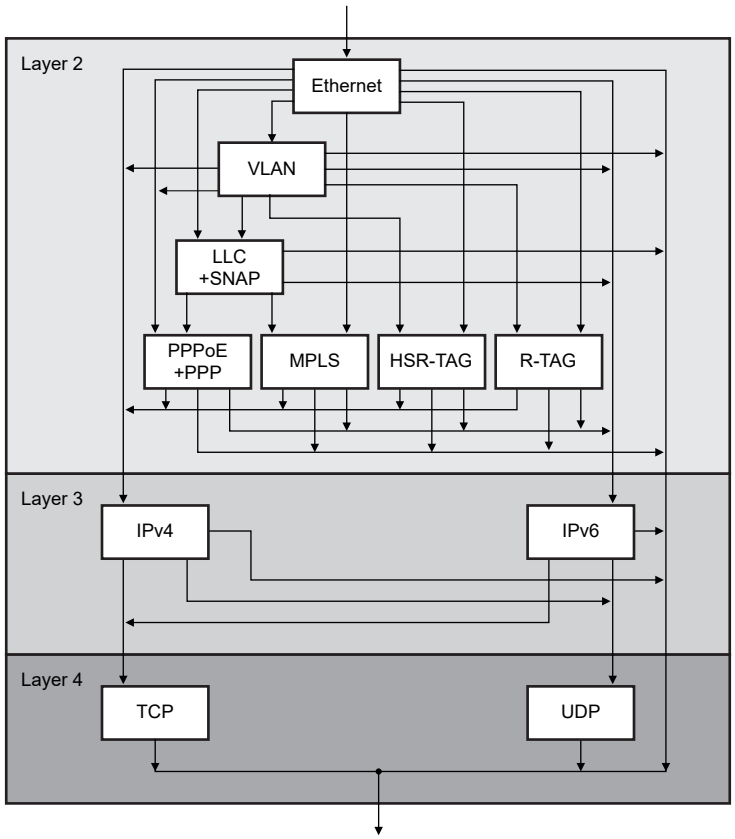

Figure 341. HTA Parse Graph

Parsing is terminated via one of the following:

- Upon reaching the natural end of a branch in the parse graph
- A parsing error is encountered; note that parse information from headers that have been successfully parsed is still used by table lookups and hash functions in subsequent receive stages of the device

If the ENETC port is connected internally to a switch port, designated as a switch management port, frames are parsed regardless of their Host Reason metadata value.

53.4.2.3.1.3.12.1 Layer 2 Headers

As the first header in a frame, the parser supports Ethernet frames of the following formats: IEEE 802.3 (Ethernet II) and 802.3 SNAP frame formats. Both Ethernet II and 802.3/SNAP frames may be tagged with the IEEE 802.1Q VLAN tagging method. The 4-byte IEEE 802.1Q VLAN tag has two 2-byte components: Tag Protocol Identifier (TPID, residing within the type/length field) and the Tag Control Information (TCI). The following 4 TPID values are recognized as VLAN tags:

- The standard types 0x8100 and 0x88A8
- Two optional user programmable EtherType values known as CustTag1 and CustTag2; configured through CVLANR1 and CVLANR2 registers.

The TCI includes the following fields:

- PCP - Priority Code Point, the first three bits of the TCI define user priority.
- DEI - Drop Eligibility/ (single-bit field)
- VID - The 12-bit VLAN ID (VID) field identifies the VLAN the frame belongs to. The 12 bits allow for 4096 different VLANs. Out of the 4096 VLANs, the VID of zero is used to identify priority tagged frames and the value of 4095 is reserved.

Parser supports frames with multiple VLAN tags. VLAN tags are named based on their position in the frame relative to other VLAN tags and the beginning of the frame i.e. the 802.3/Ethernet header consisting of Destination followed by Source MAC addresses.

The VLAN tag or header nearest the 802.3/Ethernet header is called the outer (or first) tag. The VLAN tag which is next closest to the 802.3 header is the inner (or second) tag. VLAN tags are expected to be contiguous, following one after the other, with no intervening non-VLAN tags.

Note that any VLAN tags which are within encapsulated frames and after any ULP header are not recognized. If only one VLAN tag is present in the frame, the inner VLAN tag is considered not present.

The outer and inner VLAN tag data (PCP, DEI and VID), if present, are extracted from the frame. The TPID from each VLAN tag is matched against the 4 known VLAN EtherTypes (2 standard, up to 2 custom) and a 2-bit TPID value is assigned identifying which known value matched (00: 0x8100, 01: 0x88A8, 10: CustTag1, 11: CustTag2). If the inner VLAN tag is present, the parser also indicates whether 3 or more VLAN tags are present. Matching is done against the list {0x8100, 0x88A8, CustTag1, CustTag2} in order and matching stops on the first match found. A 4-bit vector where each bit represents a TPID code point (bit 0 -> 00, bit 1 -> 01, bit 2 -> 10 and Bit 3 -> 11) is used by subsequent HTA receive processing stages to perform non-contiguous masked matching operation against the TPID.

The information found in the next EtherType field (after VLAN parsing) is used to determine the next ULP header to parse. The EtherType field is located following the Source MAC address field if no VLAN tag present, or following the last VLAN tag. The ULP header is determined according to the “Ethernet - EtherType to Next ULP” mapping described in the table below.

EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends. If parsing reached end of frame, while more octets are expected to extract the 2-byte EtherType, the extracted EtherType is set to 0.

Table 404. HTA Parser - Ethernet - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0806	ARP	Ends parsing, ARP reported in the Parse Summary
x05DC or less	LLC+SNAP	LLC+SNAP
x0800	IPv4	IPv4
x22F0	IEEE 1722	Ends parsing
x86DD	IPv6	IPv6
x8847	MPLS Unicast	MPLS
x8848	MPLS Multicast	MPLS
x8864	PPPoE+PPP Session Stage	PPPoE+PPP
x8892	Profinet RT Unicast	Ends parsing
x88A4	EtherCat	Ends parsing
x88d7	TT-Ethernet	Ends parsing
x88F7	PTP	Ends parsing
x88FB	PRP/HSR Supervision	Ends parsing
x8906	FCoE	Ends parsing
x8914	FCoE Initialize Protocol (FIP)	Ends parsing
x891D	TT-Ethernet	Ends parsing
x892F	HSR Tag	HSR Tag

Table continues on the next page...

Table 404. HTA Parser - Ethernet - EtherType to Next ULP Mapping (continued)

EtherType	Recognized Protocol	Next ULP to be parsed
xF1C1	CB Redundancy tag	CB Redundancy tag
CustEtype1	Configurable EtherType 1 (PARCE0CR)	Ends parsing
CustEtype2	Configurable EtherType 2 (PARCE1CR)	Ends parsing
CustEtype3	Configurable EtherType 3 (PARCE2CR)	Ends parsing
CustEtype4	Configurable EtherType 4 (PARCE3CR)	Ends parsing

For an LLC+SNAP header, the parser checks that the first 3 bytes (the LLC header) is 0xAAAA03 and the next 3 bytes (OUI) are 0. If both conditions aren't true, the header is not considered an LLC+SNAP header and parsing ends. If both condition are met, then the parser uses the value in the EtherType field to determine the next ULP header to parse. The next ULP header is determined according to the "HTA Parser - 802.3/SNAP - EtherType to Next ULP" mapping described in the table below. If the EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 405. HTA Parser - 802.3/SNAP - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0800	IPv4	IPv4
x86dd	IPv6	IPv6
x8847	MPLS	MPLS
x8848	MPLS	MPLS
x8864 PPPoE+PPP	PPPoE+PPP	PPPoE+PPP

For an MPLS header, the parser traverses the stack of MPLS labels looking for a label with the S bit set, identifying the last label. When the last label has been reached, the next ULP header is determined based on the interpretation of the last label. If the label is set to 0, then the next header is IPv4. If the label is set to 2, then the next header is IPv6. Otherwise parsing ends.

For PPPoE+PPP header, the parser locates the PPP protocol field. If the protocol field is set to 0x0021, then the next header is IPv4. If the protocol is set to 0x0057, then the next header is IPv6. Otherwise parsing ends.

For High Availability Seamless Redundancy (HSR) tag, the parser locates the EtherType field following the 6-byte HSR tag. The next ULP header is determined according to the "HTA Parser - HSR tag - EtherType to Next ULP" mapping described in the table below. If the EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 406. HTA Parser - HSR tag - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0800	IPv4	IPv4
x86dd	IPv6	IPv6

For the 802.1CB R-TAG (or CB Redundancy tag), the parser locates the EtherType field following the 6-byte 802.1CB R-TAG. The next ULP header is determined according to the "HTA Parser - CB Redundancy tag - EtherType to Next ULP" mapping described in the table below. If the EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 407. HTA Parser - CB Redundancy tag - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0800	IPv4	IPv4
x86dd	IPv6	IPv6

Four custom Ethertype values can be configured, and if any of the custom EtherType is detected, parsing ends with the Parse Summary set to the "Non-IP" (6) code point in bits 6-4 and to the L2 Only "Unknown" code point in bits 3-0.

Following information is captured by the parser for updating the Parse Summary and/or for usage by subsequent HTA receive processing stages:

- Indication of whether the outer VLAN tag header is present is passed as frame metadata to subsequent HTA receive processing stages. If header is present and valid (no parsing error), extracted VLAN tag data along with a 2-bit code identifying the TPID is also passed as frame metadata.
- Indication of whether the inner VLAN tag header is present and valid (no parsing error) is passed as frame metadata to subsequent HTA receive processing stages. If header is present and valid, extracted VLAN tag data along with a 2-bit code identifying the TPID is also passed as frame metadata. Additionally, an indication of whether 3 or more VLAN tags are present in the frame are also passed as frame metadata. If only one VLAN tag is present in the frame, the inner VLAN tag is considered not present.
- Whether destination MAC address is unicast, multicast or broadcast; this is passed as frame metadata to subsequent HTA receive processing stages.
- Whether the frame is a BPDU frame: MAC DA is 01:80:C2:00:00:00; this is reported in the Parse Summary.
- Whether the frame is an ARP frame (can be of any type/opcode); this is reported in the Parse Summary
- Whether the frame is a Control Protocol : MAC DA is 01:80:C2:00:00:00-01:80:C2:00:00:00:FF; this is reported in the Parse Summary.
- For each parsed L2 header (e.g. Ethernet, VLAN, MPLS, etc.), the L2 header type is reported in the Parse Summary.
- EtherTypes that are recognized but not parsed (e.g. custom EtherType, FCoE, etc.) are reported in the Parse Summary.

There are no validation checks performed on the Source and Destination MAC addresses, and EtherType fields. Subsequent HTA receive processing stages can assume the Ethernet header to be always present, that the Ethernet header starts at byte position zero within the frame and that there are no parsing errors for the Ethernet header.

Possible parsing errors for L2 headers are:

- Frame parsing reached end of frame while parsing a header that expects more data.
- For LLC+SNAP header, if 802.3 length is larger than the frame received.
- For PPPoE+PPP header, if any of the following conditions are detected
  - VER field is not set to 0x1 (RFC2516 section 4),
  - TYPE field is not to set to 0x1 (RFC2516 section 4),
  - Code field on PPP Session Stage frames is not set to 0 (RFC2516 section 4),
  - Session ID is set to 0xFFFF which is reserved and thus must not be used. (RFC2516 section 4)

53.4.2.3.1.3.12.2 Layer 3 Headers

The parser supports parsing of both IPv4 and IPv6 packets.

Only the first IPv4 or IPv6 header encountered in a packet is parsed.

If a non-fragmented IPv4 packet (Fragment Offset is set to zero and the More Fragments flag is set to zero) or an initial fragment packet ((Fragment Offset is set to zero and the More Fragments flag is set to one) is parsed, then the parser uses the information stored in the Protocol field to determine the next ULP header to be parsed.

Packets with IPv4 options are supported, thus enabling Layer 4 header recognition although no examination of the IPv4 option, unless it is an initial fragment packet. For initial fragment packets, IPv4 options are not parsed. They are also not skipped meaning that the next ULP header will not be parsed if the initial fragment packet has IPv4 options.

For IPv4 header, the next ULP header is determined according to the "HTA Parser - IPv4 - Protocol to Next ULP" mapping described in the table below. If the Protocol field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 408. HTA Parser - IPv4 - Protocol to Next ULP Mapping

Protocol (decimal)	Recognized Protocol	Next ULP to be parsed
1	ICMP	Ends parsing, ICMP reported in the Parse Summary
2	IGMP	Ends parsing, IGMP reported in the Parse Summary
6	TCP	TCP
17	UDP	UDP
33	DCCP	Ends parsing, DCCP reported in the Parse Summary
50	ESP	Ends parsing, IPsec ESP reported in the Parse Summary
132	SCTP	Ends parsing, SCTP reported in the Parse Summary
136	UDP Lite	Ends parsing, UDP-Lite reported in the Parse Summary

For IPv6 header, the IPv6 main header may be followed by an arbitrary number (0, 1 or multiple) of extension headers chained together through the Next Header field. The extension header chain typically ends with the last header corresponding to the upper-layer protocol carrying the packet's payload (for example, TCP, UDP). In the presence of extension headers, the parser traverses the extension header chain for the main purpose of finding the upper-layer protocol header (for example, TCP or UDP).

Parsing of the IPv6 extension headers is described in the table below. If an unrecognized extension header is detected (not present in the table below), parsing ends but the IPv6 header is considered successfully parsed (with relevant information captured) if no other errors are detected.

Table 409. IPv6 Extension Headers Parsing

Extension Header (decimal)	Extension Header Processing
0 (Hop-by-Hop Options)	Hop-by-Hop Options Extension header is parsed without being examined (values not checked nor captured). If present, it must immediately proceed the IPv6 main header and there can only be one of these in a packet
43 (Routing)	Routing Extension header is parsed without being examined (values not checked nor captured) The pseudo header generation for the L4 checksum considers the IP addresses of the main IPv6 header ignoring any IP address in the Routing Extension header. Therefore, checksum calculation for packets with the Routing Extension header may result in erroneous value.

Table continues on the next page...

Table 409. IPv6 Extension Headers Parsing (continued)

Extension Header (decimal)	Extension Header Processing
44 (Fragment)	If it is a non-initial fragment, then the parser does not process the next header (if any) and ends parsing
50 (ESP)	Ends parsing, IPsec ESP reported in the Parse Summary
51 (AH)	Ends parsing
60 (Destination Options)	Destination Options Extension header is parsed without being examined (values not checked nor captured).
135 (mobility)	Mobility Extension header is parsed without being examined (values not checked nor captured).
139 (Host Identity Protocol)	Host Identity Protocol Extension header is parsed without being examined (values not checked nor captured).
140 (Shim6 Protocol)	Shim6 Protocol Extension header is parsed without being examined (values not checked nor captured).
253 (Reserved)	Use for experimentation and testing. This extension header is parsed without being examined (values not checked nor captured).
254 (Reserved)	Use for experimentation and testing. This extension header is parsed without being examined (values not checked nor captured).

The parser uses the information stored in the IPv6 Next Header to determine the next ULP header. The next ULP header is determined according to the “HTA Parser - IPv6 – Next Header to Next ULP” mapping described in the table below. If the Next Header is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 410. HTA Parser - IPv6 - Next Header to Next ULP Mapping

Next Header (decimal)	Recognized Protocol	Next ULP to be parsed
6	TCP	TCP
17	UDP	UDP
33	DCCP	Ends parsing, DCCP reported in the Parse Summary
58	ICMPv6	Ends parsing, ICMPv6 reported in the Parse Summary
59	No Next Header	Indicates no more data to follow. Ends parsing
132	SCTP	Ends parsing, SCTP reported in the Parse Summary
136	UDP Lite	Ends parsing, UDP-Lite reported in the Parse Summary

Following information is captured by the parser for updating the Parse Summary and/or for usage by subsequent HTA receive processing stages.

- Indication of whether the outer IP header is present and valid (no parsing error) is passed as frame metadata to subsequent HTA receive processing stages. If the header is present and valid, its location in the frame is also passed as frame metadata.
- For each parsed L3 header (IPv4 and IPv6), the L3 header type is reported in the Parse Summary. If the outer IP header is a fragment (IPv4 "more fragments" flag is set or the IPv4 "fragment offset" field is non-zero or IPv6 Fragment Extension Header is present), the parse summary L4 field is set to the code point "1" (fragment)
- Protocols (or next ULP headers) that are recognized but not parsed (e.g. ICMP, UDP lite, etc.) are reported in the Parse Summary.
- L4 Protocol Present indicator will be set to 1, along with extracting the IPv4 Protocol field, If the outer IPv4 header is present and valid.
- L4 Protocol Present indicator will be set to 1, along with extracting the IPv6 Next Header field , if the outer IPv6 header is present and valid, and if any of the conditions below are encountered:
  - Upper-layer protocol header is found (doesn't end with an extension header) and is not set to the "No Next Header".
  - The AH and ESP extension headers are encountered.

Possible parsing errors for L3 headers are:

- Frame parsing reached end of frame while parsing a header that expects more data.
- For each IPv4 header parsed, if any of the following conditions is detected:
  - IP Checksum is incorrect (if checking is enabled)
  - Version number in IPv4 header is not equal to 4
  - IPv4 fragment does not contain at least eight data bytes and this is not the last fragment
  - IPv4 Header Length field value is less than 20 bytes, or exceeds the received packet length (excludes L2 header), or exceeds the IPv4 header Total Packet Length field value
- For each IPv6 header parsed, if any of the following conditions is detected:
  - Version number in IPv6 header packet is not equal to 6,
  - Hop by Hop extension header did not immediately follow the IPv6 main header or there is more than one Hop by Hop header.

53.4.2.3.1.3.12.3 Layer 4 Headers

The parser supports parsing of both TCP and UDP packets. Only the first TCP or UDP header encountered in a packet is parsed.

For the TCP or UDP header, the hardware calculates the expected checksum including the pseudo IP header. For IPv6 headers, the IP addresses are taken from the main IPV6 header ignoring the optional extension headers. Therefore, checksums for TCP/UDP packets encapsulated in IPv6 with extension headers that contain IP addresses may results in erroneous value.

TCP and UPD checksums are not validated for IPv4 and IPv6 fragmented packets.

For both TCP and UDP checksum offloads, hardware excludes any padding bytes on received frame with length that is shorted than 81 bytes (length of the entire received frame from the MAC). Checksum calculation is not performed for received frames with padding that have a length larger than 80 bytes.

The TCP header may have any options but these aren’t examined.

Take note that the actual calculation of the expected TCP and UDP checksums of a frame is performed later on when the hardware transfers the frame into receive data buffers in the host system memory.

For the TCP header, the next ULP header is determined according to the Destination Port field. If the Destination Port field is set 3386 (decimal), then the next header to parse is the GTP' header (i.e. header type captured in Parse Summary but no GTP' fields are extracted/validated). Otherwise parsing ends.

For the UDP header, the next ULP header is determined according to the “HTA Parser - UDP - Destination Port to Next ULP” mapping described in the table below. If the Protocol field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

There two configurable UDP Destination Port values to indicate an encapsulated VxLAN header in addition to the to the common value 4789 (decimal).

Table 411. HTA Parser - UDP - Destination Port to Next ULP Mapping

Destination Port (decimal)	Recognized Protocol	Next ULP to be parsed
319	PTP	Ends parsing, UTP PTP reported in the Parse Summary
320	PTP	Ends parsing, UTP PTP reported in the Parse Summary
2123	GTP-C	Ends parsing, UTP GTP reported in the Parse Summary
2152	GTP-U	Ends parsing, UDP GTP reported in the Parse Summary
3386	GTP'	Ends parsing, UDP GTP' reported in the Parse Summary
4500	ESP	Ends parsing, UDP ESP reported in the Parse Summary
4789	VxLAN	Ends parsing, UDP VxLAN reported in the Parse Summary
5246	CapWap-ctrl	Ends parsing, UDP CapWap-ctrl reported in the Parse Summary
5247	CapWap	Ends parsing, UDP CapWap reported in the Parse Summary
Configured VxLAN DP1	VxLAN	Ends parsing, UDP VxLAN reported in the Parse Summary
Configured VxLAN DP2	VxLAN	Ends parsing, UDP VxLAN reported in the Parse Summary

IPSec, SCTP, DCCP, GTP, ESP and VxLAN headers are recognized with their header type captured in the Parse Summary. However, parser doesn't parse these headers; i.e. no fields are extracted, no header checks are performed and the next ULP header for these headers is not located.

Following information is captured by the parser for updating the Parse Summary and/or for usage by subsequent HTA receive processing functions

- Indication of whether an L4 header (i.e. TCP or UDP) is present and valid (no parsing error) is passed as frame metadata to subsequent HTA receive processing stages. If an L4 header is present and valid, its location in frame is also passed in the metadata.
- If an L4 header is present, an indication of whether L4 header is TCP(0) or UDP(1) is passed as frame metadata for subsequent HTA receive processing.
- For each parsed L4 header (TCP, UDP), the L4 header type is reported in the Parse Summary.
- Protocols (or next ULP headers) that are recognized but not parsed (e.g. PTP, CapWap, etc.) are reported in the Parse Summary.

Possible parsing errors for L4 headers are:

- Frame parsing reached end of frame while parsing a header that expects more data.
- For TCP header, if any of the following conditions are detected:
  - TCP Checksum is incorrect (checking is enabled and hardware was able to calculate the checksum) This checks is performed later on when the hardware completed the transfer of the frame into receive data buffers in the host system memory.
  - SYN and FIN flags set
  - SYN and RST flags set
  - FIN and RST flags set
  - SYN, FIN and RST flags set
  - Node of the flags are set
- For UDP header, if any of the following conditions are detected:
  - UDP Checksum is incorrect (if checking is enabled and hardware was able to calculate the checksum); if a UDP header that has a checksum of zero is encapsulated in IPv4, no validation is carried out, however if the UDP header is encapsulated in a IPv6 packet, this is considered an error. This checks is performed later on when the hardware completed the transfer of the frame into receive data buffers in the host system memory.
  - UDP length is smaller than 8, or larger than the IP length when the latter only if it is not a fragmented packet.
  - UDP length is equal to 8 bytes and Destination Port is set to 2123 (GTP-C) , 2152 (GTP-U), or 3386 GTP'.
  - GTP (0 bytes).

53.4.2.3.1.3.12.4 Parse Summary

The parser generates a 16-bit Parse Summary of the header types identified. This summary is returned in the metadata of the receive descriptor for the frame. See table below for the parse summary fields.

Table 412. Parse Summary Fields

<table>
<tr><th>15</th><th>14</th><th>13</th><th>12</th><th>11</th><th>10</th><th>9</th><th>8</th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td rowspan="3">Parsing Error:
0 None
1 Parsing error detected</td><td colspan="2" rowspan="3">Reserved</td><td colspan="3" rowspan="3">L2:
0 Eth-II
1 LLC-SNAP
2 MPLS
3 PPPoE+PPP
4 HSR Tag
5 R-TAG</td><td colspan="2" rowspan="3">VLAN:
0 None
1 1 tag
2 2 or more tags</td><td rowspan="3">IPv4 Opt / IPv6 Ext</td><td colspan="2">L3:
0 IPv4
1 IPv6</td><td colspan="6">L4: 0-27</td></tr>
<tr><td colspan="2">2 -</td><td colspan="6"></td></tr>
<tr><td colspan="4">Non-IP: 6</td><td colspan="4">L2 Only: 0-11</td></tr>
</table>

Parsing Error: This field is set to 1 if any parsing error is detected. When a parsing error is detected, the header at which the error is detected, is identified in the following Parse Summary header type identification fields unless the errors was detected in an upper layer header not identified in the Parse Summary; in this case it would be the last header identified in the Parse Summary.

IPv4 Opt / IPv6 Ext: For IPv4, this bit is set if the outer IPv4 header has options. For IPv6, this is bit is set if the outer IPv6 header has one or more Extension headers. Note that value 59 (No Next Header) in the Next Header field of the IPv6 main header, is not considered an IPv6 extension header.

L3: When this field holds either 0 or 1

L4: When a fragment is detected, no upper layer beyond the current IP header is reported in the Parse Summary.

Non-IP: These code points are used to indicate the detection of protocols other than IP.

Table 413. Parse Summary L3 and L4 Field Descriptions

L3 (6:5)	L4 (4:0)		
0 IPv4 1 IPv6	0 Undetermined 1 Fragment 2 - 3 ICMP/ICMPv6 4 IGMP 5 IPsec ESP 6 - 7 - 8 - 9 IPv4	10 IPv4-UDP/TCP 11 IPv6 12 IPv6-UDP/TCP 13 - 14 TCP GTP' 15 DCCP 16 TCP 17 UDP 18 UDP-Lite 19 SCTP	20 UDP PTP 21 UDP ESP/IKE 22 UDP GTP 23 UDP GTP' 24 UDP CapWap-ctrl 25 UDP CapWap-data 26 - 27 UDP VxLAN

53.4.2.3.1.3.12.5 Receive Checksum offloads

The device supports the offloading of the receive checksum validation for IPv4, TCP and UDP headers.

Checksum validation for IPv4, TCP and UDP headers in the presence of IPv4 options are supported.

For IPv6 headers, the IP addresses are taken from the main IPV6 header ignoring the optional extension headers. Therefore, checksums for TCP/UDP packets encapsulated in IPv6 with extension headers that contain IP addresses may results in erroneous value. TCP and UPD checksums are not validated for IPv4 and IPv6 fragmented packets.

Take note that the actual calculation of the expected TCP and UDP checksums of a frame is performed when the hardware transfers the frame into receive data buffers in the host system memory.

Receive checksum validation for IPv4, TCP and UDP headers can be independently enabled/disabled on per port basis (see Parser checksum configuration register (PARCSCR)). If a UDP header that has a checksum of zero, is encapsulated in IPv4, no validation is carried out, however if the UDP header is encapsulated in a IPv6 packet, this is considered an error.

Failure of the L3 (IPv4) header checksum validation or the L4 (TCP or UDP) checksum validation, is reported as an error in the ERROR field of the receive buffer descriptor. Whether the L3 (IPv4) header checksum and/or L4 (TCP or UDP) checksums were validated and found correct are also reported in the received buffer descriptor.

Calculation of a bulk checksum (1's complement checksum) is performed by the hardware when transferring a frame into receive data buffers in the host system memory. The bulk sum is calculated over the frame from the 1st byte to the last byte, excluding the Ethernet CRC if it is transferred by the MAC (i.e. present in the frame). The bulk sum is then updated to exclude the first 14 bytes (Ethernet header). Once the entire frame has been transferred from the device to the host, the bulk checksum is inverted (in order to be Internet protocol standard compliant) and then placed in the metadata of the receive descriptor for the frame.

53.4.2.3.1.3.12.6 Parsing support for Wake-on-LAN filtering

To support Wake-on-LAN filtering, the parser provides the identification of the following frames:

- TCP SYN set in the TCP header
- ICMPv6 header detected with the Type Identifier set to MLD/Query (ICMPv6 Type 130 decimal)
- ICMPv6 header detected with the Type Identifier set to ND/NS (ICMPv6 Type 135 decimal).

In addition to the above Wake-on-LAN frame types, magic packets are also supported as a Wake-on-LAN frame type. Magic packet detection is performed by the Ethernet I/F block.

53.4.2.3.1.3.13 Receive Buffer Descriptor Ring Selection

This processing stage determines which receive BD ring is used for the frame received.

To determine the receive descriptor ring for the ingress frame, a multi step classification/mapping is performed by the SI. The receive BD rings assignment to group is performed by setting the SIRBGCR register according to the rules defined in the register definition. Once the configuration of groups and ring allocation to SIs is complete, the receive BD rings can be properly initialized and setup. See Receive Buffer Descriptor Ring for more details. The steps to determine the BD ring are described below:

1. Firstly, an SI default group is selected using SIMR[DEFAULT_RX_GROUP]. If groups are not enabled/used (i.e. SIRBGCR[NUM_GROUPS]=0), then BD ring numbered 0 is selected as the default. If the ENETC port is connected internally to a switch port, designated as a switch management port, and the frame metadata field Host Reason is set to non-zero (i.e. not a regular forwarded frame), this step is not applicable, go to step #2. Otherwise go to step #3.
2. If the ENETC port is connected internally to a switch port, designated as a switch management port, and the frame metadata field Host Reason is set to non-zero (i.e. not a regular forwarded frame), the BD ring is selected by mapping the Host Reason to a receive BD ring using the switch management Host Reason a receive BD ring mapping register SMHRaBDRMR, where a is the Host Reason codepoint number. There are no more steps in classification afterwards. Note that frames with the metadata field Host Reason set to non-zero can only be received from SI 0.
3. Receive Flow Steering (RFS) is used first to determine whether to discard the frame, direct to a BD ring group or direct to a BD ring. If RFS is disabled (PRFSMR[RFSE]=0) or not supported, this step is by-passed. If there is a match and the BD ring is found directly, there are no more steps in classification. If there is a match and the BD group is found directly, step #4 is by-passed. As stated in step #2, if the ENETC port is connected internally to a switch port, designated as a switch management port, and the frame metadata field Host Reason is set to non-zero (i.e. not a regular forwarded frame), the RFS function is not performed (by-passed).
4. If RFS is disabled or did not find a match, Receive Side Scaling (RSS) is used to find the BD ring group. If RSS is disabled or not supported, the SI default group BD ring is selected as determined in step #1. As stated in step #2, if the ENETC port is connected internally to a switch port, designated as a switch management port, and the frame metadata field Host Reason is set to non-zero (i.e. not a regular forwarded frame), the RSS function is not performed (by-passed).
5. If groups are enabled, IPV to be used for mapping to a BD ring within the selected BD ring group is determined according to the following steps:
    a. Use the IPV received from ICM if it was set as a result of an Ingress Port Filtering table lookup match or was set by PSFP. Otherwise go to the next step.
    b. If SIMR[V2IPVE]=1 and VLAN tag is present, VLAN tag PCP+DEI field is used to map to an IPV value by the SI (SIVLANIPVMR0/1 registers). The VLAN tag selection is described in HTA - VLAN Selection.
    c. If SIMR[V2IPVE]=0, the port default IPV is used (PQOSMR[DIPV]).
    d. If SIMR[V2IPVE]=1 and no VLAN tag present, the port default IPV is used (PQOSMR[DIPV])
6. IPV maps to a ring within the selected BD ring group (SIIPVBDRMR register).

To assign and configure rings to a SI, the following steps are required:

1. Assign transmit rings to SIs by setting the SI configuration register field PSI*a*CFGR0[NUM_TX_BDR].
2. Assign receive rings to SIs by setting the SI configuration register field PSI*a*CFGR0[NUM_RX_BDR].
3. Configure the receive BD rings assignment to group by setting SIRBGCR register according to the rules defined in the register definition.

4. Define the default BDR group for each SI by setting register SIMR[DEFAULT_RX_GROUP] unless the maximum number of groups supported is 1, in which case, the SI default group is set to group number 0 (note that SIMR[DEFAULT_RX_GROUP] is not provided when the maximum number of groups supported is 1).
5. Define the VLAN PCP+DEI to IPV mapping by setting register SIVLANIPVMR0/1.
6. Define the SI IPV to receive BDR mapping by setting register SIIPVBDRMR.
7. Program receive ring registers as desired.

For example:

- SI 0 and SI 1 are assigned 8 receive rings each. SI 0 configures 2 groups (0-1) with 4 rings in each. SI 1 configures 1 group (0) with 8 rings in the group.
- SI 0 is assigned 7 rings and SI 1 assigned 1 ring. SI 0 has an odd number of rings but can still define any number of groups (0-2), but may end up with unassigned rings since number of rings per group has to be the same, see SIRBGCR description.

53.4.2.3.1.3.13.1 HTA - VLAN Selection

VLAN tag selection for HTA is as follows:

1. a. If the outer VLAN tag is not valid, then the steps below are skipped and no field is present for the VLAN tag
   b. If removal of SI-based VLAN tag is disabled for this SI (PSI*a*CFGR0[VTE] set to 0), go to step #4.
   c. If removal of SI-based VLAN tag is enabled for this SI (PSI*a*CFGR0[VTE] set to 1), go to step #2.
2. The outer extracted VID and outer 2-bit TPID from the frame are matched against the SI-based VLAN (VLAN ID and TPID from PSI*a*VLANR register) if PSI*a*VLANR[E] is set to 1. If the SI-based VLAN tag removal is enabled and the outer VLAN tag matched the configured SI-based VLAN, this VLAN tag is skipped for the purpose of VLAN tag selection as the SI-Based VLAN tag is hidden from the SI driver. If there is no match against the SI-based VLAN, go to step #4.
3. If the inner VLAN is present and valid, the inner 2-bit TPID is checked against the SI's VLAN extraction bit map (PSI*a*CFGR0[SIVC]) by using the 2-bit TPID value as an index into the SIVC bitmap. If the appropriate bit is set then the VLAN tag has an "acceptable" Ethertype, and the inner VLAN tag extracted from the frame is used as the key for the VLAN tag. Otherwise no field is present for the VLAN tag. The following step is skipped.
4. The outer 2-bit TPID is checked against the SI's VLAN extraction bit map (PSIaCFGR0[SIVC]). By using the 2-bit TPID value as an index into the SIVC bitmap. If the appropriate bit is set then the VLAN tag has an "acceptable" Ethertype, and, the outer VLAN tag extracted from the frame is used as the key for the VLAN tag. Otherwise no field is present for the VLAN tag.

53.4.2.3.1.3.14 VLAN Removal

HTA Receive provides offload support for the removal of 802.1Q VLAN information from single or double tagged frames.

For the purposes of removal, the inner/outer VLAN identifications are taken from the HTA parser. The removal logic is applied on per SI.

Any outer VLAN tag (starting immediately after the SMAC address) may be removed if it matches the SI-based VLAN for the SI. A remaining VLAN tag, which is now the outer tag on the frame, may also be removed if the SI RX BD ring is configured for removal. This removed tag may optionally be presented to software in the Rx BD.

The following VLAN processing is applied for each SI when of a frame is copied from internal memory to system memory buffers.

1. If the outer VLAN is present and valid, and if removal of SI-based VLAN tag is enable for this SI (PSI*a*CFGR0[VTE] set to 1), go to step #2. If the outer VLAN is not valid, then the steps below are skipped. If the outer VLAN is present and valid, and if removal of SI-based VLAN tag is disable for this SI (PSI*a*CFGR0[VTE] set to 0), go to step #5.
2. The outer extracted VID and outer 2-bit TPID from the frame are matched against the SI-based VLAN (VLAN ID and TPID from PSI*a*VLANR register) if PSI*a*VLANR[E] is set to 1. If there is a match against the SI-based VLAN, then the tag is removed for this SI. The parse summary VLAN code point is also updated; i.e., if parse summary VLAN code

point is 1, then it is set to 0. If parse summary VLAN code point is 2, then it is set to 1 only if the "3 or more VLAN tags present" indicator is not set. If there is no match against the SI-based VLAN, go to step # 5.

3. VLAN removal configuration (RB*a*MR[VTE]) is checked to determine whether the VLAN tag is to be removed (in this case the second tag). If VLAN removal is disabled, the next steps are skipped.
4. If the inner VLAN is present, the inner 2-bit TPID is checked against the SI's VLAN extraction bitmap (PSI*a*CFGR0[SIVC]) by using the 2-bit TPID value as an index into the SIVC bitmap. If the appropriate bit is set then the VLAN header is removed. Note that the parse summary is also not updated. If the SI's VLAN presentation is enabled (RBaMR[VTPD] bit set 0), then the VLAN information from the removed VLAN header is provided to software in the Rx BD. Next step is skipped.
5. VLAN removal configuration for this SI (RB*a*MR[VTE]) is checked to determine whether the VLAN tag is to be removed (in this case the first tag). If enable, the outer 2-bit TPID is checked against the SI's VLAN extraction bitmap (PSI*a*CFGR0[SIVC]) by using the 2-bit TPID value as an index into the SIVC bitmap. If the appropriate bit is set then the VLAN header is removed. Note that the parse summary VLAN code point is not updated. If the VLAN presentation is enable (RBaMR[VTPD] bit set 0), then the VLAN information from the removed VLAN header is provided to software in the Rx BD.

53.4.2.3.1.3.15 Receive Buffer Descriptor Ring

A Station Interface (SI) will normally be assigned one or more receive buffer descriptor rings (BDRs) during initialization, see PSI*a*CFGR0[NUM_RX_BDR], these will be numbered 0-*n* in the SI address map. It is therefore important to initialize the ring groups before receive ring programming. When the SI has been assigned receive ring, each rings is configured as follows:

1. Ensure group/ring assignment is completed first. Refer to section Receive Buffer Descriptor Ring Selection.
2. Configure the receive ring base address registers RB*a*BAR0/1. The address must be 128B aligned.
3. Configure the receive ring producer index register RB*a*PIR with a value of 0. The producer index is initially configured by software but owned by hardware after the ring has been enabled. Hardware increments the index when a frame is received which may consume one or more BDs. Hardware is not allowed to increment the producer index to match the consumer index since it is used to indicate an empty condition. The ring can hold at most RB*a*LENR[LENGTH]*8-1 received BDs.
4. Configure the receive ring consumer index register RB*a*CIR. The consumer index is owned by software and updated during operation of the of the BD ring by software, to indicate that any receive data occupied in the BD has been processed and it has been prepared for new data.
   - If consumer index and producer index are initialized to the same value, it indicates that all BDs in the ring have been prepared and hardware owns all of the entries.
   - If consumer index is initialized to producer index plus N, it would indicate N BDs have been prepared. Note that hardware cannot start if only a single buffer is prepared due to the restrictions described in (2).
   - Software may write consumer index to match producer index anytime while the ring is operational to indicate all received BDs prior have been processed and new BDs prepared for hardware.
5. Configure the receive ring size RB*a*LENR[LENGTH]. Note that the maximum number of received BDs allowed on the ring is one less than the ring size.
6. Configure the receive rings buffer descriptor format, standard 16B or extended 32B. The extended format supports timestamping (PTP).
7. Configure the grouping of rings using SIRBGCR for load spreading.
8. Configure the receive ring MSI-X vector number SIMSIRR*a*VR[VECTOR]. Interrupt grouping can be accomplished by assigning two or more rings to the same vector.
9. Configure the receive ring buffer size RB*a*BSR[BSIZE]. If buffer chaining is not desirable, buffer size must be large enough to hold the maximum frame size.
10. Before enabling the receive ring at least two BDs should be prepared in memory by software, as indicated by the consumer index, since there is no condition for zero prepared BDs allowed.

11. Enable the receive ring RB*a*MR[EN]=1. If a frame is steered to a receive ring which is not enabled, a programming error will occur and the frame will be dropped.

53.4.2.3.1.3.15.1 Operation of the Receive Buffer Descriptor Ring

The operation of the receive BD ring is as follows:

1. SW initializes the receive ring as described above.
2. A prefetch mechanism is used to load buffer descriptors from the receive BD rings in host memory (e.g. DDR) to an internal cache in the prefetcher. As BDs are loaded into the internal memory, they are put onto an internal BD queue that is associated with the receive BD ring from which the BDs were fetched. There is one queue for each possible receive BD ring. Each internal BD queue can hold up to 8 receive BDs. When an internal BD queue has 3 or less receive BDs, a fetch is initiated as soon as there are any receive BDs ready for reception in the corresponding receive BD ring. When an internal BD queue has 4 receive BDs, the prefetch mechanism waits until there are at least 4 receive BDs in the corresponding receive ring before loading the next BDs. This results in fetching BDs aligned on a 64B cache line boundary. Receive BD ring selection for the purpose of fetching BDs is performed in a round robin manner. The BD transfers have higher priority than the frame data transfers on the system memory interface.
3. If the ring is not full (i.e. BDs/buffers are available), HTA Receive will write data to the buffer referenced by the next prefetched BD and then update the BD by writing either 16B (standard format) or 32B (extended format) to the BD memory location. The final bit BD[F] is set if this is the last BD in a chain. The ready bit, BD[R], will be set for the (first) BD only after the frame has been fully committed to memory. Note that a full condition occurs when the producer index trails the consumer index by one.
4. HTA Receive will update the producer index register when the last BD of a chain has been written to memory to reflect that one or more BDs were added.
5. Software may use the producer index register (RB*a*PIR) or polling of BD[R] bit to determine when the next frame is available.
   - If software relies mainly on the ready bit, BD[R], for processing of received BDs, it should clear the ready bit after processing the BD. There may be a performance benefit of using the ready bit since the producer index register (RB*a*PIR) update has to wait for BDs to be committed to memory. This introduces a small window between when BD[R] is asserted and the producer index register (RB*a*PIR) is updated. Normal operation of clearing BD[R] as indicated followed by updating the consumer index register (RB*a*CIR) will avoid violating this window. The memory location of the BD ring versus reading producer index, i.e. cached or not, should be considered as well.
   - If software relies solely on the producer index register (RB*a*PIR) for processing of frames, it does not need to poll the BD for readiness and does not need to clear the BD ready bit after processing a BD. Software may use interrupt coalescing to determine when new BDs have been added to a ring to avoid polling the producer index register (RB*a*PIR).
6. Software increments the consumer index register (RB*a*CIR) after processing the received frame and adding new buffers as needed. Software must not advance the consumer index (RB*a*CIR) before hardware has updated the producer index (RB*a*PIR).

53.4.2.3.1.3.15.2 FCS Processing

An FCS is an error-detecting code added to a frame to verify the integrity of the frame as it traverses the network. On NETC, the FCS is used to check frame integrity when a frame is entering NETC (that is received from an Ethernet link) and when a frame is exiting NETC. The later check is referred to as an internal FCS check. On an ENETC function, the internal FCS check is performed as frames are transferred from shared internal buffer memory into receive data buffers in the host system memory. As frames are read out from the shared internal buffer memory, the FCS is calculated. When the end of the frame is reached, the calculated FCS is compared against the FCS associated with the frame. If there is a mismatch, the ERROR field of the receive descriptor for the frame is updated to indicate that the frame is bad (code point set to 0x20 (Frame CRC (FCS) validation failed)). Note that the internal FCS check does not include any frame modifications performed by HTA Receive, as these frame modifications are applied to the frame after the internal FCS check is performed that is frame modifications are applied when the frame is loaded into receive data buffers in the host system memory.

For frames received from a pseudo MAC, only frame descriptors are transferred across a pseudo link. Frame descriptors received on a pseudo link include references to the original frame (including FCS) and annotated frame header if present as a result of the switch performing frame modifications. This annotated frame header represents the first n bytes of the frame, along with an indication of how many bytes from the start of the original frame are no longer valid. There is an FCS covering the annotated frame header, which is distinct from the FCS covering the entire original frame. As part of the internal FCS check, the FCS of the annotated frame header and the FCS of the entire original frame are recalculated, prior to re-assembling the frame and transferring it to the receive data buffers in the host system memory. If any of the two recalculated FCSs do not match their original FCS, an internal FCS error is reported for the frame. If the FCS is to be preserved when delivering the frame to software (specified through register RBaMR[CRC], where 'a' is the BD ring number), HTA receive will regenerate a new FCS. The regenerated FCS does not include any frame modifications performed by HTA Receive, as these frame modifications are applied afterwards, when the frame is loaded into receive data buffers in the host system memory.

53.4.2.3.1.3.15.3 Receive Buffer Descriptor Ring Congestion Management

A receive BD ring will experience congestion (instantaneously (versus average) BD ring depth growing) whenever the processing core is not able to keep up with the traffic steered to the receive BD ring. This could be due to poor usage of load spreading or BD ring too small to handle temporal processing delays by the core. There are two modes of congestion management for managing receive BD ring congestion; lossless and lossy.

In the lossless mode, pausing the other end of the link is the main method of dealing with congestion. If a receive BD ring reaches full level (i.e. no BDs/buffers are available), HTA will wait for more BDs to be added to the ring by software. This will cause back-pressure to the Ingress Congestion Manager (ICM) which in turn will request the MAC to signal the other end of the link, to pause its data transmission on the link, if congestion persists (it starts running out of internal memory). The PAUSE On/Off thresholds (PPAUONTR and PPAUOFFTR) must be set for ICM to request the MAC to pause the other end of the link. It is recommended that pausing the other end of the link, should not be used with time-sensitive networks, since the transmission of all traffic classes from the other end of the link would be paused when the port is flow controlled.

In the lossy mode, tail drop is the main method for dealing with congestion (i.e. when receive BD ring reaches full level meaning that no BDs/buffers are available). This means that frames are simply dropped if the destination BD ring is enabled but has no BDs/buffers at the time when HTA needs to store that frame to the host memory.

The congestion management mode (lossless or lossy) is configurable on per BD ring basis by setting the RBaMR[CM] register.

Note that hardware does not account for FCS removal (see RBaMR[CRC], for more details) or VLAN removal (see VLAN Removal, for more details) when determining if there are sufficient BDs/buffers available to store the frame to the host memory.

The congestion management mode (lossless or lossy) is not applicable to transmit timestamp reference responses which are identified by their Host Reason code (0x3 Timestamp Response). If a receive BD ring reaches full level (i.e. no BDs/buffers are available when a transmit timestamp reference response is ready to be delivered to the host, HTA will wait for more BDs to be added to the ring by software; the transmit timestamp reference response will not be dropped.

53.4.2.3.2 Table Management Commands

Table management commands use the NTMP protocol. Familiarity with the basic NTMP concepts, described in the NETC Table Management Protocol (NTMP) section of this document, is needed to understand the material documented in this section.

Some functionality is configured and controlled using control messages sent to ENETC using a BD ring interface like the transmit BD ring. This BD ring interface is referred to as the command BD ring.

Control messages are primarily used when the underlying functionality being configured may be too large to configure using direct registers (e.g. large tables). Each SI (PSI and VSI(s) if present) has a command BD ring.

Command BD ring selection amongst all NETC functions' command BD rings (i.e. the pair of switch rings plus the per-SI ENETC rings) is performed in a round robin manner. Each command BD ring is serviced (one command per round) once in each round of the robin. Each round considers all command BD rings defined amongst all NETC functions.

The NETC serializes commands within a single ring. It is safe to pipeline commands A and B within a ring where command A must complete before command B begins. Any ordered processing must be done either using a single ring, or waiting until command A has completed before issuing command B.

Each SI command ring is configured as follows:

1. Configure the command ring base address registers SICBDRBAR0 and SICBDRBAR0. The address must be 128 byte aligned.
2. Configure the command ring producer index register SICBDRPIR. Software should initialize the index value at this address to 0 to reflect an empty ring. Optionally if the ring is pre-initialized with BDs the index values should reflect the number of BDs added.
3. Configure the command ring consumer index register SICBDRCIR. This index value indicates the next BD to be processed by the hardware. When the ring is re-initialized this register should be set to 0. The consumer index is later updated by the hardware during processing of the ring.
4. Configure the command ring size SICBDRLENR to indicate how many 32B entries, are allowed in the ring. There is no wrap bit to indicate full/empty; one entry is used to differentiate between full and empty. When producer index + 1 equals consumer index, the ring is considered full. When the producer/consumer indices match, the ring is always considered empty.
5. Enable the command ring SICBDRMR [EN]=1.

To add one or more buffer descriptors (or commands) to an enabled transmit ring, follow the procedure below. To add one or more buffer descriptors (or commands) to an enabled transmit ring, follow the procedure below:

1. Software checks to make sure the ring is not full by examining the consumer index (CI) register, SICBDRCIR. Note that maximum number of BDs allowed on a ring is one less than ring size.
2. Software adds one or more BDs to the ring. A memory barrier must be used to guarantee update to memory. If software requires an interrupt when a BD has been transmitted, set BD[CI/CCI] =1 and enable the interrupt through SICBDRIER[CBDCIE].
3. When SICBDRCIR [BDR_INDEX] match SICBDRPIR [BDR_INDEX], the ring is empty. After one or more BDs have been processed, the consumer index will be updated by hardware.

53.4.2.3.2.1 Table Management Protocol Version 1.0 Commands

Commands supported by ENETC are described in the table below. The format of the descriptor is detailed in NTMP Version 1.0.

Table 414. Supported Commands

Class	Command	Description
0	-	Reserved
1	0	Set entry in MAC address filter table
1	1	Query entry in MAC address filter table
2	0	set entry in VLAN filter table
2	1	query entry in VLAN filter table

Some command classes can only be issued by a PSI. The table below indicates for each command class, the type of SIs that can issue the command class.

Table 415. Functions of the Command BD Ring

Function	Owner	Access From	Register Support	BD Format	Notes
MAC address filtering	Port	PSI command BD ring	Capability only	short	VSI access through messaging to request PSI to modify
VLAN filtering	Port	PSI command BD ring	Capability only	short	VSI access through messaging

53.4.2.3.2.1.1 MAC Address Filter Table

Table 416. CBD Class 1: MAC Address Filter Table Entry Set Descriptor - Short Format

53.4.2.3.2.2 Table Management Protocol Version 2.0 Commands

Commands supported by the ENETC are described in the table below. The format of the descriptor is detailed in NTMP Request Message Data Buffer and NTMP Response Message Data Buffer.

Table 422. Supported ENETC Commands

Table ID	Table Name	Table Type	Access From
5	Time Gate Scheduling table	Indexed table	PSI command BD ring
10	Rate Policer Table	Indexed table	PSI command BD ring
13	Ingress Port Filter table	Ternary match table	PSI command BD ring
30	Ingress Stream Identification table	Hash table	PSI command BD ring
31	Ingress Stream table	Indexed table	PSI command BD ring
32	Ingress Stream Filter table	Hash table	PSI command BD ring
36	Stream Gate Instance table	Indexed table	PSI command BD ring
37	Stream Gate Control List table	Indexed table	PSI command BD ring
38	Ingress Stream Count table	Indexed table	PSI command BD ring

53.4.2.3.2.2.1 Time Gate Scheduling Table

Table 423. Table ID 5 - Time Gate Scheduling Table Common Attributes

TABLE_ID	5
TABLE_VERSION	0
Table Type	Static bounded index table

Table continues on the next page...

Table 423. Table ID 5 - Time Gate Scheduling Table Common Attributes (continued)

Table Description	The Time Gate Scheduling table contains time gate scheduling configuration and operational information for a NETC function. There is one Time Gate Scheduling table for each ENETC instance and one Time Gate Scheduling table for the entire switch. For the switch, there is one entry for each switch port, whereby for an ENETC instance, there is a single entry for the entire ENETC instance. Each entry includes both an administrative gate control list and an operational gate control list, along with related configuration and status parameters. There is an internal memory that is used to store the administrative gate control list and the operational gate control list of each table entry. The number of words available for all entries in the Time Gate Scheduling table is specified in register TGSTCAPR[NUM_WORDS]. The memory is managed using a single free list of fixed equal size units (or words) of memory. Free memory units from the free list are available to be dynamically allocated to any gate control lists subject to the total memory available and maximum gate control list length (TGSTCAPR[MAX_GCL_LEN]. Each gate control list is comprised of a sequence of gate operation entries where each entry occupies one word of memory. Table management command operations Update and Query are supported. After reset, each entry is present with all fields cleared to zero; there is no administrative gate control list and operational gate control list, indicated by their gate control list length being set to 0. An administrative gate control list can only be added by an Update operation, on a entry that contains no administrative gate control list (length is set to 0). An existing administrative gate control list cannot be directly updated/modified. The administrative gate control list contained in the entry must be first removed by issuing an Update operation that sets the administrative gate control list length to zero, followed by another Update operation that adds the new administrative gate control list. An administrative gate control list cannot be removed if its config change time is 1 ms away. Therefore, before attempting to remove an administrative gate control list, a check must be performed to determine if the config change time minus the current time is less than 1 ms. If so, then the administrative gate control list can no longer be removed as it will become the operational gate control list. There are two ways to obtain the config change time: • config change time is returned in the STATUS field of a command response to a command configuring an administrative gate control list. • config change time can be retrieved by issuing a query operation against the Time Gate scheduling table entry. Once an operational gate control list is installed, it cannot be removed by a table management command. Disabling time gate scheduling on a port (PTGSCR[TGE]=0), will remove both the operational gate control list and the administrative gate control list from the corresponding table entry. When adding an administrative gate control list while there is a currently running gate control list (that is operational gate control list), the base time of the administrative gate control list (ADMIN_BASE_TIME value) must be set to a time in the future. The minimum future time is equal to: *CurrentTime* + *LookAheadTime* + *TableCmdProcessingTime* + (2 × *OperCycleTime*) Where: *CurrentTime* = 1588 (synchronized) time at which software is to issue the Time Gate Scheduling table update command *LookAheadTime* = E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET] *TableCmdProcessingTime* = Hardware processing time of the Time Gate Scheduling table update command 21,200 NETC clock cycles; for example, @240Mhz ~ 90µs *OperCycleTime* = Cycle time of the operational gate control list Thus, if there is a currently running gate control list and the base time of the administrative gate control list to be added is within the following range: *AdminBaseTime* < *CurrentTime* + *LookAheadTime* + *TableCmdProcessingTime* + (2 × *OperCycleTime*)

Table continues on the next page...

Table 423. Table ID 5 - Time Gate Scheduling Table Common Attributes (continued)

	Where: *AdminBaseTime* = Base time of the administrative gate control list Then software must adjust the base time of the administrative gate control list (ADMIN_BASE_TIME value) as follows: *Adjusted AdminBaseTime* = *AdminBaseTime* + (N × *AdminCycleTime*) where N is the smallest integer for which the relation *Adjusted AdminBaseTime* ≥ *CurrentTime* + *LookAheadTime* + *TableCmdProcessingTime* + (2 × *OperCycleTime*) would be TRUE. When the administrative gate control list is installed (by the hardware) as the operational gate control list, the gate control list itself is not copied, instead the gate control list is assigned as the operational gate control list. A query to the administrative gate control list will then return 0 for the length indicating that there is no administrative gate control list present in the table entry. However, note that ADMIN_ BASE_TIME, ADMIN_CYCLE_TIME and ADMIN_CYCLE_TIME_EXT values are preserved, until a new administrative gate control list is configured.			
Number of Entries	For the switch, the number of entries is equal to the number of switch ports; number of switch ports is indicated in register SCAPR0[NUM_PORT]. For ENETC, there is a one table entry per table.			
Default Reset Behavior	After reset, each entry is present with all fields cleared to zero; there is no administrative gate control list and operational gate control list, indicated by their gate control list length being set to 0			
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**

Table 429. Table ID 5 - Time Gate Scheduling Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
63-0	64	ADMIN_BASE_TIME	Administrative Base Time This field sets the base time, i.e., the start time, of the administrative gate control sequence. The time is expressed in units of nanoseconds. The field implements the AdminBaseTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 AdminBaseTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expects the time to be specified as a 64-bit integer number of nanoseconds. Therefore, if this field is to be set to a value which was obtained from a managed object using the IEEE 802.1Q-2018 PTP time format, the value must be converted by software from the IEEE 802.1Q-2018 format to the 64-bit integer number of nanoseconds.
95-64	32	ADMIN_CYCLE_TIME	Administrative Cycle Time Sets the cycle time of the administrative gate control list. This is the period of time over which the sequence of operations in a gate control list repeats. Command will be rejected if ADMIN_CYCLE_TIME=0. The time is expressed as an integer number of nanoseconds. The field implements the AdminCycleTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 AdminCycleTime parameter, which is a rational number in units of seconds (numerator and denominator). Instead of using the IEEE 802.1Q-2018 AdminCycleTime parameter format, the field expects the time to be specified as a 32-bit integer number of nanoseconds. Therefore, if this field is to be set to a value which was obtained from a IEEE 802.1Q-2018 managed object, the value must be converted by software from the IEEE 802.1Q-2018 format to the 32-bit integer number of nanoseconds. Note that if the cycle time is shorter than the sum of the time intervals (see ADMIN_TIME_INTERVAL_GE_i), the sequence of operations is truncated, which in turn could cause the undesirable effect of overrunning a next gate-close event.
127-96	32	ADMIN_CYCLE_TIME_EXT	Administrative Cycle Time Extension This is the maximum amount of time by which the ADMIN_CYCLE_TIME is permitted to be extended when a new gate control sequence is being installed. The cycle time extension is used to extend the last complete cycle so that it ends at the new base time,

Table continues on the next page...

Table 429. Table ID 5 - Time Gate Scheduling Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			or in other words, that the old and new cycles line up. Setting the cycle time extension to a value that extends the last complete cycle to complete before the new base time (too short), will result in undefined behavior of the time gate operation. The time is expressed as an integer number of nanoseconds.
143-128	16	ADMIN_CONTROL_LIST_LENGTH	Administrative Control List Length This field indicates the number of entries in the administrative gate control list. Valid values for N are 1 to TGSTCAPR[MAC_GCL_LEN] for creating a new administrative gate control list and 0 to remove the administrative gate control list. The command will be rejected if list length is invalid.
159-144	16	--	Reserved
(223 + 64i) - (160 + 64i)	32	ADMIN_TIME_INTERVAL_GE_i	Administrative Time Interval for Gate Entry i, where i = 0, ..., N-1 Specified in nanoseconds. A minimum of 2 gate entries must be specified. Restrictions (applies to any time interval entries): - Minimum gate time interval specified must not be less than (((TGP +2) * 4) + 20)/NETC clock frequency, where TGP is the number of NETC ports (ENETC and switch) where time gating is enabled.
	8	ADMIN_TC_STATES_GE_i	Administrative Traffic Class Gate States for Gate Entry i, where i = 0, ..., N-1. Bit 0: Gate state for traffic class 0. Bit 1: Gate state for traffic class 1. Bit 2: Gate state for traffic class 2. Bit 3: Gate state for traffic class 3. Bit 4: Gate state for traffic class 4. Bit 5: Gate state for traffic class 5. Bit 6: Gate state for traffic class 6. Bit 7: Gate state for traffic class 7. For each of the traffic classes above, the following values apply: 0b = Gate closed. 1b = Gate open.
	8	--	Reserved
	4	ADMIN_HR_CB_GE_i	Administrative gate operation type (as per IEEE 802.1Q-2018) field for gate control list entry i. 0x0: SetGateStates. HoldRequest is unchanged. 0x1: Set-And-Hold-MAC. HoldRequest is set to value hold (1). 0x2: Set-And-Release-MAC. HoldRequest is set to value release (0).
	12	--	Reserved

Table 431. Table ID 5 - Time Gate Scheduling Table OLSE_DATA Description

Bits	Width [bits]	Name	Description
63-0	64	CONFIG_CHANGE_TIME	This field specifies the time at which the administrative gate control list is to become active. The time is expressed in units of nanoseconds. The field implements the ConfigChangeTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 ConfigChangeTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expresses the time as a 64-bit integer number of nanoseconds. Therefore, if this field is to be queried from an IEEE 802.1Q-2018 managed object, the value must be converted by software from the 64-bit integer number of nanoseconds to the IEEE 802.1Q-2018 PTP time format.
127-64	64	CONFIG_CHANGE_ERROR	Count of the number of times that a configuration change (new schedule) has been requested with the old schedule still running and the requested base time was in the past.
191-128	64	OPER_BASE_TIME	Operational Base Time Indicates the base time, i.e., the start time, of the operational gate control sequence.

Table continues on the next page...

Table 431. Table ID 5 - Time Gate Scheduling Table OLSE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			The time is expressed in units of nanoseconds. The time indicated in the field is advanced by the amount of time specified in EaTGSLR/ S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]. The field implements the OperBaseTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 OperBaseTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expresses the time as a 64-bit integer number of nanoseconds. Therefore, if this field is to be queried from an IEEE 802.1Q-2018 managed object, the value must be converted by software from the 64-bit integer number of nanoseconds to the IEEE 802.1Q-2018 PTP time format.
223-192	32	OPER_CYCLE_TIME	Operational Cycle Time Indicates the cycle time of the operational gate control list. This is the period of time over which the sequence of operations in a gate control list repeats. Command will be rejected if ADMIN_CYCLE_TIME=0. The time is expressed as an integer number of nanoseconds.
255-224	32	OPER_CYCLE_TIME_EXT	Operational Cycle Time Extension This is the maximum amount of time by which the OPER_CYCLE_TIME is permitted to be extended when a new gate control sequence is being installed. The time is expressed as an integer number of nanoseconds.
271-256	16	OPER_CONTROL_LIST_LENGTH	Operational Control List Length This field indicates the number of entries in the operational gate control list.
287-272	16	--	Reserved
(351 + 64i) - (288 + 64i)	32	OPER_TIME_INTERVAL_GE_i	Operational Time Interval for Gate Entry i, where i = 0, ..., M-1 Specified in nanoseconds. Restrictions (applies to any time interval entries): - Minimum time interval time is the time required to transmit 128 bytes. - Time interval needs to be greater than the advance offset time configured in PTGATOR[ADV_TIME_OFFSET]. - The sum of any 15 consecutive time intervals must be greater than the advance offset time configured in EaTGSLR[MIN_LOOKAHEAD] / S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]. - An entries' time interval should be able to transmit the Traffic Classes' MAX_SDU when fusing.
	8	OPER_TC_STATES_GE_i	Operational Traffic Class Gate States for Gate Entry i, where i = 0, ..., M-1 Bit 0: Gate state for traffic class 0. Bit 1: Gate state for traffic class 1. Bit 2: Gate state for traffic class 2. Bit 3: Gate state for traffic class 3. Bit 4: Gate state for traffic class 4. Bit 5: Gate state for traffic class 5.

Bits	Width [bits]	Name	Description
			Bit 6: Gate state for traffic class 6. Bit 7: Gate state for traffic class 7. For each of the traffic classes above, the following values apply: 0b = Gate closed. 1b = Gate open.
	8	--	Reserved
	4	OPER_HR_CB_GE_i	Operational gate operation type (as per 802.1Q) field for gate control list entry i. 0x0: SetGateStates. HoldRequest is unchanged. 0x1: Set-And-Hold-MAC. HoldRequest is set to value hold (1). 0x2: Set-And-Release-MAC. HoldRequest is set to value release (0).
	12	--	Reserved

53.4.2.3.2.2.2 Rate Policer Table

Table 432. Table ID 10 - Rate Policer Table Common Attributes

TABLE_ID	10
TABLE_VERSION	0
Table Type	Dynamic bounded index table
Table Description	The Rate Policer table contains the rate policer configuration and operational information for a NETC function. There is one Rate Policer table for each ENETC instance and one Rate Policer table for the entire switch. Each table entry contains a set of parameters that defines a single rate policer instance. A rate policer instance controls the amount of traffic that is allowed to go through for a particular received flow of frames. A rate policer instance can be pointed to in the Ingress Port Filter, Ingress Stream, Ingress Stream Filter tables and storm control registers. Table entries used for storm control and table entries used for rate policing are mutual exclusive; these entries cannot be shared between these two distinct functions. Rate policers can be used across switch ports, and streams. In the case of bandwidth violations, a rate policer instance can change the drop resilience parameter associated with each frame and can discard frames on various basis such as the drop resilience of the frame. Table management command operations Add, Delete, Update and Query are supported. This table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. The entries are stored in contiguous manner in a common memory. For this table, each table entry occupies four words. Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers; S0RPITMAR[NUM_WORDS] for switch and EaRPITMAR[NUM_WORDS] for ENETC. These allocations can also be changed when the functions are initialized through their respective base function register RPITMAR[NUM_WORDS].
Number of Entries	Maximum number of entries is indicated in RPITCAPR[NUM_ENTRIES]. Number of entries in-use is indicated in RPITOR[NUM_ENTRIES].

31-0	32	CIR	Committed Information Rate Expressed in units of 3.725 bits per second, this parameter limits the average rate of frames declared green by the rate policer instance.

Table continues on the next page...

Table 438. Table ID 10 - Rate Policer Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
63-32	32	CBS	Committed Burst Size Expressed in bytes, this is the maximum fill (number of bytes) allowed in the Committed (C) token bucket. This parameter limits the number of bytes allowed in a burst of frames that are declared green by the rate policer instance.
95-64	32	EIR	Excess Information Rate Expressed in units of 3.725 bits per second, this parameter limits the average rate of frames declared yellow by the rate policer instance.
127-96	32	EBS	Excess Burst Size Expressed in bytes, this is the maximum fill (number of bytes) allowed in the Excess (E) token bucket. This parameter limits the number of bytes allowed in a burst of frames that are declared yellow by the rate policer instance.
128	1	MREN	Mark All Frames Red Enable This field enables the rate policer blocking function called "mark all frames red". When the "mark all frames red" feature is enabled, any frames dropped because they were marked red or yellow (if drop on yellow is enabled) will cause all subsequent frames to be marked red and the MR bit to be set to 1 within the Policer State Element. Frames marked "red" are always dropped unless the NDOR field is set to 1, in which case the red frames are not dropped, but their DR is set to 3. The hardware will continue to mark red all frames arriving at this rate policer instance until the MR bit is cleared via an update command to the Policer State Element. 0b = The rate policer blocking function "mark all frames red" feature is disabled. 1b = The rate policer blocking function "mark all frames red" feature is enabled. Not valid when NDOR=1.
129	1	DOY	Drop on Yellow 0b = Frames marked as yellow by the rate policer instance are not dropped. 1b = Frames marked as yellow by the rate policer instance are dropped.
130	1	CM	Color mode 0b = Color blind; pre-color information (encoded in the Drop Resilience (DR)) is not taken into account by the rate policer instance. 1b = Color aware; pre-color information (encoded in the Drop Resilience (DR)) is taken into account by the rate policer instance.
131	1	CF	Coupling flag This field enables the feature of coupling the Committed (C) bucket and Excess (E) bucket. When the buckets are coupled, and the C bucket becomes full (C tokens = CBS), any overflow C tokens will be added to the E bucket, up to the max fill of the E bucket (EBS). 0b = C and E token buckets are not coupled. 1b = C and E token buckets are coupled.

Table continues on the next page...

Table 438. Table ID 10 - Rate Policer Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
132	1	NDOR	No Drop on Red. When this field is set to 1, the red frames from this rate policer instance, are not dropped, but their DR is set to 3. Frames marked red by the flow meter blocking feature "mark all frames red" (enable/disable via the MREN) will also not be dropped. When this field is set to 0, frames marked "red" are always dropped.
134-133	2	SDU_TYPE	Service Data Unit Type This field specifies the type of PDU/SDU (Protocol/Service Data Unit) for a frame received by this rate policer instance when performing flow meter calculations. Overhead values are specified by register PRXSDUOR. 00b = PPDU (Physical Layer PDU). 01b = MPDU (MAC PDU). 10b = MSDU (MAC SDU). All other values reserved.
143-135	9	--	Reserved

Table 440. Table ID 10 - Rate Policer Table FEE_DATA Description

Bits	Width [bits]	Name	Description
0	1	FEN	Functional Enable This field is used to enable/disable a rate policer instance. 0b = The rate policer instance is disabled, but the token buckets and statistics counters and other configuration information are left intact, to allow reading them after a policer instance has been disabled. Frames directed to a policer instance that is disabled are passed through (not discarded). 1b = The rate policer instance is enabled based on the configuration information within the Configuration Element. Enabling a rate policer instance consists of setting the committed (C) token bucket to its full value (which is CBS), setting the excess (E) token bucket to its full value (which is EBS), and clearing all of the statistics counters to 0. Note that the timer function must be configured and enabled before any rate policer instance is enabled. Either the default nanosecond timer or the 1588 timer can be used to generate the required nanosecond resolution time. The default nanosecond timer is configured and enabled by default out of reset. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer

Bits	Width [bits]	Name	Description
63-0	64	BYTE_COUNT	Number of bytes received by the rate policer instance. Refer to SDU_TYPE for the SDU type used for byte count updates..
95-64	32	DROP_FRAMES	Number of frames dropped by the rate policer instance.
159-128	32	DR0_GRN_FRAMES	Number of frames marked green with DR=0 by the rate policer instance.
223-192	32	DR1_GRN_FRAMES	Number of frames marked green with DR=1 by the rate policer instance.
287-256	32	DR2_YLW_FRAMES	Number of frames marked yellow with DR=2 by the rate policer instance.
351-320	32	REMARK_YLW_FRAMES	Number of frames re-marked from green to yellow by the rate policer instance. If CM=(color-blind mode), this will equal DR2_YLW_FRAMES.
415-384	32	DR3_RED_FRAMES	Number of frames marked red (DR=3) by the rate policer instance.
479-448	32	REMARK_RED_FRAMES	Number of frames re-marked from green or yellow to red by the rate policer instance. If CM=0 (color-blind mode), this will equal DR3_RED_FRAMES.

Table continues on the next page...

Table 444. Table ID 10 - Rate Policer Table STSE_DATA Description (continued)

Bits	Width [bits]	Name	Description
543-512	32	LTS	Last timestamp. This is the timestamp of the last frame (or periodic update) received by this rate policer instance. Frame timestamps in the receive datapath are applied at the MAC, and use the 32 lsb of the 64 bit 1588 time base, see also the TIMESTAMP field in the receive buffer descriptor.
575-544	32	BCI	Bucket Committed Integer (part) Indicates the integer part (32 bits) of the committed token bucket fill level, expressed in units of bytes.
606-576	31	BCF	Bucket Committed Fractional (part) Indicates the fractional part (31 bits) of the committed token bucket fill level, expressed in units of bytes.
607	1	BCS	Bucket Committed Sign-bit. Indicates the sign-bit value of the committed token bucket fill level. The committed token bucket fill level, expressed in units of bytes, is represented as a 64-bit 2’s complement value (BCI) with a 32-bits integer part and a 31-bits fractional part (BCF). The 2’s complement notation is used as the amount of tokens in the bucket can go negative (effectively borrowing future tokens) when forwarding cut-through frames. In cut-through mode, the amount of tokens required (and consumed initially) in the bucket for considering a frame ‘conforming’, is the initial segment size of the cut-through frame. Tokens then continue to get consumed as the rest of the cut-through frame is received, and then possibly resulting in the bucket going negative. The fractional part is mainly due to the replenishment of the bucket, as the replenishment rate is in units of 3.725 bits per second. Note that a fraction of a token (or byte) means from an algorithm perspective that the token is not considered available in the bucket.
639-608	32	BEI	Bucket Excess Integer (part) Indicates the integer part (32 bits) of the excess token bucket fill level, expressed in units of bytes.
670-640	31	BEF	Bucket Excess Fractional (part) Indicates the fractional part (31 bits) of the excess token bucket fill level, expressed in units of bytes.
671	1	BES	Bucket Excess Sign-bit. Indicates the sign-bit value of the excess token bucket fill level. The excess token bucket fill level, expressed in units of bytes, is represented as a 64-bit 2’s complement value with a 32-bits integer part (BEI) and a 31-bits fractional part (BEF). The 2’s complement notation is used as the amount of tokens in the bucket can go negative (effectively borrowing future tokens) when forwarding cut-through frames. In cut-through mode, the amount of tokens required (and consumed initially) in the bucket for considering a frame ‘conforming’, is the initial segment size of the cut-through frame. Tokens then continue to get consumed as the rest of the cut-through frame is received, and then possibly resulting in the bucket going negative. The

			fractional part is mainly due to the replenishment of the bucket, as the replenishment rate is in units of 3.725 bits per second. Note that a fraction of a token (or byte) means from an algorithm perspective that the token is not considered available in the bucket.

53.4.2.3.2.2.3 Ingress Port Filter Table

Table 445. Table ID 13 - Ingress Port Filter Table Common Attributes

TABLE_ID	13
TABLE_VERSION	0
Table Type	Hardware Managed Ternary Match table
Table Description	The Ingress Port Filter table contains a set of filters each capable of classifying incoming traffic using a mix of L2, L3, and L4 parsed and arbitrary field data. As a result of a filter match, several actions can be specified such as on whether to deny or allow a frame, overriding internal QoS attributes associated with the frame and setting parameters for the subsequent frame processing functions (e.g. stream identification, policing, ingress mirroring). Each entry corresponds to a filter. The Ingress Port Filter table is enabled per-port via PIPFCR[EN], when there is at least one entry added for that port. If disabled, or if no match is found, the frame is allowed and passed to the next frame processing function. The Ingress Port Filter entries are added using a precedence value. If a frame matches multiple entries, the entry with the higher precedence is used. The Ingress Port Filter table is implemented using a Ternary Content Addressable Memory (TCAM). TCAM provides deterministic and high-speed lookups, however they consume significant amount of die size area compared to other types of memories, and thus the need to optimize storage is important. As a result, a narrow (48-bit wide), but deep TCAM organization is used, where a table entry can occupy multiple sequential lines of the TCAM. The maximum number of TCAM lines occupied by an Ingress Port Filter entry is 14 lines. With the exception of the first TCAM line, TCAM lines for which all fields are masked out (their corresponding mask field set to all 0s) will not actually exist in the TCAM. However, if only the first line is not completely masked out, TCAM line 4 is added, where the reserved portion of the TCAM line (bits 47:40) are not masked out. As a result, an Ingress Port Filter entry may occupy from 2 lines to 14 lines, depending on how many TCAM lines are entirely don't cares. See IPF Entry Format for the Ingress Port Filter entry implementation format (that is, Ingress Port Filter table entry fields contained in each TCAM line). A maximum of 24 consecutive bytes can be used as payload data for a Ingress Port Filter entry. The per-port parser register PPCR is used to limit the amount of payload data needed, if no entries are added attempting to match the full 24B of payload. If the end of frame is received before the desired amount of payload has been extracted, then the payload data will be padded with zeros up to the next 6B multiple (TCAM line). There is a small opportunity for false matches, where the zero-padded payload matches an entry with actual payload data of zeros. However, since the payload is only padded to the next 6B boundary, the likelihood of false matches is reduced, since it only can false match an entry with zeros as the last few payload bytes, and the payload data ends at that 6B boundary. For example, if 16B of payload is required, and the end of frame happens after extracting 12B of payload, there will be no zero padding, since the payload data extracted ended on a 6B boundary. If the end of frame occurs after extracting 14B, then there will be 4B of zero padding, to complete that TCAM line. In this case, only the first 2B of zero padding will have a valid mask, the last 2B of padding will have a mask of "don't care" since we only care about 16B of payload data.

Table continues on the next page...

Table 445. Table ID 13 - Ingress Port Filter Table Common Attributes (continued)

	Software adds entries using the "Add followed by Query" operation and the Ternary Match Key Element Match Access Method. The PRECEDENCE value is used to insert the entry. Hardware automatically moves entries with lower PRECEDENCE values when adding a new entry. The ENTRY_ID assigned to the entry is returned as part of the response to the Query operation. Software can issue a Search operation to dump entries that have been added along with their ENTRY_ID values. A query operation cannot be performed using the Key Element (KEYE_DATA). If the entry being added is too large for the available memory, an error will be returned. The IPFTMOR per-function register can be used to help determine the current usage. When deleting entries, Software provides the ENTRY_ID of the entry to be deleted. Hardware will find the entry specified, delete all lines associated to the entry, and shift entries up to close the gap (if any). When software performs a Query operation, and requests the Key Element of a ternary match (TCAM) table to be returned, the Key Element information in the Response Data Buffer may not precisely match the data which was used when an Add operation was issued. Ternary match tables perform a lossy compression when storing the key element data within the key element and thus, when querying a ternary match table's key element, software must be aware of the following behavior: for any data bits which had their associated mask bit set to 0 (don't care), the resulting data bit in the query response will be 0 regardless of how that bit was set in the key element data when adding or updating the key element. The precedence value within a Key Element will be returned precisely upon query. The Search Access Method can only be used to dump the Ingress Port Filter table entries for a given function (i.e. match all entries for a given ENETC, or the Switch as a whole). Table management operations Add, Delete, Update and Query are supported.		
Number of Entries	Maximum number of words is indicated in IPFTCAPR[NUM_WORDS]. Number of words in-use is indicated in IPFTMOR[NUM_WORDS]. Note: Port Filter entries can vary in size, from 2 to 14 words.		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x6 = Query, followed by Update.
	Exact Match Key Element Match (KEY_ELEMENT)	No	--
	Ternary Match Key Element Match (KEY_ELEMENT)	Yes	Following table management command operation is supported: 0xC = Add followed by a Query. When adding multiple entries with the same Key Element,

			Precedence value of an entry. When adding an entry, the existing entries are walked until an entry is found with a lower or equal Relative Priority value. The new entry will be inserted at that point. In the case of an equal Relative Priority value, the new entry will have precedence over the existing entry.
63-16	48	--	Reserved.
79-64	16	FRM_ATTR_FLAGS	Frame Attribute Flags The frame attribute flags to match. Bit 0: Switch port masquerading (Switch function) 0b = Switch port is not masqueraded. 1b = Switch port is masqueraded. Applicable only if the incoming port is designated as a switch management port. There is the option on per frame basis, to indicate to the switch to process the frame as it was received from a specified switch port other than the switch management port. This option is referred to as the switch port masquerading option. Bit 0: Reserved (ENETC function) Bit 1: Reserved. Bit 2: Outer VLAN Present. The outer VLAN tag is considered present if VLAN classification has deemed the outer VLAN tag valid and the VLAN tag wasn't taken from the port VLAN configuration register. 0b = Outer VLAN is not present. 1b = Outer VLAN is present. Bit 3: Inner VLAN Present. The inner VLAN tag is considered present if VLAN classification has deemed the inner VLAN tag valid and the VLAN tag wasn't taken from the port VLAN configuration register. 0b = Inner VLAN is not present. 1b = Inner VLAN is present. Bits 6-4: Sequence Tag Code. 000b = R-TAG/HSR tag is not present. 001b = 802.1CB draft 2.0 R-TAG is present. 010b = 802.1CB R-TAG is present. 011b = HSR Tag is present. 100b ... 111b = Reserved. Bit 7: IP Header Present. 0b = IP header is not present. 1b = IP header is present.

Table continues on the next page...

Table 451. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			Bit 8: IP Version. 0b = IPv4. 1b = IPv6. Bit 9: IPv4 option / IPv6 extension present. 0b = IPv4 option / IPv6 extension is not present. 1b = IPv4 option / IPv6 extension is present. Bits 11-10: L4 Code. 00b = Other L4. The L4 Header is considered as other L4 if it is not one of the following L4 Headers. 01b = TCP header is present. 10b = UDP header is present. 11b = SCTP header is present (not supported for NETC 3.0 and 3.1). Bit 12: Wake-on-LAN Magic Packet Present. 0b = WoL magic packet is not present. 1b = WoL magic packet is present. Note: Valid if IPFCAPR[WOL]=1. Reserved for Switch function. Bits 15-13: Reserved. Note: When adding an entry, all fields and masks must be correctly set, regardless of the value of this field. i.e. if Bit 8 indicates this entry is for IPv4, the IP address masks must be set for the IPv4 bits only.
95-80	16	FRM_ATTR_FLAGS_MASK	Frame Attribute Flags Mask This field is used to mask the FRM_ATR_FLAGS field when determining matches.
101-96	6	DSCP	Differentiated Services Code Point This field is matched against the differentiated services code point (DSCP) of the received frame.
107-102	6	DSCP_MASK	Differentiated Services Code Point Mask This field is used to mask the DSCP field when hardware is matching this entry.
111-108	4	--	Reserved.
116-112	5	SRC_PORT	Source Port ID This field is matched against the Source port ID. Note: this field is reserved for ENETC.
121-117	5	SRC_PORT_MASK	Source Port ID Mask This field is used to mask the SRC_PORT field when hardware is matching this entry. Note: this field is reserved for ENETC.

Table continues on the next page...

Table 451. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
127-122	6	--	Reserved.
143-128	16	OUTER_VLAN_TCI	Outer VLAN Tag Control Information This field is matched against the outer VLAN tag TCI of the received frame. TCI includes 3-bit Priority Code Point (PCP), 1-bit Drop Eligibility (DEI) and 12-bit VLAN ID (VID). This field is defined in network byte order (big-endian). Most significant byte of the TCI is stored at the lowest byte offset of this field.
159-144	16	OUTER_VLAN_TCI_MASK	Outer VLAN Tag Control Information Mask This field is used to mask the OUTER_VLAN_TCI field when hardware is matching this entry.
207-160	48	DMAC	Destination MAC Address This field is matched against the destination MAC address of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the destination MAC address is stored at the lowest byte offset of this field.
255-208	48	DMAC_MASK	Destination MAC Address Mask This field is used to mask the DMAC field when hardware is matching this entry.
303-256	48	SMAC	Source MAC Address This field is matched against the source MAC address of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the source MAC address is stored at the lowest byte offset of this field.
351-304	48	SMAC_MASK	Source MAC Address Mask This field is used to mask the SMAC field when hardware is matching this entry.
367-352	16	INNER_VLAN_TCI	Inner VLAN Tag Control Information This field is matched against the inner VLAN tag TCI of the received frame. TCI includes 3-bit Priority Code Point (PCP), 1-bit Drop Eligibility (DEI) and 12-bit VLAN ID (VID). This field is defined in network byte order (big-endian). Most significant byte of the TCI is stored at the lowest byte offset of this field.
383-368	16	INNER_VLAN_TCI_MASK	Inner VLAN Tag Control Information Mask This field is used to mask the INNER_VLAN_TCI field when hardware is matching this entry.
399-384	16	ETHERTYPE	EtherType This field is matched against the 2-byte EtherType after VLAN tag(s)/R-TAG/HSR tag (if any), of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the EtherType is stored at the lowest byte offset of this field.

Table continues on the next page...

Table 451. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
415-400	16	ETHERTYPE_MASK	EtherType Mask This field is used to mask the ETHERTYPE field when hardware is matching this entry.
423-416	8	IP_PROTOCOL	IP Protocol Indicates which L4 protocol is encapsulated. This field is matched against the IPv4 Protocol or the IPv6 Next Header (upper layer) field of the received frame.
431-424	8	IP_PROTOCOL_MASK	IP Protocol Mask This field is used to mask the IP_PROTOCOL field when hardware is matching this entry.
543-432	112	--	Reserved.
671-544	128	IP_SRC_ADDR	IP Source Address This field is matched against the IP source address of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the IP address is stored at the lowest byte offset of this field. If this IP address defines an IPv6 address, then: Bits 127-0: IPv6 source address. If this IP address defines an IPv4 address, then: Bits 95-0: Reserved. Bits 127-96: IPv4 source address .
735-672	64	--	Reserved.
863-736	128	IP_SRC_ADDR_MASK	IP Source Address Mask This field is used to mask the IP_SRC_ADDR field when hardware is matching this entry. Note: If the IP_SRC_ADDR is intended to match an IPv4 frame, then bits 95-0 of this field must be 0.
879-864	16	L4_SRC_PORT	L4 Source Port This field is matched against the L4 destination port of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the port number is stored at the lowest byte offset of this field.
895-880	16	L4_SRC_PORT_MASK	L4 Source Port Mask This field is used to mask the L4_SRC_PORT field when hardware is matching this entry.

Table continues on the next page...

Table 451. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
927-896	32	--	Reserved.
1055-928	128	IP_DEST_ADDR	IP Destination Address This field is matched against the IP destination address of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the IP address is stored at the lowest byte offset of this field. If this IP address defines an IPv6 address, then: Bits 127-0: IPv6 destination address. If this IP address defines an IPv4 address, then: Bits 95-0: Reserved. Bits 127-96: IPv4 destination address .
1119-1056	64	--	Reserved.
1247-1120	128	IP_DEST_ADDR_MASK	IP Destination Address Mask This field is used to mask the IP_DEST_ADDR field when hardware is matching this entry. Note: If the IP_DEST_ADDR is intended to match an IPv4 frame, then bits 95-0 of this field must be 0.
1263-1248	16	L4_DEST_PORT	L4 Destination Port This field is matched against the L4 destination port of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the port number is stored at the lowest byte offset of this field.
1279-1264	16	L4_DEST_PORT_MASK	L4 Destination Port Mask This field is used to mask the L4_DEST_PORT field when hardware is matching this entry.
1311-1280	32	--	Reserved.
1319-1312	8	PLD_DATA_BYTE_0	Payload Byte 0 This field is matched against the most significant byte (or first byte) of the payload data of the received frame. Payload data starting position in the received frame is dependent at which point of the frame the parser has ended. - When no IP header is present, the payload data starts immediately after the payload EtherType. The payload EtherType is located immediately after the source MAC address or VLAN tag(s)/R-TAG/HSR tag (if any).

Table continues on the next page...

Table 451. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			- When IP header is present and no TCP or UDP header is present, payload data starts immediately after the IP header except when IPv4 options or IPv6 extensions are present. For the latter, payload data starts at the beginning of the IPv4 Options/IPv6 Extensions header. - When TCP or UDP header is present, the payload data starts immediately after the TCP/UDP Ports.
1327-1320	8	PLD_MASK_BYTE_0	Payload Mask for Byte 0 This field is used to mask the PLD_DATA_BYTE_0 field when hardware is matching this entry.
1335-1328	8	PLD_DATA_BYTE_1	Payload Byte 1 This field is matched against the second-most significant byte (or second byte) of the payload data of the received frame.
1343-1336	8	PLD_MASK_BYTE_1	Payload Mask for Byte 1 This field is used to mask the PLD_DATA_BYTE_1 field when hardware is matching this entry.
...	...	...	...
1671-1664	8	PLD_DATA_BYTE_22	Payload Byte 22 This field is matched against the second-least significant byte (or second last byte) of the payload data of the received frame.
1679-1672	8	PLD_MASK_BYTE_22	Payload Mask for Byte 22 This field is used to mask the PLD_DATA_BYTE_22 field when hardware is matching this entry.
1687-1680	8	PLD_DATA_BYTE_23	Payload Byte 23 This field is matched against the least significant byte (or last byte) of the payload data of the received frame.
1695-1688	8	PLD_MASK_BYTE_23	Payload Mask for Byte 23 This field is used to mask the PLD_DATA_BYTE_23 field when hardware is matching this entry.

Table 452. Table ID 13 - Ingress Port Filter Table CFGE_DATA Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset

FLTA_TGT																																0x4

Table 453. Table ID 13 - Ingress Port Filter Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
3-0	4	IPV	Internal Priority Value New IPV to be assigned to frame, if OIPV is set. The least significant 3 bits are used, most significant bit is reserved.
4	1	OIPV	Override Internal Priority Value (IPV) 0b = Don't override frame IPV. 1b = Override frame IPV with value in IPV field of this entry.
6-5	2	DR	Drop Resilience New DR to be assigned to frame, if ODR is set.
7	1	ODR	Override Drop Resilience (DR) 0b = Don't override frame DR. 1b = Override frame DR with value in DR field of this entry.
9-8	2	FLTFA	Filter Forwarding Action (Switch function) 00b = Discard. 01b = Permit. 10b = Redirect frame to switch management port without any frame modification, along with Host Reason metadata set to the value configured in the HR field of this entry. Rate policing function will be applied to the frame if enabled (i.e. FLTA = 01b). Ingress Stream and 802.1Q bridge forwarding functions are by-passed. 11b = Copy frame to switch management port without any frame modification, along with Host Reason metadata set to the value configured in the HR field of this entry. Frame forwarding action not impacted. Filter Forwarding Action (ENETC function) 00b = Discard. 01b = Permit. 10b, 11b = Reserved.
10	1	--	Reserved.
11	1	IMIRE	Ingress Mirroring Enable 0b = No ingress mirroring action specified in this entry. 1b = The frame is mirrored to the mirror destination specified in the IMDCR0 register. Note: Not applicable to ENETC function.
12	1	WOLTE	Wake-on-LAN Trigger Enable 0b = WoL trigger is disabled. 1b = WoL trigger is enabled. When this field is set to 1b (WoL trigger is enabled), FLTA should be set to 11b (setting a pre L2 filtering SI bitmap) and optionally Override Internal Priority Value (IPV) and Override Drop Resilience (DR). Other actions should not be specified. Note: Valid if IPFCAPR[WOL]=1. Reserved for the Switch function.

Table continues on the next page...

Table 453. Table ID 13 - Ingress Port Filter Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
14-13	2	FLTA	Filter Action (Switch function) 00b = No action. 01b = Rate action with the Rate Policer Entry ID (RP_EID) set to the value configured in the FLTA_TGT field of this entry. 10b = Ingress stream identification action where the Ingress Stream Entry ID (IS_EID) is set to the value configured in the FLTA_TGT field of this entry. 11b = Reserved. Filter Action (ENETC function) 00b = No action. 01b = Rate policing action with the Rate Policer Entry ID (RP_EID) set to the value configured in the FLTA_TGT field of this entry. 10b = Ingress stream identification action where the Ingress Stream Entry ID (IS_EID) is set to the value configured in the FLTA_TGT field of this entry. 11b = Setting a pre L2 filtering SI bitmap that will be used by the L2 filtering function to determine the final SI bitmap. The value of pre L2 filtering SI bitmap is set to the value configured in the FLTA_TGT field of this entry.
16-15	2	RPR	Relative Precedent Resolution This field is used to select the final Ingress Stream Entry ID (IS_EID) when more than one table lookup can yield an IS_EID. This field specifies the precedence/priority of this table lookup entry relative to other table lookups that can yield the IS_EID. (IS_EID) Precedence Value for this entry. 00b = Highest precedence. 01b = Precedence is between ISIDKC0CR0 & ISIDKC1CR0 Ingress Stream Identification exact match lookup. Note that ISIDKC0CR0 lookup match has higher precedence value than ISIDKC1CR0's lookup match. 10b = Lowest precedence. 11b = Reserved. Valid if FLTA = 10b.
17	1	CTD	Cut through disable. 0b = No action. 1b = Cut-through is disabled for a frame matching this entry with this bit set. Valid when FLTFA = 01b. Note: Not applicable to ENETC function.
21-18	4	HR	Host Reason. This field specifies the Host Reason metadata when frame is redirected/copied to the switch management port (i.e. FLTFA = 10b or 11b). Value specified has to be a software defined Host Reason (8-15). See Switch Management Port for details. Note: Not applicable to ENETC function.
22	1	TIMECAPE	Timestamp Capture Enable 0b = No change to the timestamp.

Table continues on the next page...

Table 453. Table ID 13 - Ingress Port Filter Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			1b = Timestamp is to be captured; valid if FLTFA = 01b. Note: Not applicable to ENETC function.
31-23	9	--	Reserved.
63-32	32	FLTA_TGT	Target For Selected Filter Action (Switch function) If FLTA = 01b, this is a RP_EID (Rate Policer Table Entry ID). 0x0..RPITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); rate policing function is by-passed Other values are reserved If FLTA = 10b, this is an IS_EID (Ingress Stream Table Entry ID). 0x0..ISITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); stream filtering function is by-passed Other values are reserved Target For Selected Filter Action (ENETC Function) If FLTA = 01b, this is a RP_EID (Rate Policer Table Entry ID). 0x0..RPITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); rate policing function is by-passed Other values are reserved If FLTA = 10b, this is an IS_EID (Ingress Stream Table Entry ID). 0x0..ISITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); stream filtering function is by-passed Other values are reserved If FLTA = 11b, this is a pre L2 filtering SI bitmap. Each bit of the bitmap corresponds to an SI on a given port. Least significant bit of the bitmap corresponds to the smallest SI number. The SIs to which the frame is to be delivered, are identified by having their corresponding bit set to 1 in the bitmap. Bits 0-15: Bit wise setting of bitmap. LSB is the lowest order of SI. Bits 16-31: Reserved.

53.4.2.3.2.2.4 Ingress Stream Identification Table

Table 459. Table ID 30 - Ingress Stream Identification Table Common Attributes

TABLE_ID	30		
TABLE_VERSION	0		
Table Type	Hash table		
Table Description	The Ingress Stream Identifier table contains a set of entries each capable of classifying incoming traffic using a mix of L2 parsed and arbitrary data fields, into streams. As a result of an entry match, an Ingress Stream Entry ID is provided, which is a locally significant identifier (global to the switch), that identifies a stream within an ENETC instance or the switch. The Ingress Stream Identification table can be used to support the IEEE 802.CB stream identification functions. The Ingress Stream Identifier table is an exact match table where four logical tables can be defined using four different L2 parsed and arbitrary data fields key (key construction types). The key construction type (defined in registers) is included in the key element of an entry, to identify to which of the four logical tables the entry belongs to. The datapath can perform two exact match lookups, each against different Ingres Stream Identifier logical table. The two logical tables (or key construction type) to be used is configurable on per port basis. Table management command operations Add, Delete, Update and Query are supported.		
Number of Entries	The memory allotment to store the hash entries is shared across all of the (ENETC instance/ switch) function hash tables. The maximum amount of memory words available to store all of the function hash tables entries, is indicated in the register HTMCAPR[NUM_WORDS]). If the number of memory words in-use to store hash table entries for the function has reached this limit, the Add operation will fail. The number of memory words in-use by the function for hash table entries is indicated in the register HTMOR[AMOUNT].		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query.
	Exact Match Key Element Match (KEY_ELEMENT)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x8 = Add. 0xC = Add, followed by a Query.
	Ternary Match Key Element Match (KEY_ELEMENT)	No	--

Table continues on the next page...

Table 459. Table ID 30 - Ingress Stream Identification Table Common Attributes (continued)

	Search (SEARCH_CRITERIA)	Yes	Only supported when command operation = 0x4 (Query). In the event of a search command requiring multiple iterations (see RESUME_ENTRY_ID), the user must not delete any entries in the table between iterations of that search.	
Data Buffer Component Attributes	**Name**	**Description**	**Size [bytes]**	**Alignment [bytes]**
	ENTRY_ID	Entry Id (ISI_EID)	4	4
	ACCESS_KEY	Access Key	20	4
	CFGE_DATA	Configuration Element	4	4
	KEYE_DATA	Key Element	20	4
Entry Alignment [bytes]	4			
Entry ID Management	Hardware assigns entry IDs.			
Response STATUS Applicable	Yes			
ERROR codepoints specific to this table	0x000 = no errors 0x001-0x07F = reserved 0x080-0x0FF = Generic codepoints; see ERROR field description. 0x260 = Port ID or specified in KEYE_DATA is out of range. Valid range of values for Port ID are {0..CAPR0[NUM_LINKS]-1}. KEY_TYPE for ENETC is not valid. 0x261 = IS_EID in invalid. Valid range of values for IS_EID are {0.. ISITCAPR[NUM_ENTRIES]-1} and not NULL IS_EID.

Table 465. Table ID 30 - Ingress Stream Identification Table KEYE_DATA Description

Bits	Width [bits]	Name	Description
1-0	2	KEY_TYPE	Key Type Switch Function 00b = Key construction is specified in ISIDKC0CR0 (header) and ISIDKC0PFbCR (payload), where 'b' represents the payload field. 01b = Key construction is specified in ISIDKC1CR0 (header) and ISIDKC1PFbCR (payload), where 'b' represents the payload field. 10b = Key construction is specified in ISIDKC2CR0 (header) and ISIDKC2PFbCR (payload), where 'b' represents the payload field. 11b = Key construction is specified in ISIDKC3CR0 (header) and ISIDKC3PFbCR (payload), where 'b' represents the payload field. ENETC Function 00b = Key construction is specified in ISIDKC0CR0 (header) and ISIDKC0PFbCR (payload), where 'b' represents the payload field. 01b = Key construction is specified in ISIDKC1CR0 (header) and ISIDKC1PFbCR (payload), where 'b' represents the payload field. All other values reserved.
6-2	5	SRC_PORT_ID	Source Port ID Switch Function Switch port ID expressed as an integer value to be used in key construction if PORTP is set to 1 in key construction register. ENETC Function Reserved. This field is not used for ENETC function.
7	1	SPM	Source Port Masquerading Switch port masquerading to be used in key construction if SPMP is set to 1 in key construction register. Switch Function 0b = Match frames from switch port(s). 1b = Match frame from switch management port(s) that has switch port masquerading. ENETC Function Reserved. This field is not used for ENETC function.
31-8	24	--	Reserved.
159-32	128	FRAME_KEY	Frame portion of the Key Key format is specified by the key construction registers ISIDKCaCR0 (frame header) and ISIDKCaPFbCR (frame payload), where ‘a’ represents the key construction rule ID and ‘b’ represents the payload field. The key entered has to be in packed form in the order they appear in the frame with each field formatted in big endian format (order they are received from the link). Maximum key size for the frame portion is 16 bytes. If the constructed key is less than 16 bytes then rest of the bytes have to padded with zeros (i.e. zeros must be entered in this field for the remaining bytes). If the key constructed is larger than 16 bytes, then this will result in no match.

53.4.2.3.2.2.5 Ingress Stream Table

Table 470. Table ID 31 - Ingress Stream Table Common Attributes

TABLE_ID	31
TABLE_VERSION	0
Table Type	Dynamic bounded index table
Table Description	The Ingress Stream table contains configuration and operational information about streams identified by the stream identification function. Each entry includes the actions (or functions) that are to be applied to frames belonging to a particular stream, such as: • Whether a frame is accepted or discarded • Specifies the PSFP (IEEE 802.1Qci) filtering and policing actions. To support a PSFP (IEEE 802.1Qci) stream filtering function that uses the 3-bit PCP value (priority) of the received frame and the stream handle (i.e. Ingress Stream Entry ID) to select a stream filter, an

Table continues on the next page...

Table 470. Table ID 31 - Ingress Stream Table Common Attributes (continued)

<table>
<tr><td></td><td colspan="4">additional lookup (i.e. Ingress Stream Filter table lookup) can be specified in the Ingress Stream table entry.
• FREF (IEEE 802.1CB) sequence generation function (switch only)
• Stream forwarding function; the 802.1Q bridge forwarding function is by-passed, instead the Ingress Stream table provides the port(s) to which the frame should be output to (switch only)
• Ingress frame modification in addition to adding a sequence tag (switch only)
• Egress packet processing actions to be applied to packets received on this specific stream; typically used along with the stream forwarding function. (switch only)
The Ingress Stream table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. The entries are stored in contiguous manner in the common memory. Ingress Stream Entry ID (IS_EID) is used as an index to an entry in this table. For this table, each table entry occupies one word. Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers; S0ISITMAR[NUM_WORDS] for switch and EaISITMAR[NUM_WORDS] for ENETC. These allocations can also be changed when the functions are initialized through their respective base function registers ISITMAR[NUM_WORDS]. Table management command operations Add, Delete, Update and Query are supported.</td></tr>
<tr><td>Number of Entries</td><td colspan="4">Maximum number of entries is indicated in ISITCAPR[NUM_ENTRIES]. Number of entries in-use is indicated in ISITOR[NUM_ENTRIES].</td></tr>

Table 476. Table ID 31 - Ingress Stream Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
0	1	SFE	Stream Filtering Enable To support a PSFP (IEEE 802.1Qci) stream filtering function that uses the 3-bit PCP value (priority) of the received frame and the stream handle (i.e. Ingress Stream Entry ID) to select a stream filter, an additional lookup (i.e. Ingress Stream Filter table lookup) must be performed to obtain the PSFP stream filter information. 0b = The Ingress Stream Filter table lookup is by-passed (or not required). 1b = The Ingress Stream Filter table lookup is performed using as a key, the Ingress Stream Entry ID and PCP (extracted from the received frame outer VLAN tag). If the

Table continues on the next page...

Table 476. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			received frame has no VLAN tag (determined from VLAN classification output; i.e. if the outer VLAN tag is not valid or that VLAN tag data is taken from port outer VLAN configuration register), this additional lookup is not performed.
3-1	3	--	Reserved.
7-4	4	IPV	Internal Priority Value New Internal Priority Value (IPV) to be assigned to the frame, if OIPV is set to 1. The least significant 3 bits are used, most significant bit is reserved.
8	1	OIPV	Override Internal Priority Value (IPV) 0b = Don't override frame IPV. 1b = Override frame IPV with value configured in IPV field of this entry.
10-9	2	DR	Drop Resilience New Drop Resilience (DR) to be assigned to the frame, if ODR is 1.
11	1	ODR	Override Drop Resilience (DR) 0b = Do not override frame DR. 1b = Override frame DR with value configured in DR field of this entry.
12	1	IMIRE	Ingress Mirroring Enable 0b = No ingress mirroring action specified in this entry. 1b = Frame is mirrored to the mirror destination specified by IMDCR0 register. Note: Not applicable to ENETC function
13	1	TIMECAPE	Timestamp Capture Enable 0b = No change to the timestamp. 1b = Timestamp is to be captured. Note: Not applicable to ENETC function
14	1	--	Reserved.
15	1	SPPD	Source Port Pruning Disable. This field is used to enable/disable source port pruning. Source port pruning ensures that frames do not get forwarded back to the port they originated from. Once the final destination ports have been determined, source pruning when enabled, will set the port from which the frame originated from, to 0 in the destination port bitmap. This field is valid only if the FA field of this entry is set 010b or 100b (stream forwarding) and will overwrite any previous configuration/setting for source pruning. 0b = Source port pruning enabled. 1b = Source port pruning disabled. Note: Not applicable to ENETC function.

Table continues on the next page...

Table 476. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
17-16	2	ISQA	Ingress Sequence Action This field specifies whether the Frame Replication and Elimination for Reliability (FRER) sequence generation function (or action) is to be performed. Sequence generation consists of tagging a frame with a sequence number, following which the frame can be replicated and transmitted along multiple paths for redundancy. Implemented as per the IEEE 802.1CB. 00b = FRER sequence generation function is not performed. 01b = FRER sequence generation function is performed. 10b, 11b = Reserved. Note: Sequence Generation action is not applicable for ENETC function.
18	1	ORP	Override Rate Policer (instance) ID. 0b = Rate policer instance ID not overridden. 1b = Rate policer instance ID overridden. If ORP = 1, RP_EID specified in this entry overrides the default RP_EID (which is NULL) or PR_EID specified in Port filter.
19	1	OSGI	Override Stream Gate Instance Entry ID 0b = Stream Gate Instance Entry ID not overridden. 1b = Stream Gate Instance Entry ID overridden if OSGI = 1, specified SGI_EID in this entry overrides the default NULL SGI_EID.
23-20	4	HR	Host Reason This field specifies the Host Reason metadata when frame is redirected to the switch management port or copied to the switch management port (i.e. FA = 01b, 100b or 101b). Value specified has to be a software defined Host Reason (8-15). See Switch Management Port for details. Note: Not applicable to ENETC function.
26-24	3	FA	Forwarding Actions Switch function 000b = Discard. 001b = Re-direct frame to switch management port without any frame modification, along with Host Reason metadata set to the value configured in the HR field of this entry. Policing function will be applied to the frame if enabled. Stream and 802.1Q bridge forwarding functions are by-passed. 010b = Stream forwarding. It by-passes the 802.1Q bridge forwarding function. Frame is forwarded to the port(s) specified in the EGRESS_PORT_BITMAP field of this entry. 011b = 802.1Q bridge forwarding (VLAN processing and L2 forwarding). 100b = Copy to switch management port with specified HR and stream forwarding (stream forwarding action is as specified in FA = 010b). 101b = Copy to switch management port with specified HR and Bridge forwarding (Bridge forwarding action is as specified FA = 011b). All other values reserved.

Table continues on the next page...

Table 476. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			ENETC function 00b = Discard; 01b = Allow without setting the pre L2 filtering SI bitmap. 10b = Allow with setting the pre L2 filtering SI bitmap to the value configured in the SI_MAP field of this entry. If the pre L2 filtering SI bitmap was already set up by the ingress port filtering function, the pre L2 filtering SI bitmap is overwritten with the value configured in the SI_MAP field of this entry, The pre L2 filtering SI bitmap is used by the L2 filtering function to determine the final SI bitmap. All other values reserved.
28-27	2	SDU_TYPE	Service Data Unit type to use for MSDU (Maximum Service Data Unit) field. Overhead values are specified by register PRXSDUOR. 00b = PPDU (Physical Layer PDU). 01b = MPDU (MAC PDU). 10b = MSDU (MAC SDU). All other values reserved. Note: This field has to be valid if MSDU field is not 0.
31-29	3	--	Reserved.
47-32	16	MSDU	Maximum Service Data Unit This field specifies the maximum service data unit size allowed for packets received on this stream. This is part of IEEE 802.1Qci (Per-Stream Filtering and Policing) specification. If the received frame length exceeds this value, the frame is discarded. A value of zero in this field, disables the maximum service data unit check. Note: This check is not performed for cut-through frames.
54-48	7	IFME_LEN_CHANGE	Ingress Frame Modification Entry Frame Length Change This field represents the effective frame length change of the ingress frame modification actions which are configured in the ingress frame modification entry (IFM_EID) referred by this entry. This frame length change value is used to adjust the frame length metadata, which in turn is passed along the frame processing pipeline, and used by the egress scheduling and management function to determine the actual length of the frame on the transmission link. Note that the egress queue scheduling and management function is executed prior to applying the frame modification actions to the frame, and thus the need to know of the frame length change resulting from the frame modification actions since it requires knowledge of the exact length of a frame transmitted on a link. Specifying explicitly the frame length change avoids having the hardware to read the ingress frame modifications entry and compute the frame length change itself. Fame length change is specified in unit of bytes using a 2's complement notation. Supported range is -4 bytes (removing one VLAN tag) to +4 bytes (adding one VLAN tag). This field is ignored by hardware if the IFM_EID field is set to NULL.

Table continues on the next page...

Table 476. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			Note: Not applicable to ENETC function.
59-55	5	EPORT	Egress Port This field specifies the identifier of the port requiring egress packet processing when the OETEID field of this entry is set to 01b (single-port Egress Treatment table access option). The port is expressed as an integer value. Switch Range: {0..SCAPR0[NUM_PORT]-1} Note: Not applicable to ENETC function.
61-60	2	OETEID	Override ET_EID This field is used to convey the egress packet processing actions to be applied to packets belonging to the stream associated with this entry. The egress packet processing actions are specified in the Egress Treatment table, where each table entry contains the egress packet processing actions to be applied to a scope of packets (e.g. stream) exiting on a particular egress port of the switch. The means by which one specifies the Egress Treatment table entries to be accessed, is through the Egress Treatment group. Within the hardware, an Egress Treatment group is determined by a base index (first Egress Treatment table entry of the group) and an applicability port bitmap (a bitmap corresponding to all ports of the switch) which indicates (with a 1) which ports have Egress Treatment table entries present. For more details, see Egress Treatment table access. Specifically, this field specifies how to derive the applicability port bitmap of the primary Egress Treatment group being assigned to packets belonging to the stream associated with this entry. The base index is specified in the ET_EID field of this entry. 00b = No egress packet processing actions specified. 01b = Single-port Egress Treatment table access. Only one port requires egress packet processing. That port identifier is specified in the EPORT field of this entry. The applicability port bitmap is set with a 1 for the port that is been identified in the EPORT field of this entry. For other ports, the applicability port bitmap is set to 0. The group assigned to packets belonging to the stream associated with this entry will have a single Egress Treatment table entry, for the port identified in the EPORT field of this entry. 10b = Multi-port packed Egress Treatment table access. Applicability port bitmap is set to the port bitmap specified in EGRESS_PORT_BITMAP field of this entry. The group assigned to packets belonging to the stream associated with this entry will have an Egress Treatment table entry for each port set to 1 in the applicability port bitmap. 11b = Multi-port absolute Egress Treatment table access. Applicability port bitmap is set with 1 for all ports. The group assigned to packets belonging to the stream associated with this entry will have Egress Treatment table entries for all ports on the switch.

Table continues on the next page...

Table 476. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			Valid if FA = 010b..101b and ET_EID is not NULL. Note: Not applicable to ENETC function.
63-62	2	CTD	Cut-Through Disable 00b = Do not override cut-through state. 01b = Disable cut-through for the outgoing port specified in the EPORT field. Cut-through is not disabled for the other ports specified in destination port bitmap (i.e. EGRESS_PORT_BITMAP field of this entry). 10b = Disable cut-through for all ports specified in the destination port bitmap (i.e. EGRESS_PORT_BITMAP of this entry). 11b = Reserved. Valid if FA = 010b .. 101b. All other values reserved. Note: Not applicable to ENETC function.
95-64	32	ISQ_EID	Ingress Sequence Generation Entry ID This field specifies the Ingress Sequence Generation Entry ID to be used as an index into the Ingress Sequence Generation table. Valid only when ISQA is set to 1. 0x0..ISQGITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); ingress sequence generation function is by-passed Other values are reserved Note: Not applicable to ENETC functions.
127-96	32	RP_EID	Rate Policer Entry ID This field specifies the Rate Policer Entry ID to be used as an index into the Rate Policer table. Valid if ORP is set to 1. Override Rate Policer Entry ID with this value when ORP =1. 0x0..RPITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); rate policing function is by-passed Other values are reserved
159-128	32	SGI_EID	Stream Gate Instance Entry ID This field specifies the Stream Gate Instance Entry ID to be used as an index into the Stream Gate Instance table. 0x0..SGIITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); stream gating function is by-passed Other values are reserved
191-160	32	IFM_EID	Ingress Frame Modification Entry ID This field specifies the Ingress Frame Modification Entry ID which is encoded either as an index into the Frame Modification table or encoded as a set of frame modification actions. For the latter,

Table continues on the next page...

Table 476. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			there is no need to access the Frame Modification table as the actions are encoded in the Ingress Frame Modification Entry ID itself. If IFM_EID is set to 0xFFFF_FFFF (NULL), no ingress frame modification is performed. If IFM_EID is not set to NULL, bits 15-0 are used for IFM_EID, upper bits are ignored. Refer to Table Frame Modification Entry Definition for IFM_EID format. Note: Not applicable to ENETC function
223-192	32	ET_EID	Egress Treatment Entry ID This field specifies the index (or base index) to be used when accessing the Egress Treatment table. This field is valid if FA field is set to 010b .. 101b, and the OETEID field is set to value other than 00b. 0x0..ETTCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); egress treatment processing is by-passed Other values are reserved Note: Not applicable to ENETC function.
255-224	32	ISC_EID	Ingress Stream counter Index Index to a set of counters in common memory that will be updated for this Stream. 0x0..ICITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); no Ingress Stream Count table counters are updated Other values are reserved
279-256	24	EGRESS_PORT_BITMAP	Egress Port bitmap For FA = 010b, 100b (stream forwarding), this field identifies the destination port(s) to which the frame is to be forwarded for this stream. For FA = 011b, 101 (802.1Q bridge forwarding), this field identifies destination ports to which egress packet processing is required. The destination port(s) are represented as a bitmap, where each bit of the bitmap corresponds to a port on the switch. Least significant bit of the bitmap corresponds to the smallest port number; i.e. bit offset 0 of the bitmap corresponds to port numbered 0, bit offset 1 to port numbered 1, and so on. The port(s) to which the frame are to be forwarded (stream forwarding) and/or egress packet processing is required (VLAN/FDB), are identified by having their corresponding bit set to 1 in the bitmap. Valid bits in the bitmap is from 0..CAPR0[NUM_LINKS]-1 Bits beyond the valid range will be ignored. Note: Not applicable to ENETC function.
287-280	8	--	Reserved.
303-288	16	SI_MAP	Station Interface Map This field specifies a pre L2 filtering SI bitmap. Each bit of the bitmap corresponds to

Table 476. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			an SI on a given port. Least significant bit of the bitmap corresponds to the smallest SI number. The SIs to which the frame is to be delivered, are identified by having their corresponding bit set to 1 in the bitmap. Bit wise setting of Station Interface map. LSB is the lowest order of SI which is the primary SI, rest are VSIs. Number of VSIs are specified in CAPR0[NUM_VSI]. Bits beyond the valid range will be ignored. Note: This field is only valid for ENETC function when FA field is set to 10b.

53.4.2.3.2.2.6 Ingress Stream Filter Table

Table 477. Table ID 32 - Ingress Stream Filter Table Common Attributes

TABLE_ID	32		
TABLE_VERSION	0		
Table Type	Hash table		
Table Description	The Stream Filter table contains PSFP (IEEE 802.1Qci) stream filter information for stream filters selected based on the 3-bit PCP value (priority) of the received frame and the stream handle (i.e. Ingress Stream Entry ID). Table management command operations Add, Delete, Update and Query are supported.		
Number of Entries	The memory allotment to store the hash entries is shared across all of the (ENETC instance/ switch) function hash tables. The maximum amount of memory words available to store all of the function hash tables entries, is indicated in the register HTMCAPR[NUM_WORDS]). If the number of memory words in-use to store hash table entries for the function has reached this limit, the Add operation will fail. The number of memory words in-use by the function for hash table entries is indicated in the register HTMOR[AMOUNT].		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query.
	Exact Match Key Element Match (KEY_ELEMENT)	Yes	Following commands are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x8 = Add. 0xC = Add, followed by a Query.

Table continues on the next page...

Table 477. Table ID 32 - Ingress Stream Filter Table Common Attributes (continued)

	Ternary Match Key Element Match (KEY_ELEMENT)	No	--	
	Search (SEARCH_CRITERIA)	Yes	Only supported when command operation = 0x4 (Query). In the event of a search command requiring multiple iterations (see RESUME_ENTRY_ID), the user must not delete any entries in the table between iterations of that search.

Table 485. Table ID 32 - Ingress Stream Filter Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
3-0	4	IPV	Internal Priority Value New Internal Priority Value (IPV) to be assigned to the frame, if OIPV is set to 1. The least significant 3 bits are used, most significant bit is reserved.
4	1	OIPV	Override Internal Priority Value (IPV) 0b = Don't override frame IPV. 1b = Override frame IPV with value configured in IPV field of this entry.
6-5	2	DR	Drop Resilience New Drop Resilience (DR) to be assigned to the frame, if ODR is set 1.
7	1	ODR	Override Drop Resilience (DR) 0b = Don't override frame DR. 1b = Override frame DR with value configured in DR field of this entry.
8	1	IMIRE	Ingress Mirroring Enable 0b = No ingress mirroring action specified in this entry. 1b = The frame is mirrored to the mirror destination specified in the IMDCR0 register. Note: Not applicable to ENETC function.
9	1	TIMECAPE	Timestamp Capture Enable 0b = No change to the timestamp. 1b = Timestamp is to be captured. Note: Not applicable to ENETC function.
10	1	OSGI	Override Stream Gate Instance Entry ID 0b = Stream Gate Instance Entry ID not overridden 1b = Stream Gate Instance Entry ID overridden; specified SGI_EID in this entry overrides the default null SGI_EID or SGI_EID specified in Ingress Stream table.
11	1	CTD	Cut-Through Disable 00b = Do not override cut-through state. 01b = Disable cut-through for all destined ports. Note: Not applicable to ENETC function.
12	1	ORP	Override Rate Policer (instance) ID 0b = Rate policer instance ID not overridden 1b = Rate policer instance ID overridden If the rate policer instance was already set by a match in the Ingress Port Filter table or Ingress Stream table and if ORP is set to 1, the rate policer instance value is overwritten with the value configured in the RP_EID field of this entry.
14:13	2	SDU_TYPE	Service Data Unit type to use for MSDU (Maximum Service Data Unit) field. Overhead values are specified by register PRXSDUOR. 00b = PPDU (Physical Layer PDU). 01b = MPDU (MAC PDU).

Table continues on the next page...

Table 485. Table ID 32 - Ingress Stream Filter Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			10b = MSDU (MAC SDU). All other values reserved. Note: This field has to be valid if MSDU field is not 0.
15	1	--	Reserved.
31-16	16	MSDU	Maximum Service Data Unit This field specifies the maximum service data unit size defined for the stream. This is part of IEEE 802.1Qci (Per-Stream Filtering and Policing) specification. If the received frame length exceeds this value, the frame is discarded. A value of zero in this field, disables the maximum SDU check. This field overrides the maximum SDU check field specified in the previous matched Ingress Stream table entry. Note: This check is not performed for cut-through frames.
63-32	32	RP_EID	Rate Policer Entry ID This field specifies the Rate Policer Entry ID to be used as an index into the Rate Policer table. Valid if ORP is set to 1. Override Rate Policer Entry ID with this value when ORP = 1. 0x0..RPITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); rate policing function is by-passed Other values are reserved
95-64	32	SGI_EID	Stream Gate Instance Entry ID This field specifies the Stream Gate Instance Entry ID to be used as an index into the Stream Gate Instance table. Stream Gating action will be performed if SGI_EID is not null. Valid if OSGI is set to 1. 0x0..SGIITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); stream gating function is by-passed Other values are reserved
127-96	32	ISC_EID	Ingress Stream Count Entry ID Index to a set of counters in common memory that will be updated for this stream. This field overrides the Ingress Stream Counter ID field specified in the previous matched Ingress Stream table entry. 0x0..ICITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); no Ingress Stream Count table counters are updated Other values are reserved

Bits	Width [bits]	Name	Description
31-0	32	RESUME_ENTRY_ID	Resume Entry ID When starting a search, pass the NULL Entry ID. To continue a search, pass the RESUME_ENTRY_ID value returned in the CBD Response of the previous search command. Note: A NULL Entry ID is 0xFFFF_FFFF

53.4.2.3.2.2.7 Stream Gate Instance Table

Table 488. Table ID 36 - Stream Gate Instance Table Common Attributes

TABLE_ID	36
TABLE_VERSION	0
Table Type	Dynamic bounded index table
Table Description	The Stream Gate Instance (SGI) table contains the stream gate configuration and operational information for a NETC function. There is one SGI table for each ENETC instance and one SGI table for the entire switch. Each entry contains a set of parameters that defines a single stream gate instance. The stream gate instance parameters includes an administrative stream gate control list and an operational stream gate control list, along with related configuration and status parameters. A stream gate control list (SGCL) is used to specify time gates or time slots during which incoming frames from one or more streams will be accepted. This table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. The entries are stored in contiguous manner in the common memory. For this table, each table entry occupies one word (one to one corresponding between words and entries). Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers; S0SGIITMAR[NUM_WORDS] for switch and EaSGIITMAR[NUM_WORDS] for ENETC. These allocations can also be changed when the functions are initialized through their respective base function registers SGIITMAR[NUM_WORDS]. The index to access this table, is obtained earlier on, via lookups in the Ingress Stream or in the Ingress Stream Filter table. An SGI can hold two SGCLs, one as operational and the other as administrative. An administrative SGCL becomes operational at Config Change Time as defined in the IEEE 802.1Qci standard and remains operational till another SGCL is installed. An administrative SGCL is added to a SGI using the Add or Update operations. The actual SGCLs are stored in a separate table called the Stream Gate Control List table, with references to these SGCLs (that is, entry IDs) specified in the SGI table. It is recommended that the entry ID for each of these two SGCLs be predetermined and known by software, and persist till the SGI is no longer in use. Take the following into consideration when accessing the SGI table[1]: • **Initialization** - The 1588 timer must be initialized and configured before adding any SGCL to an SGI. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer is in normal operation, any change to the 1588 timer configuration (for example TMROFF_H/L), except for TMR_ADD updates, requires that all SGIs with an operational SGCL be deleted, and for SGIs that have no operational SGCLs, that the administrative SGCL, if present, be removed from the SGI.

Table continues on the next page...

Table 488. Table ID 36 - Stream Gate Instance Table Common Attributes (continued)

	• **Stream association -** An SGI can be associated with only one switch port. Streams from different switch ports cannot use the same SGI. • **Config Change Time** - Note that when Config Change Time has been reached, the actual installation of a new SGCL, will occur at the next event that will cause the operational SGCL to be traversed; that is reception of a frame or expiry of the refresh timestamp timer. For any SGI command processed by hardware prior to this event, the administrative SGCL is considered to be still pending although the Config Change Time may have been reached. • **Add operation** - When an ADMIN_SGCL_EID is specified in the Add operation, the SGI will operate with the initial SGI configuration till the ADMIN_SGCL_EID is installed at Config Change Time. An SGI can operate without an SGCL and with just the initial SGI configuration. To operate in this mode, specify a NULL ADMIN_SGCL_EID in the Add operation. • **Update operation** - This operation is used to add a new administrative SGCL to an existing SGI or to remove an administrative SGCL from an SGI. For the details on how to add a new administrative SGCL, refer to the sequence described below in Adding an administrative SGCL to an SGI. For the details on how to remove an administrative SGCL, refer to the sequence described below in Removing an administrative SGCL from an SGI. Note that if the operational SGCL is present, it will continue to operate as normal. • **Delete operation** - Perform the following steps to delete an SGI table entry: 1. Remove, if present in the SGI, the administrative SGCL by means of an SGI command containing an Update operation to the SGI's Admin Configuration Element with ADMIN_SGCL_EID set to NULL. 2. Issue a Delete operation against the SGI table entry that is to be deleted. 3. If needed, delete the SGCLs from the Stream Gate Control List table. Since there are two possible SGI_EIDs, which the deleted SGI may have used, software can then safely issue SGCL commands containing a Delete operation to those two SGCLs. A Delete operation to an SGCL has not been added before or has been already deleted, will execute with no error; that is, the Delete operation is not performed, and the response message indicates that no entry has been found (NUM_MATCHED in Response Message Header is set to 0). ***Adding an administrative SGCL to a SGI*** Follow these steps to add an administrative SGCL to an SGI: 1. Since software has only two possible SGCLs (and therefore, SGCL_EIDs) to use, software must first verify that at least one of them is unused by the hardware, and therefore, "free" to be configured and associated to the SGI. This procedure is started by issuing a query on the SGI to record the presence of both the administrative and operational SGCLs (found in SGISE_DATA[STATE]), and the SGCL_EIDs (found in ACFGE_DATA[ADMIN_SGCL_EID] and SGISE_DATA[OPER_SGCL_EID]), respectively, if valid, based on the value of SGISE_DATA[STATE]. • **Case 0** - Neither SGCL is present. An administrative SGCL may be configured and associated to the SGI. Proceed to Step 3. • **Case 1** - An administrative SGCL only is present. Execute the sequence described below in Removing an administrative SGCL from an SGI, but starting at step 2 (as step 1 has already performed in this sequence), to remove the administrative SGCL and then retry this sequence.

Table continues on the next page...

Table 488. Table ID 36 - Stream Gate Instance Table Common Attributes (continued)

	• **Case 2** - An administrative SGCL and an operational SGCL is present. Both SGCLs are currently in use; a new one may not be configured. Execute the sequence described below in Removing an administrative SGCL from an SGI, but starting at step 2 (as step 1 has already performed in this sequence), to remove the administrative SGCL and then retry this sequence. • **Case 3** - An operational SGCL only is present. An administrative SGCL can be configured and associated to the SGI. Proceed to Step 2. 2. Ensure that any stale SGCL is deleted from the SGCL table; a stale SGCL is an operational SGCL that ceased to be operational as it was replaced by a new SGCL. a. Since there are two possible SGI_EIDs which this SGI may use, any of the two lists which are not present, may be deleted. The SGI_EID(s) present in the SGI is indicated based on the combination of SGISE_DATA[STATE] and ACFGE_DATA[ADMIN_SGCL_EID]/SGISE_DATA[OPER_SGCL_EID]. b. Software can then safely issue SGCL commands containing a Delete operation to those SGCLs. A Delete operation to an SGCL has not been added before or has been already deleted, will execute with no error; i.e. the Delete operation is not performed, and the response message indicates that no entry has been found (NUM_MATCHED in Response Message Header is set to 0). 3. Software may chose an SGCL from its pool of two SGCLs for this SGI which is currently unused by the hardware (or not present) and issue a command containing an Add operation to SGCL table, to add the new administrative SGCL. 4. The new added SGCL may now be associated with the SGI by means of an SGI command containing an Update operation to the SGI's Admin Configuration Element with the new SGCL (e.g. setting ADMIN_SGCL_EID to new added SGCL_EID). ***Removing an administrative SGCL from an SGI*** Follow these steps to remove an administrative SGCL from an SGI: 1. This procedure is started by issuing a query on the SGI. Software records the presence of both the administrative and operational SGCLs (found in SGISE_DATA[STATE]), and the SGCL_EIDs (found in ACFGE_DATA[ADMIN_SGCL_EID] and SGISE_DATA[OPER_SGCL_EID]), respectively, if valid, based on the value of SGISE_DATA[STATE]. 2. Remove the administrative SGCL by means of an SGI command containing an Update operation to the SGI's Admin Configuration Element with ADMIN_SGCL_EID set to NULL. 3. Query the SGI again. a. If the query response indicates that no administrative SGCL is present, and if the “operational SGCL” encoding from SGISE_DATA[STATE] and SGISE_DATA[OPER_SGCL_EID] (if operational SGCL is present) are matching the queried values from Step 1, this indicates that the administrative SGCL was successfully removed from the SGI. Proceed to Step 4. b. If software finds that either an operational SGCL is now present when it did not in the Step 1 query, or if the SGCL_EID of the operational SGCL is different from the one in the Step 1 query, this indicates that the update command in Step 2 was processed by the hardware only after the administrative SGCL (which software was attempting

Table continues on the next page...

Table 488. Table ID 36 - Stream Gate Instance Table Common Attributes (continued)

	to uninstall) had become operational. In this case, software must not proceed to delete the SGCL. Do not proceed to step 4. 4. The administrative SGCL was successfully removed from the SGI, it is now safe to issue a SGCL command containing a Delete operation to the administrative SGCL.			
Number of Entries	Maximum number of entries is indicated in SGIITCAPR[NUM_ENTRIES]. Number of entries in-use is indicated in SGIITOR[NUM_ENTRIES].			
Default Reset Behavior	No entries in the table by default.			
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**	
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x8 = Add.

Table 494. Table ID 36 - Stream Gate Instance Table ACFGE_DATA Description

Bits	Width [bits]	Name	Description
31-0	32	ADMIN_SGCL_EID	Administrative Stream Gate Control List Entry ID This field specifies the Entry ID in the Stream Gate Control List table (expressed in units of words) of the administrative stream gate control list to be used for this stream gate instance. 0x0..SGCLITCAPR[NUM_WORDS]-1 0xFFFF_FFFF (NULL); implies no Gate Control List specified. Other values are reserved
95-32	64	ADMIN_BASE_TIME	Admin Base Time This field sets the base time, that is, the start time, of the administrative gate control sequence. The time is expressed in units of nanoseconds. The field implements the PSFPAdminBaseTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 PSFPAdminBaseTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expects the time to be specified as a 64-bit integer number of nanoseconds. Therefore, if this field is to be set to a value which was obtained from a managed object using the IEEE 802.1Q-2018 PTP time format, the value must be converted by software from the IEEE 802.1Q-2018 format to the 64-bit integer number of nanoseconds. This field is reserved when ADMIN_SGCL_EID is NULL.
127-96	32	ADMIN_CYCLE_TIME_EXT	Admin Cycle Time Extension The value supplied in this field is equivalent with the 802.1.Qci definition of "Cycle Time Extension". When the administrative stream gate control list becomes operational, this is the maximum amount of time by which the cycle time is permitted to be extended before a new administrative stream gate control list takes effect. The time is expressed as an integer number of nanoseconds. Only least significant 30 bits are valid. Upper two bits are ignored. It is required that CYCLE_TIME in Stream gate control list + ADMIN_CYCLE_TIME_EXT must be < 2^{30} -1. This field is reserved when ADMIN_SGCL_EID is NULL.

Bits	Width [bits]	Name	Description
			list and if an operational gate control list exists then this is the time the operational list became active. The actual value stored by hardware (and thus available to query) is expressed in units of nanoseconds. If this field is to be queried from an IEEE 802.1Q-2018 managed object, the value must be converted by software from the 64-bit integer number of nanoseconds to the IEEE 802.1Q-2018 PTP time format.
159:96	64	OPER_BASE_TIME	Operational Base Time The base time (start time) of the operational stream gate control sequence. The actual value stored by hardware (and thus available to query) is expressed in units of nanoseconds. The field implements the PSFPOperBaseTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 PSFPOperBaseTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expresses the time as a 64-bit integer number of nanoseconds. Therefore, if this field is to be queried from an IEEE 802.1Q-2018 managed object, the value must be converted by software from the 64-bit integer number of nanoseconds to the IEEE 802.1Q-2018 PTP time format.
191-160	32	OPER_CYCLE_TIME_EXT	Oper Cycle Time Extension The value supplied in this field is equivalent with the 802.1.Qci definition of "Cycle Time Extension". If Operational Gate Control List is active, this is the maximum amount of time by which the cycle time is permitted to be extended before a new Admin Gate Control List takes effect. Only least significant 30 bits are valid. Upper two bits are ignored.
192	1	OEX	Octets Exceeded Flag 0b = Normal operation. 1b = Gate closed permanently due to octets exceed. If OEXEN = 1, detection of octets received exceeding INTERVAL_OCTET_MAX in a gate interval results in the stream gate being permanently set to closed. OEX can be cleared by performing Stream Gate State Element Update (SGISEU) action.
193	1	IRX	Invalid Receive Flag 0b = Normal operation. 1b = Gate closed permanently due to invalid receive. If IRXEN=1, detection of incoming frames during time periods when the stream gate is in the closed state results in the stream gate being permanently set to closed state. IRX can be cleared by performing Stream Gate State Element Update (SGISEU) action.
195-194	3	STATE	Current Gate Instance State 000b = Reserved. 001b = Gate instance is operational but no stream gate control list specified. Default Gate Instance parameters are applied to received frame. 010b = New administrative stream gate control list pending. Default Gate Instance

			parameters will be applied to frames till administrative stream gate control list takes effect. 011b = New administrative stream gate control list is pending while stream gate control list is operational. 100b = No administrative stream gate control list is pending. Operational stream gate control list is active. 101b .. 111b = Reserved.
199-196	3	--	Reserved.

53.4.2.3.2.2.8 Stream Gate Control List Table

Table 501. Table ID 37 - Stream Gate Control List Table Common Attributes

TABLE_ID	37
TABLE_VERSION	0
Table Type	Dynamic bounded index table
Table Description	This table stores the stream gate control lists (SGCLs). A SGCL is used to specify the time gates or time slots during which incoming frames from one more streams will be accepted. Each SGCL can have a variable number of gate control operation entries. For each Stream Gate Instance used, only two SGCLs may be allocated to the instance. It is recommended that the entry ID for each of these two SGCLs be predetermined and fixed by software, and persist till the Gate Stream Instance is no longer in use. This table is implemented as a linear array of words, accessed using an index (0, 1, 2, ..., n) that uniquely identifies a word within the array. The words are stored in a contiguous manner in the common memory. When accessing the table, the actual memory position of a word is calculated by hardware from the index based on the size of the word and the base memory address of the table. Each table entry is of variable size, and is used to hold one stream gate control list. The first word of the entry contains information specific to the entire stream gate control list. Subsequent consecutive words are contains gate control operation (or gate) specific configuration. Each word can hold 2 gate configurations. Number of words required for a stream gate control list is 1+N/2 where N is number of gates in the stream gate control list. If N is odd, only one gate configuration will be specified in the last word. The Stream Gate Control Entry ID (SGCL_EID) has to be specified in units of words such that it points to the first word in a stream gate control list. Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers; S0SGCLITMAR[NUM_WORDS] for switch and EaSGCLITMAR[NUM_WORDS] for ENETC. These allocations can also be changed when the functions are initialized through their respective base function registers SGCLITMAR[NUM_WORDS]. Table management command operations are performed using Add, Delete or Query operations. Note that the Update operation is not supported for this table. Memory fragmentation may occur if stream gate control lists of different sizes are repeatedly added/deleted. There is no hardware assist to manage such memory fragmentation, software must take care of this situation.

Table continues on the next page...

Table 501. Table ID 37 - Stream Gate Control List Table Common Attributes (continued)

	Following are the behavior of operations: • Add operation: This operation adds a stream gate control list to the Stream Gate Control List table. Hardware will perform the following checks to determine if the Add operation is valid before executing the Add operation. — Checks if the specified stream gate control list is within the allocated region to the Stream Gate Control List table in common memory. — Checks if the common memory locations for the stream gate control list are not already allocated. — Checks if the cumulative gate time in the stream gate control list is <2^30. If above conditions are not met the operation will be rejected. • Delete operation: This operation deletes a stream gate control list from the Stream Gate Control List table. The SGCL_EID must point to the first word of the stream gate control list that is to be deleted. Following checks are performed before executing the Delete operation. — Checks if SGCL_EID is in valid range of words for this table. — Checks if the stream gate control list has already been added by software. — Checks if stream gate control list is not in use (that is,. stream gate control list is not operational nor installed as an administrative list. Note that REF_COUNT is non zero if the stream gate control list is in use. — If above conditions are not met the operation will be rejected. • Query operation: This operation queries a stream gate control list. The following checks are performed before executing the Query operation. — Checks if SGCL_EID is in valid range of words for this table. — Checks to see if the stream gate control list has already been added. — If above conditions are not met the operation will be rejected. Note that due to dynamic size of stream gate control lists that get added/deleted can cause memory fragments.		
Number of Entries	Maximum number of entries is indicated in SGCLITCAPR[NUM_WORDS]. Number of entries in-use is indicated in SGCLTMOR[NUM_ENTRIES]. Number of words required for a stream gate control list is 1+N/2 where N is number of gate time slots in the stream gate control list.		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x4 = Query. 0x8 = Add.

Table 507. Table ID 37 - Stream Gate Control List Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
31-0	32	CYCLE_TIME	Cycle Time This field specifies the cycle time of the stream gate control list. This is the period of time over which the sequence of operations in a stream gate control list repeats. The time is expressed in units of nanoseconds. Only least significant 30 bits are valid. Upper two bits are ignored. This value has to be a non-zero value else operation will be rejected. It is also required that ADMIN_CYCLE_TIME + ADMIN_CYCLE_TIME_EXT must be < 2^30 -1.
39-32	8	LIST_LENGTH	List Length This field indicates the number of entries in the stream gate control list. Software must set this value to the size of the list being configured minus one. Valid values are 0 (one entry) to 255 (256 entries). The operation will be rejected if list length is invalid.
47-40	8	--	Reserved.
48	1	EXT_OIPV	Extension Override Internal Priority Value This field specifies whether to override the frame IPV after the stream gate control list ends and before CYCLE_TIME restarts. 0b = Don't override frame IPV. 1b = Override frame IPV with the value configured in the EXT_IPV field of this entry.
52-49	4	EXT_IPV	List Extension Internal Priority Value This field specifies the IPV to be assigned to frames after the stream gate control list ends and before CYCLE_TIME restarts. Valid if the EXT_OIPV field of this entry is set to 1. The least significant 3 bits are used, most significant bit is reserved.
53	1	EXT_CTD	Extension Cut Through Disabled This field specifies whether to disable cut-through for frames received after the stream gate control list ends and before CYCLE_TIME restarts. 0b = No action. 1b = Cut-through disabled. Note: Not applicable to ENETC function.
54	1	EXT_GTST	Extension Gate State This field specifies the gate state that will be applied after the stream gate control list ends and before CYCLE_TIME restarts. List started. 0b = Closed. 1b = Open.
63-55	9	--	Reserved.
(127 + 64i)	32	TIME_INTERVAL_GE_i	Time Interval for Gate Entry i, where i = 0, ..., N-1 This field specifies the time interval for a gate entry. The time is expressed in units of nanoseconds. Only least significant 30 bits are valid. Upper two bits are ignored.

Table continues on the next page...

Table 507. Table ID 37 - Stream Gate Control List Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
- (64 + 64i)			This field has to be a non-zero value and the cumulative TIME_INTERVAL amount in a Gate List must not exceed 2^30-1. Cumulated TIME_INTERVAL amount in a Gate List is allowed to be greater than CYCLE_TIME, in such case the CYCLE TIME restarts before Gate List completes.
	24	IOM_GE_i	Interval Octets Maximum for Gate Entry i, where i = 0, ..., N-1 This field specifies the maximum bytes (octets) allowed to pass (open) gate entry i when IOMEN is enabled.
	4	IPV_GE_i	Internal Priority Value for Gate Entry i, where i = 0, ..., N-1 This field specifies the Internal Priority Value (IPV) that will be assigned to frames. Valid if OIPV_GE_i field of this entry is set to 1. The least significant 3 bits are used, most significant bit is reserved.
	1	OIPV_GE_i	Override Internal Priority Value for Gate Entry i, where i = 0, ..., N-1 0b = Don't override frame IPV. 1b = Override frame IPV with the value configured in IPV_GE_i of field this entry.
	1	CTD_GE_i	Cut Through Disable for Gate Entry i, where i = 0, ..., N-1 This field specifies whether to disable cut-through for frames received in this gate. 0b = No action. 1b = Cut-through is disabled. Note: Not applicable to ENETC function.
	1	IOMEN_GE_i	Interval Octet Maximum Enabled for Gate Entry i, where i = 0, ..., N-1 This field specifies whether to track the number of bytes (octets) received in the gate when the gate is permanently closed; if OEXEN=1 and octets received in this gate exceeds IOM_GE. 0b = Don't track count. 1b = Track count.
	1	GTST_GE_i	Gate State for Gate Entry i, where i = 0, ..., N-1 0b = Closed. 1b = Open. Frames received in this gate are dropped if gate state is closed.

Table 508. Table ID 37 - Stream Gate Control List Table SGCLSE_DATA Format

Table 509. Table ID 37 - Stream Gate Control List Table SGCLSE_DATA Description

Bits	Width [bits]	Name	Description
0	8	REF_COUNT	Reference Count Indicates whether a stream gate control list (SGCL) is in-use in a Stream Gate Instance (SGI). An SGCL becomes in-use when it is added to an SGI (as the administrative SGCL), and remains in-use when it is installed as the operational SGCL. An administrative SGCL is no longer considered in-use when if it is removed from an SGI. An operational SGCL is no longer in-use when it is replaced with a new SGCL or when the SGI is deleted. 0x00 = Not in-use by an SGI. 0x01 = In-use by an SGI. All other values reserved. Note: An attempt to delete an SGCL with a Reference Count set to 1 will result in an error response; in this case, the SGCL is not deleted from the Stream Gate Control List table.

TABLE_ID	38		
TABLE_VERSION	0		
Table Type	Dynamic bounded index table		
Table Description	Ingress stream related statistics are maintained in this table. The Ingress Stream Count table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. The entries are stored in contiguous manner in a common memory. Ingress Stream Counter Entry ID (ISC_EID) is used as an index to an entry in this table. The ISC_EID is specified in the Ingress Stream table. For this table, each table entry occupies 1 word. Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers; S0ISCITMAR[NUM_WORDS] for switch and EaISCITMAR[NUM_WORDS] for ENETC. These allocations can also be changed when the functions are initialized through their respective base function register ISCITMAR[NUM_WORDS]. Table management operations Add, Delete, Update and Query are supported.		
Number of Entries	Maximum number of entries is indicated in ISCITCAPR[NUM_ENTRIES]. Number of entries in-use is indicated in ISCITOR[NUM_ENTRIES].		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete.

Bits	Width [bits]	Name	Description
31-0	32	RX_COUNT	Receive Count Count of received frames in the Ingress Stream table entry or Ingress Stream Filter table entry associated with this counter. \
95-64	32	MSDU_DROP_COUNT	MSDU Drop Count Count of received frames in the Ingress Stream table entry or Ingress Stream Filter table entry associated with this counter that did not pass the maximum SDU filter. Counter implemented in hardware is 32 bits.
159-128	32	POLICER_DROP_COUNT	Policer Drop Count Count of received frames in the Ingress Stream table entry or Ingress Stream Filter table entry associated with this counter that were dropped by the Policer.
223-192	32	SG_DROP_COUNT	Stream Gating Drop Count Count of received frames in the Ingress Stream table entry or Ingress Stream Filter table entry associated with this counter that did not pass the stream gate.

53.4.2.3.3 PSI-VSI Messaging

Hardware supports messages passing between the Virtual Station Interfaces and Physical Station Interface and vice-versa. Depending on the direction of the message, the format also differs since the usage cases vary.

VSIs may send a message to the PSI for general notification or to gain access to hardware resources which requires host inspection. These messages may vary in size and are handled as a partition copy between two memory regions owned by the respective participants. The PSI will respond with fail or success and a 16-bit message code. Both sides can be programmed to receive an interrupt during this event.

The PSI can send a register based message to one or more VSIs. This method is much simpler than the reverse and only provide a 16-bit message code. The intention could be to notify the VSI of a link state change. Only the VSI can be programmed to receive an interrupt during this event.

53.4.2.3.3.1 PSI-to-VSI Messaging

NETC supports sending and receiving 16-bit messages between the Physical Station Interface (PSI) and one or more Virtual Station Interfaces (VSIs).

To send a message from the PSI to one or more VSI the following takes place:

1. The VSI enables message receive interrupt by setting VSIIER[MRIE]=1.
2. The PSI writes the message send register PSIMSGSR with the 16-bit message code in the MC field and sets one or more MS bits to indicate the recipient of the message. Note that one message at a time is supported from the PSI to one or more VSIs.
3. The VSI will be interrupted when the message is received, alternatively the VSI can poll register bit VSIMSGRR[MR].
4. The VSI reads VSIMSGRR to get the message code from the MC field. The VSIMSGRR[MR] bit and the PSIMSGSR[MS] bit will clear automatically.
5. PSI detects PSIMSGSR[MS]=0 and knows the corresponding VSI has received the message.

53.4.2.3.3.2 VSI-to-PSI Messaging

NETC supports sending and receiving programmable sized messages between the Virtual Station Interface(s) and Physical Station Interface. The generic message format consists of a multiple of 32 bytes. The message format is software defined, NETC puts no restrictions on the content of a message.

To send a message from a virtual station interface (VSI) to the physical station interface (PSI), the following steps takes place:

1. VSI*n* guest software creates a message in memory.
2. VSI*n* guest software writes message send register VSIMSGSNDAR0 with lower address of message location in memory and the message size. This will set the message busy bit in the message status register VSIMSGSR[MB]=1. Note that this will also clear the previous message status and code in the message status register VSIMSGSR[MS/MC].
3. NETC will copy the message to the PSI's memory address space as indicated by the PSI-VSI message receive registers PSIV*a*MSGRCVAR0/1.
4. When the message has been copied, the message received bit is set in the PSI receive register, PSIMSGRR[MR*n*]. The PSI may set the interrupt enable bit SIIER[MR*a*IE] associated with a message received to receive an interrupt, or may opt to poll the message receive register PSIMSGRR.

   If a transfer error is encountered when copying the data, The PSI's message receive bit will never get set, only the VSI is notified by the error in VSIMSGSR[MS].
5. The host software will process the message and when ready to respond clear the message received bit by writing a 1 to PSIMSGRR[MR*n*]=1 (write to clear). At the same time the code field, PSIMSGRR[MC], is written to indicate a software defined response type back to the VSI. NETC will clear the senders busy bit VSIMSGSR[MB] and set the code field VSIMSGSR[MC] by copying from PSIMSGRR.

6. The sender can poll the message busy bit VSIMSGSR[MB] to see if it has been cleared or enable the interrupt enable bit SIIER[MSIE] associated with message send. When the message status register is read, fields VSIMSGSR[MS/MC] will indicate the result of the message request.

53.4.2.3.4 ENETC Statistics Counters

53.4.2.3.4.1 MAC Statistics Counters

For the MAC statistic counters, see section Ethernet MAC Statistics Counters for the Ethernet MAC statistics counters and section Pseudo MAC Statistics Counters for the pseudo MAC statistics counters.

53.4.2.3.4.2 Port Statistics Counters

The table below lists the available port level traffic statistics counters.

Table 517. Port Traffic Statistics Counters

Direction	Counter	Description
Rx	Ingress Stream Count table - RX_COUNT	Received frames counter on a per stream basis
Rx	Rate Policer table - statistics counters	Bytes count on a per Rate Policer instance. Also available are marked/remarked frames counts
Rx	Ingress Port Filter table - MATCH_COUNT	Ingress Port Filter entry matched count

The table below lists the available port level frame drops statistics counters.

Table 518. Port Frame Drop Counters

Direction	Counter	Description
Rx	PRXDCR	Frame drops count in the receive port datapath processing pipeline with the setting of the discard reason in the port's Rx discard count reason register 0/1 (PRXDCRR0/1)
Rx	PUFDMFR	Incremented for each dropped unicast frame by the L2 filtering function, due to MAC filtering yielding no SIs to receive the frame, unless the reason for yielding no SIs is MAC source address pruning, in which case the PFDMSAPR counter is incremented instead.
Rx	PMFDMFR	Incremented for each dropped multicast frame by the L2 filtering function, due to MAC filtering yielding no SIs to receive the frame, unless the reason for yielding no SIs is MAC source address pruning, in which case the PFDMSAPR counter is incremented instead.
Rx	PBFDSIR	Incremented for each dropped broadcast frame by the L2 filtering function, due to MAC filtering yielding no SIs to receive the frame due to all SI's having broadcast reject enabled.
Rx	PUFDVFR	Incremented for each dropped unicast frame by the L2 filtering function, due to VLAN filtering yielding no SIs to receive the frame.
Rx	PMFDVFR	Incremented for each dropped multicast frame by the L2 filtering function, due to VLAN filtering yielding no SIs to receive the frame.

Table continues on the next page...

Table 518. Port Frame Drop Counters (continued)

Direction	Counter	Description
Rx	PBFDVFR	Incremented for each dropped broadcast frame by the L2 filtering function, due to VLAN filtering yielding no SIs to receive the frame.
Rx	PFDMSAPR	Incremented for each dropped frame by the L2 filtering function, due to MAC filtering yielding no SIs to receive the frame due to MAC source address pruning.
Rx	Ingress Stream Count table - frame drops counters	Maximum SDU frame drops count, stream gate frame drops count and Rate Policer instance frame drops count on a per stream basis
Rx	Rate Policer table - DROP_FRAMES	Frame drops count on a per Rate Policer instance basis
Rx	PICDR*a*DCR	Number of frames discarded by Ingress Congestion Manager; a separate register is provided for each DR value. PICPDSR provides status flag for each DR and priority combination indicating if one or more frames have been discarded at this DR and priority

53.4.2.3.4.3 Station Interface (SI) Statistics Counters

The table below lists the Station Interface (SI) level traffic statistics counters.

Table 519. Station Interface (SI) Traffic Statistics Counters

Direction	Counter	Description
Rx	SIROCT0/1	Number of octets received (without frame errors) by the SI except preamble, SFD and CRC (if CRC has been removed from the frame).
Rx	SIRFRM0/1	Number of frames received by the SI without errors
Rx	SIRUCA0/1	Number of unicast frames received by the SI without errors
Rx	SIRMCA0/1	Number of multicast frames received by the SI without errors
Tx	SITOCT0/1	Number of octets transmitted (without error) by the SI except preamble, SFD and CRC (if CRC has been appended to the frame by the hardware)
Tx	SITFRM0/1	Number of frames transmitted by the SI without errors, with the exception of frames with error (BD status code point) 0x020 (frame dropped due to port reset) or 0x0A0 (multi-bit ECC error), which will be counted in this counter.
Tx	SITUCA0/1	Number of unicast frames transmitted by the SI without errors, with the exception of frames with error (BD status code point) 0x020 (frame dropped due to port reset) or 0x0A0 (multi-bit ECC error), which will be counted in this counter.
Tx	SITMCA0/1	Number of multicast frames transmitted by the SI without errors, with the exception of frames with error (BD status code point) 0x020 (frame dropped due to port reset) or 0x0A0 (multi-bit ECC error), which will be counted in this counter.

Table below lists the Station Interface (SI) level frame drops counters

Table 520. Station Interface (SI) Frame Drop Counters

Direction	Counter	Description
Rx	SIUPECTR	Frame drops counter due to non-existing BD ring or non-existing group, or due to SI disabled or BD ring disabled
Rx	RBaDCR	Receive BD ring frame drops counter due to lack of Rx BDs available
Rx/Tx	SIUNSBECTR	Frame drops counter due to system bus error

53.4.2.4 Switch

53.4.2.4.1 Switch Datapath

The switch datapath is implemented as a series of functional processing blocks pipelined together as shown in the figure below. This includes the Ethernet Rx I/F, the Ingress Packet Processing, the Replication and Egress Packet Processing, the Egress Queuing and Traffic Management and the Ethernet Tx I/F. A shared internal buffer memory used for internal frame buffering.

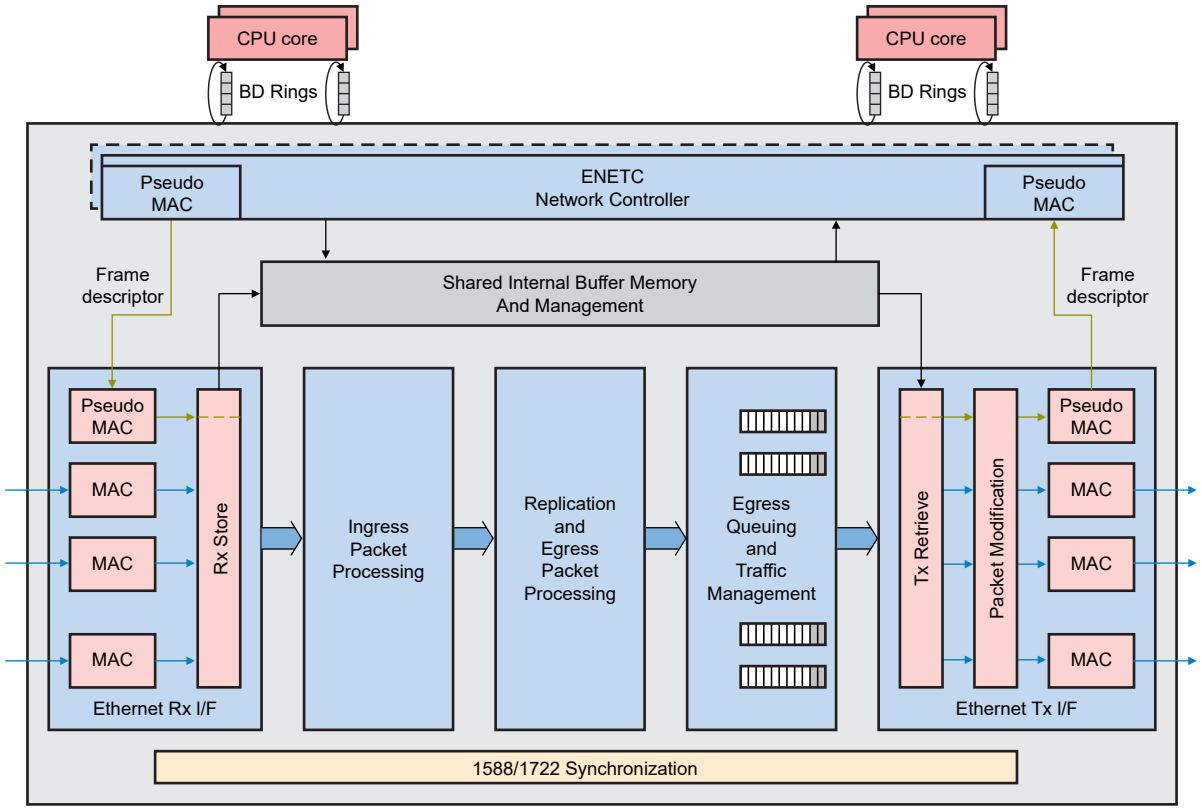

Figure 342. Switch datapath functional block diagram

The shared internal buffer memory is used to store and buffer data arriving from the Ethernet MACs; in the case of a pseudo MAC, frames have already been stored in the shared internal buffer memory by the ENETC port connected to the pseudo MAC. Frames remain stored in this memory as they move through the switch processing pipeline up to the point where frames have been transmitted to the outgoing port(s). In the case where the frame is being transmitted on a pseudo MAC, the frame remains stored in the shared internal buffer memory as only a frame descriptor is being transferred across that interface.

The Ingress Packet Processing block responsibilities are to parse the frame headers, to do the necessary table lookups (or classification) to determine the data that will drive the execution of the ingress packet processing functions such as filtering,

forwarding, policing and frame modifications. The actual execution of these ingress packet processing functions is also the responsibility of the Ingress Packet Processing, with the exception of the frame modifications. The frame modification actions are passed as frame metadata for actual modification into the frame when the frame is being transmitted on a MAC.

The Replication and Egress Packet Processing is responsible for implementing the frame replication (frame descriptor only) if needed, and packet processing functions in the context of the output port(s).

The Egress Queuing and Traffic Management block includes the support of 2 classes of traffic management mechanisms: queue scheduling and queue management. Queue scheduling refers to the procedures used to determine which frame to send next when bandwidth on the outgoing port is available. It is used primarily to manage the allocation of bandwidth among traffic classes. Queue management refers to the procedures that manage the queue sizes by primarily deciding when to start dropping frames.

In the case where the frame is being transmitted on a pseudo link (switch port connected internally to an ENETC port), there is no memory copy when transferring a frame across a pseudo link. Instead the frame descriptor along with the associated metadata, is passed to the other end of the link (i.e. in this case an ENETC port) when sending a frame across a pseudo link.

Both store-and-forward and cut-through modes of operation are supported. For both mode of operations, once the first 24 bytes of data is received and stored in internal memory, the Ingress Packet Processing (IPP) starts parsing the frame header (first 24 bytes). If the end of the parse graph has not been reached while parsing the first 24 bytes of the frame, the IPP waits for the next 24 bytes to be received so that it can resume parsing, and so on up to the maximum number of bytes that can be parsed which is 144 bytes.

In store-in-forward mode of operation, once parsing is completed and although the entire frame may not have been entirely received, the IPP carries on executing functions that do not require knowledge of the frame length (e.g. table lookups, ingress frame modifications). Once the entire frame is received, it will execute the processing functions that rely on the knowledge of the frame length, and then it will pass the frame to the next processing stage.

In cut-through mode of operation, once parsing is completed and although the entire frame may not have been entirely received, frame moves through the switch processing pipeline and starts getting transmitted on all the destination ports.

The cut-through mode of operation is not applicable (or not supported) for frames received from a pseudo MAC as a complete frame (or frame descriptor) is received one at a time (frame is already stored in the shared internal buffer memory).

53.4.2.4.1.1 Switch Shared Internal Buffer Memory Management

The shared internal buffer memory used for the switch internal frame buffering, is allocated from the common internal shared memory region. An allotment is configured at initialization time in the common internal shared memory region to track overall frame buffering usage of the switch.

Switch shared internal buffer memory is managed as set of memory buffer pools.

A buffer pool is a quantity of memory available for buffering a group of flows (e.g. frames having the same priority, frames received from the same port), while waiting to be transmitted on a port. A buffer pool tracks internal memory consumption with upper bound limits and optionally a non-shared portion when associated with a shared buffer pool. See figure below for an illustration of buffer pools and shared buffer pools.

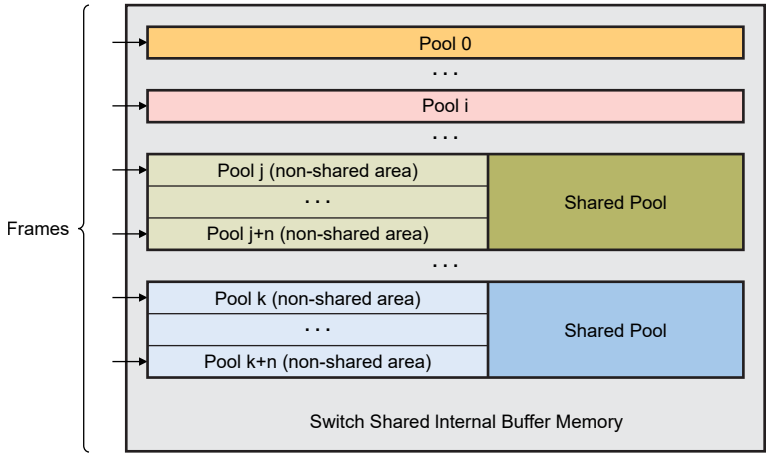

Figure 343. Buffer Pools and Shared Buffer Pools

A shared buffer pool has a set of pools as members and tracks only the amount that have exceeded the buffer pools' non-shared portion. If a buffer pool is below its maximum non-shared consumption, then there is no contribution to its associated shared pool.

A set of drop thresholds and flow control thresholds are defined to control internal memory consumption within a buffer pool and its associated shared buffer pool.

The sum of the maximum sizes of each buffer pool with no shared buffer pool association plus the sum of the non-shared allocations of each buffer pool associated with a shared buffer pool, and plus the sum of the maximum sizes of each shared buffer pool cannot exceed the total size of the switch shared internal buffer memory.

The maximum size of a buffer pool with no shared buffer pool association corresponds to the size configured in the Maximum Threshold field of its Buffer Pool table entry plus one maximum frame size. The non-shared allocation of a buffer pool associated with a shared buffer pool corresponds to the amount configured in the Shared Buffer Pool Threshold field of its Buffer Pool table entry. The maximum size of a shared buffer pool corresponds to the size configured in the Maximum Threshold field of its Shared Buffer Pool table entry plus one maximum frame size.

As frames are received from the MACs, their shared internal buffer memory usage is initially tracked as "unassigned". A received frame remains accounted as "unassigned" as it moves through the processing pipeline of the Ingress Packet Processing. The buffer pool assignment function is performed towards the end of the ingress packet processing pipeline, where the final QoS attributes (IPV and DR) of the frame have been determined. The buffer pool is selected by mapping the IPV of the frame to a buffer pool ID using the port buffer pool mapping configuration register 0/1 (PBPMCR0/1). This mapping allows each IPV (or set of IPV's) to be mapped to a specific buffer pool for QoS distinction. Once the Ingress Packet Processing buffer pool assignment logic has selected a buffer pool, the buffer pool (and its associated shared buffer pool) is checked to determine if there is available memory space to accommodate the new frame. The overall switch shared internal buffer memory usage is also checked to ensure that the switch shared internal buffer memory is not full. The memory availability checks for the buffer pool and overall switch shared internal buffer memory are performed without considering the length of the frame; the reason why a buffer pool or the switch buffering may exceeds its configured maximum size by one maximum frame size. The frame will be discarded if either the usage count of the selected buffer pool is already equal or above its configuration limit or the usage count of the overall switch shared internal buffer memory is already equal or above its configuration limit. If there is available memory space, then the buffer pool usage and the overall switch shared internal buffer memory usage is updated as follows:

- **Store-and-forward frame** - The buffer pool usage is updated by adding to the buffer pool usage, the length of the frame and the memory space required the store the frame descriptor (24 bytes) for each egress enqueue that will be attempted.
- **Cut-through frame** - The buffer pool usage is updated by adding to the buffer pool usage, the length of the first frame segment and the memory space required the store the frame descriptor for each egress enqueue that will be attempted. As subsequent segments of the frame are received the buffer pool usage is updated accordingly. No memory availability checks are performed for the subsequent segments of a cut-through frame.

Note that the shared internal buffer memory allocation for the frame descriptors is performed later, at the point where the egress enqueues are performed. If there is no memory available to store a frame descriptor, the hardware waits until memory becomes available; no egress frame drops are performed for this condition.

After frame transmission or when frame is dropped, buffer pool accounting and overall switch shared internal buffer memory accounting are updated accordingly; i.e. the accounting update occurs when the memory units used to store the frame are returned to the shared common memory free list.

The figure below shows an example of a buffer pool assignment configuration where the switch shared internal buffer memory is first partitioned by IPV, and then within a given a IPV partition, each source port is provided a guaranteed/dedicated amount of memory and a portion that is shared between all source ports.

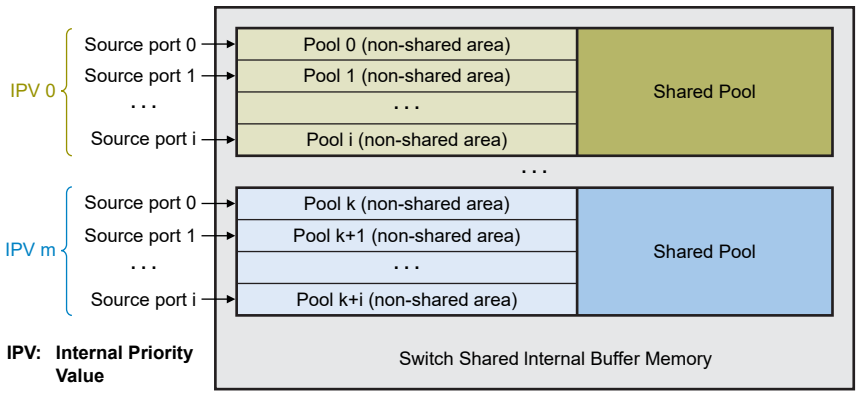

Figure 344. Buffer pools assignment example; by IPVs, followed by Source Ports

The figure below shows an example of a buffer pool assignment configuration where each source port or IPV pair is provided a guaranteed/dedicated amount of memory and the remaining switch shared internal buffer memory is shared.

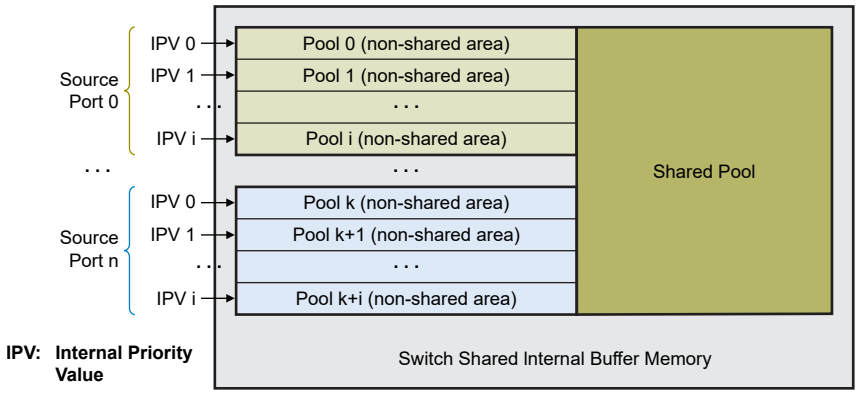

Figure 345. Buffer pools assignment example; non-shared per (source port, IPV) pair + shared portion

53.4.2.4.1.1.1 Buffer Pool Configuration

Buffer pool configuration parameters are as follows (see Buffer Pool Table):

- Buffer pool maximum threshold (12 bits) - Any assignment where the buffer pool usage count is already equal or above this threshold limit, will be denied.
- Shared buffer pool enable (1 bit) - If set to 1, this buffer pool is associated with a shared buffer pool.
- Shared buffer pool id (4 bits) - If shared buffer pool enable is set to 1, then this indicates the shared buffer pool ID to which this buffer pool belongs.

- Shared buffer pool threshold - If shared buffer pool enable is set to 1 and if buffer pool usage exceeds this threshold then the excess contribution is tracked in the shared buffer pool.
- Flow control configuration (2 bits)
  - 00 = Flow control disabled.
  - 01 = Flow control enabled using only buffer pool flow control state.
  - 10 = Flow control enabled using only shared buffer pool flow control state.
  - 11 = Flow control enabled using both buffer pool and shared buffer pool flow control state. The combined flow control states of both the buffer pool and the shared buffer pool must be 1 to assert flow control on. The flow control state of the buffer pool or the shared buffer pool must be 0 to assert flow control off.
- Flow control on threshold (12 bits) - Valid if flow control configuration = 01 or 11, if buffer pool usage crosses above this threshold the flow control state of the buffer pool is set to 1.
- Flow control off threshold (12 bits) - Valid if flow control configuration = 01 or 11, if buffer pool usage drops to this threshold or below, the flow control state of the buffer pool is set to 0.
- Priority vector (8 bits) - Valid if flow control is not equal to 0, when a flow control notification is sent (flow control on), this vector indicates which priorities are to be flow controlled for this buffer pool, one bit per priority level. If the MAC is configured in link pause mode, this vector is ignored. Note that NETC 3.0 and 3.1 doesn't support priority flow control, it only supports link pause mode.
- Flow control ports (1 bit per port) - Valid if flow control is not equal to 0, when a flow control notification is sent, this per-port bit mask indicates which ports are to be flow controlled for this buffer pool.
- Pool size (usage); also includes shared pool contribution.

53.4.2.4.1.1.2 Shared Buffer Pool Configuration

Shared buffer pool configuration parameters are as follows (see Shared Buffer Pool Table):

- Shared buffer pool maximum threshold (12 bits) - Any assignment where the shared buffer pool usage count is already equal or above this threshold limit, will be denied.
- Flow control on threshold (12 bits) - Valid if any associated buffer pool flow control configuration = 10 or 11. If shared buffer pool usage crosses above this threshold the flow control state of the shared buffer pool is set to 1.
- Flow control off threshold (12 bits) - Valid if any associated buffer pool flow control configuration = 10 or 11. If shared buffer pool usage drops to this threshold or below, the flow control state of the shared buffer pool is set to 0.

53.4.2.4.1.2 Ethernet Rx I/F

The Ethernet Rx I/F block integrates the Rx MAC (Ethernet and pseudo MACs) functionality and implements the interface functions specific from the MAC to the switch receive path.

53.4.2.4.1.2.1 Ethernet MAC

In the case where frames are received from an Ethernet MAC, the Ethernet Rx I/F stores them immediately in the shared internal buffer memory.

The Ethernet MAC detects the SFD or SMD, receives the frame, and checks for layer 2 data integrity (FCS errors) while forwarding data to MAC client. All frames >= 18B with valid SFD are forwarded to MAC client.

The last 4 bytes of the frame which represents the frame check sequence (FCS), are also stored in the shared internal buffer memory. The Ethernet MAC doesn't remove the FCS from the frame. The FCS carried in the received frame remains as the frame is processed by the switch. On transmission, if the data covered by the FCS is not modified, then the FCS value in the received frame is re-used as the FCS for the transmitted frame.

The first 144 bytes of the received frame in addition of being stored in the shared internal buffer memory, are also stored in a frame header memory which is accessed by the Ingress Packet Processing (IPP) for processing the received frame. Once the first 24 bytes of data is received and presented to the IPP, it starts parsing the frame header (first 24 bytes). If the end of the parse graph

has not been reached while parsing the first 24 bytes of the frame, the IPP waits for the next 24 bytes to be received so that it can resume parsing, and so on up to 144 bytes.

Both store-and-forward and cut-through modes of operation are supported.

In store-in-forward mode of operation, once parsing is completed and although the entire frame may not have been entirely received, the IPP proceeds with executing the required lookup-ups and resulting packet processing actions that aren't dependent on at the end of frame status (good/bad) and/or frame length. The IPP will then wait for the entire frame to be received before executing actions that are dependent on the end of frame status and/or frame length (e.g. policing, forwarding, byte counters updates).

In cut-through mode of operation, once parsing is completed and although the entire frame may not have been entirely received, frame moves through the switch processing pipeline and starts getting transmitted on all of the destination ports.

No drops are expected when delivering frames from the Ethernet Rx I/F to the IPP as the IPP is engineered to operate at wire-rate; no back-pressure is expected from the IPP. If an unforeseen overload condition of the IPP is detected, received frames from the MAC will be discarded. These frames discards are counted against the port's Rx discard count register (PRXDCR) along with the setting of the Pre-Classification Discard Reason (PCDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).

The following metadata is passed along with the frame:

- Two timestamps (one sampling the synchronized clock whereby the other sampling the free running clock); for all receive frames, the timestamps are captured when MAC detects the one-octet start frame delimiter (SFD) of the frame. Currently, only the synchronized timestamp is used inside the switch. To report a frame receive timestamp from a switch port, the frame must be redirected or copied to the switch management port, with a Host Reason set to a codepoint other than a "regular forwarded frame" (for example, Ingress Port Filter (IPF) table entry match with the action to redirect or copy the frame to the switch management port, with Host Reason set to a non-zero value). PCR[TIMER_CS] determines which of the two timestamps (synchronized or free running) is to be reported.
- Indication that the frame was received from an Ethernet MAC and whether it was received from the Express MAC or the Preemptable MAC.
- Port number; acquired from the register LaBCR[SW_PORT_ENETC_INST], where a corresponds to the link number from which the frame was received.
- Frame length; calculated by the Ethernet RX I/F as it transfers the frame from the MAC Rx FIFO to internal memory.
- Indicator if MAC detected an error (for example, CRC error, invalid frame length). Errored frames are passed to the IPP where they will be discarded, or marked internally as bad, in the case where transmission of the frame has already started (cut-through mode of operation). On transmission, a bad CRC value is put in the frame FCS field to frames that have been internally marked as bad, to ensure that the next-hop device will correctly identify these frames as being bad.
- Indicator that the received frame was truncated due to the lack of free shared internal buffer memory available to store the entire frame. These frames are passed to the IPP where they will be discarded, or marked internally as bad, in the case where transmission of the frame has already started (cut-through mode of operation). These frames discards are counted against the port's Rx discard count register (PRXDCR) along with the setting of the Shared Memory Resource Exhaustion Discard Reason (SMREDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).

For ports supporting IEEE 802.1Qbu frame preemption, there are two MACs used per port (express MAC and preemptable MAC). In this case, the Ethernet RX I/F implements the interface functions to both MACs.

53.4.2.4.1.2.2 Pseudo MAC

In the case where frames are received from a pseudo MAC, there is no need to store or copy these frames as they have already been stored in the shared internal buffer memory by the switch. The frame check sequence (FCS) is always present in the frame; the pseudo MAC doesn't remove the FCS from the frame. The FCS carried in the received frame remains as the frame is processed by the switch. On transmission, if the data covered by the FCS is not modified, then the FCS value in the received frame is re-used as the FCS for the transmitted frame.

When a frame is received, the first 144 bytes the frame is loaded in a frame header memory which is accessed by the Ingress Packet Processing for processing the received frame.

Cut-through mode is not applicable as frames are already stored in the shared internal buffer memory.

No drops are expected when delivering frames from the Ethernet Rx I/F to the Ingress Packet Processing (IPP) as the IPP is engineered to operate at wire-rate (assuming a minimum frame length of 64 bytes); no back-pressure is expected from the IPP. If an unforeseen overload condition of the IPP is detected, received frames from the pseudo MAC are no longer accepted; frames are not dropped, instead back-pressure is applied towards the ENETC port.

The following metadata is passed along with the frame:

- Two timestamps (one sampling the synchronized clock and the other sampling the free running clock) at the time the frame was transferred across the pseudo link. Currently, only the synchronized timestamp is used in the switch.
- Indication that the frame was received from a pseudo MAC.
- Port number; acquired from the register LaBCR[SW_PORT_ENETC_INST], where a corresponds to the link number from which the frame was received, unless the frame is received from a switch management port with an out of band indication that the frame should be processed as it was received from a specified switch port number that is different than the switch management port number. In this case, the specified switch port number is passed to the IPP, instead of the port number obtained via the aforementioned register.
- Frame length.

No errors are expected; FCS is not checked as there are no transmission of bits on pseudo link interface as only a frame descriptor is being transferred across that interface.

53.4.2.4.1.3 Ingress Packet Processing

The processing through the Ingress Packet Processing is shown in the figure below.

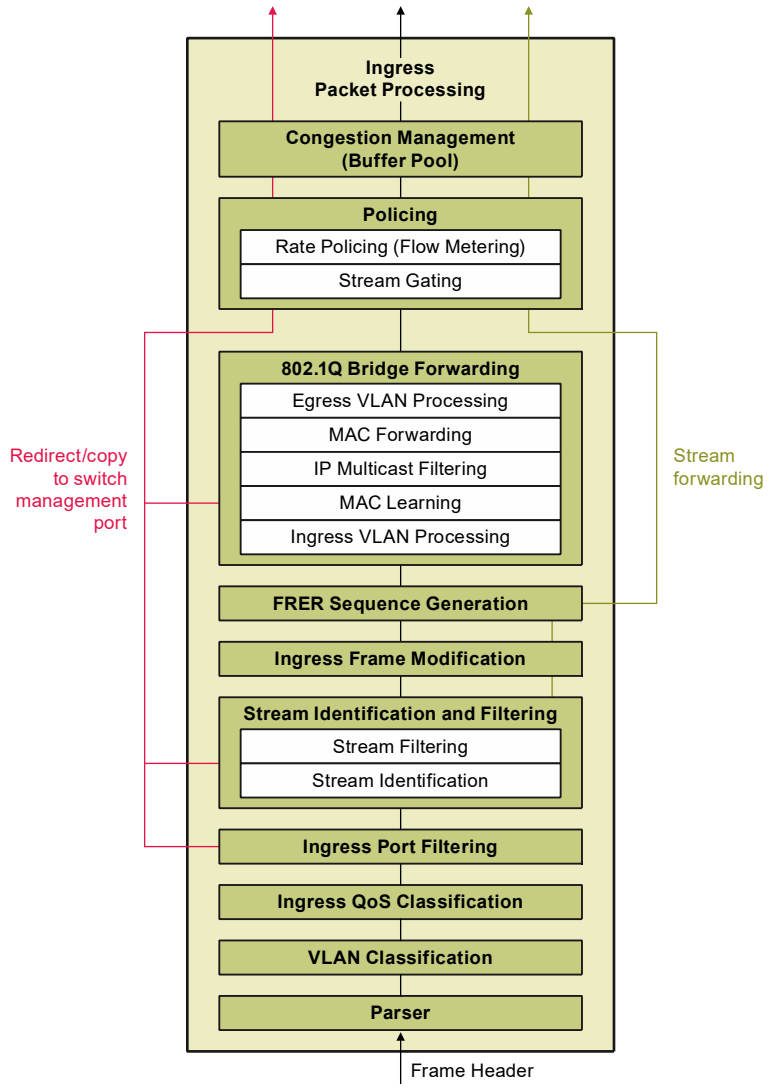

Figure 346. Ingress Packet Processing diagram

The Ingress Packet Processing block performs the following ingress packet processing functions in a pipeline manner:

- **Parser** - Parses the frames and extracts the required packet header fields in preparation for classification. Supports major protocols such as Ethernet, IPv4, IPv6, TCP and UDP.
- **VLAN classification** - Determines what VLAN tag data from the frame will be passed with the frame for later ingress processing.
- **Ingress QoS classification** - Provides initial internal identification of the QoS attributes that are used for subsequent QoS processing as frames go through the device. Internal QoS attributes indicate the given QoS (queueing priority and drop priority) as the frame moves through the device. At any queuing point, frames can be placed in the appropriate queue based on the internal queuing priority and can be dropped based on the internal drop priority.
- **Ingress port filtering** - Can deny or allow a frame. It may also override internal QoS attributes associated with the frame and set the stream ID or rate policer instance ID. It can also redirect/copy a frame to the switch management port and have the frame mirrored.
- **Stream identification and filtering** - Implements stream identification and filtering; compliant with IEEE 802.1CB and IEEE 802.1Qci (Per-Stream Filtering and Policing). It also provides the ability to specify, on per stream basis, the port(s) to which a frame should be output along with the egress processing actions that are to be applied, and with the ability

to enable/disable source port pruning. This capability is referred to as "stream forwarding" which by-passes the 802.1Q bridge forwarding function.

- **Ingress frame modification** - Provides ability to remove, add and modify a VLAN tag, along with replacing MAC addresses.
- **Frame Replication and Elimination for Reliability (FRER) sequence generation**- Sequence generation consists of tagging a frame with a sequence number, following which the frame can be replicated and transmitted along multiple paths for redundancy. Implemented as per the IEEE 802.1CB.
- **802.1Q bridge forwarding** - Performs the required forwarding lookups to determine the outgoing port(s), including flooding and broadcast/multicast handling. Supported bridge forwarding functions are
  - Ingress VLAN processing - Performs functions such as VLAN tagging checking, VLAN membership checking and Spanning Tree Protocol (STP) input port state checking. It also indicates the Filtering ID to be used by the forwarding function.
  - MAC learning - Entries are added to the FDB table when new unique MAC addresses are learned on the datapath. Entries found with port ID not matching incoming port ID are updated with incoming port ID. There is also the option to redirect/copy unknown frames to the switch management port for MAC learning purposes (software MAC learning).
  - IPv4 multicast filtering - Multicast frames are forwarded based on source IPv4 addresses and destination Iv4P addresses using IPv4 multicast filtering tables.
  - MAC forwarding - Frames are forwarded based on Layer 2 destination MAC addresses using the provided MAC Filtering or Forwarding Database (FDB) table.
  - Egress VLAN processing - Performs functions such as VLAN membership checking, Spanning Tree Protocol (STP), and output port state checking.
  - Storm control - Limits the amount of broadcast, multicast, and flooded unicast/multicast traffic.
- **Policing** - Implements traffic policing as per IEEE 802.1Qci (Per-Stream Filtering and Policing) to protect against time window and bandwidth violations.
- **Congestion Management** - Buffer pool assignment and checking that there is available memory space to accommodate the new frame.

53.4.2.4.1.3.1 Parser

The Parser parses up to L4 protocol headers in up to the first 144 bytes of the frame. Extracted field values and locations of relevant L2, L3 and L4 headers values are then used to perform the various table lookups and hash functions in subsequent processing stages of the switch.

During parsing, the parser examines and validates headers.

The parsing process can be expressed as a directed graph with nodes representing header types and edges (arrows) representing the sequence of headers. Parsing starts at the root node then walks from node to node using the next-header field values. Specifically, each node works within a protocol layer presuming a certain type of header, confirms the validity of the header, identifies boundaries of the header, extracts attributes and offsets, and determines the next header to examine beyond the current header.

Figure below shows the parse graph supported in the switch. The parse graph is structured by layers (L2, L3, and L4), with the details per each layer provided in the next sections.

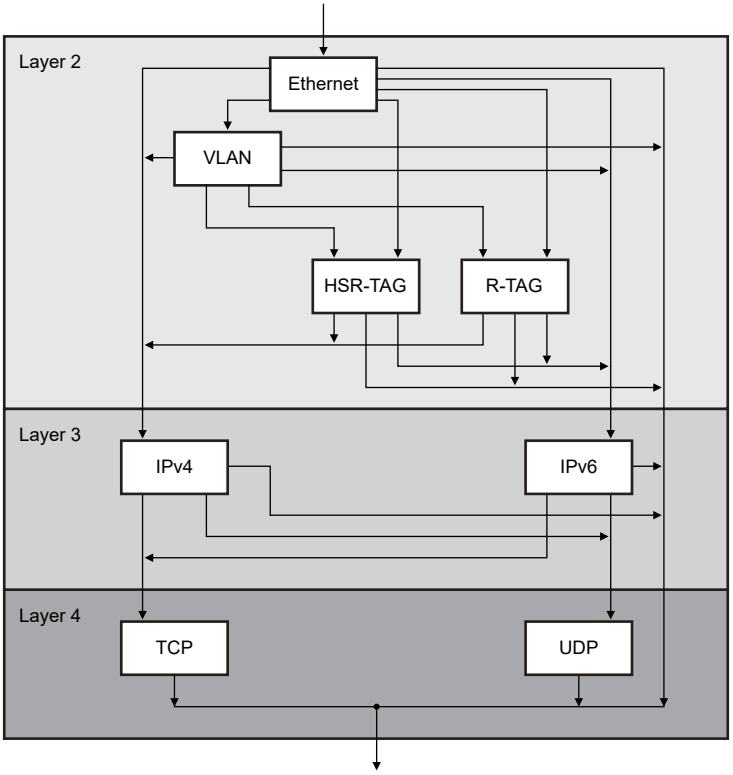

Figure 347. Switch Parse Graph

By default, the parser will parse and extract fields from each layer. There is the option to configure the parser to end parsing at L2 or L3 regardless of the content of the frame (for more details, see the port parser configuration register (PPCR)). The parser will also extract the payload (up to 24 bytes by default) of the last layer parsed (L2, L3 or L4). The maximum amount of payload to extract is configurable for each layer via the port parser configuration register (PPCR).

Parsing is terminated via one of the following:

- Upon reaching the natural end of a branch in the parse graph.
- Upon reaching a layer (L3 or L4) for which the parser has been configured not to parse.
- A parsing error is encountered; note that parse information from headers that have been successfully parsed is still used by table lookups and hash functions in subsequent processing stages of the switch.

53.4.2.4.1.3.1.1 Layer 2 Headers

As the first header in a frame, the parser supports Ethernet frames of the IEEE 802.3 (Ethernet II) format. IEEE 802.3 (Ethernet II) frames may be tagged with the IEEE 802.1Q VLAN tagging method. The 4-byte IEEE 802.1Q VLAN tag has two 2-byte components: Tag Protocol Identifier (TPID, residing within the type/length field) and the Tag Control Information (TCI). The following 4 TPID values are recognized as VLAN tags:

- The standard types 0x8100 and 0x88A8
- Two optional user programmable EtherType values known as CustTag1 and CustTag2; configured through CVLANR1 and CVLANR2 registers.

The TCI includes the following fields:

- PCP - Priority Code Point, the first three bits of the TCI define user priority.
- DEI - Drop Eligibility/ (single-bit field)
- VID - The 12-bit VLAN ID (VID) field identifies the VLAN the frame belongs to. The 12 bits allow for 4096 different VLANs. Out of the 4096 VLANs, the VID of zero is used to identify priority tagged frames and the value of 4095 is reserved.

Parser can parse frames with up to 2 VLAN tags. VLAN tags are named based on their position in the frame relative to other VLAN tags and the beginning of the frame i.e. the 802.3/Ethernet header consisting of Destination followed by Source MAC addresses.

The VLAN tag or header nearest the 802.3/Ethernet header is called the outer (or first) tag. The VLAN tag which is next closest to the 802.3 header is the inner (or second) tag. VLAN tags are expected to be contiguous, following one after the other, with no intervening non-VLAN tags.

Note that any VLAN tags which are within encapsulated frames and after any Upper Layer Protocol (ULP) header are not recognized. If only one VLAN tag is present in the frame, the inner VLAN tag is considered not present.

The outer and inner VLAN tag data (PCP, DEI and VID), if present, are extracted from the frame. The TPID from each VLAN tag is matched against the 4 known VLAN EtherTypes (2 standard, up to 2 custom) and a 2-bit TPID value is assigned identifying which known value matched (00: 0x8100, 01: 0x88A8, 10: CustTag1, 11: CustTag2). Matching is done against the list {0x8100, 0x88A8, CustTag1, CustTag2} in order and matching stops on the first match found. A 4-bit vector where each bit represents a TPID code point (bit 0 -> 00, bit 1 -> 01, bit 2 -> 10 and Bit 3 -> 11) is used by subsequent processing stages within the switch to perform non-contiguous masked matching operation against the TPID.

The information found in the next EtherType field (after VLAN parsing) is used to determine the next ULP header to parse. The EtherType field is located following the Source MAC address field if no VLAN tag present, or following the last VLAN tag. The ULP header is determined according to the “Ethernet - EtherType to Next ULP” mapping described in the table below.

EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends. If parsing reached end of frame, while more octets are expected to extract the 2-byte EtherType, the extracted EtherType is set to 0.

Table 521. Ethernet - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0800	IPv4	IPv4
x86DD	IPv6	IPv6
x88F7	PTP	Ends parsing
x892F	HSR Tag	HSR Tag
xF1C1	IEEE 802.1CB R-TAG	Redundancy tag
Pre-standard R-TAG EtherType register	IEEE 802.1CB draft 2.0 R-TAG	Redundancy tag

For High Availability Seamless Redundancy (HSR) tag, the parser extracts the 16-bit sequence number (last 2 bytes of the 6-byte HSR tag) and then locates the EtherType field following the 6-byte HSR tag. The next ULP header is determined according to the "HSR tag - EtherType to Next ULP" mapping described in the table below. If the EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 522. HSR tag - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0800	IPv4	IPv4
x86DD	IPv6	IPv6

For the 802.1CB R-TAG, the parser extracts the 16-bit sequence number (last 2 bytes of the 6-byte 802.1CB R-TAG) and then locates the EtherType field following the 6-byte R-TAG. The next ULP header is determined according to the “Redundancy tag - EtherType to Next ULP” mapping described in the table below. If the EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

The 4-byte pre-standard (802.1CB draft 2.0) R-TAG is also supported, The format of this tag is 2 bytes for the EtherType followed by 2 bytes for the sequence number. The recognized value for the Ethertype value of the pre-standard R-TAG is configured through the pre-standard R-TAG Ethertype register (PSRTAGETR). For the 4-byte pre-standard R-TAG , the parser extracts the 16-bit sequence number (last 2 bytes of the tag) and then locates the EtherType field following the 4-byte pre-standard R-TAG.

The next ULP header is determined according to the “Redundancy tag - EtherType to Next ULP” mapping described in the table below. If the EtherType field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 523. Redundancy tag - EtherType to Next ULP Mapping

EtherType	Recognized Protocol	Next ULP to be parsed
x0800	IPv4	IPv4
x86dd	IPv6	IPv6

Following information is captured by the parser for usage by subsequent processing stages within the switch:

- Source and Destination MAC addresses are extracted.
- Indication of whether the outer VLAN tag header is present and valid (no parsing error). If the header is present and valid, extracted VLAN tag data along with a 2-bit code identifying the TPID is also provided.
- Indication of whether the inner VLAN tag header is present and valid (no parsing error). If the header is present and valid, extracted VLAN tag data along with a 2-bit code identifying the TPID is also provided. If only one VLAN tag is present in the frame, the inner VLAN tag is considered not present.
- Whether destination MAC address is unicast, multicast or broadcast.
- A 3-bit redundancy tag type codepoint
  000b = No redundancy tag present
  001b = 802.1CB draft 2.0 R-TAG.
  010b = 802.1CB R-TAG.
  011b = HSR Tag
  100b ... 111b = Reserved.
- The sequence number is extracted if a redundancy tag is present (no parsing error).
- The last parsed EtherType is extracted; i.e. 2 bytes immediately after source MAC address or VLAN tag(s)/R-TAG/HSR (if any). If the EtherType wasn't parsed successfully (e.g. missing one byte due to frame too short), the EtherType is set to all 0s.
- Extracting up to 24 bytes located immediately after the payload EtherType. The payload EtherType is located immediately after the source MAC address or VLAN tag(s)/R-TAG/HSR (if any) if parsing is ending at this layer. The maximum amount of payload to extract is configurable via the port parser configuration register (PPCR).

Possible parsing errors for L2 headers are:

- Frame parsing reached end of frame while parsing a VLAN tag or R-TAG/HSR that expects more data. Frames shorter than 14 bytes excluding 4-byte FCS will never reach the parser as they will be discarded by the Ethernet Rx I/F.

There are no validation checks performed on the Source and Destination MAC addresses, and EtherType fields. Note that if an L2 header parsing error is detected, the frame is not discarded. Instead, only successfully parsed L2 header fields are extracted, but payload data is not extracted. The parse information is then passed along with the frame for subsequent processing within the IPP (e.g. table lookups and hash functions).

Note that any sequence tag information extracted by the parser for usage by subsequent processing stages, is overwritten if FRER sequence generation is enabled for the frame. NETC only supports ONE CB redundancy tag, one added as part of sequence generation if enabled, or a parsed redundancy tag if present.

53.4.2.4.1.3.1.2 Layer 3 Headers

The parser supports parsing of both IPv4 and IPv6 packets. Only the first IPv4 or IPv6 header encountered in a packet is parsed.

IPv4 options are not parsed. They are also not skipped meaning that the next ULP header will not be parsed if the packet has IPv4 options.

There is the option to configure the parser on per port basis, of not parsing the L3 header. This option is configured by setting PPCR[L3HFP] to 0. This option can be used to reduce the number of bytes required to be received before the frame can move through the switch processing pipeline and, in the case of cut-through, starts getting transmitted. This in turn can improve cut-through forwarding latency across the switch. This option should not be used if there are any table lookup entries that contain L3/L4 key fields that could be matched for that frame.

If a non-fragmented IPv4 packet (Fragment Offset is set to zero and the More Fragments flag is set to zero) or an initial fragment packet ((Fragment Offset is set to zero and the More Fragments flag is set to one) is parsed, then the parser uses the information stored in the Protocol field to determine the next ULP header to be parsed.

For IPv4 header, the next ULP header is determined according to the “IPv4 - Protocol to Next ULP” mapping described in the table below. If the Protocol field is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 524. IPv4 - Protocol to Next ULP Mapping

Protocol (decimal)	Recognized Protocol	Next ULP to be parsed
6	TCP	TCP
17	UDP	UDP

For IPv6 header, the IPv6 main header may be followed by an arbitrary number (0, 1 or multiple) of extension headers chained together through the Next Header field. IPv6 extension headers are not parsed. They are also not skipped meaning that the next ULP header will not be parsed if the packet has extension headers.

The parser uses the information stored in the Next Header field of the IPv6 main header to determine the next ULP header. The next ULP header is determined according to the “IPv6 – Next Header to Next ULP” mapping described in the table below. If the Next Header is set to a value other than the ones included in the table below, the next header is considered an unknown type and parsing ends.

Table 525. IPv6 - Next Header to Next ULP Mapping

Next Header (decimal)	Recognized Protocol	Next ULP to be parsed
6	TCP	TCP
17	UDP	UDP

Following information is captured by the parser for usage by subsequent processing stages.

- Indication of whether the outer IP header is present and valid (no parsing error). If the header is present and valid, indication of whether IP header is v6 or v4, is also provided.
- Indication of whether IPv4 options / IPv6 extensions are present. Note that value 59 (No Next Header) in the Next Header field of the IPv6 main header, is not considered an IPv6 extension header; as a result the IPv4 options / IPv6 extensions present indicator will be set to not present. See table below for the recognized IPv6 extension headers.
- IP source address , IP destination address, DSCP and Protocol fields are extracted.
- Extracting up to 24 bytes located immediately after the IP header if parsing is ending at this layer. The maximum amount of payload to extract is configurable via the port parser configuration register (PPCR). Note that if IPv4 options or IPv6 extensions are present, payload extraction starts at the beginning of the IPv4 Options/IPv6 Extensions header.

Possible parsing errors for L3 headers are:

- Frame parsing reached end of frame while parsing a header that expects more data.
- For each IPv4 header parsed, if any of the following conditions is detected:
  - Version number in IPv4 header is not equal to 4.
  - IPv4 Header Length field value is less than 20 bytes, or exceeds the received packet length (excludes L2 header), or exceeds the IPv4 header Total Packet Length field value

- For each IPv6 header parsed, if any of the following conditions is detected:
  - Version number in IPv6 header packet is not equal to 6.

Note that if an L3 header parsing error is detected, the frame is not discarded. Instead, the L3 header is considered not present, and parsing ends. The parse information from the L2 headers (including L2 payload if extracted) is passed along with the frame for subsequent processing within the IPP (e.g. table lookups).

Table 526. IPv6 extension headers

Protocol Number (decimal)	Description
0	IPv6 Hop-by-Hop Option
43	Routing Header for IPv6
44	Fragment Header for IPv6
50	Encapsulating Security Payload
51	Authentication Header
60	Destination Options for IPv6
135	Mobility Header
139	Host Identity Protocol
140	Shim6 Protocol
253	Use for experimentation and testing
254	Use for experimentation and testing

53.4.2.4.1.3.1.3 Layer 4 Headers

The parser supports parsing of both TCP and UDP packets. Only the first TCP or UDP header encountered in a packet is parsed.

The TCP header may have options but these aren't examined.

There is the option to configure the parser on per port basis, of not parsing the L4 header. This option is configured by setting PPCR[L4HFP] to 0. This option can be used to reduce the number of bytes required to be received before the frame can move through the switch processing pipeline and, in the case of cut-through, starts getting transmitted. This in turn can improve cut-through forwarding latency across the switch. This option should not be used if there are any table lookup entries that contain L4 key fields that could be matched for that frame.

Following information is captured by the parser for usage by subsequent processing stages within the switch:

- If the L4 header parsed is TCP, an indication that TCP is present (L4 codepoint set 01b).
- If the L4 header parsed is UDP, an indication that UDP is present (L4 codepoint set 10b).
- Source and destination port numbers are extracted.
- If no TCP nor UDP header is detected, an indication that other L4 is present (L4 codepoint set 00b).
- Extracting up to 24-bytes located immediately after the first 4 bytes of the TCP/UDP header. The maximum amount of payload to extract is configurable via the port parser configuration register (PPCR).

Possible parsing errors for L4 headers are:

- Frame parsing reached end of frame while extracting source and destination port numbers (L4 header shorter than 4 bytes).

Note that if an L4 header parsing error is detected, the frame is not discarded. Instead, the L4 header is considered other L4, and parsing ends. The parse information from the L3 headers (including L3 payload if extracted) is passed along with the frame for subsequent processing within the IPP (e.g. table lookups).

53.4.2.4.1.3.2 VLAN classification

VLAN classification processing stage determines what VLAN tag data will be passed with the frame for later ingress processing.

Following VLAN tag metadata provided by the parser is used by VLAN classification:

- Indication of whether the outer VLAN tag header is present and valid (no parsing error)
- Indication of whether the inner VLAN tag header is present and valid (no parsing error)
- Extracted outer VLAN tag data from frame
  - PCP, DEI, VID
  - TPID expressed as 2-bit code point
- Extracted inner VLAN tag data from frame
  - PCP, DEI, VID
  - TPID expressed as 2-bit code point

Output of the VLAN classification is:

- VLAN tag attribute indicators
  - Indication of whether the frame is untagged
  - Indication of whether outer VLAN tag is valid, if valid then the following attributes further qualifies it
    - VLAN tag data taken from port outer VLAN configuration; not asserted for the switch as VLAN assignment is performed later on.
    - VID is set 0 in the frame outer VLAN tag; i.e. priority tag
    - VLAN tag data taken from port inner VLAN configuration; not asserted for the switch as inner VLAN assignment is not supported.
  - Indication of whether inner VLAN tag is valid, if valid then the following attributes further qualifies it
    - VID is set to 0 in the frame inner VLAN tag; i.e. priority tag
- Outer VLAN tag data (PCP, DEI, VID) if outer VLAN tag is valid
- Inner VLAN tag data (PCP, DEI, VID) if inner VLAN tag is valid

The setting of the above VLAN classification output attribute indicators (along with appropriate VLAN tag data) is provided in the following steps:

1. All VLAN classification output indicators are cleared at the start of VLAN classification processing except for the outer/inner tag presence indicators which are taken from the parser. Outer/inner tag data and 2-bit TPID code point are also taken from the parser
2. If no tags are present then frame metadata is marked as untagged. No default VID is assigned at this point of the packet processing pipeline.
3. For each of the inner/outer tags which are (deemed) present the appropriate acceptance bitmap (PTAR[IVTPIDL/OVTPIDL]) is checked. If the tag's TPID's bit is set then the tag is acceptable otherwise it is deemed not present.
4. For each of the inner/outer tags if the tag is (deemed) present then frame metadata is marked as tag data being valid, and with the "VID is set to 0" qualifier set to 1 if the VID in the tag is 0. The "VID is set to 0" qualifier is a frame metadata attribute indicating whether this VLAN tag is a priority tag. When the "VID is set to 0" qualifier is set to 1, it indicates that this VLAN tag is a priority tag.

The resulting VLAN tag data and attribute indicators are passed along for upstream use.

53.4.2.4.1.3.3 QoS classification

QoS classification involves setting the internal QoS. The internal QoS indicates the given QoS (Internal Priority Value and Drop Resilience) as the frame moves through the device, and encounters resource contention and possibly be conditioned (e.g.

policing). Internally at any queuing point, frames can be placed in the appropriate queue based on the Internal Priority Value and can be dropped based on the Drop Resilience.

Internal Priority Value (IPV) is a 3-bit attribute assigned to a frame which is used for certain scheduling decisions in subsequent processing stages. A higher IPV value generally indicates higher priority , assuming strict priority scheduling is applied. The lowest priority is 0 and the highest is 7.

Drop Resilience (DR) is a 2-bit attribute assigned to a frame which is used to determine the likelihood of dropping the frame if there is congestion. A higher DR value generally indicates being more discardable. For example:

- Drop resilience 0

  Committed frames. With proper allocation of buffer and bandwidth resources within the network, it is possible to guarantee a lossless and timely delivery of a committed frames. In a "colored" mapping scheme such as IEEE 802.1Qci flow metering, this corresponds to Green.

- Drop resilience 1

  Normal frames. In a "colored" mapping scheme such as IEEE 802.1Q flow metering, this corresponds to Green.

- Drop resilience 2

  Non-committed frames. At sign of congestion, these frames can be dropped but should otherwise be delivered. In a "colored" mapping scheme such as IEEE 802.1Q flow metering, this corresponds to Yellow.

- Drop resilience 3

  Violating frames. These frames are delivered on a "best effort" basis. In a "colored" mapping scheme such as IEEE 802.1Q flow metering, this corresponds to Red.

Received frames are initially assigned an IPV and DR based on the setting for the port (PQOSMR[DIPV] and PQOSMR[DDR]).

The PCP and DEI from one of the sets of VLAN tag data may be used to override the default settings. This is achieved by setting PQOSMR[VE] to 1 to enable the use of VLAN tag data to determine IPV and DR and configuring PQOSMR[VS] to determine which VLAN tag (inner/outer) to be used.

If the selected VLAN tag is valid (VLAN classification output), the PCP and DEI from the selected VLAN tag data are used to determine IPV and DR based on the configured per port mapping VLANIPVMP*a*R0/1 and VLANDRMP*a*R, where *a* identifies a mapping profile. The profile to use (*a*) is specified in PQOSMR[VQMP].

IPV and DR values for the frame may also be changed by subsequent processing stages.

53.4.2.4.1.3.4 Ingress Port Filtering

This stage implements the ingress port filtering functions. There are two functions being performed; denial of service checks function and the ingress port filtering lookup function.

The denial of service (DOS) checks function is first executed to determine whether admit or drop incoming frames. The denial of service checks to be performed are specified in DoS L2 configuration register (DOSL2CR). Whether to perform the L2 DOS checks is specified in register PCR[L2DOSE].

If the frame hasn't been discarded by the previous function, the ingress port filtering lookup function is then executed by examining the frame header information to determine on whether to deny or allow a frame. It may also be used to override internal QoS attributes associated with the frame and set parameters (e.g. Rate Policer Entry ID, stream ID, SI bitmap) for the subsequent frame processing functions.

The ingress port filtering lookup function must be enabled to be executed (i.e. PIPFCR[EN] set to 1). If the ingress port filtering lookup function is disabled, the ingress port filtering lookup function is by-passed, and frames are passed to the next frame processing function.

The ingress port filtering lookup function involves performing a lookup against the ingress port filter table. The ingress port filter table is defined as a ternary match table. In a ternary match table, all entry key matching fields are composed of pairs of data and mask values, to support a per-bit ternary match capability. For each {data, mask} bit pair, the following combinations are supported:

- 00 = always match (X)
- 01 = match on 0
- 11 = match on 1
- 10 = always match (X); note that the table management query operation will always be returning 0 for any data bits which have their corresponding mask bit set to 0, regardless of whether they are set to 0 or 1 by the table management add or update operations.

In other words, to look for a match on a particular bit, set its mask bit to 1, and its corresponding data bit to the desired matching value, 0 or 1. A mask value of all 1's for a particular field means that field is required. To make a bit don't care, set its mask bit to 0.

In a ternary match table, a single lookup key can be matched by multiple table entries, and thus every entry must have a priority assigned by the software. When multiple entries match, the entry with the highest priority, is returned as the matching entry. Numerically higher values indicate higher priority when matching packets.

If no entry matches the frame, the frame is allowed in, and passed to the next frame processing function.

The ingress port filter table is implemented using a Ternary Content Addressable Memory (TCAM).

For programming of the table entries, see Ingress Port Filter Table.

The ingress port filter table entry includes the following matching key fields (each field is bit-wise maskable):

- Source port ID
- Switch port masquerading; frame received on a switch management port with an out of band indication that the frame should be processed as it was received from a switch port that is different from the switch management port.
- Source and destination MAC address
- Outer VLAN tag PCP, DEI and VID
- Inner VLAN tag PCP, DEI and VID
- Payload EtherType, located immediately after the source MAC address or VLAN tag(s)/R-TAG/HSR (if any).
- IPv4 source address and IPv4 destination address
- IPv6 source address and IPv6 destination address
- Protocol field present; for IPv6 packets the Protocol key (called the "Next Header" in IPv6) is not extracted if the packet has IPv6 extension headers.
- Protocol
- IP DSCP
- TCP/UDP header source and destination port
- Payload (up to 24-bytes)
  - When no IP header is present, the payload is matched against the frame bytes located immediately after the payload EtherType. The payload EtherType is located immediately after the source MAC address or VLAN tag(s)/R-TAG/HSR (if any).
  - When IP header is present and no TCP or UDP header is present, the payload is matched against the frame bytes located immediately after the IP header except when IPv4 options or IPv6 extensions are present. For the latter, payload matching starts at the beginning of the IPv4 Options/IPv6 Extensions header.
  - When TCP or UDP header is present, the payload is matched against the frame bytes located immediately after the first 4 bytes of the TCP/UDP header.
- Frame attributes bit fields
  - o Outer VLAN tag present
  - o Inner VLAN tag present
  - o IP header present

- Indication of whether IP header is v6 or v4
- TCP header present
- UDP header present
- Other L4 header present (not TCP or UDP)
- IPv4 option / IPv6 extension present
- Sequence Tag present

Note that when hardware constructs a table lookup key for a frame header field for which the frame header is not present in the frame, it sets the key field to zero. If zero corresponds to a valid value in a frame header field, this could lead to a false positive match. To avoid these false positive matches, the present frame header (or field) 1-bit key matching fields are defined in the table entry to explicitly specify whether the presence of a frame header (or field) must be present or not present in a frame header, for an entry to match.

Following are the possible actions when an ingress port filter entry is matched:

- Filtering action, one of the following:
  - Discard
  - Permit
  - Redirect/copy to switch management port
- Modifying internal QoS attributes (IPV and DR)
- Ingress Mirroring
- Capturing timestamp
- Disabling cut-through
- Setting internal parameter, one of the following
  - Enabling policing with a specified Rate Policer Entry ID
  - Specifying a Ingress Stream Entry ID along with lookup precedence

53.4.2.4.1.3.5 Stream Identification and Filtering

This stage implements the stream identification and filtering functions. Steam identification mainly involves classifying incoming traffic into a locally-significant identifier (global to the device), that identifies a stream within the device. This identifier is referred to as the Ingress Stream Entry ID (IS_EID). The stream identification function is implemented as per IEEE 802.1CB (Frame Replication and Elimination for Reliability (FREF)). Note that IEEE 802.1Qci (Per-Stream Filtering and Policing) exploits the stream identification functions specified in IEEE 802.1CB. The stream filtering function identifies the actions/functions to be applied to frames belonging to the identified stream. Namely, the main actions/functions are:

- Whether a frame is accepted or discarded.
- Maximum service data unit size defined for the stream as per IEEE 802.1Qci (Per-Stream Filtering and Policing).
- Stream gate instance and rate policer instance to be used to police the stream as per IEEE 802.1Qci (Per-Stream Filtering and Policing). The stream gating and rate policer functions are applied later in the ingress processing pipeline after it has been determined where to forward the frame.
- FREF (IEEE 802.1CB) sequence generation function. This function applies only to the switch.
- Stream forwarding function; the port(s) to which the frame should be output are provided in the stream context along with the egress packet processing actions to be applied to packets for each of the outgoing port(s); when the stream forwarding function is selected, the 802.1Q bridge forwarding function is by-passed. This function applies only to the switch.
- Ingress frame modifications such as ingress VLAN translation and IEEE 802.1CB active stream identification (replacing DMAC and/or VLAN). This function applies only to the switch.

- The Ingress Stream Counter ID that indicates the Ingress Stream Count table entry to be used to count matched frames and count discarded frames.

53.4.2.4.1.3.5.1 Stream Identification

Stream identification function mainly involves performing a series of table lookups to determine the Ingress Stream Entry ID (IS_EID), which in turn is used to access the Ingress Stream table to retrieve the action(s) to be applied to the frame. A default IS_EID, can be specified on a per port basis in PISIDCR register. Following are the lookup tables that can yield the IS_EID.

- **Ingress Port Filter table** - IS_EID can be specified in an Ingress Port Filter entry along with its relative precedent resolution value. Specifying IS_EID in ingress port filter entry is optional. If specified, its relative precedent resolution value determines if further lookups are required for stream identification.
- **Ingress Stream Identification table** - The Ingress Port Filter table lookup (prior stage) is followed up by a series of up to 2 hash based exact match table lookups into the Ingress Stream Identification table. The key used for stream identification exact match lookup is specified through a "key construction rule". A key construction rule specifies how the lookup key should be constructed. Specifically, it specifies metadata, specific frame header fields, and payload data that should be concatenated to form a key for the table lookup. A key construction rule is specified through a set of registers. For the switch, there are 4 key construction rules available for the entire switch, and are identified by the decimal number (0-3). For ENETC, there are 2 key construction rules per ENETC instance, and are identified by the decimal number (0-1). Note that the key construction register names imbeds the ID of the key construction rule that they are associated with. For example, ISIDKCaCR0, "a" represents the rule ID (decimal) that the register is associated with. Assignment of key construct rules to Ingress Stream Identification table lookups is achieved through key construction rule profiles. A key construction rule profile contains 2 construction key rules (one for the first exact match lookup and one for the second exact match lookup). Key construction rule profiles are derived through a static hard-wired assignment; profile 0 includes rules ID 0 and 1, profile 1 includes rules ID 2 and 3, and so on if it needs to be expanded in the future. For the switch, which of the two key construction rule profiles to use, is configurable on per switch port basis (register PISIDCR[KCPAIR]). For ENETC, key construction rule profile 0 is always used.

The following details the sequence of table lookups for determining the IS_EID (also illustrated in Figure 348).

1. If the Ingress Port Filtering function has yield an IS_EID and its relative precedent resolution value indicates that it has the highest precedence level (set to 0), then this IS_EID is selected, else go to step #2.
2. The first of the two hash based exact match lookups is performed (if enabled (PISIDCR[KC0EN]=1)) based on the key construction rule specified for this lookup. If a matching entry is found, the IS_EID specified in the entry is then selected. If this lookup is not enabled or a matching entry is not found and if the Ingress Port Filtering function has yield an IS_EID with a relative precedent resolution value falling between first and second exact match lookup (i.e. value set to 1), then this IS_EID is selected. Otherwise go to step #3.
3. The second of the two hash based exact match lookups is performed (if enabled (PISIDCR[KC1EN]=1)) based on the key construction rule specified for this lookup. If a matching entry is found then the IS_EID specified in the entry is selected. If this lookup is not enabled or a matching entry is not found and the Ingress Port Filtering function had yield an IS_EID then this IS_EID is selected. Else the default IS_EID is selected.

Note that if the selected IS_EID is NULL, the ingress stream frame processing will not be performed and the frame is passed on to the next stage of processing.

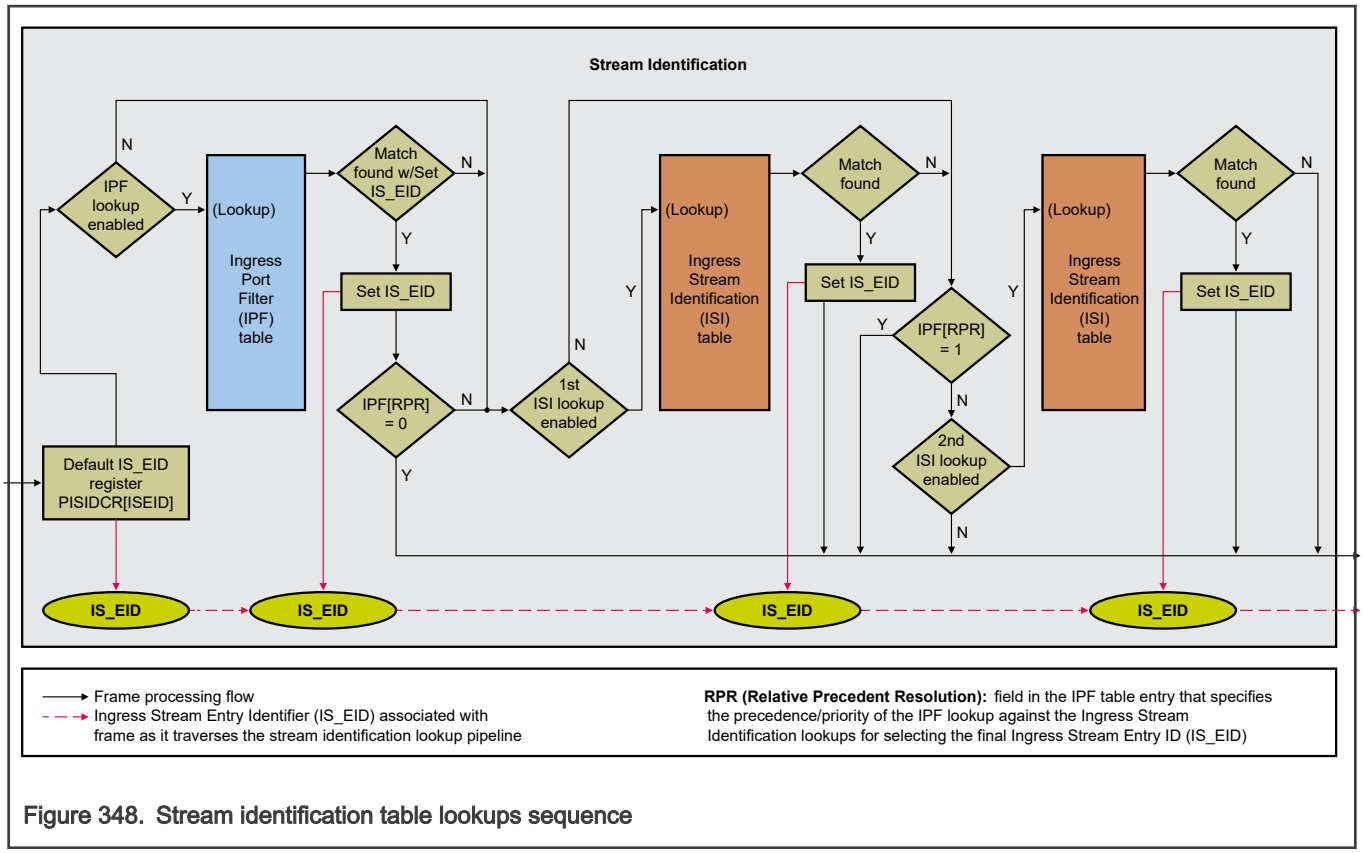

Figure 348. Stream identification table lookups sequence

Following registers are associated with lookups in the Ingress Stream Identification table.

- Ingress Stream Identification Capability Register (ISIDCAPR); indicates number of key construction rules, maximum key size, and so on.
- Ingress Stream Identification Hash Table Capability Register (ISIDHTCAPR); indicates which configuration access methods are supported.
- Switch registers for ingress stream identification key construction rules are noted below.
  - Ingress Stream Identification Key Construction a Operational register (ISIDKC*a*OR); indicates the number of entries in the Ingress Stream Identification table for particular key construction rule, where *a* =0..3 represents the key construction rule ID.
  - Ingress Stream Identification Key Construction Configuration Register 0 (ISIDKC*a*CR0) , where *a*=(0..3) represents the key construction rule ID.
  - Ingress Stream Identification Key Construction a Payload Field 0 Configuration Register (ISIDKC*a*PF0CR), where *a*=(0..3) represents the key construction rule ID.
  - Ingress Stream Identification Key Construction a Payload Field 1 Configuration Register (ISIDKC*a*PF1CR), where *a*=(0..3) represents the key construction rule ID.
  - Ingress Stream Identification Key Construction a Payload Field 2 Configuration Register (ISIDKC*a*PF2CR), where *a*=(0..3) represents the key construction rule ID.
  - Ingress Stream Identification Key Construction a Payload Field 3 Configuration Register (ISIDKC*a*PF3CR), where *a*=(0..3) represents the key construction rule ID.
  - Port Ingress Stream Identification Configuration Register (PISIDCR); used to enable/disable exact match ingress stream identification lookups and to specify which key construction rule profile to use.
- ENETC registers for ingress stream identification key construction are noted below.

- Ingress Stream Identification Key Construction a Operational register (ISIDKC*a*OR); indicates the number of entries in the Ingress Stream Identification table for particular key construction rule, where *a* =0..1 represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Configuration Register 0 (ISIDKC*a*CR0), where *a*=(0..1) represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Payload Field 0 Configuration Register (ISIDKC*a*PF0CR), where *a*=(0..1) represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Payload Field 1 Configuration Register (ISIDKC*a*PF1CR), where *a*=(0..1) represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Payload Field 2 Configuration Register (ISIDKC*a*PF2CR), where *a*=(0..1) represents the key construction rule ID.
- Ingress Stream Identification Key Construction a Payload Field 3 Configuration Register (ISIDKC*a*PF3CR), where *a*=(0..1) represents the key construction rule ID.
- Port Ingress Stream Identification Configuration Register (PISIDCR); used to enable/disable exact match ingress stream identification lookups.

The Ingress Stream Identification table is managed using command messages. See Ingress Stream Identification Table for the switch and Ingress Stream Identification Table for ENETC.The Ingress Stream Identification table entry includes the following matching key fields:

- Key construction rule ID (referred to as KEY_TYPE in the Ingress Stream Identification table)
- Source port ID; applicable to the switch only
- Source Port Masquerading (SPM); applicable to the switch only
- Frame portion of the key (up to 16 bytes) frame header key construction is specified in ISIDKC*a*CR0 and frame payload key construction is specified in ISIDKC*a*PF*b*CR , where *a* represents the rule ID and *b* represents the payload field.

The frame portion of the key format (frame key) is specified by the aforementioned key construction rule registers. The frame key entered in the Ingress Stream Identification table entry has to be in packed form in the order they appear in the frame with each field formatted in big endian format (order they are received from the link). If the constructed key is less than 16 bytes then the frame key entered in the Ingress Stream Identification table entry, must be padded with zeros for the rest of the bytes.

Protocol header data or payload data has to be added to the key in the Ingress Stream Identification entry if indicated as 'present' in key construction register. Format of protocol header data or payload data in 16 byte key (referred to as Key) is specified below.

- Source port and SPM are included in the key if respective 'present' bit is set in the key construction register. These values are part of the reserved area in the hash key and do not add bytes to the frame portion of the key.
- Following are the options for the Ethernet header:
  - If SMAC or DMAC is present in key construction register then each of these adds 6 bytes of data to the key. If both are present then DMAC has to follow SMAC.
  - If VID or PCP are indicated as present in key construction register then the following is added to the key: VID only, PCP only, VID and PCP, or 'no VLAN tag present in the frame'. VID and PCP can be specified for both inner and outer VLANs.
  - A one-byte frame attribute code point is included in the key indicating whether there is no 802.1CB R-TAG/HSR tag, 802.1CB draft 2.0 R-TAG present, 802.1CB R-TAG present or HSR tag present.
  - If EtherType is present in key construction register then an EtherType is added to the key. The EtherType extracted is located immediately after source MAC address or VLAN tag(s)/R-TAG/HSR (if any).
  - ISIDKCaPFbCR registers specify the key format for the payload data (where 'a' indicates the key construction rule used for the exact match lookups and 'b' indicates the payload field). The key format is big endian (network byte order).

53.4.2.4.1.3.5.2 Per-Stream Filtering

Based on the selected IS_EID, the Ingress Stream table entry is read from Ingress Stream table to obtain the actions to be performed for the received frame:

- Forwarding options for switch function - Discard frame, redirect/copy frame to switch management port, use 802.1Q bridge forwarding function or use stream forwarding which by-passes the 802.1Q bridge forwarding function.
- Forwarding options for ENETC function - Discard frame, forward with SI bitmap or forward without SI bitmap set.
- Specify whether to perform the maximum Service Data Unit (SDU) check. See Maximum SDU Check for more details.
- Override IPV, DR
- The frame is to be mirrored to the mirror destination specified in the IMDCR0 register (applicable to the switch only).
- Enable timestamp capture if not already enabled (applicable to the switch only).
- Enable/disable Ingress Sequence Generation (applicable to the switch only).
- Enable/disable Ingress Stream Gating operation. If enable, the stream gate instance identifier is provided to indicate the stream gate instance to be used.
- Option to override Rate Policer Entry ID.
- Option to disable cut through frame transfer on a specific destination port or on all destination ports (applicable to the switch only).
- Specify egress packet processing actions (applicable to the switch only)
- Specify the Ingress Stream Counter ID to count matched frames and count discarded frames. Discard counts are maintained for maximum SDU drops, Stream Gating frame drops and Rate Policing frame drops. If Ingress Stream Counter ID is set to NULL, no Ingress Stream Counter table entry is updated. If the entry referred to by the Ingress Stream Count ID is not found in the Ingress Stream Count table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).
- Option to specify performing an Ingress Stream Filter table lookup; to support a PSFP (IEEE 802.1Qci) stream filtering function that uses the 3-bit PCP value (priority) of the received frame and the stream handle (i.e. Ingress Stream Entry ID) to select a stream filter. Note that the Ingress Stream table is used to support stream filters that require an exact match only on the stream Id (PCP is wild-carded). Note that to support stream filters that requires exact match only on the PCP (stream Id is wild-carded), multiple Ingress Stream table entries must be created for a given stream, one for each of the PCP value that requires matching. For the latter, the PCP must be included as one of the parameter/key field to determine the Ingress Stream Entry ID (IS_EID).
- Option to specify Ingress Frame Modification Entry ID (IFM_EID) to perform ingress frame modification operation (applicable to the switch only).

If a frame is discarded, in addition to updating the relevant discard counts in the Ingress Stream Count table, discard count and discard reasons are updated in PRXDCR, PRXDCRRR and in PRXDCRR0/1 registers.

The Ingress Stream table is an index table. There is a single instance of this table for the switch and an instance per ENETC function. The IS_EID is used as the index to this table. For more details, see Ingress Stream Table for the switch and Ingress Stream Table for ENETC. Ingress stream table capabilities and configuration are specified in following registers:

- Ingress Stream Index Table Capability Register (ISITCAPR)
- Ingress Stream Index Table Memory Allocation Register (ISITMAR)
- Ingress Stream Index Table Operational Register (ISITOR)

If the entry referred to by the selected IS_EID (non-NULL value) is not found in the Ingress Stream table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). If the selected IS_EID is the default IS_EID specified in PISIDCR[ISEID], and is set to a value which indexes outside of the available Ingress Stream table entries, the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along

with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). Note that IS_EIDs configured in tables (Ingress Port Filter table, Ingress Stream Identification table), are checked at configuration time to ensure that the ID falls within the range of valid indexes. If the IS_EID is out of range and is not set to NULL, the table configuration operation is not performed. If the IS_EID is set to NULL, the stream filtering function is by-passed.

53.4.2.4.1.3.5.3 Per-Stream, Per-Priority Filtering

To support a PSFP (IEEE 802.1Qci) stream filtering function that uses the 3-bit PCP value (priority) of the received frame and the stream handle (i.e. Ingress Stream Entry ID) to select a stream filter, an additional lookup (i.e. against the Ingress Stream Filter table) must be performed to obtain the PSFP (IEEE 802.1Qci) filtering and policing actions. If a lookup is performed against the Ingress Stream Filter table, the PSFP (IEEE 802.1Qci) filtering and policing actions from the Ingress Stream table entry are overridden by the actions from the matched Ingress Stream Filter table entry. If no match is found in the Ingress Stream Filter table, processing moves on with the actions from the matched Ingress Stream table entry.

As stated earlier on, in the case where the stream handle (i.e. Ingress Stream Entry ID) is used to select a stream filter, the Ingress Stream table entry contains the PSFP (IEEE 802.1Qci) filtering and policing actions that are to be applied to frames received on this stream. Furthermore to support stream filters that requires exact match only on the PCP (stream Id is wild-carded), multiple Ingress Stream table entries must be created for a given stream, one for each of the PCP that requires matching. Additionally, the PCP must be included as one of the parameter/key field to determine the Ingress Stream Entry ID (IS_EID).

The Ingress Stream Filter table is a hash table accessed using the IS_EID specified in the Ingress Stream table entry and PCP in the VLAN tag of the received frame. For more details, see Ingress Stream Filter Table for the switch and Ingress Stream Filter Table for ENETC.

If a match is found, the following actions can be specified:

- Options to override IPV, DR.
- Option to mirror frame to the mirror destination specified in the IMDCR0 register (applicable to the switch only).
- Option to disable cut through forwarding of frame if not already disabled (applicable to the switch only).
- Enable timestamp capture if not already enabled (applicable to the switch only).
- Option to enable/disable Ingress Stream Gating. If enable, the stream gate instance identifier is provided to indicate the stream gate instance to be used.
- Option to override Rate Policer Entry ID.
- Specify the Ingress Stream Counter ID to count matched frames and count discarded frames. Discard counts are maintained for maximum SDU drops, Stream Gating frame drops and Rate Policing frame drops. If Ingress Stream Counter ID is set to NULL, no Ingress Stream Counter table entry is updated. This field overrides the Ingress Stream Counter ID field specified in the previous matched Ingress Stream table entry. If the entry referred to by the Ingress Stream Count ID is not found in the Ingress Stream Count table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).
- Specify the maximum SDU check. See the following section for more details.

If a frame is discarded, in addition to updating the relevant discard counts in the Ingress Stream Count table, discard count and discard reasons are updated in PRXDCR, PRXDCRRR and in PRXDCRR0/1 registers.

53.4.2.4.1.3.5.4 Maximum SDU Check

Maximum SDU check is performed prior to policing where frame will be dropped if frame size exceeds maximum SDU. Note that the maximum SDU check is not performed, if the frame is being forwarded in the cut-through mode of operation, to at least one egress port. This means that the maximum SDU check is not performed for a frame that is replicated, where some copies are forwarded as cut-through frames while others are forwarded as store-and-forward frames. A value of zero disables the maximum SDU check.

53.4.2.4.1.3.6 Ingress Frame Modification

This function handles the ingress frame modifications, with the exception of the R-TAG/HSR header modification which is handled by the FRER sequence generation function. It provides ability to modify the MAC address and to remove, insert, swap VLAN tag.

The ingress frame modifications are specified in a Frame Modification table entry which in turn is referred to in an Ingress Stream table entry. For more details, see Frame Modification Table. If the index refers to an entry that is not found in the Frame Modification table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). There is also the option of encoding a subset of the frame modification actions in the actual frame modification entry ID. For the latter there is no need to access the frame modification table as the actions are encoded in the ID itself. For more details on the definition of the Frame Modification table entry ID, see Frame Modification Entry Definition.

The supported frame modification actions/operations are:

- Replacing destination MAC address (DMAC) with specified MAC address.
- Replacing VLAN tag (TPID, VID, PCP, and DEI).
- Adding one VLAN tag.
- Deleting one VLAN tag.

The above frame modifications take effect for constructing keys in subsequent 802.1Q bridge forwarding lookups.

As for other frame modifications, the effective frame length change of the ingress frame modification actions will be reflected in any of the egress processing functions. However, frame length changes resulting from the ingress frame modification actions will not be reflected in any ingress packet processing functions (e.g. policing function). Note that the ingress frame modifications effective length change must be explicitly configured by software.

The ingress frame modification actions along with other frame modification actions (i.e. FRER sequence generation modification and egress frame modifications) are passed along with the frame as metadata up to the Ethernet Tx I/F (or Tx MAC client) for actual frame modification (except for switch management port traffic with Host Reason set to non-zero where the actual frame modification will not take place, as the frame is to be delivered as received from the link). Ingress frame modification operations on the VLAN headers are based on the VLAN classification validated outer and inner VLAN header (present and valid).

In the case of replication, all ingress frame modification actions must also be applied to each replicated frame.

When adding or replacing a VLAN tag, TPID, PCP, DEI and VID are set as follows:

- The VID can be explicitly specified or copied from outer VLAN tag header.
- The PCP and DEI can be explicitly specified, copied from outer VLAN tag header of the frame. PCP can also be derived from a specified PCP to PCP mapping profile.
- The TPID can be explicitly specified or copied from outer VLAN tag header of the frame.

In general, if an ingress frame modification action cannot be performed (e.g. a delete outer VLAN header action on a frame that has no VLAN header), this will result in a misconfiguration event. This misconfiguration event is handled by discarding the frame and incrementing the port's Rx discard count register (PRXDCR) along with the setting of the Frame Modification Misconfiguration Error Discard Reason (FMMEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0).

53.4.2.4.1.3.7 Frame Replication and Elimination for Reliability (FRER) sequence generation

Sequence generation (ingress) consists of tagging a frame with a sequence number, following which the frame can be replicated and transmitted along multiple paths for redundancy. Implemented as per the IEEE 802.1CB. Egress sequence generation is not supported.

Frames entering the switch can be identified by a stream ID, which indexes the Ingress Stream table. The contents of the ingress stream table can enable sequence generation, and if so then the ingress stream table also provides an index into a sequence generation table (See Ingress Sequence Generation Table for more detail). If the index refers to an entry that is not found in the Ingress Sequence Generation table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the

port's Rx discard count reason register 0 (PRXDCRR0). If the index is set to NULL, the ingress sequence generation function is by-passed.

The sequence generation table provides the tag type to be inserted (currently 802.1CB R-TAG, 802.1CB draft 2.0 R-TAG and HSR tag are supported), and the next sequence number value (SQG_NUM) to be used in that tag. SQG_NUM resets to 0 when the sequence generation function is initialized, increments by one after each packet that passes through the sequence generation function, and wraps around from max value (all 1's) to 0. The sequence number space is 16 bits, therefore sequence numbers will roll over and repeat every 65536 packets.

Logically, after the sequence tag (containing the generated sequence number) is applied to the frame, the frame is then replicated to be carried to its destination via multiple paths, with each copy of the frame carrying the same sequence number. Implementation-wise, the insertion of the sequence tag is done as each copy of the frame is read from internal memory and transmitted.

When inserted, the sequence tag can be located either immediately after the source MAC address of the frame, or with 1 or 2 VLAN tags between the source MAC and the sequence tag. If there was already a sequence tag in the received frame, the new sequence tag will be inserted before the existing sequence tag. Sequence number from the new sequence tag will be used in the sequence FRER recovery function, if the function is enabled.

53.4.2.4.1.3.8 802.1Q Bridge Forwarding

The 802.1Q bridge forwarding function is used to perform the required lookups to determine the outgoing ports, including flooding and broadcast/multicast handling.

Supported 802.1Q bridge forwarding functions are

- **Ingress VLAN processing** - Performs VLAN tagging checking, VLAN membership checking and Spanning Tree Protocol (STP) input port state checking. It also indicates the Filtering ID to be used by the forwarding function.
- **MAC learning (hardware)** - Entries are added to the FDB table when new unique MAC addresses are learned on the datapath.
- **IP multicast filtering** - Multicast frames are forwarded based on source IP addresses and destination IP addresses using L2 IP multicast filtering tables.
- **MAC forwarding** - Frames are forwarded based on Layer 2 destination MAC addresses using a MAC Filtering or Forwarding Database (FDB) table.
- **Egress VLAN processing** - Performs VLAN membership checking and Spanning Tree Protocol (STP) output port state checking.
- **Storm control** - Limits the amount of broadcast, multicast, and flooded unicast/multicast traffic.

53.4.2.4.1.3.8.1 Ingress VLAN Processing

The following checks are performed to determine to whether admit or drop incoming frames. See the per port registers BPDVR[RXTAGA] for more details.

- Accept Untagged frames
- Accept Priority tagged frames
- Accept Single tagged frames
- Accept Double tagged frames

For the above checks, the outer VLAN tag in a received frame is considered present if VLAN classification has deemed the outer VLAN tag valid. Similarly, The inner VLAN tag in a received frame is considered present if VLAN classification has deemed the inner VLAN tag valid. These checks do not take into consideration, any VLAN header modification specified by an earlier frame modification function.

If the frame is admitted, the next step consists of assigning a VID to the frame. All frames to be forwarded using the 802.1Q bridge forwarding function must be a member of a VLAN, either assigned from the frame VLAN header or through the port default configuration. The frame VLAN header input into this function takes into account any VLAN header modification operations specified in previous functions. For example, if the incoming frame was untagged and a VLAN header "add" action was specified

in the ingress frame modification function, the resulting VLAN header from that action is used as input to the VLAN assignment operation (i.e. treated as the VLAN header of the frame).

Assigned VID for a frame is dependent on whether the port is configured as VLAN unaware bridge or a VLAN aware bridge (see register BPDVR[RXVAM]).

- **VLAN-unaware** - If the source port of the incoming frame is attached to a VLAN-unaware bridge, a VID from the port default (BPDVR[VID]) is assigned to the frame regardless of whether the frame is tagged or untagged, and this VID is used for subsequent VLAN operations.
- **VLAN-aware** - If the source port of the incoming frame is attached to a VLAN-aware bridge, received frames are treated as described below.
  - If frame is untagged, or VLAN classification has deemed the outer VLAN tag valid with VID=0 (priority tag) or VLAN classification has deemed the outer VLAN tag not valid, and no ingress frame modifications have been specified, an internal VLAN header is built using the VID, DEI, PCP and TPID from the per port register BPDVR. This internal VLAN header is carried along with the frame as metadata, and the VID from this header is used for the subsequent VLAN operations.
  - If VLAN classification has deemed the outer VLAN tag valid with a non-zero VID (not a priority tag) and no ingress frame modifications have been specified, the assigned VID is taken from the frame's outer VLAN header.
  - If there are any ingress frame modification actions that have been specified, and the resulting ingress frame modification actions result in the frame containing an outer VLAN header with a non-zero VID (not a priority tag), the VID from this outer VLAN header is used for the subsequent VLAN operations. If the resulting ingress frame modification actions result in the frame containing no VLAN headers, or with an outer priority tag (VID=0), the frame is discarded and counted against the bridge port discard count register (BPDCR) along with the setting of the Untagged Frame Modification Misconfiguration Discard Reason (UFMMDR) flag to 1 in the Bridge port discard count reason register 0 (BPDCRR0).

Once a VID has been assigned to the frame, a lookup against the VLAN Filter table (See VLAN Filter Table for more details) using the VID assigned to the frame, is performed to determine the following:

- **VLAN membership** - The VLAN membership defines which ports belong to the VLAN. A check is performed to determine if the source port of the incoming frame matches one of the port that is a member of the VLAN. If no match is found, the frame is discarded.
- **Spanning tree group** - Spanning tree group to which the VLAN belongs is provided. The state of the source port in the spanning tree group is checked to determine action to be performed.
- **Filtering ID** - Filtering ID to be used when performing lookups against the FDB table and the L2 IPV4 Multicast Filter table.
- **VLAN handling options** - For example:
  - MAC learning options.
  - MAC forwarding options (e.g. whether to perform an FDB lookup).
  - Whether to perform an L2 IP Multicast Filtering lookups.

The related egress VLAN information retrieved from the VLAN Filter entry is carried along with the frame for usage during egress VLAN processing. If no match is found in the VLAN Filter table, information specified in the default VLAN configuration registers VFHTDECR0-VFHTDECR2 is used to determine the VLAN handling parameters and actions.

53.4.2.4.1.3.8.2 MAC Learning and Forwarding

The following tables are used to support the 802.1Q bridge forwarding operations:

L2 MAC Filtering or Forwarding Databases (FDB) table

Exact match table (augmented with a CAM for guaranteed entries) containing forwarding and/or filtering information about MAC addresses. Each table entry includes a FID and MAC address that may be unicast or multicast and a forwarding destination field containing a port bitmap identifying the associated port(s) with the MAC. The entry also specifies the egress packet processing to be performed for each of the destination ports. FDB table entries can be static or dynamic (can be aged out by software). Static

entries are added by the host whereby dynamic entries are added either by the host or by the hardware as MAC addresses are learned in the datapath. See FDB Table for more details.

The FDB is implemented as a hash table optionally augmented with a CAM for guaranteed entries. Entries are added as a hash entry first (hash space), and if an entry is unable to be added due to collision chain length having reached its maximum length, defined in the register HBTCAPR[MAX_COL], it will be added to the CAM and its associated indexed table. An entry will not be added to the hash space or CAM/indexed table if an entry limit has been hit. If there is at least one entry added to the CAM/indexed table (tracked internally), then the CAM is searched in parallel with searching of the hash table. If there is a match in the CAM, then the indexed table is read to find the full entry. If there is no match in the CAM, the hash search is checked for a match entry. This does not add any processing time since the read/search operations are done in parallel.

L2 IPv4 Multicast Filter table

Exact match table containing forwarding and/or filtering information about IP multicast addresses. The L2 IPv4 Multicast Filter table is implemented as hash table. L2 IPv4 Multicast Filter table entries can be static or dynamic (can be aged out by software). Contrary to the FDB table, entries whether static or dynamic can only be added by the host software. The following two L2 IPv4 Multicast Filter table entry types are supported:

- **IPV4 Source Specific Multicast (SSM) Multicast Filter table entry** - Each table entry includes the key type identifying the entry as a SSM table entry, a FID, source IPv4 address and destination multicast IPv4 address, and a forwarding destination field containing a port bitmap identifying the ports to which the frame should be forwarded for frames matching this entry. The entry also specifies the egress packet processing to be performed for each of the destination ports. For more details, see L2 IPV4 Multicast Filter Table.
- **IPV4 Any Source Multicast (ASM) Multicast Filter table entry** - Each table entry includes the key type identifying the entry as a ASM table entry, a FID and destination multicast IPv4 address, and a forwarding destination field containing a port bitmap identifying the port(s) within to which the frame should be forwarded for frames matching this entry. The entry also specifies the egress packet processing to be performed for each of the destination ports. For more details, see L2 IPV4 Multicast Filter Table.

An activity element is also present for each entry in the FDB or L2 IPv4 Multicast Filter table to allow the Host to age the entry if necessary. The activity element is represented as an 8-bit value where bit 0 (least significant bit) corresponds to the activity flag and bits 7-1 correspond to the activity counter.

When an FDB lookup (for the purpose of frame forwarding) or L2 IPv4 Multicast Filtering lookup finds a match, and the activity flag is set to 0, hardware will set the activity flag to 1, to indicate the entry has been accessed. In the case of impending congestion due to the hardware being heavily loaded simultaneously from both the control-plane and data-plane, hardware will not perform the above activity bit update operation to ensure adequate data-plane control-plane and command processing capacity. The activity element is updated by software when issuing the appropriate table management command as follows:

- If the activity flag is set to 1, then the entire 8-bit activity element is set to 0.
- If the activity flag is set to 0, then the 7-bit activity element counter is incremented by 1, however it does not roll over if the counter reaches the value of 127.

The MAC learning and forwarding function implements a 3-stage table lookup pipeline; MAC learning lookup followed by IP Multicast filtering and then MAC forwarding (details of this is given below).

MAC Learning

MAC learning is the process where one dynamically updates the FDB using the MAC source address of the frames received and the port in which the frames have entered the switch.

The MAC learning options (MLO) code point set by the ingress VLAN processing function determines what MAC learning processing occurs on the frame:

- 0x0 = Reserved.
- 0x1 = Disable MAC learning. SMAC FDB lookup is by-passed.
- 0x2 = Hardware MAC learning is enabled. See the Hardware MAC Learning sub-section below, for more details.
- 0x3 = Software MAC learning secure. FDB lookup based on FID and SMAC is performed and if an entry is not found, the frame is redirected to the switch management port. If an entry is found and the ingress port of the incoming frame

is not set in the FDB entry Destination Port Bitmap and BPCR[STAMVD] is set to 0 (station move allowed), the frame is redirected to the switch management port regardless of whether it is a dynamic or static FDB entry. If BPCR[STAMVD] is set to 1, the frame is discarded.

- 0x4 = Software MAC learning unsecure. FDB lookup based on FID and SMAC is performed and if an entry is not found, the frame is copied to the switch management port. If an entry is found and the ingress port of the incoming frame is not set in the FDB entry Destination Port Bitmap and BPCR[STAMVD] is set to 0 (station move allowed), the frame is copied to the switch management port regardless of whether it is a dynamic or static FDB entry. If BPCR[STAMVD] is set to 1, the frame is discarded.
- 0x5 = Disable MAC learning with SMAC validation. FDB lookup based on FID and SMAC is performed and if an entry is not found, the frame is discarded. If an entry (dynamic or static) is found and the ingress port of the incoming frame is not set in the FDB entry Destination Port Bitmap, the frame is discarded. The frame discard is counted against the bridge port discard count register (BPDCR) with discard reason BPDCRR0[MACLNFDR] set to 1.
- All other values reserved

The figure below shows the MAC learning flowchart.

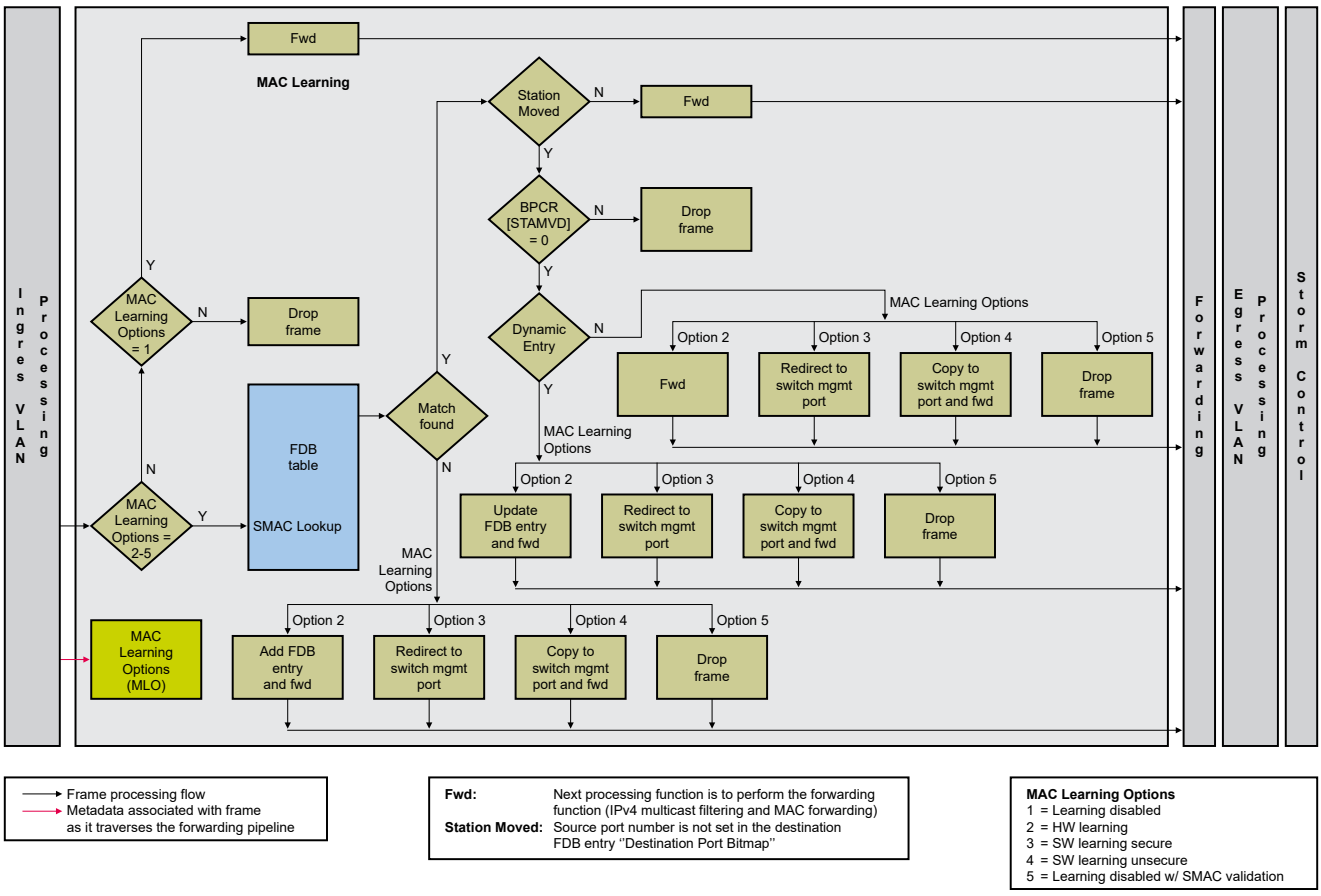

Figure 349. MAC Learning Flowchart

Hardware MAC Learning

When the hardware MAC learning function is selected, a lookup is made into FDB table using the FID and source MAC address. If there is no match then a new entry (dynamic) is added in the FDB table for that source MAC address unless:

- Maximum number of dynamic FDB entries from a port has been reached (see BPCR[DYN_LIMIT]); entries created by the MAC learning function are dynamic entries, note that software can also create dynamic entries via table management commands.

- Maximum number of dynamic FDB entries for the entire switch has been reached (see FDBHTMCR[DYN_LIMIT]); entries created by the MAC learning function are dynamic entries, note that software can also create dynamic entries via table management commands.
- Hash collision chain limit has been reached (limit is specified in HBTCAPR[MAX_COL]) and the CAM (guaranteed FDB entries) if present is full.
- Memory allocated to store the switch hash tables is full (the maximum amount of memory words available to store all hash tables entries, is indicated in the register HTMCAPR[NUM_WORDS]) or,
- Impeding congestion has been detected due to the hardware being heavily loaded simultaneously from both the control-plane and data-plane. In this situation, updating the FDB table with the learned MAC address is not performed to ensure adequate datapath and control-plane command processing capacity.

If the entry cannot be added, the frame is still forwarded normally and the Bridge Port MAC Learning Failure Status Register (BPMLFSR) is updated accordingly. The BPMLFSR register includes a bit field (w1c) for each of the possible MAC learning failure reasons.

- The per port dynamic FDB table entries limit has been reached.
- Memory allocated to store the hash tables is full (the maximum amount of memory words available to store all hash tables entries, is indicated in the register HTMCAPR[NUM_WORDS]) or FDB table dynamic entries limit has been reached.
- Hash collision chain limit has been reached (limit is specified in HBTCAPR[MAX_COL]).

If the source MAC address is found but the ingress port of the incoming frame is not set in the FDB entry Destination Port Bitmap and BPCR[STAMVD] is set to 0 (station move allowed), then the FDB entry is updated unless it is a static entry. The FDB table entry is updated by setting the ingress port of the incoming frame to 1, in the Destination Port Bitmap and setting all other ports in the Destination Port Bitmap to 0. In addition to updating the entry, the BPOR[NUM_DYN] counter for the port that has its bit changing from 0 to 1, will be incremented and the BPOR[NUM_DYN] counter for each of the ports that has its bit changing from 1 to 0, will be decremented. If it is a static entry, no update takes place and the frame moves to the next function (forwarding). If BPCR[STAMVD] is set to 1, the frame is discarded. Note that the port which has the bit changing from 0 to 1 may result in exceeding its maximum number of dynamic entries specified in BPCR[DYN_LIMIT]. If impeding congestion has been detected due to the hardware being heavily loaded simultaneously from both the control-plane and data-plane, the update to the FDB is not performed to ensure adequate datapath and control-plane command processing capacity.

No messages are sent to the host when hardware adds or updates an entry in the FDB table.

MAC Forwarding

The figure below shows the forwarding flowchart.

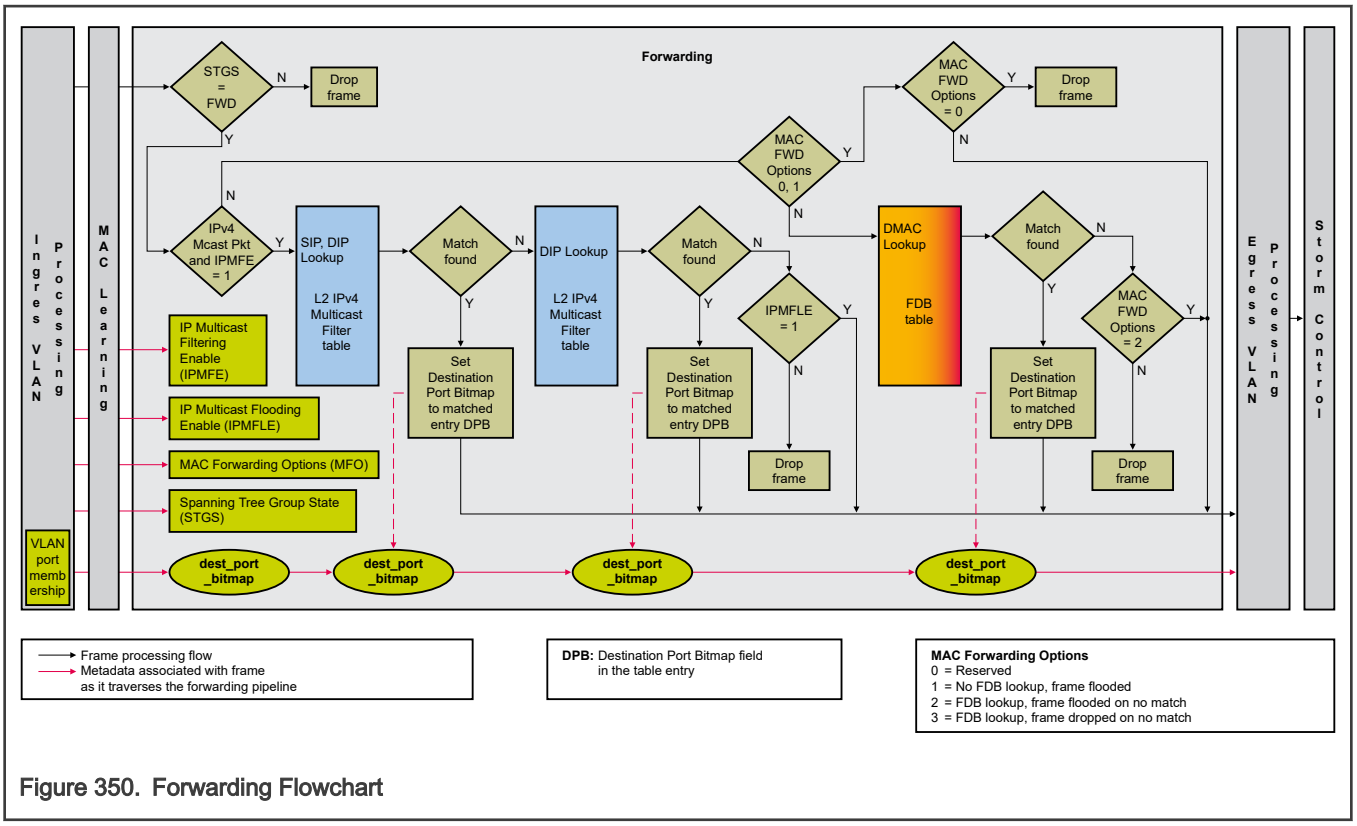

Figure 350. Forwarding Flowchart

IP Multicast Filtering

If the indicator of whether IP multicast filtering is to be performed (IP Multicast Filtering Enable (IPMFE) flag from ingress VLAN processing), is set to 1, and the frame is identified as a multicast IP packet (destination IPv4 address is 224.0.1.0-238.255.255.255), then IP multicast filtering is performed.

IP multicast filtering consists of performing a Source Specific Multicast (SSM) exact match lookup (if at least one entry added) utilizing both source IP address and destination IP address, and if there is no match, followed by Any Source Multicast (ASM) exact match lookup (if at least one entry added) utilizing destination IP address only.

If IP multicast filtering finds a match, frame is processed according to the matched entry; i.e. forward according to the port bitmap stored in the entry, followed by skipping MAC forwarding. If no match is found, frame is either admit or drop according to the setting of the IP Multicast Flooding Enable (IPMFLE) flag (from ingress VLAN processing). If the frame is discarded, the frame discard is counted against the bridge port discard count register (BPDCR) along with the setting of the IP Multicast Filter Discard Reason (IPMFDR) flag to 1 in the Bridge port discard count reason register 0 (BPDCRR0). If the frame is not identified as an IP multicast packet, processing moves to MAC forwarding.

If the indicator of whether IP multicast filtering is to be performed (IP Multicast Filtering Enable (IPMFE) flag from ingress VLAN processing), is set to 0, then processing moves to MAC forwarding.

MAC Forwarding

The MAC forwarding options (MFO) code point set by the ingress VLAN processing function determines what MAC forwarding processing occurs on the frame:

- If MFO=1, no FDB lookup is performed, the frame is flooded.
- If MFO=2, a lookup into the FDB using the destination MAC address and FID, is performed. If a match is found, the frame is forwarded according to the port bitmap stored in the entry. If the FDB lookup does not find a match, the frame is flooded.
- If MFO=3, a lookup into the FDB using the destination MAC address and FID, is performed. If a match is found, the frame is forwarded according to the port bitmap stored in the entry. If the FDB lookup does not find a match, the frame is discarded.

53.4.2.4.1.3.8.3 Egress VLAN Processing

Information obtained earlier from the VLAN Filter table entry is used to determine:

- **VLAN membership** - The 802.1Q bridge function can only forward a frame to ports that are members of the VLAN. Ports outside the VLAN membership are filtered out; i.e. their corresponding bit in the destination port bitmap is set to 0.
- **Spanning tree group** - Spanning tree group to which the VLAN belongs is provided. The state of the output port in the spanning tree group is checked to determine action to be performed. If the port state is not set to 2 (forwarding), the frame is not forwarded towards that port. No transmit discard counter is incremented unless the resulting destination port bit map is null, then the bridge port discard count register (BPDCR) is incremented with the NODESTDR reason flag set to 1 in the bridge port discard count register 0 (BPDCRR0).
- **Source pruning** - If source pruning is enabled (BPCR[SRCPRND]=0), a received frame is not allowed to be transmitted on the same port it was received. If source pruning is disabled (BPCR[SRCPRND]=1), a received frame is allowed to be transmitted on the same port it was received.
- **Egress processing actions** - For each port member of the VLAN, optionally specifies additional egress processing actions such as whether to delete and/or add a VLAN tag. These actions are specified using the Egress Treatment table. If there is no Egress Treatment entry configured or if the frame modification entry ID configured in the Egress Treatment table entry is set to null, port level egress VLAN header modifications specified through Bridge port default VLAN register (BPDVR) register are applied to the frame if the port is configured as a VLAN aware bridge.

53.4.2.4.1.3.8.4 Storm Control

A storm control policer can be specified via BPSCR0/R1 registers. A rate policer instance can be specified for each of the following types of traffic

- Multicast traffic
- Broadcast traffic
- Unknown (or flooded) unicast traffic
- Unknown (or flooded) multicast

If a frame belongs to a traffic type that has a storm control rate policer configured in BPSCR0/R1 registers, the Rate Policer Entry ID (RP_EID) specified in the register is used to access the Rate Policer Instance table. For more details on managing this table , See Rate Policer Table. If the entry referred to by RP_EID (non-NULL value) is not found in the Rate Policer table (entry has not been added to the table), or if the RP_EID is set to a value which indexes outside of the available Rate Policer table entries, the frame is discarded and counted against the bridge port discard count register (BPDCR) along with the setting of the Misconfiguration Discard Reason (MISCDR) flag to 1 in the port's bridge port discard count reason register 0 (BPDCRR0).

Rate policer instances used for storm control are distinct from the ones used for the rate policing. Rate policer instances cannot be shared between these two distinct functions. Note that a given frame can be subjected to both the storm control policing function and the rate policing function, but different rate policer instances must be used.

If the frame is being forwarded in the cut-through mode of operation, to at least one port, the initial segment size of the cut-through frame is used by the rate policer for checking if it accepts the frame. If the frame is accepted, the rate policer byte credits get updated as data is received (cut-through segment transfers).

Dropped frames by a rate policer instance are counted in against the Bridge port discard count register (BPDCR), the port's Rx discard count register (PRXDCR), the Rate Policer table entry drop counter and the Ingress Stream Count table entry counter.

53.4.2.4.1.3.9 Policing

This function implements traffic policing as per IEEE 802.1Qci (Per-Stream Filtering and Policing) to protect against time window (stream gating) and bandwidth violations (rate policing).

53.4.2.4.1.3.9.1 Stream Gating

Whether to perform stream gating is determined earlier by the stream identification and filtering function. If stream gating is to be performed, a Stream Gate Instance Entry ID (SGI_EID) is provided to access the Stream Gate Instance table.

The Stream Gate Instance table contains the stream gate configuration and operational information for the switch or an ENETC instance. Each entry contains a set of parameters that defines a single stream gate instance. A stream gate instance includes a gate control list, which specifies the time gates or time slots during which incoming frames from one or more streams will be accepted.

The gate control lists are typically generated offline, and then timely configured on each network device. To support no-downtime gate control list configuration changes, the standard requires that a network device supports two sets of gate control lists:

- **Operational gate control list** – Represents the currently active gate control list.
- **Administrative gate control list** - Provides a means of configuring a new gate control list prior to its installation in a running system. An administrative gate control list becomes operational at Config Change Time as defined in the IEEE 802.1 Qci specification and remains operational till another administrative stream gate control list is installed.

The hardware executes the gate control list cyclically based on a global time. The hardware starts executing the gate control list from the head, and then goes through the gate control entries as time goes on, and after the cycle time is passed, the hardware jumps back to the head of the gate control list.

A stream gate in a gate control list entry can be in one of the two states:

- **Open**: Frames pass through the gate
- **Closed**: Frames do not pass through the gate; frames are discarded.

There are two "Open Gate Check" modes (PSGCR[OGC]) available for determining if a frame can pass through an open gate:

- Only the start of frame needs to be within the open gate interval.
- Both the start and end of the frame need to be within the open gate interval.

For more details on managing this table, see Stream Gate Instance Table for ENETC and switch. If the entry referred to by SGI_EID is not found in the Stream Gate Instance table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). If the SGI_EID is set to NULL, the stream gating function is by-passed.

Note that a Stream Gate Instance has to be associated with streams received from the same port. Streams received from different ports cannot use the same Stream Gate Instance. This is not enforced by hardware; considered a software configuration error.

The actual stream gate control lists are stored in separate table called the Stream Gate Control List table, with their entry ID being specified in the Stream Gate Instance table. For a given Stream Gate Instance, only two stream gate control lists may be allocated to the instance. It is recommended that the entry ID for each of these two stream gate control lists be predetermined and fixed by software, and persist till the Gate Stream Instance is no longer in use.

Each Stream Gate Control List entry is of variable size, and is used to hold one stream gate control list. One or up to 256 gates can be specified for a gate control list. A list consists of one configuration 24-byte word plus a variable number of words to configure stream gates. Up to two stream gates can be specified in a word. The Stream Gate Control Entry ID (SGCL_EID) has to be specified in units of words such that it points to the first word in a stream gate control list.

The configuration word and the gate configurations for a gate control list has to be in consecutive words in Stream Gate Control List table. For example, if a gate control list starts at address offset 0x100 in SGCL table and has 9 gates specified, then, the gate list SGCL_EID is 0x100 and the stream gate control list configuration will be at address offset 0x100, configuration for gates 0 and 1 will be in 0x101, configuration for gates 2 and 3 are in 0x102, and so on, and configuration for gate 8 is in 0x105. Hence the gate control list starts at address offset 0x100 and ends at offset 0x105. As such the next gate control list can start at address offset 0x106.

For more details on managing the SGCL table, see Stream Gate Control List for ENETC and the switch.

For stream gating, frame reception timestamp can be aligned to an earlier reference timing point (e.g. at the remote port's transmit timing point). This is achieved by having the frame reception timestamp(s) adjusted by subtracting the delay specified in PSGCR[PDELAY], from the Start of Frame receive timestamp and from the End of Frame receive timestamp (in the case where PSGCR[OGC] is set to 1).

A stream gate control list contains an ordered list of gate operations. Each gate operation specifies the following:

- Gate state (open/close) that determines whether a frame is allowed to pass through the gate or not.
- Internal priority value (IPV).
- Time interval in nanoseconds.
- Interval maximum number of PDU/SDU (Protocol/Service Data Unit) bytes. An optional feature to limit the number of frame bytes that can pass an open gate during its time interval.
- Option to disable cut-through forwarding of frame if not already disabled (applicable to the switch only).

If the frame is being forwarded in the cut-through mode of operation, to at least one port, the initial segment size of the frame is used for checking interval maximum number of bytes. Frame is accepted if the accumulated interval byte count in a gate plus the number of bytes received in the first segment of the frame is less than or equal to the interval maximum number of PDU/SDU bytes, else the frame is discarded. If frame is accepted, accumulated interval byte count gets updated later when the entire frame is received. Note that in cut-through operation, it is possible that the interval maximum number of PDU/SDU bytes can be exceeded (at most by an PDU/SDU size minus the initial segment size).

If the frame is being forwarded in the store-and-forward mode of operation, to all ports identified as the destination for the frame, the frame is accepted if accumulated interval byte count in a gate plus the frame size is less than or equal to the interval maximum number of PDU/SDU bytes. Accumulated interval byte count in a gate is not updated if frame is discarded.

Statistics for stream gating related frame drops are kept in the Ingress Stream Count table.

Gate control list installation is carried on, as defined by IEEE 802.1Qci (Per-Stream Filtering and Policing)

NOTE

The 1588 timer must be initialized and configured before adding any administrative gate control list to a Stream Gate Instance. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer is in normal operation, any change to the 1588 timer configuration (for example, TMROFF_H/L), except for TMR_ADD updates, requires that all Stream Gate Instances with an operation gate control list be deleted, and for Stream Gate Instances that have no operation gate control list, that the administrative gate control list if present, be removed from the Stream Gate instance.

IERB registers:

- Stream Gating Lag Time For Timestamp Refresh Register (SGLTTR). Common for both ENETC and switch. Lag time is in units of nanoseconds. The refresh timestamp timer is used to trigger the hardware to traverse the stream gate control list up to the entry corresponding to the current time minus a lag time (value in SGLTTR) when there is no traffic being received on the port.
- Switch Stream Gate Instance Index Table Memory Allocation Register (S0SGIITMAR)
- Switch Stream Gate Control List Index Table Memory Allocation Register (S0SGCLITMAR)
- ENETC a Stream Gate Instance Index Table Memory Allocation Register (EaSGIITMAR)
- ENETC a Stream Gate Control List Index Table Memory Allocation Register (EaSGCLITMAR)

Switch / ENETC function registers:

- Stream Gate Capability Register (SGCAPR)
- Stream Gate Instance Index Table Capability Register (SGIITCAPR)
- Stream Gate Instance Index Table Memory Allocation Register (SGIITMAR)
- Stream Gate Instance Index Table Operational Register (SGIITOR)
- Stream Gate Control List Index Table Capability Register (SGCLITCAPR)
- Stream Gate Control List Index Table Memory Allocation Register (SGCLITMAR)
- Stream Gate Control List Table Memory Operational Register (SGCLTMOR) Port Rx Discard Count related Registers (PRXDCR, PRXDCRR0/1). When a discard is due to stream gate function the discard count will be updated in this register and following reasons will be specified.

— [SGCDR] - Stream Gate Closed discard reason.

— [MSDUEDR] Maximum SDU Exceed discard reason

53.4.2.4.1.3.9.2 Rate Policing

Whether to perform rate policing is determined in prior ingress processing functions. A rate policer instance (or more specifically a Rate Policer Entry ID (RP_EID)) can be specified in the Ingress Port Filter table, Ingress Stream table, and/or Ingress Stream Filter table. When more than one source specifies a rate policer instance, only one instance can be applied to a frame with the following precedent (with 1 having higher precedence):

1. Ingress Stream Filter table
2. Ingress Stream table
3. Ingress Port Filter table

By default (prior to any lookups), the RP_EID is set to NULL, meaning that no rate policing is to be applied to the frame.

Rate policing (or flow metering) is compliant to IEEE 802.1Qci specification.

If rate policing is to be performed, the Rate Policer Entry ID (RP_EID) specified by one of the above table lookups, is used to access the Rate Policer Instance table. For more details on managing this table , see Rate Policer Table for ENETC and Rate Policer Table for the switch. If the entry referred to by RP_EID (non-NULL value) is not found in the Rate Policer table (entry has not been added to the table), the frame is discarded and counted against the port's Rx discard count register (PRXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Rx discard count reason register 0 (PRXDCRR0). If the RP_EID is set to NULL, the rate policing function is by-passed.

The Rate Policer table contains the rate policer configuration and operational information for the entire function (switch or an ENETC function). Each entry contains a set of parameters that defines a single rate policer instance. A rate policer instance controls the amount of traffic (or bytes) that is allowed to go through for a particular received flow of frames.

The MEF (Metro Ethernet Forum) 10.3 technical specification "bandwidth profile algorithm for one flow per envelope processing without token sharing", is used.

When the rate policer instance is configured to operate in the color-aware mode, the incoming frame "color" is indicated through the Drop Resilience (DR) associated with the frame. When the rate policer instance is configured to operate in the color-blind mode, the incoming frame is assumed to always be green for the rate policer. The figure below shows the default decision making process. Some of the default decisions can be modified by configuration, for example setting MR, DOY or NDOR in a rate policer instance will change the default packet marking and drop decisions. Dropped frames by a rate policer instance are counted in against the port's Rx discard count register (PRXDCR), the Rate Policer table entry drop counter and the Ingress Stream Count table entry counter.

If the frame is being forwarded in the cut-through mode of operation (switch only), to at least one port, the initial segment size of the cut-through frame is used by the rate policer for making the decision to declare an arriving frame as Green, Yellow, or Red and then based on the color assigned to the frame, whether the frame is dropped or marked (overwriting the Drop Resilience (DR) assigned to the frame). If the frame is accepted, the rate policer byte credits get updated as data is received (cut-through segment transfers). If the total frame length turns out to be greater than the number of tokens in the bucket that was used to declare the color of the frame, then the bucket token count will go negative (effectively borrowing future tokens). This has a side effect of increasing the effective committed or excess burst size by up to a maximum frame size minus the size of the initial cut-through frame segment.

NOTE

The timer function must be configured and enabled before any rate policer instance is enabled (see Rate Policer table entry Functional Enable Element Data). Either the default nanosecond timer or the 1588 timer can be used to generate the required nanosecond resolution time. The default nanosecond timer is configured and enabled by default out of reset. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer is in normal operation, any change to the 1588 timer configuration (for example, TMROFF_H/L), except for TMR_ADD updates, requires that all rate policer instances be disabled (see Rate Policer table entry Functional Enable Element Data).

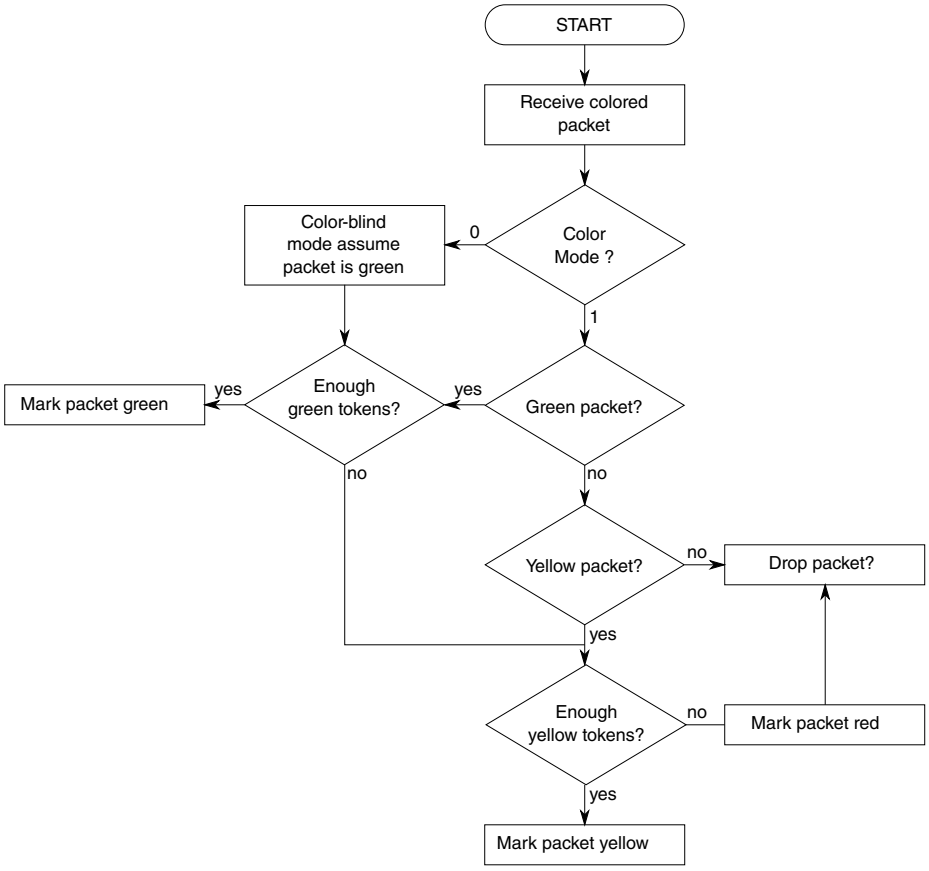

Figure 351. Bandwidth Profile Coloring Flow Diagram

53.4.2.4.1.3.10 Congestion Management

Buffer pool assignment and checking function is performed to ensure that there is available memory space to accommodate the new frame. If there is available memory space, then buffer pool accounting is updated accordingly, otherwise the frame is dropped.

The buffer pool is selected by mapping the IPV of the frame to a buffer pool ID using the port buffer pool mapping configuration register 0/1 (PBPMCR0/1). This mapping allows each IPV (or set of IPV's) to be mapped to a specific buffer pool for QoS distinction.

53.4.2.4.1.4 Replication and Egress Packet Processing

The Replication and Egress Packet Processing block is responsible for implementing the frame replication if needed, and packet processing functions in the context of the output port(s).

The switch destination port or set of destination ports to which the frame should be forwarded are determined by the Ingress Packet Processing block and are expressed as a destination bitmap, one bit per destination port.

For each of the ports that has its corresponding bit set in the destination bitmap, there may be the need to access the Egress Treatment table to retrieve the egress packet processing actions to be performed on the frame such as:

- **Egress frame modification** - Provides ability to remove, add and modify a single VLAN tag. It also provides the ability to modify Ethernet payload and Frame Replication and Elimination for Reliability (FRER) related egress header modifications. The actual frame modifications are not performed at this point, instead metadata is passed along with the

frame so that the actual frame modifications on the frame can be performed when the frame is being transferred to the MAC.

- **Frame Replication and Elimination for Reliability (FRER) sequence recovery** - Sequence recovery processing at this point involves checking that only one frame for each sequence number is passed, all duplicates are discarded. This way, multiple copies of the same frame that have been sent along different paths for redundancy will result in the first arriving frame being passed, and all other copies being removed. Implemented as per the IEEE 802.1CB.

In the case where the frame is destined to more than one port, only the frame descriptor is actually replicated, the frame itself is not. The frame is then passed to the Egress Queuing and Traffic Management block where it will be queued internally. In the case where the frame is destined to more than one port, multiple frame descriptors are passed, one for each egress port. If there is no memory available to store a frame descriptor, the hardware waits until memory becomes available; no egress frame drops are performed for this condition

53.4.2.4.1.4.1 Egress Treatment table access

Each entry in the Egress Treatment table contains the egress packet processing actions to be applied to a grouping or scope of packets exiting on a particular egress port of the switch. A scope of packets, for example could be the packets exiting a particular VLAN, matching a particular 802.1Q bridge forwarding entry or belonging to a stream identified at ingress. See Egress Treatment Table, for more details on the Egress Treatment table.

The means by which previous functions convey the Egress Treatment table entries to be accessed, is through the Egress Treatment group. An Egress Treatment group represents a group of Egress Treatment table entries.

Table entries belonging to the same group must have sequentially numbered indices and each table entry specifies the treatment of a scope of packets when they exit through a particular port of the switch. To conserve Egress Treatment table entries, an Egress Treatment group can omit table entries for ports for which there is no special treatment for that scope of packets. Therefore within the hardware, an Egress Treatment group is determined by a base index (first Egress Treatment table entry of the group) and an applicability port bitmap (a bitmap corresponding to all ports of the switch) which indicates (with a 1) which ports have Egress Treatment table entries. If the entry is not found in the Egress Treatment table (entry has not been added to the table), the frame towards that port associated with that entry is discarded. The frame discard is counted against the port's Tx discard count register (PTXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Tx discard count reason register 0 (PTXDCRR0).

Hardware allows a packet to belong to two scopes (or groupings) for the purpose of egress treatment, a primary (narrower) scope that is nested within a broader secondary scope. This is achieved by providing the ability to assign a primary and secondary Egress Treatment group to each packet. As a packet egresses on a particular port, hardware will only apply the egress processing actions defined by the secondary Egress Treatment group if there is no egress processing actions defined for that port by the primary Egress Treatment group or no primary Egress Treatment group has been assigned to the packet.

Ingress Stream table entries and FDB/L2 IPv4 Multicast filter table entries contain fields that allow matching frames to be (optionally) assigned to a primary Egress Treatment group. They contain a base index of the group and fields to convey the applicability port bitmap of the group. A primary Egress Treatment group assignment from the FDB/L2 IPv4 Multicast filter table has precedence over any assignment made via the Ingress Stream table.

The secondary Egress Treatment group may only be assigned through a lookup against the VLAN Filter table.

An example of a use case that makes use of both treatment groups simultaneously would be an ingress stream that forwards its packets through the 801.Q bridge forwarding function with the requirement to apply a specific egress treatment for that stream and not the egress treatment configured on the VLAN to which the stream belongs. In this example, other packets exiting the same VLAN but not identified to belong to that stream have the requirement of using the egress treatment configured on the VLAN. This use case can be supported with using both the primary and secondary treatment groups; i.e. packets belonging to the stream would be assigned 2 treatment groups (primary (stream) and secondary (VLAN)) whereby packets not belonging to the stream would be assigned only one treatment (secondary (VLAN)).

For each port that has its bit set in destination port bitmap, hardware determines the Egress Treatment table entry ID (or index) as follows:

1. Checks if the port has its bit set in the applicability port bitmap of the primary Egress Treatment group. If so then the index to access the Egress Treatment table is computed by adding an offset to the base index of the primary Egress Treatment group. That offset is derived from the applicability port bitmap as follows: starting from the lowest significant

bit of the bitmap, the first encountered bit set to 1, corresponds to offset 0, and so on. This continues till the port location in the bitmap is reached. If the port hasn't had its bit set in the applicability port bitmap of the primary Egress Treatment group, then step 2, below, is executed.

2. Checks if the port has its bit set in the applicability port bitmap of the secondary Egress Treatment group. If so then the index to access the Egress Treatment table is computed by adding an offset to the base index of the secondary Egress Treatment group. That offset is derived from the applicability port bitmap as follows: starting from the lowest significant bit of the bitmap, the first encountered bit set to 1, corresponds to offset 0, and so on. This continues till the port location in the bitmap is reached.

53.4.2.4.1.4.2 Egress frame modification

Egress frame modifications can be specified through the Egress Treatment table. Each Egress Treatment table entry stores a Frame Modification table entry ID. Bits 15-13 of the 32-bit Frame Modification table entry ID qualify whether the Frame Modification table entry ID is an index into the Frame Modification table or the frame modification actions are encoded in the Frame Modification table entry ID itself, and thus allowing the configuration of basic frame modification actions without needing to configure (or add) a Frame Modification table entry. For more details, see Frame Modification Table. When bits 15-13 of the Frame Modification table entry ID are all set to 000b, the modification table entry ID represents an index into the Frame Modification table. If the index refers to an entry that is not found in the Frame Modification table (entry has not been added to the table), the frame is discarded and counted against the port's Tx discard count register (PTXDCR) along with the setting of the Invalid Table Entry Discard Reason (ITEDR) flag to 1 in the port's Tx discard count reason register 0 (PTXDCRR0). When bits 15-13 of the Frame Modification table entry ID are set to a value other than 000b, the modification actions are encoded in the Entry ID itself. Note that bits 31-16 are reserved in the entry ID. For more details on the definition of the Frame Modification table entry ID, see Frame Modification Entry Definition.

Following are the egress packet modification actions/operations that can be specified through an entry in the frame modification table:

- Delete sequence generation tag (R-TAG, draft 2.0 R-TAG or HSR).
- Replacing destination MAC address (DMAC) and/or source MAC address (SMAC) with specified MAC address or copied from frame L2 header.
- Replacing VLAN tag (TPID, VID, PCP, and DEI).
- Deleting one VLAN tag.
- Adding one VLAN tag.
- Replacing up to 128 bytes of Ethernet payload.*
- Removing entire Ethernet payload and replacing with up to 2047 bytes of new payload.*
- Removing entire frame and replacing with a new frame of up to 2047 bytes.*

__ *Not valid for frames destined for pseudo link, or for any frames on an ASIL-B enabled device.

When adding or replacing a VLAN tag, TPID, PCP, DEI and VID are set as follows:

- The VID can be explicitly specified or copied from outer VLAN tag header of the frame.
- The PCP can be explicitly specified, copied from outer VLAN tag header or derived from a QoS to PCP mapping profile. PCP can also be derived from a specified PCP to PCP mapping profile.
- The DEI can be explicitly specified, copied from outer VLAN tag header or derived from a DR to DEI mapping.
- The TPID can be explicitly specified or copied from outer VLAN tag header of the frame.

For a particular port, if there is no Egress Treatment entry configured or if the frame modification entry ID configured in the Egress Treatment table entry is set to null, and the 802.1Q bridge forwarding function was executed, port level egress VLAN header modifications specified through Bridge port default VLAN register (BPDVR), are applied to the frame if the port is configured as a VLAN aware bridge (BPDVR[RXVAM=0]).

The egress frame modification actions along with other frame modification actions (i.e. FRER sequence generation modification and ingress frame modification) are passed along with the frame as metadata up to the Ethernet Tx I/F (or Tx MAC client) for actual frame modification (except for switch management port traffic with trap reason set to non-zero).

As for other frame modifications, the effective frame length change of the egress frame modification actions are reflected in the frame length metadata. Note that the egress frame modifications effective length change must be explicitly configured by software.

The updated frame length metadata is used by the egress queue scheduling and management function, which is executed prior to applying the frame modification actions to the frame, to determine the exact length of a frame transmitted on a link.

In general, if an egress frame modification action cannot be performed (e.g. a delete outer VLAN header action on a frame that has no VLAN header), this will result in a misconfiguration event. This misconfiguration event is handled according to the setting of the port's PFMCR register.

53.4.2.4.1.4.3 Frame Replication and Elimination for Reliability (FRER) sequence recovery

FRER recovery consists of recognizing packets with a sequence tag (R-TAG, draft 2.0 R-TAG or HSR tag), extracting the sequence number from that tag, and passing only one packet for each sequence number, rejecting all duplicates. This way, multiple copies of the same packet that have been sent along different paths for redundancy will result in the first arriving packet being passed, and all other copies removed.

Implementation-wise, the FRER recovery function in NETC is performed right before egress queuing in the switch, such that accepted packets are queued and rejected packets are discarded instead of being queued.

An Egress Treatment table entry (see Egress Treatment Table for more details) can specify the execution of FRER recovery function, and if so then the Egress Treatment table entry also provides an index into a Egress Sequence Recovery table (see Egress Sequence Recovery Table for more details).

Also note that cut-through forwarding must be disabled on any stream in which FRER recovery is enabled, because only frames that have passed FCS check must be passed to the recovery function. This is to prevent the possibility of a frame with bad FCS from being passed on by the recovery function.

The Egress Sequence Recovery table contains one entry per recovery function, and each entry contains a number of configuration elements, whose value is set when the table entries are configured, and operational elements, which are managed by the hardware and can be queried by software.

Summary of recovery function configuration element:

- **SQ_TAG (3b):** Indicates the sequence tag type (no tag, R-TAG, draft 2.0 R-TAG or HSR tag) expected by the recovery function. If a packet passing through the recovery function does not have a sequence tag, or the sequence tag type does not match SQ_TAG, then the packet is treated as a tag-less packet.
- **SQR_TNSQ (1b):** Take packets with no Sequence. Specifies the action taken (accept or reject) on packets passing through the recovery function (using the vector recovery algorithm) that are tagless, i.e. with no sequence tag or with a sequence tag type that does not match SQ_TAG. Used only if SQR_ALG = Vector recovery algorithm. If SQR_ALG = Match recovery, then tagless packets are always accepted.
- **SQR_TP (12b):** Recovery Timeout Period. Specifies the recovery timeout period in increments of 1.048576 milliseconds. A value of 0 disables recovery timeout. Each recovery function stores a timestamp of the last packet accepted (for sequence recovery) or the last packet seen (for individual recovery). Each time a packet passes through the recovery function, the time that has expired since the last packet timestamp (current time minus last packet time) is calculated, and if the expired time exceeds the configured recovery timeout period, then the recovery function is reset. The recovery timeout mechanism means that if a recovery function somehow gets out of step with its corresponding sequence generation function, then after the timeout period the next received packet will cause the recovery function to be reset, and data will again be passed.
- **SQR_ALG (1b): Recovery function algorithm:** Vector or Match. After reset, the vector recovery algorithm starts by always accepting the first received packet as valid. After the first packet has been accepted, all subsequent packets whose sequence number is in the window (last sequence number accepted +/- (recovery history length-1)) are checked against the recovery history to see if a previous packet with the same sequence number has already been accepted, and if so the current packet is rejected, otherwise it is accepted and the recovery history is updated to indicate the newly accepted sequence number. Packets whose sequence number falls outside of the recovery history window are rejected

and counted as rogue packets. The match recovery algorithm starts by always accepting the first received packet as valid, same as vector recovery. After the first packet has been accepted, all subsequent packets either match the last packet number accepted, and are therefore discarded, or do not, in which case they are accepted. The recovery history is not used by the match recovery algorithm.

- **SQR_TYPE: Recovery Function type:** Sequence or Individual. The recovery function type affects the way recovery timeout works. For a sequence recovery function, the stored packed timestamp is updated only for accepted packets, it is not updated for rejected packets. This means that a sequence recovery function that is out of step and is continually rejecting packets will be reset after the timeout period is reached, allowing it to resume sending packets. For an individual recovery function, the stored packed timestamp is updated for all packets. This means that an individual recovery function will not timeout even if all received packets are rejected, and can only timeout if packets stop arriving for a long time (timeout period or greater), and then start arriving again. The individual recovery function is intended to protect against a stuck transmitter that is sending the same packet over and over, by removing the repeating sequence numbered packets without timing out. Note that the implementation doesn't support performing individual recovery followed by sequence recovery.
- **SQR_HL (7b):** Recovery History Length. The history length used by the vector recovery algorithm is equal to SQR_HL + 1. This field is used only if SQR_ALG = Vector Recovery. The maximum supported history length is SoC specific and is limited by the width of the internal memory resource used to store the sequence recovery history. The maximum supported value of SQR_HL is indicated by FWDSQRCAPR[SQR_MAX_HL]. Any attempt to set a history length larger than the maximum supported will result in the history length being set to its maximum. The minimum valid history length for vector recovery is 2, and attempting to set a smaller history length of 1 (SQR_HL = 0) will result in a history length of 2.

Summary of recovery function operational data:

- SQR_NUM (16b): Holds the highest sequence number value received so far by the recovery function, or 0xFFFF after reset of the recovery function. The sequence number is an unsigned integer that rolls over from max to 0, therefore at the rollover boundary sequence number 0 is treated as larger than sequence number 0xFFFF.
- SQR_HISTORY (up to 128b): Recovery History. This is a bit vector that maintains a history of the sequence numbers of recently received packets, with each bit corresponding to sequence numbers from SQR_NUM down to SQR_NUM ? SQR_HL + 1. A 1 in a history bit indicates that a packet with that sequence number has been previously received, a 0 indicates that no packet with that sequence number has yet been received.
- TAKE_ANY (1b): Accept the next packet, regardless of its sequence number. This is set to 1 when the recovery function is reset, and cleared after the first packet is received. The recovery function always accepts the first packet after reset, which updates SQR_NUM and SQR_HISTORY. All subsequent packets are then accepted or rejected based on their sequence number and the recovery algorithm used.
- SQR_TS (12b): Recovery timestamp. This is the timestamp of the last packet accepted (for sequence recovery) or the last packet seen (for individual recovery).

In addition to the above listed configuration and operational elements, each recovery function maintains a number of statistics counters, which are described in Table 668.

Latent error detection provides a mechanism for detecting the failure of a path in a system using FRER to provide multiple redundant paths for a stream of packets. The receiver cannot detect such a failure since FRER is still providing valid packets from another path that has not failed, therefore detection of a path failure must be done at the point where the replicated packets are recovered and accepted or rejected.

The 802.1CB standard specifies that every instance of the sequence recovery function must also support a latent error detection function. But unlike the sequence recovery function, the latent error detection function is a periodic function driven by timers, not by packet arrivals.

Latent error detection operates on the assumption that, in a properly functioning Compound Stream employing n paths into the current system, there will be n - 1 packets discarded for every packet passed through the sequence recovery function (latent error detection is not used for individual recovery functions).

The latent error detection function is triggered periodically, and calculates the difference between the actual and expected number of rejected packets (expected = PassedPackets * (num_paths - 1)), and triggers an error if this difference exceeds a configured threshold.

In NETC the latent error detection function is performed in software. The Egress Sequence Recovery table query command is used to periodically read the PassedPackets and DiscardedPackets counters for each sequence recovery function that is in use, and determine if a latent error needs to be signaled.

53.4.2.4.1.5 Egress Queuing and Traffic Management

Frames received from the Replication and Egress Packet Processing block are queued internally onto Egress Traffic Management (ETM) class queues. ETM class queues are queues of frame descriptors and provide the main buffering for frames waiting to be scheduled for transmission to the port. For each outgoing switch port, a total of 8 ETM class queues is provided. Within a port, class queues are numbered from zero to N-1, where N is the number of class queues (currently at 8). There is a one-to-one mapping between class queues and traffic classes, class queue 0 maps to traffic class 0, class queue 1 to traffic class 1, and so on. Frames are placed in the appropriate queue based on the internal queuing priority (IPV) and can be dropped based on the internal drop priority (DR). An IPV to class queue number mapping is specified in the PIPV2QMR0 register. Class queue state, that is whether a class queue is empty or contains one or more frames, is indicated in PQOR register.

Egress traffic management processing involves the following mechanisms (details of this are given in the following sections).

- **ETM class queue scheduling** - Determines which frame to send next when an outgoing link is free. Used primarily to manage the allocation of bandwidth among ETM class queues.
- **ETM class queue congestion management** - Manages the queue sizes by primarily deciding when to start dropping frames. Multi priority (color-aware) tail drop based on instantaneous queue depth is supported.

A switch port can be configured to support IEEE 802.1Qbu preemption (if capability is provided). Preemption is enabled on a per port basis by setting MAC_MERGE_MMCSR[ME] to 1 or 2. The ability to designate one or more traffic classes (or class queues) as express (and the remaining traffic classes as preemptable) means that, when an express frame is ready for transmission and a preemptable frame is already in the process of being transmitted, the delay before the express frame transmission starts is at worst the sum of the minimum final (64B) and non final (MAC_MERGE_MMCSR[RAFS]) fragment sizes minus four octet times and will often be 64 octet times or less. For more details, see Preemption.

53.4.2.4.1.5.1 ETM Class Queue Scheduling

Following scheduling algorithms are supported:

- **IEEE 802.1Qav** - Credit-based shaping (CBS), also referred to as Forwarding and Queueing Enhancements for Time Sensitive Streams (FQTSS). A maximum of 7 traffic classes is supported with credit-based shaping (CBS) enabled. CBS should be enabled on numerically the highest traffic class(es). CBS requires that IEEE 802.1Qbv be enabled, with or without a gate control list configured.
- **IEEE 802.1Qbv** - Enhancements for Scheduled Traffic (EST), which provides time "slots" for specific classes of traffic in a manner similar to TDM. EST is also referred in the document as to 'time gate scheduling'.
- **Strict priority and fair queuing** - Configurable combinations of strict priority and fair queuing are supported. A proprietary algorithm, Weighted Bandwidth Fair Scheduling (WBFS) is used to implement the weighted fair queuing function. WBFS is not supported if EST is enabled or if preemption is enabled, that is only strict priority can be configured if EST and/or preemption are enabled.

A physical port supporting IEEE 802.1Qbu frame preemption contains two MACs; that is, MAC 0 and MAC 1. MAC 0 is called the express MAC and is used to handle the express traffic, whereby MAC 1 is called the preemptable MAC and is used to handle the preemptive traffic. When preemption is enabled, the express traffic classes tier and the preemptable traffic classes tier are scheduled independently based on the next transmission opportunity from their respective link tier. Furthermore, in-flight data is tracked and limited independently for both MACs using the same comfort threshold configured in the IERB register LaTXBCCTR.

When the port is attached to a pseudo MAC, the internal flow control signals from the pseudo link are connected directly to the scheduler. When asserted, the scheduler enters a pause state where it stops scheduling frames for all traffic classes. When de-asserted, the scheduler resumes to normal transmission of frames.

In order to support 802.1Qbv, the scheduling structure supports the concept of ‘transmission gates’. A transmission gate is a construct that connects or disconnects the scheduler (or the transmission selection function) from a traffic class (or queue), allowing or preventing the scheduler from selecting frames from that traffic class. A transmission gate has two states: open and closed. Only frames in a traffic class with an open transmission gate are eligible for scheduling.

When 802.1Qbv is disabled (or enabled but no gate control list is operational), the states of the transmission gates are set according to the state values configured in PDGSR[DGS_TC*n*], where '*n*' is the traffic class number. The power-on-reset settings for PDGSR[DGS_TC*n*], are gate open. The PDGSR[DGS_TC*n*] settings can be written at any time and take effect immediately if no gate control list is operational or if 802.1Qbv is disabled. When a traffic class transmission gate is set to the 'closed' state, frames are still queued onto its ETM class queue unless congested, but frames remain in the class queue as long as the transmission gate is closed.

The figure below shows ETM queuing structure, and with 2 traffic classes configured with CBS.

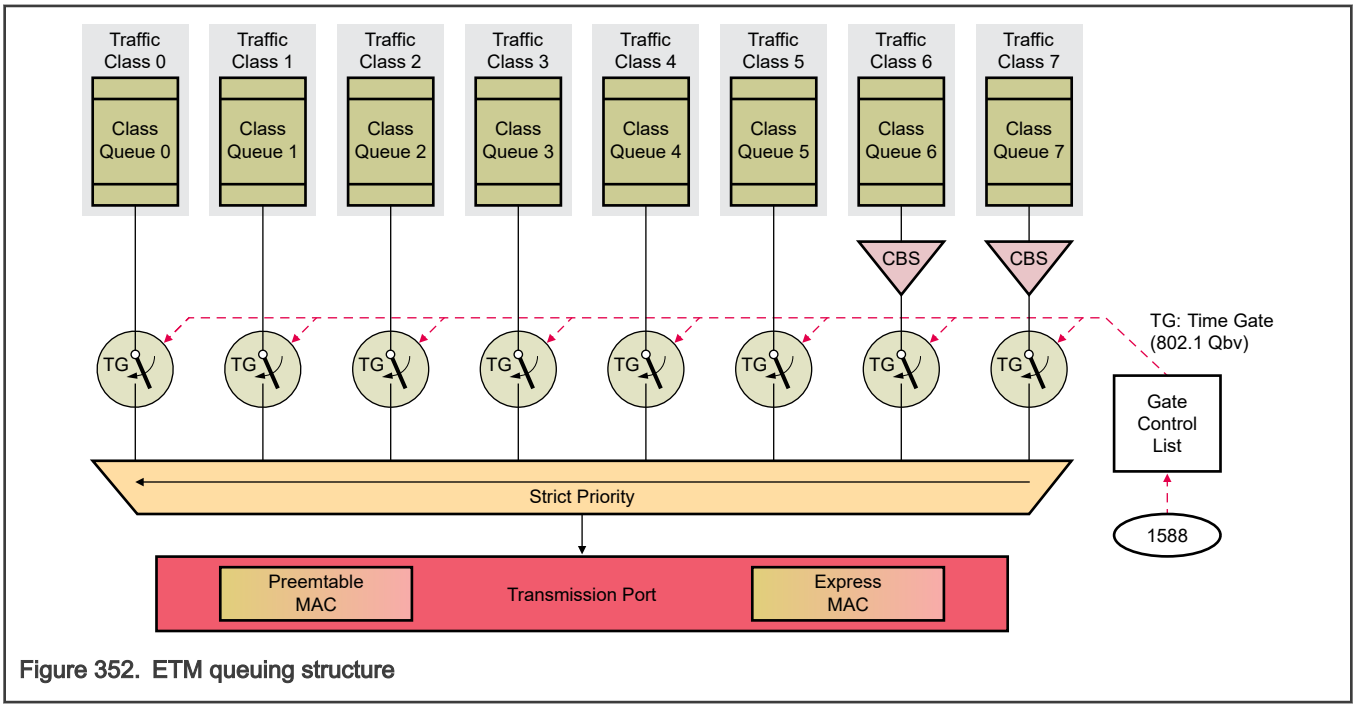

Figure 352. ETM queuing structure

53.4.2.4.1.5.1.1 Credit-Based Shaper - IEEE 802.1Qav

A credit-based shaper is implemented, as per IEEE 802.1Qav (Forwarding and Queueing Enhancements for Time Sensitive Streams (FQTSS)), which is needed for applications requiring bandwidth allocation. The credit-based shaper acts independently, per traffic class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. In order for the credit-based shaper algorithm to operate as intended, it is necessary for all traffic classes that support the algorithm to be numerically higher than any traffic classes that support the strict priority algorithm.

The Audio Video Bridging (AVB) profile specification (IEEE 802.1BA) states that the sum of AVB Class A and Class B traffic may not exceed 75% of the port transmit rate. The following example uses 70% for AVB frames and 30% for non-AVB frames. AVB class A and B uses one credit-based shaper each, while non AVB classes do not use any credit-based shapers.

Table 527. Bandwidth allocation example for AVB

Class	Percent Bandwidth (total 100%)
AVB Class A	50%
AVB Class B	20%
Non-AVB classes	30%

The following bandwidth availability parameters exist for each port, and for each traffic class that supports the credit-based shaper algorithm.

- *idleSlope*

  The actual bandwidth that is currently reserved for use by the queue(s) associated with a traffic class. Once the frame transmission is complete, *credit* increases back to zero at the rate of *idleSlope*, at which point, a further frame can be selected for transmission. Credits also increase at the rate of idleSlope up to *hiCredit* when there are frames available to send waiting for conflicting traffic to complete. If there is an operational gate control list that is active, then credits are accumulated only while the gate for the credit-based shaper traffic class, is open.

- *sendSlope*

  Credit consumption (per byte) while traffic class is transmitting is calculated as: sendSlope = idleSlope - portTxRate. If a class had 100% bandwidth, sendSlope would be 0, allowing for continuous transfers.

- *hiCredit*

  hiCredit is the maximum number of credits that can be accumulated by the credit-based shaper. The hiCredit is dependent on the maximum interference time for the traffic class.

  For the AVB Class A (highest priority), hiCredit is calculated as follows:

  hiCredit = maxSizedFrame * (idleSlope/portTxRate)

  For the AVB Class B (second highest priority), the maximum interference size is equal to the maximum burst size for the AVB Class A plus the maximum interference size for SR class A (which is equal to the maximum frame size for the port). Maximum burst size for the AVB Class A is calculated as follows:

  maxAVBClassABurst = (RA * M0)/(R0 - RA) + MA (equation (L-16) in IEEE Std 802.1Q-2018), where

  — RA: idleSlope for AVB Class A

  — R0: port transmit rate (specified in PCR[PSPEED])

  — M0: maximum sized frame for the port

  — MA: maximum sized frame for AVB Class A

  hiCredit = (maxAVBClassABurst + maxSizedFrame) * (idleSlope/portTxRate)

  The maximum sized frame for a traffic class is determines by PTCaTMSDUR[MAXSDU] (where a is the traffic class number)

- *loCredit*

  loCredit is the minimum number of credits that can be accumulated by the credit-based shaper. The loCredit is computed by hardware as follows:

  loCredit = (idleSlope - portTxRate) * maxSizedFrame/portTxRate

The figure below shows the different stages of credit changes for a traffic class as it transmits, waits or is idle.

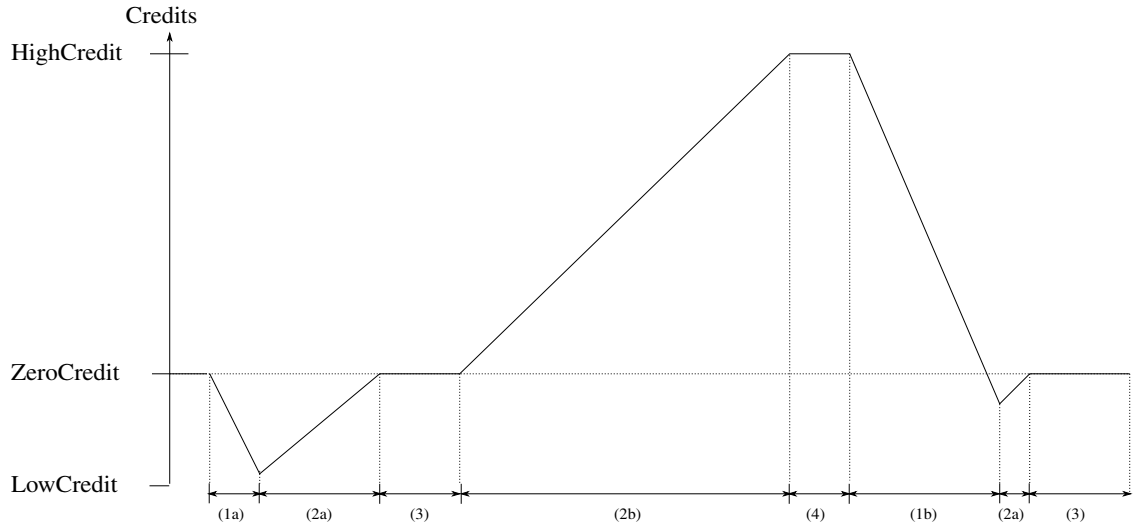

Figure 353. Stages of credit changes for shaper

To program the credit-based shaper for a class, follow these steps:

1. Enable time gate scheduling for the port by setting PTGSCR[TGE] to 1. An administrative gate control list does not need to be configured, for the credit-based shaper to operate. This also requires the timer function to be configured and enabled. Either the default nanosecond timer or the 1588 timer can be used to generate the required nanosecond resolution time.
2. Enable credit-based shaper for the port traffic class *a* by setting PTC*a*CBSR0[CBSE]=1.
3. Determine *hiCredit* from the formula described above and set PTC*a*CBSR1[HI_CREDIT].
4. Set the allocated bandwidth for the traffic class credit-based shaper which ranges from 1-100 (%), in register PTC*a*CBSR0[BW]. The total bandwidth for all enabled shapers must not exceed 100% or the allotted bandwidth.
5. Set PTXSDUOR register with the appropriate per frame overhead; that is number of bytes to be added to the actual length of each frame, to determine the Physical Layer PDU (PPDU) frame length on the link.

53.4.2.4.1.5.1.2 Time Gate Scheduling - IEEE 802.1Qbv

IEEE 802.1Qbv, also referred in this document as time gate scheduling, introduces a time based transmission mechanism operating on a global (offline) configured periodic schedule called the gate control list. IEEE 802.1Qbv amendment has been incorporated in the IEEE standard 802.1Q 2018; the mechanism itself is referred in the standard as "enhancements for scheduled traffic."

The mechanism is shown in the diagram below.

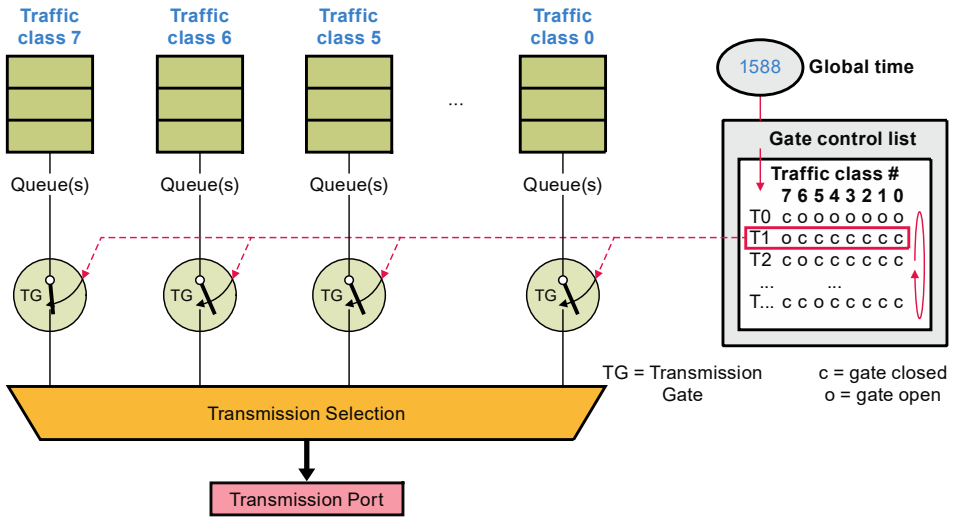

Figure 354. Time Gate Scheduling - IEEE 802.1Qbv

Each traffic class has a gate, which controls if the traffic class is open or closed. Only frames in traffic classes with open gate are eligible for transmission. For the switch, each traffic class has a single queue, and for ENETC, it is possible that a traffic class may have more than one queue (or Tx BD ring). In this case, all queues (or Tx BD rings) in a traffic class have/shared the same gate state.

The gate state in each traffic class is controlled by the gate control list. A gate control list consists of an ordered list of gate control entries, where each entry specifies an 8 bit gate state vector where each bit (one per gate), indicates whether the gate is open or closed. The gate control entry also specifies the time duration for the states.

The gate control lists are typically generated offline, and then timely configured on each network device. To support no-downtime gate control list configuration changes, the standard requires that a network device supports two sets of gate control lists:

- **Operational gate control list** – Represents the currently active gate control list.
- **Administrative gate control list** - Provides a means of configuring a new gate control list prior to its installation in a running system.

The hardware executes the (operational) gate control list cyclically based on a global time. The hardware starts executing the gate control list from the head, and then goes through the gate control entries as time goes on, and after the cycle time is passed, the hardware jumps back to the head of the gate control list.

The transmission selection process (or the scheduler) which executes at the port level, may only select frames from traffic classes that have their gates in the open state. The transmission selection uses a strict priority algorithm to select the next frame for transmission by querying/checking the open traffic classes in descending order from the highest priority traffic class to the lowest priority traffic class. If the open traffic class being queried has one or more frames waiting to be transmitted, then the scheduler determines if the frame at the head of the queue can be transmitted entirely before its traffic class gate closes. If it is determined that there is insufficient time available to transmit the entirety of that frame (transmission of the frame does not fit in the current open window), that frame will remain queued, and an attempt to schedule it will be made in the next open window associated with the frame traffic class. The transmission selection process then moves to the next lowest priority traffic class that has its gate open.

To set up time gate scheduling, follow these steps:

1. The 1588 timer must be initialized and configured before enabling time gate scheduling. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer is in normal operation, any change to the 1588 timer configuration (for example, in TMROFF_H/L), except for TMR_ADD updates, requires that time gate scheduling be disabled ((PTGSCR[TGE]=0). The state of each gate while time gate scheduling is disabled, can be controlled via register PDGSR[DGS_TCn], where n is the traffic class number.
2. Enable time gate scheduling for the port by setting PTGSCR[TGE] to 1.

3. The initial state of each gate, when no gate control list is operational, is determined by the setting in PDGSR[DGS_TCn], where n is the traffic class number. The power-on-reset setting for PDGSR[DGS_TCn] is gate open. The initial state of each gate can be changed by configuring PDGSR[DGS_TCn]. Note that the PDGSR[DGS_TCn] settings can be written at any time and take effect immediately if no gate control list is operational or if time gate scheduling is disabled. Thus, it may be required to re-configure PDGSR[DGS_TCn], before disabling time gate scheduling, if the state of the gates when time gate scheduling is disabled, differ from their initial state when time gate scheduling is enabled.
4. Set the maximum frame size for each traffic class in PTC*a*TMSDUR[MAXSDU]. Frames that exceed the limit are discarded.
5. Configure the (administrative) gate control list through the use of the Time Gate Scheduling table; for more details, see Time Gate Scheduling Table for the ENETC and Time Gate Scheduling Table for the switch. The Time Gate Scheduling table contains time gate scheduling configuration and operational information for a given NETC function. There is one Time Gate Scheduling table for each ENETC instance and one Time Gate Scheduling table for the entire switch. For the switch, there is one entry for each switch port, whereby for an ENETC instance, there is a single entry for the entire ENETC instance. Each entry includes both an administrative gate control list and an operational gate control list, along with the related configuration and status parameters. The gate control list includes the following parameters:
   - Size of the gate control list.
   - Base time (start time) of the schedule. Base time is expressed in units of nanoseconds.
   - Cycle time of gate control list. Cycle time is expressed in units of nanoseconds. The cycle time cannot be shorter than the sum of all gate control list entry durations.
   - Cycle extension time of gate control list. Cycle extension time is expressed in units of nanoseconds.
   - Gate control list.
6. When hardware processes a Time Gate Scheduling table command to configure a new (administrative) gate control list, it calculates the time at which the administrative gate control list is to become active (config change time), based upon the values of the base time and cycle time of the administrative gate control list. When the config change time of the administrative gate control list is reached, the hardware installs the gate control list (the gate control list becomes operational) and starts the execution of the gate control list. This function is performed in advance by having its time reference set to the 1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET], to adjust for latency encountered in the transmit processing pipeline. Register PTGSATOR[ADV_TIME_OFFSET] is used to specify the latency across the MAC plus if needed, delays outside of NETC (for example, PHY delay). Register E*a*TGSLR[MIN_LOOKAHEAD] is used only for ENETC, to specify the latency encountered for scheduling, dequeuing, and loading frames from the host memory to NETC internal memory. Register S0TGSLR[MIN_LOOKAHEAD] is used only for the switch, to specify the latency encountered for scheduling and dequeuing frames. Note that E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] are IERB registers, and thus can only be setup at pre-boot initialization time.
7. Similarly, time gate scheduling of all frames is also done in the future to adjust for latency encountered in the transmit processing pipeline. As in the previous step, this is achieved by advancing the 1588 time reference by the amount of time (*LookAheadTime*) configured in E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET].
8. Set PTXSDUOR register with the appropriate per frame overhead; that is number of bytes to be added to the actual length of each frame, to determine the PPDU (Physical Layer PDU) frame length on the link.

Time Gate Scheduling Operation

The setting of the transmission gate state for the gate associated with each of the port's traffic classes and the execution of transmission selection function are performed in advance to mitigate against any long latency (e.g. DMA latency in the case of ENETC) and latency variation encountered in the transmit processing pipeline. This in turn leads to better timing accuracy and reduction in jitter. The time used to perform these function, is set to the 1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]. Since the transmission selection function is performed in advance, it no longer relies on the MAC/link being idle for the indication that there is a transmission opportunity to transmit a frame. Instead the link is modeled by the transmission selection function to determine when frames are selected for transmission. Once the transmit transmission function selects a frame for transmission, next transmission opportunity provided by the link model, will occur after the time interval corresponding to the transmission time of the current selected frame at the rate configured in PCR[SPEED], with physical frame

overhead (IFG, preamble, SFD) accounted. The frame overhead is specified in PTXSDUOR. Time remaining for the transmission of a frame is tracked on every clock cycle. Note that the modeling of link also models the preemption function if enabled (such as stopping transmission of preemptible frame with added overhead of non-final fragments (mCRC, IFG, preamble, SFD) being accounted for, in the link model).

Each frame selected for transmission is tagged with a timestamp corresponding to the advance time that the time gate scheduler is operating on (1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]). The timestamp of a frame determines its departure time, that is the time at which the frame should be transmitted to the link. Then at the point where frames are transferred to the MAC, a timestamp-based shaper is implemented where the frames are released only when their transmission time (timestamp) is reached. The timestamp-based shaper function can also be performed in advance by having the time used to perform this function advanced by the amount of time specified in PTGSATOR[ADV_TIME_OFFSET], to adjust for the latency encountered through the Ethernet interface logic (MAC + physical layer latency).

Time gate scheduling proceeds as follows when there is transmission opportunity on the link to transmit a frame. It first selects the highest priority traffic class for which there is a frame waiting to be transmitted at the head of the traffic class. It then determines if that frame can be transmitted. A frame for a given traffic class can only be transmitted if the transmission gate associated with that traffic class is open and there is sufficient time for the entire frame (length of the frame is known) to be transmitted before the next gate-closed operation associated with that gate is executed. If both conditions are not met, then the next highest priority traffic class for which there is a frame waiting to be transmitted at the head of the traffic class, is selected to determine if that frame can be transmitted based on the criteria described above.

To determine if a frame can be transmitted, the scheduler first checks if there is sufficient time left in the current gate control entry interval, to transmit the entirety of the frame. If there is insufficient time, then the pre-processed gate control list data is accessed to extract how many bytes (up to the maximum SDU length) that can be transmitted in the next gate operations for this traffic class. This gate control list pre-processing, which is performed when the gate control list is configured, consists of performing the following computation for each entry in the gate control list.

- For each traffic class that has its gate open, the next gate operations in the gate control list (next gate control entries) are inspected to accumulate the number of bytes that can be transmitted in each gate control entry, until the accumulated number of bytes reaches the configured maximum SDU frame size, or a gate-closed operation is found.
- If the end of the gate control list is reached and the gate control cycle time is longer than the total execution time of the sequence of gate operations, the last gate control entry is extended to the end of the gate control list cycle. Once the end of the gate control list cycle is reached (no gate-closed operation found), and the accumulated the number of bytes that can be transmitted has not reached the size of a maximum SDU frame, inspection continues from the beginning of the same gate control list.
- This accumulated number of bytes that can be transmitted, is then stored in the gate control list entry, to be used later by the scheduler to determine for a given traffic class, how many bytes that can be transmitted in the next gate operations. This pre-processed data avoids having the scheduler at run-time, examining the next entries in the gate control list.

If it is determined that there is insufficient time available to transmit the entirety of that frame (transmission of the frame does not fit in the current open window), that frame will remain queued, and an attempt to schedule it will be made in the next open window associated with the frame traffic class.

In the case where the existing gate control list cycle is extended so that it ends at the base time of the new gate control list to be installed, any inspection from previous gate control entries will not continue into this extension time interval. Frame scheduling during the extension time internal is permitted with the gate states set to the values of the last gate control entry of the existing gate control list.

If there is a new gate control list scheduled to be installed in the next gate control list cycle, the scheduler cannot take into consideration the new configuration as the scheduler is using pre-processed gate control list data to determine how many bytes that can be transmitted in the next gate operations. Furthermore, any of the next gate operations accumulated byte fields in the current operational gate control list, that resulted from inspecting back to the beginning of the gate control list, are no longer accurate. As a result, all of the next gate operations accumulated byte fields in the last cycle are overwritten to 0.

Note that once the time gate scheduler has cycled through the entire operational gate control list and has detected a condition where a frame at the head of a traffic class will never be able to be transmitted, that frame will be discarded in the case of switch. These frame discards are counted against the port's Tx discard count register (PTXDCR) along with the setting of the Time Gate Scheduling Frame Too Large Discard Reason (TGSFTLDR) flag to 1 in the port's Tx discard count reason register 0 (PTXDCRR0).

In the case of ENETC, the frame is not transmitted and the STATUS field of the transmit buffer descriptor is updated with the error code 0x080 (frame too large for time gating window). The conditions where a frame at the head of a traffic class will never be able to be transmitted are:

- A frame at the head of a traffic class, although shorter than the value configured in PTC*a*TMSDUR[MAXSDU] (where *a* is the traffic class number), cannot be transmitted because there is no time interval between any gate-open event and a subsequent gate-close event, sufficient, long enough to transmit the entirety of the frame.
- There are no gate-open events for that traffic class in the entire operational gate control list; its gate is closed in every entry of the operational gate control list.

In the absence of any gate control list configuration, the time gate scheduler if enabled, still executes the transmission selection function ahead of time based on the setting of E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD], E*a*TGSLR[ZERO_LOOKAHEAD] and PTGSATOR[ADV_TIME_OFFSET].

Gate Control List Installation

The time when a new gate control list takes affect is calculated based on the rules described below (where *LookAheadTime* = E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET])

If the operational gate control list is not active, PTGAGLSR[TG]=0, the time (i.e. *ConfigChangeTime*) at which the next gate control list configuration change is scheduled to occur is determined as follows (where *CurrentTime* is at the 1588 time reference):

- if *AdminBaseTime* >= *CurrentTime* + *LookAheadTime*, then *ConfigChangeTime* = *AdminBaseTime*
- if *AdminBaseTime* < *CurrentTime* + *LookAheadTime*, then *ConfigChangeTime* = (*AdminBaseTime* + N**AdminCycleTime*) where N is the smallest integer for which the relation (*ConfigChangeTime* >= *CurrentTime* + *LookAheadTime*) would be TRUE.

If the operational gate control list is active, PTGAGLSR[TG]=1, the time (i.e. *ConfigChangeTime*) at which the next gate control list configuration change is scheduled to occur is determined as follows (where the end of the current operational cycle (*EndCurrentCycle*), is the absolute end time of the currently operational cycle without the cycle extension time, at the time reference of 1588 time + EaTGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]):

- if *AdminBaseTime* < *EndCurrentCycle* + *OperCycleTime*, then *ConfigChangeTime* = *AdminBaseTime* + N**AdminCycleTime*) where N is the smallest integer for which the relation (*ConfigChangeTime* >= *EndCurrentCycle* + *OperCycleTime*) would be TRUE.
- if *AdminBaseTime* >= *EndCurrentCycle* + *OperCycleTime*, then *ConfigChangeTime* = *AdminBaseTime*

The *ConfigChangeTime* can be retrieved by issuing a query command against the Time Gate Scheduling table entry associated with the port.

When the administrative gate control is about to be installed, and operational gate control list is not active, PTGAGLSR[TG]=0, then *CycleStartTime* is set to *ConfigChangeTime*. If the operational gate control list is active, PTGAGLSR[TG]=1, *CycleStartTime*, is determined according to the following rules:

- If *ConfigChangeTime* > *EndCurrentCycle* + *OperCycleTimeExtension*, then *CycleStartTime* = *EndCurrentCycle*
- If *ConfigChangeTime* <= *EndCurrentCycle* + *OperCycleTimeExtension*, then *CycleStartTime* = *ConfigChangeTime*

If a new gate control list configuration is installed and starts to execute in the current cycle, the current cycle is truncated in order to start the first new cycle and any inspection in the old cycle would not continue into the new cycle in order to start the first new cycle. This could result for the time interval of the last entry of the old gate control list to be very short. This is turn could cause overrunning the next gate-close event, or cause not being able to transmit a frame because the time interval was shortened, and that frame could then get discarded if it had been waiting to be transmitted for a full cycle interval.

Time Gate Scheduling Example

Time gating may be better understood with an example gate control list showing how scheduling will be performed. The example below, Table 528, shows a non-overlapping open gate case, where two traffic classes are never allowed to transmit at the same time. The interval normally defines a multiple of time ticks, in this example assume that the interval and number of bytes allowed to be transferred are the same. The number of bytes per interval would normally be calculated based on the interval length, transmit rate, and time tick granularity.

The total length of the gate control list is 3000B when adding up each individual time interval. The (admin) cycle time provided must be 3000B or greater. If the cycle time is 3000B, then when entry 15 completes, entry 0 would start immediately. Additional time added to the cycle time will extend the entry 15 interval. Assume here that the cycle time is set to 3100.

Table 528. Example: Non-Overlapping Gate Control List

Entry	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Interval (bytes)	100	200	100	300	100	200	100	300	500	100	200	200	300	100	100	100
TC 0	0	0	**1**	**1**	0	0	0	0	**1**	**1**	0	0	0	0	0	0
TC 3	0	0	0	0	0	**1**	0	0	0	0	0	**1**	0	0	0	0
TC 7	**1**	**1**	0	0	0	0	**1**	**1**	0	0	0	0	**1**	**1**	**1**	**1**

In this example, traffic class 7 gate has an open window (gate in the open state) of 1000 bytes starting at the beginning of the 4th last entry and ending at the end of the 2nd entry of the next cycle (if no new gate control list is to be installed).

Lets look at a first scheduling example where two frames are about to be scheduled. Both frames are available at least *LookAheadTime* before they are required to be transmitted in the open time gate window (Interval 1). This time is needed for the device to fetch the frame from memory and prepare it for transmission.

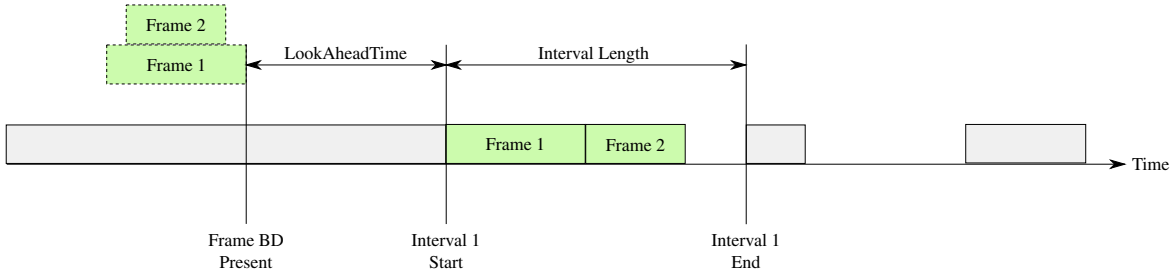

Figure 355. Scheduling of Frames

In this next example, consider the case where a best-effort first frame arrives "late" for scheduling within the next open gate window. Since the scheduler is always looking at LookAheadTime in the future it will calculate the amount of time left in a window at LookAheadTime from the current time to the end of the window. If the frame can still fit it will be scheduled for that window.

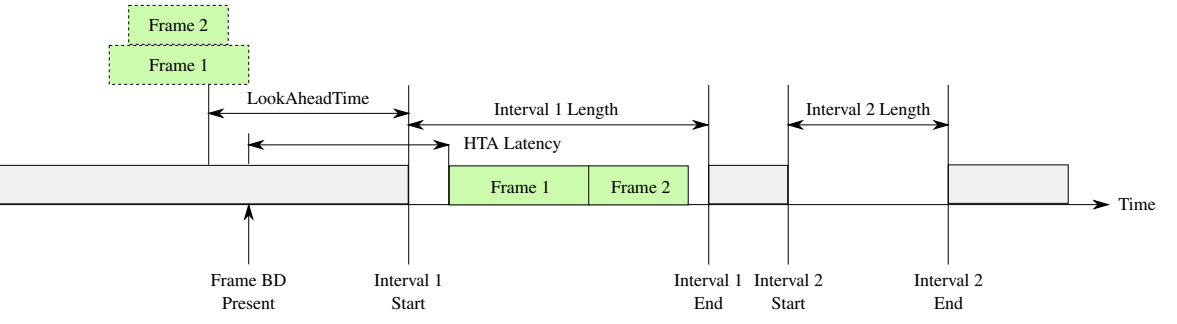

Figure 356. Scheduling of Frames - Late Arrival

Time Gate Scheduling in Combination with Preemption

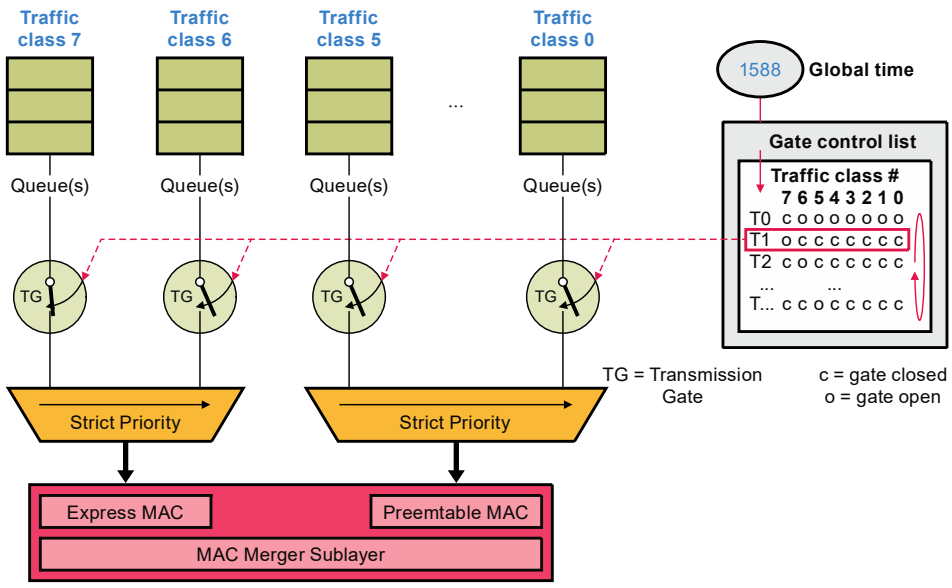

Figure 357. Time gate scheduling in combination with frame preemption

When time gate scheduling is used in combination with frame preemption, the "Hold and Release" mechanism can be used to protect the express traffic class window from interference from preemptable traffic, while at the same time minimizing the impact of the protected window on the amount of bandwidth that is available to preemptable traffic. The "Set-And-Hold-MAC" and "Set-And-Release-MAC" gate operations are used to specify the start and the end of a protected window.

When the time gate scheduler is processing a "Set-And-Hold-MAC" gate operation, asserting the Hold signal to the MAC merge sublayer is not always performed. Specifically, at the point of time where an Hold signal needs to be asserted (start of the hold advance interval), the time gate scheduler will not assert an Hold signal to the MAC merge sublayer under the following conditions:

- The preemptible frame transmission will complete its transmission before the Set-And-Hold-MAC time slot begins.
- There is no preemptible frame transmission.

The time gate scheduler will not schedule a preemptible frame during the Set-And-Hold-MAC time slot, regardless of whether or not an Hold signal was asserted. Furthermore, the time gate scheduler will not schedule a preemptible frame during the hold advance interval, if the preemptible frame transmission would continue into the Set-And-Hold-MAC time slot.

Delaying the scheduling of preemptable traffic classes to the start of the "Set-And-Release-MAC" time slot, has the benefit of selecting a newly arrived higher-priority preemptible frame, instead of the lower priority preemptible frames that were hold off by the scheduler prior and during the "Set-And-Hold-MAC" time slot. Note that once the time gate scheduling decides to not schedule a preemptible frame, any subsequent preemptible frames received will not be scheduled till the "Set-And-Release-MAC" time slot begins even if they there were of higher-priority.

In all other cases, the time gate scheduler will assert the Hold signal, in advance to the Set-And-Hold-MAC time slot by the time interval corresponding to the transmission of the worst case (longest) fragment length that cannot be preempted plus associated physical layer overheads. IEEE Std 802.3-2018 Clause 99 defines a minimum final fragment size of 64 bytes and allows the minimum non-final fragment size to be 64, 128, 192, or 256 bytes. For example, with a non-final fragment size of 64 bytes, a fragment that is 123 or fewer bytes in length cannot be preempted, because the non-final fragment would be less than 64 bytes (60 bytes + 4 bytes for mCRC). The minimum non-final fragment size is configured in MAC_MERGE_MMCSR[RAFS].

Note that time gate scheduler operates at the time reference of 1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET] and assumes that there is no delay from asserting the Hold/Release signal to the MAC merge

sublayer and the MAC merge sublayer ceasing/resuming to transmit any preemptible frame. Since it operates in advance, instead of immediately asserting the Hold/Release signal, an Hold/Release message is generated, and tagged with a timestamp set to the advance time (1588 time + E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]), at which the Hold/Release signal must be asserted assuming no internal pipeline delay from the point where frames are transferred to the MAC to the point where frame preemption occurs. Then at the point where frames are transferred to the MAC, a timestamp-based shaper is implemented where the Hold/Release messages are released, which trigger immediate assertion of the Hold/Release signal to the MAC merge sublayer when their time (timestamp) is reached. This timestamp-based shaper function is performed in advance by the amount of time specified in PTGSHCR [HOLD_SKEW] (that is, 1588 time + PTGSHCR [HOLD_SKEW]), to adjust for the Hold/Release latency encountered through the Ethernet interface logic (Hold Release delay to the MAC merge sublayer + any external delay (for example, PHY delay)).

Take for example, where MAC_MERGE_MMCSR[RAFS] is set to 64 bytes, meaning that the minimum fragment size that can be preempted is 124 bytes. If the time gate schedule determines that the Hold must be asserted, the time for asserting the hold would be set to 163 bytes transmission time prior to the start of the Set-And-Hold-MAC time slot; 20 bytes (IFG, preamble, SFD) + 123 bytes + 20 bytes (IFG, preamble, SFD).

An increased IFG length and any other overhead increases in frame transmission time are accounted for by setting the PTXSDUOR register appropriately.

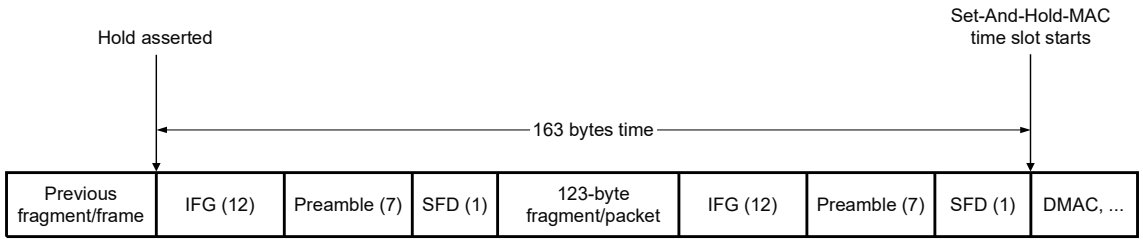

Figure 358. Hold Assertion Timing

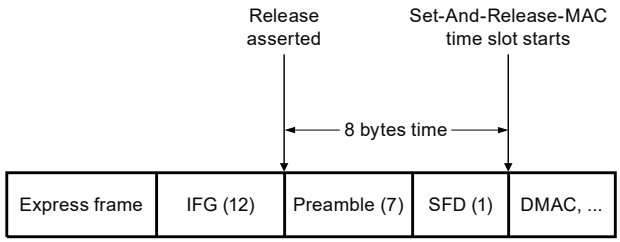

Figure 359. Release Assertion Timing

In the case where the "Hold and Release" mechanism is not used to protect the express traffic class window, and a preemptible frame has been scheduled and its transmission cannot be stopped by the time the express traffic gate opens, the scheduling of the express traffic class is delayed up to the point where the transmission of the preemptible frame has ceased.

If the schedule that applies to the preemptible traffic classes is constructed to disallow preemptible traffic to be transmitted at certain time (that is, there are "gate close" events for the preemptible traffic classes), then there is no way of telling in advance how many times a given frame will be preempted before its transmission is complete, and thus this configuration may result in overrunning the next gate-close event for the preemptible traffic classes concerned.

Note that the when gate control list preprocessing is inspecting the next gate operations in the gate control list (next gate control entries) for a preemptible traffic class, and encounters a gate control list entry that contains an express traffic class with its gate open, the accumulated number of bytes that can be transmitted is set to the configured maximum SDU frame size for the preemptible traffic class being inspected.

Time Gate Scheduling in Combination with Half Duplex Transmission

When time gate scheduling (802.1Qbv) is used in combination with half duplex transmission, the time gate scheduler compensates for deferred transmissions. Accurate transmission scheduling (that is, transmitting only within open gate time intervals) will be recovered for future frames in the event that one or more scheduled frame transmissions are deferred. These deferred frame(s) may violate their classes' open gate times as a result of the deferral, but it will not create a frame scheduling backlog that results in persistent gate violations once the deferred transmission has completed.

The time gate scheduler does not compensate for transmission back off delays due to collisions. A back off delay that follows a collision event may result in gate violations by the re-transmitted frames. In addition, collision back off delays will result in persistently late frame transmissions (potential gate violations) so long as there are transmit frames available for selection by the time gate scheduler; that is as long as transmit traffic is continuously flowing.

The time gate scheduler will recover accurate transmission scheduling during any idle time periods when there are no transmit frames available for selection. Once the sum of the idle time periods equals the total collision delays encountered, accurate transmission scheduling is reestablished.

53.4.2.4.1.5.1.3 Transmit Scheduling Timing

The figure below shows the moments in time related to current time a frame has been scheduled for IEEE 802.1 Qbv. This is to emphasize the role of S0TGSLR[MIN_LOOKAHEAD], PTGSATOR[ADV_TIME_OFFSET] and PTGSHCR[HOLD_SKEW] values.

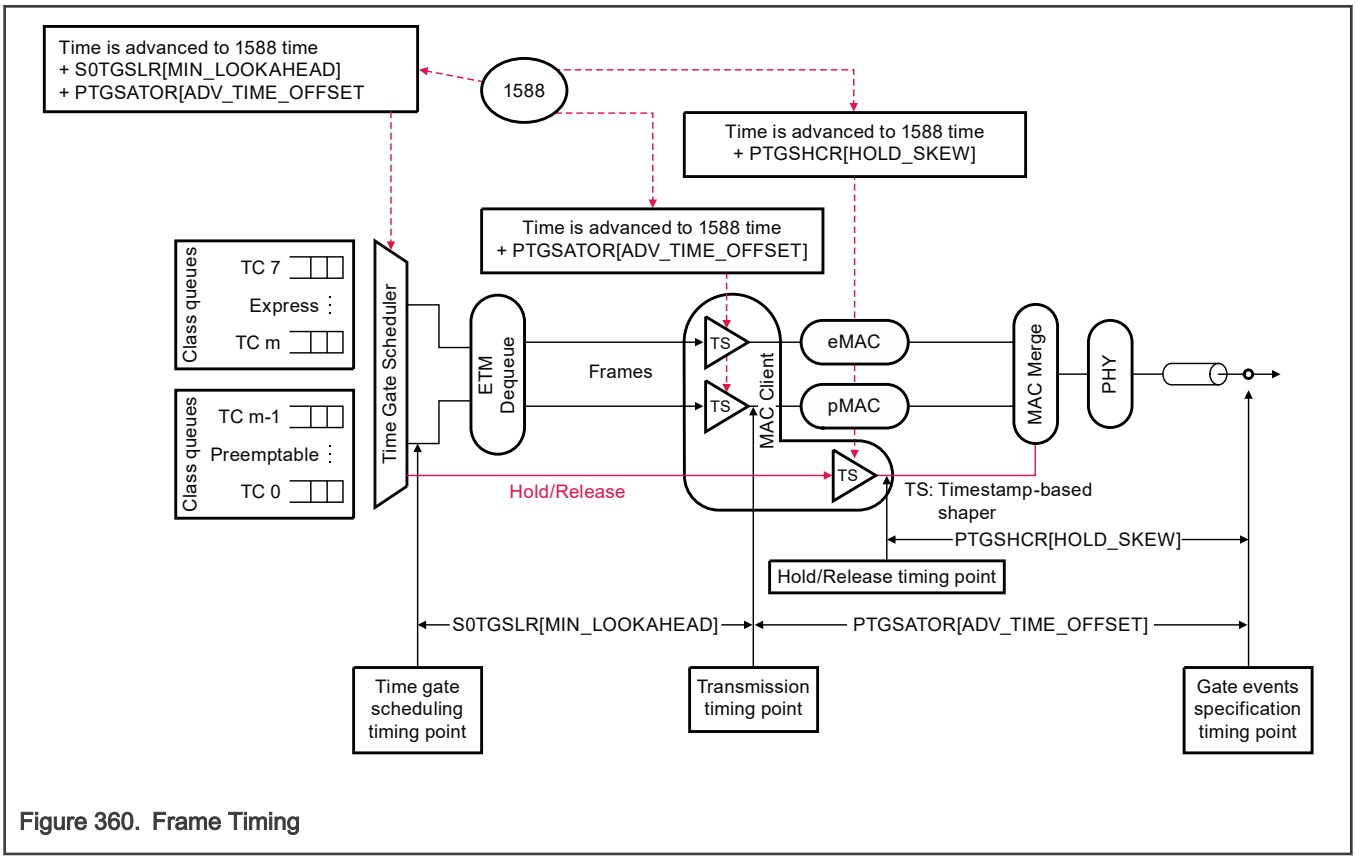

Figure 360. Frame Timing

For time gate scheduling, a frame that appears at the time gate schedule timing point (reference point at which the time of the gate events are specified (gate control list), would have been scheduled at 1588 time—S0TGSLR[MIN_LOOKAHEAD]—PTGSATOR[ADV_TIME_OFFSET] in the Egress Queuing and Traffic Management block. After which the frame would then have been dequeued, assigned a departure time corresponding to the 1588 time, and sent to the MAC client. The MAC client will then have forwarded the frame to the MAC at 1588 time—PTGSATOR[ADV_TIME_OFFSET]. The added latency through the MAC will have caused the frame to be sent out of the switch at 1588 time. For example, with a S0TGSLR[MIN_LOOKAHEAD] time of 100 ns, PTGSATOR[ADV_TIME_OFFSET] of 200 ns, and a gate opening of 50000 ns, the time gate scheduler will schedule the first frame of the gate at 49700 ns. The frame will then be forwarded to the MAC from the MAC client at 49800 ns and will appear on the output of the switch (time gate schedule timing point) at the gate opening of 50000 ns.

53.4.2.4.1.5.1.4 Strict priority and fair queuing

A total of 8 ETM class queues with configurable combinations of strict priority and fair scheduling is supported. A proprietary algorithm, Weighted Bandwidth Fair Scheduling (WBFS) is used to implement the weighted fair scheduling function. The WBFS algorithm is described in Weighted Bandwidth Fair Scheduling (WBFS) Algorithm.

The class queue scheduler of a switch port has 16 inputs numbered from 0 to 15. Input 0 to 7 are weighted fair whereby input 8 to 15 are strict priority. Strict priority input with a larger numeric value will be served before another with a smaller numeric value, Class queue 7 can be assigned to any of the scheduler inputs numbered from 8 to 15. Preceding queues are then assigned automatically in a contiguous downwards manner till the maximum number of class queues is reached (i.e. 8). For configuring the class queue schedulers, see ETM Class Scheduler Table.

For example, when class queue 7 is assigned to input 15 (the default value), all class queues (0 to 7) within the channel are treated as strict priority. When class queue 7 is assigned to input 7, all class queues (0 to 7) are treated as weighed fair queueing. Any assignment of the class queue 7 in between inputs 8 and 15 will result in some queues as strict priority and some with weighed fair queueing. If the assignment is to an input numerically lower than 7, then the behavior is that of the input 15 setting.

53.4.2.4.1.5.2 ETM class queue congestion management

A multi priority (color-aware) "tail drop" mechanism based on instantaneous queue depth is provided for managing the sizes of the egress class queues. Tail drop refers to a mechanism where arriving frames to a queue are dropped when the queue size reaches some maximum length threshold.

The multi priority (color-aware) "tail drop" mechanism is implemented through the use of congestion groups. A congestion group represents an aggregate of class queues on a given port, for the purpose of implementing queue related depth congestion control mechanisms. There are 8 congestion groups per port, allowing each class queue to have its own congestion group, or allowing several (or all) class queues in the same port to share the same congestion group, whichever is required. A congestion group tracks the number of instantaneous bytes that are queued up on all class queues that are associated with the congestion group. For each congestion group, a set of drop thresholds can be configured, one threshold for each drop resilience level, in order to decide when to start dropping frames arriving to a class queue associate with the congestion group. Note that from congestion group accounting perspective, each replicated frame is considered as a separate frame, meaning that the amount of bytes consumed by each frame reference is equivalent to the length of the entire frame.

Tail drop occurs if an enqueue is attempted with a frame marked as discard resiliency (DR) "x", and this enqueue would cause the number of bytes in the congestion group to exceed the threshold configured for DR "x". Note that hardware does a single check against the threshold corresponding to the DR value of the frame, it does not check other thresholds. Thus, it is important to configure the thresholds for all possible DR values.

Class queue association to a congestion group is configured through an update operation to the ETM Class Queue table, see ETM Class Queue Table for more details. By default, each class queue is associated with a dedicated congestion group. The tail drop thresholds are configured through an update operation to the ETM Congestion Group table, see ETM Congestion Group Table for more details. A query operation to the ETM Congestion Group table for a particular congestion group provides the number of bytes currently in use in all class queues that are members of that congestion group.

53.4.2.4.1.6 Ethernet Tx I/F

The Ethernet Tx I/F block integrates the Tx MAC functionality and implements the interface functions specific to the MAC from the transmit path.

53.4.2.4.1.6.1 Ethernet MAC

In the case where frames are transmitted to an Ethernet MAC, the Ethernet Tx I/F retrieves the frame from the shared internal buffer memory and transfers it to the Ethernet MAC.

Frame modification actions passed along with the frame as metadata, are performed as the frame is being transferred to the MAC.

For a given frame (store-and-forward or cut-through), FCS carried in the received frame is re-used as the FCS for the transmitted frame (the Ethernet MAC will not calculate and append the FCS), unless the following scenarios are encountered:

- There are frame modifications performed on the frame. In this scenario, the FCS carried in the received frame is removed from the frame, and the Ethernet MAC is instructed to calculate and append a new 4 bytes FCS to the frame. If the

Ethernet MAC is configured to pad frames to a minimum size of 64 bytes (PMa_COMMAND_CONFIG[TXP] set to 1), the Ethernet MAC will pad the frame with 0s as needed to extend the frame to 60 bytes and append a new 4 bytes FCS to the frame.

- There are no frame modifications performed on the frame and the frame length (including FCS) is shorter than 64 bytes and the outgoing port is configured to pad a frame to the minimum length of 64 bytes. (PMa_COMMAND_CONFIG[TXP] set to 1). In this scenario, the FCS carried in the received frame is not removed from the frame, and if the frame to be transmitted is shorter than 60 bytes, the MAC will pad the frame to 60 bytes with pad bytes of zeros, and then it will append a new calculated 4 bytes FCS to the frame. If the frame to be transmitted is shorter than 64 bytes but longer than 59 bytes, the MAC will append a new calculated FCS to the frame after the original FCS. If the frame to be transmitted is 64 bytes or longer, the MAC will not append an FCS to the frame.

The Ethernet MAC transmit function manages inter-packet gap and generates preamble and SFD or SMD.

The MAC supports configurable minimum frame size from 18 to 64B, and configurable maximum frame size up to 2000B. See Port MAC a Minimum Frame Length Register (PM0_MINFRM - PM1_MINFRM) and Port MAC a Maximum Frame Length Register (PM0_MAXFRM - PM1_MAXFRM) registers for more details.

NOTE

This device does not support transmitting carrier extension. If operating in half duplex mode with padding disabled, and transmitting frames shorter than 64 bytes, the system must ensure proper function since such frame transmissions are not at least one slotTime in duration.

After a frame has been sent to the Ethernet MAC, the Ethernet Tx I/F performs the following actions:

- For any given transmit frame, the Ethernet MAC returns the timestamp at the moment where the one-octet start frame delimiter (SFD) of the frame was transmitted. PMa_COMMAND_CONFIG[TS_MODE] determines which clock source (synchronized clock or free running clock) is used for sampling the timestamp. This timestamp is used as a response to a host request to capture the timestamp when the frame's SFD is transmitted by the switch's Ethernet MAC.
- Internal buffers holding the frame are released.

For any uncorrectable errors detected (such as cut-through end of frame errors, multi-bit ECC errors), the frame is discarded if the frame transfer to the MAC has not started. These frame discards are counted against the port's Tx discard count register (PTXDCR) along with the setting of the appropriate discard reason flag to 1 in the port's Tx discard count reason register 0 (PTXDCRR0). If the frame transmission has started (possible for both cut-through and store-and-forward mode of operations), the frame can no longer be discarded at this point. Instead the MAC is instructed to set the frame FCS field to a bad CRC value to ensure that the next hop identifies the frame as being bad. The error (no longer a frame discard) is counted against the port's MAC FCS counters (PMa_TERRn and PMa_TFCSn).

53.4.2.4.1.6.2 Pseudo MAC

For the pseudo MAC, if no frame modification actions have been specified, the original frame is always preserved in its entirety, including the FCS, and only the frame descriptor reference is passed across the pseudo link; thus there is no need to retrieve or copy these frames.

If frame modification actions have been specified, a new head (or start) of the frame called annotated frame header is created and stored in the shared internal memory buffer along with an FCS covering the annotated frame header. This FCS is distinct from the FCS covering the entire original frame. A reference to this annotated frame header is added to the frame descriptor before transferring the frame descriptor across the pseudo link. This annotated frame header represents the first n bytes of the frame, along with an indication of how many bytes from the start of the original frame are no longer valid. Frame descriptors transferred across a pseudo link include references to both the original frame and annotated header if present.

If there is no shared internal memory buffer available for storing the annotated frame header, the frame is discarded These frame discards are counted against the port's Tx discard count register (PTXDCR) along with the setting of the Shared Memory Resource Exhaustion Discard Reason (SMREDR) flag to 1 in the port's Tx discard count reason register 0 (PTXDCRR0).

53.4.2.4.2 Switch Management Port

A switch management port is a designated switch port to which frames can be mirrored, or redirected/copied. Redirected/copied frames include MAC control frames such as MAC learning, frames that match a classification table entry (e.g. Ingress Port Filter table) with an action to redirect or copy to the switch management port.

The switch allows one switch port that is connected internally to an ENETC port, to be designated as a switch management port (indicated in MPCR[PORT]). Switch ports connected to an Ethernet MAC cannot be designated as a switch management port.

The switch management port can also be a valid destination for the regular/normal output actions of the various lookup tables (such as FDB).

On a switch management port, each frame passed along includes out of band metadata with the following info:

- **From the switch to ENETC** - An indication of the source port ID from which the frame was received and the reason (referred to as the Host Reason) on why this frame was forwarded to the switch management port (e.g. MAC learning, ingress port filter table entry matched (i.e. software defined Host Reason), regular forwarded traffic). The Host Reason consists of a list of 4-bit codepoints; see table below for the definition of the Host Reason codepoints.
- **From ENETC to the switch** - An indication on how to forward the frame; (e.g.to direct the frame out a specific egress queue or forward as it was received from the switch management port itself or forward as it was received from another switch port (i.e. switch port masquerading).

Table 529. Host Reason Codepoints

Host Reason Codepoints (4 bits)	Description
0x0	Regular forwarded frame
0x1	Ingress mirror
0x2	MAC learning
0x3	Timestamp response. Note that a timestamp response is not associated with a received frame. It is used to identify a response that returns the transmission time of a frame on a switch port. See Tx two-step timestamp, for more details.
0x4 - 0x7	Reserved
0x8 - 0xF	Software defined Host Reason

Following are the trigger points in the ingress packet processing path where a frame can be re-directed or copied to the switch management port with a Host Reason set to a codepoint other than 0. As noted earlier, the switch management port can also be a valid destination from the regular/normal output actions of the various lookup tables (e.g. FDB).

- **Ingress port mirroring** - Any ingress mirroring trigger points can copy a frame explicitly to the switch management port (IMDCR0[MIRDEST]= 1). The mirrored frame copy metadata field Host Reason is set to "ingress mirror". The mirrored frame copy is not subjected to any further ingress processing (for example, policing, frame modifications). (See Ingress Mirroring, for more details).
- **Ingress Port Filtering** - Ingress Port Filter (IPF) table entry match with the filter forwarding action to redirect or copy the frame to the switch management port. Redirected frames to the switch management port afterwards are only subjected to the rate policing function if the IPF filter rate action is specified. Other subsequent ingress packet processing functions such as stream identification and filtering, ingress frame modification, FRER sequence generation, 802.1Q bridge forwarding, and stream gating are all by-passed. In the case of a “copy to the switch port management" action, ingress packet processing moves to the next stage of processing (that is, stream identification and filtering) but the frame copy to the switch management port is not subjected to any frame modifications (frame is delivered as received from the link). A “copy to the switch port management" action can be overridden by a “copy/redirect to the switch port management" action or a “discard” action specified in an Ingress Stream table entry, or by a “copy/redirect to the switch

port management" action resulting from MAC learning. Host Reason in the IPF table entry has to be set to a software defined Host Reason codepoint (8-15).

- **Ingress Stream** - Ingress Stream table entry match with the forwarding action to redirect or copy the frame to the switch management port. Redirected frames to the switch management port afterwards can be subjected to rate policing, stream gating, maximum SDU check, and ingress stream statistics update. Other subsequent ingress packet processing functions such as ingress frame modification, FRER sequence generation and 802.1Q bridge forwarding are all by-passed. In the case of a “copy to the switch port management" action, ingress packet processing moves to the next stage of processing but the frame copy to the switch management port is not subjected to any frame modifications (frame is delivered as received from the link). A “copy to the switch port management" action can be overridden by a “copy/redirect to the switch management port” action resulting from MAC learning. Host Reason in the Ingress Stream table entry has to be set to a software defined Host Reason codepoint (8-15).
- **Software MAC Learning** - MAC learning frames redirected or copied to the switch management port. The MAC learning frame metadata field Host Reason is set to "MAC learning". Copied/redirected MAC learning frames are subjected to storm control and policing. Note that no egress VLAN processing is performed on MAC learning frames, and any frame modification specified earlier will not be applied to the MAC learning frames.

As described above, multiple "redirect/copy to the switch port management" actions can be specified along the ingress processing path for a given frame, however, only a single "redirect/copy to the switch port management" action can be applied to a frame. For example:

- A "copy to switch management port" action set from a match in the Ingress Port Filter table lookup followed by a software MAC learning (unsecure) lookup. If the software MAC learning lookup performed into the FDB table, resulted in a match, a copy of the frame would be sent to the switch management port with the software defined Host Reason configured in the matched Ingress Port Filter entry. If the software MAC learning lookup performed into the FDB table, resulted in no match, a copy of the frame would be sent to the switch management port with the MAC learning Host Reason.
- A "redirect to switch management port" action set from a match in the Ingress Port Filter table with a software MAC learning function (secure/unsecure) enabled. The frame would be redirected to the switch management port with the software defined Host Reason configured in the matched Ingress Port Filter entry, as the software MAC learning function would not be executed.
- A "copy to switch management port" action set from a match in the Ingress Port Filter table lookup followed by "copy to switch management port" action set from a match in the Ingress Stream table lookup. A copy of the frame would be sent to the switch management port with the software defined Host Reason configured in the matched Ingress Stream entry.

Frames with Host Reason set to 0 (regular forwarded frame), are sent towards the switch management port via the Egress Queuing and Traffic Management function. Frames with a Host Reason set to a codepoint other than 0 (not regular forwarded frame), are sent directly to to the ENETC Ingress Congestion Manager (ICM) function, where they will be queued based on the internal QoS set by the switch, by-passing the switch Egress Packet Processing function, the switch Egress Queuing and Traffic Management function, and the ENETC Ingress Port Processing function. Furthermore, the pseudo MAC statistics are not updated for these frames.

Frames redirected or copied to the switch management port, as a result of matching a classification table entry (Ingress Port Filter table or Ingress Stream table), or as a result of MAC learning, may have multiple copies as a result of other functions being applied to the frame (ingress mirroring, regular forwarded traffic). Thus, a received frame may result in up to three frames being delivered to the switch management port:

- Frame with a software defined Host Reason or MAC learning Host Reason.
- Frame with an ingress mirror Host Reason.
- Frame with a regular forwarded frame Host Reason.

Frames (or management frames) redirected or copied to the switch management port, as a result of matching a classification table entry (Ingress Port Filter table or Ingress Stream table), or as a result of MAC learning, are not subjected to the switch congestion management. In the case where other copies exist, any discard to those copies does not impact the management frame copies. For example, if these copies are discarded due the switch congestion management (insufficient memory space to accommodate frame in buffer pool, or overall switch shared internal buffer memory usage is full), the management frame copy is not discarded,

and will be delivered directly to ENETC without consuming any switch buffering. Note that the management frames are subjected to ENETC congestion management (that is, ENETC Ingress Congestion Management (ICM)).

53.4.2.4.3 Cut-through Forwarding

In cut-through mode of operation, once parsing of the frame is completed and although the entire frame may not have been entirely received, the switch proceeds with ingress filtering and forwarding decisions and then queues the frame for transmission. This allows the switch to start transmission of a given frame to one or more egress ports while still receiving the remaining of frame on the ingress port.

53.4.2.4.3.1 Cut-through Forwarding Criteria

Cut-through forwarding is supported for both unicast and multicast frames. The decision on whether to proceed with cut-through forwarding is done on a per-egress port basis. Thus for a given multicast frame received on an ingress port with cut-through forwarding enabled, cut-through forwarding will only occur on the egress ports that meet the criteria listed below for cut-through forwarding. For egress ports not meeting the cut-through criteria, frame will be handled in the store-and forward mode of operation.

For cut-through forwarding to occur on a frame, all of the following criteria must be met:

- Both the frame's ingress port and egress port(s) must be configured to have cut-through forwarding enabled, using the port cut-through forwarding configuration register (PCTFCR).
- Cut-through forwarding of a frame will only occur when the link speed of the egress port is equal to or less than the link speed of the ingress port. This check is performed dynamically by the switch before deciding whether to proceed with cut-through forwarding or to revert back to the store-and forward mode of operation.
- Frame was received from the Ethernet Express MAC; cut-through forwarding is disabled for frames received from the Ethernet preemptable MAC.
- Cut-through forwarding has not been disabled by a switch packet processing action; see Disabling Cut-through Forwarding and Special Considerations for more details.

Cut-through mode of operation on a pseudo link is not applicable, and thus cut-through forwarding cannot be enabled on an ingress port or egress port attached to a pseudo link.

53.4.2.4.3.2 Cut-through Forwarding Timing

Once the first 24 bytes of data is received and presented to the Ingress Packet Processing (IPP), it starts parsing the frame header (first 24 bytes). If the end of the parse graph (up L4) has not been reached while parsing the first 24 bytes of the frame, the IPP waits for the next 24 bytes to be received so that it can resume parsing, and so on up to 144 bytes. By default, the parser will parse and extract fields from each protocol layer (L2, L3 and L4). There is the option to configure the parser to end parsing at L2 or L3 (via the port parser configuration register (PPCR)), regardless of the content of the frame. This option can be used to trigger cut-through forwarding earlier by reducing the number of bytes to be parsed.

Once parsing is completed and although the entire frame may not have been entirely received, frame moves through the switch processing pipeline and starts getting transmitted on all destination ports.

Functions such as MAC learning, counters and state updates relaying of the knowledge of the frame length, are delayed to the time when the end of frame is received.

53.4.2.4.3.3 Disabling Cut-through Forwarding

On a ingress port that has been enabled for cut-through forwarding, cut-through forwarding can be disabled as a frame moves through the switch processing pipeline, in the following ways:

- Ingress Port Filter table entry match with a cut-through forwarding disable action.
- Ingress Stream table entry match with a cut-through forwarding disable action; can be disabled on a specific destination port or on all destination ports.
- Ingress Stream Filter table entry match with a cut-through forwarding disable action.
- Stream gating

- Software can specify to disable cut-through forwarding before the administrative stream gate control list takes affect.
- Software can specify to disable cut-through forwarding for frames received after the stream gate control list ends and before CYCLE_TIME restarts.
- Software can specify to disable cut-through forwarding during a gate entry interval.

- FDB/L2 IPv4 Multicast filter table entry match with a disable cut-through action; can be disabled on a specific destination port or on all destination ports.

53.4.2.4.3.4 Special Considerations

Following are the specific frame handling actions taking when a frame is being forwarded in the cut-through mode of operation, to at least one port

- MAC learning
  - MAC learning is delayed to the end of frame. MAC learning is not performed if the received frame FCS is bad.
- Stream gating
  - The initial segment size of the cut-through frame is used for checking interval maximum number of bytes.
  - If a cut-through frame is accepted, accumulated interval byte count gets updated later when the entire frame is received.
- Rate policing
  - The initial segment size of the cut-through frame is used by the rate policer for checking if it accepts the frame.
  - If a cut-through frame is accepted, the rate policer byte credits get updated as data is received (on cut-through segment transfers).
- Storm control
  - The initial segment size of the cut-through frame is used by storm control policer to check if it accepts the frame.
  - If a cut-through frame is accepted, the storm control policer byte credit gets updated later when the entire frame is received.
- Congestion Management
  - The initial segment size of the cut-through frame is used by to determine if there is available memory space to accommodate the new frame in the selected buffer pool.
  - If a cut-through frame is accepted, buffer pool usage counts get updated as data is received (cut-through segment transfers).
- Frame Replication and Elimination for Reliability (FRER) sequence recovery
  - Cut-through forwarding must be disabled on any stream in which FRER recovery is enabled.
- Egress queuing and traffic management
  - Queue congestion management - The initial segment size of the cut-through frame is used by to determine if there is available space in the congestion group to accommodate the new frame. If a cut-through frame is accepted, congestion group usage counts get updated as data is received (cut-through segment transfers).
  - WBFS - Maximum frame size from the configured Transmit MSDU (PTCaTMSDUR, where a is the traffic class number) is assumed for a cut-through frame at the head a of the queue. Once the cut-through frame has been transmitted, the frame length is adjusted using the actual discovered length of the frame.
  - 802.1Qbv - Maximum frame size from the configured Transmit MSDU (PTCaTMSDUR, where a is the traffic class number) is assumed for a cut-through frame at the head of a queue. PTCaTMSDUR[SDU_TYPE] must be set to 1, if cut-through frames are expected.
- IEEE 802.1Qbu frame preemption

- When cut-through forwarding and IEEE 802.1Qbu frame preemption are enabled, great care should be taken to ensure that cut-through is disabled for traffic destined to the preemptable MAC. Initial IPV of a frame should be set in such way that the IPV doesn't map on egress to any traffic class that has been assigned to the preemptable MAC. Explicitly entries should be added in the Ingress Port Filter table, Ingress Stream table, or Ingress Stream Filter table to filter preemptable traffic with the action to disable cut-through forwarding and the action to set the IPV to a value that maps to a traffic class that has been assigned to the preemptable MAC. Note that sending a cut-through frame on a preemptable MAC can lead to a preempted fragment of size smaller than 64 bytes.

- HSR tag insertion
  - Cut-through mode of operation is not supported if insertion of HSR tag (or replacement R-TAG with HSR tag) has been configured, as it requires knowledge of the received frame length in order to set the HSR LSDU size field. If cut-through forwarding is occurring and insertion of HSR tag is configured, hardware will set the HSR LSDU size field based on the frame length configured In PTCaTMSDUR.
- Egress frame modification
  - Cut-through mode of operation is not supported if the frame modification action "removing entire Ethernet payload and replacing it with new Ethernet payload", has been configured or if the action "removing entire frame and replacing it with a new frame", has been configured.
- Ingress mirroring
  - Cut-through forwarding is disabled for the frames (copy) being sent to the mirrored destination.
- Per-stream filtering - maximum SDU check
  - The maximum SDU check is not applicable to cut-through frames, see Maximum SDU Check for more details.

53.4.2.4.3.5 Errored frame handling

When operating in cut-through mode, and if the frame transmission has been started already by the switch and the frame has an end of frame error, the switch puts a bad CRC value in the frame FCS field to ensure that the next hop identifies the frame as being bad.

53.4.2.4.4 Ingress Mirroring

Ingress mirroring provides capability to selectively copy frames entering the switch, to an egress switch port for the purpose of traffic monitoring. Ingress mirroring is enabled on the switch by setting register IMDCR0[MIREN] to 1. When ingress mirroring is enabled, the following methods are provided to select frames to be mirrored:

- All errored free frames entering a specific switch port. This method is selected by setting the port register flag PMCR[IMIRE] to 1.
- Ingress Port Filter table entry match with the action to mirror the frame.
- Ingress Stream table entry match with the action to mirror the frame.
- Ingress Stream Filter table entry match with the action to mirror the frame.
- FDB/L2 IPv4 Multicast filter table entry match with the action to mirror the frame.

The above methods provide the means to configure mirroring trigger points along the ingress processing path. All mirroring trigger points can be configured/active at the same time. The first mirroring trigger point hit by a frame along the ingress processing pipeline, will cause the generation of a mirrored frame copy. If the regular frame hits another mirroring trigger point afterwards as it continues to be processed by the ingress processing pipeline, that mirroring trigger point is ignored; no additional mirrored frame copies will be generated for that frame, there is only one mirrored frame copy generated for a given frame. Note that cut-through forwarding is disabled for the mirrored frame copy. The mirrored frame copy is forwarded to the mirrored destination, as a store-and-forward frame.

Once a trigger point generates a mirrored frame copy, the mirrored frame copy is forwarded immediately to the switch port designated as the destination mirror port. The mirrored frame copy is not subjected to any further ingress processing (e.g. policing, ingress frame modifications) with the following exception:

- In the case where there is insufficient space in the switch shared internal buffer memory to accommodate the received frame, the received frame is dropped and as a result none of the references to that frame can be forwarded including the mirrored frame copy.

Otherwise, any drop on the original frame afterwards doesn't impact the mirrored frame copy.

The destination mirror port is statically specified by configuring the ingress mirror destination configuration register 0 (IMDCR0); the options are:

- To forward explicitly to the switch management port (IMDCR0[MIRDEST] = 1); the exiting switch port is not explicitly specified, instead it is obtained from the register that specifies the switch port that has been designated as a switch management port. For this option, the mirrored frame copy metadata field Host Reason is set to "ingress mirror" (i.e. not as a regular forwarded frame).
- To forward explicitly to any switch port including the one designated as a switch management port (IMDCR0[MIRDEST] = 0 and mirror destination port specified in IMDCR0[PORT]). When a mirrored frame copy is forwarded explicitly to a switch port that has been designated as switch management port, the mirrored frame copy metadata Host Reason is set to "regular forwarded frame".

The DR and IPV assigned to the mirrored frame copy are obtained from the DR and IPV values configured in the ingress mirror destination configuration register 0 (IMDCR0). The mirrored frame copy DR and IPV are only used in the egress processing path (e.g. selecting egress class queue, performing congestion group check). Note that the IPV of the original frame is used to access the buffer pool mapping function to select the buffer pool.

Each frame mirrored copy is treated independently from the regular traffic (e.g. mirrored frame copy is in addition to any multicast and/or switch management port copies of the regular frame). If for example, if both regular frame and its mirrored copy exits the same port, the egress port transmits two independent copies of the frame.

From a congestion perspective, mirrored frames are treated in the same way as multicast frames, only one copy of the frame gets accounted for buffering purposes but on egress, as for multicast frames, each copy is subjected to ETM class queue congestion management; congestion group is checked to determine if there is available space to accommodate the mirrored frame copy, if so then the congestion group accounting is updated accordingly, otherwise the mirrored frame copy is dropped.

Ingress mirroring constraints are:

- Cut-through forwarding is disabled for the mirrored frame copy.
- No ingress frame modifications are supported for the mirrored frame copy.
- Egress frame modifications can be specified for the mirrored frame copy; the egress frame modifications are specified in the mirror destination configuration register 1 (IMDCR1). Egress frame modifications are supported only for the option IMDCR0[MIRDEST] = 0.

53.4.2.4.5 Time Capture

Time capture function provides the ability to measure latency of a given frame through the switch.

When measuring latency, the entry point is a physical Rx port and the exit point is a physical TX port.

The time capture function should not be used when replicating to multiple Tx Ports or when the Tx Port is attached to a pseudo link.

Latency is measured based on the captured synchronized timer timestamp at the Rx port and Tx port, and is captured relative to the SFD..

Frames whose latency is to be measured are identified through one of the following classification stages where the time capture feature may be enabled for that frame:

- Ingress Port Filter table.
- Ingress Stream table.
- Ingress Stream Filter table.
- FDB/L2 IPv4 Multicast filter table.

The time capture function operates in single arm mode, where the time capture function will be triggered for a single frame and then will disarm itself. If a trigger frame is not found within a timeout period, the time capture is disarmed. A maskable interrupt is generated when a capture trigger occurs or when timeout period elapsed. The timeout is specified in Time Capture Configuration Register (TCCR).

This time capture circuity can only operate correctly if all the Tx latency captures are done before a new Rx timestamp capture occurs. Arrival interval of trigger frames must be longer than the maximum egress queueing latency. The circuit will only arm when there is no trigger frame inflight in the switch.

53.4.2.4.5.1 Single arm mode

When the time capture function is armed, which is achieved by setting TCCR[ARM] register to 1, the first received frame which triggers a timestamp capture event, its Rx timestamp is captured in the TCRPTSR register. The latency is captured at the transmit port where the trigger frame is being forwarded to. The measured latency is captured in the transmit port registers PTCMINLR and PTCMAXLR.

A maskable interrupt is generated using the registers TCIER/TCRPIDR/TCMSIVR when either of the following occur:

- The last frame has been transmitted on the Ethernet MAC.
- The timeout value has expired.

For the first Rx trigger frame, in addition to capture its receive timestamp in TCRPTSR register, the TCRPSR[RX_CNT] register is incremented by 1 and the TCRPSR[RX_PORT] register is updated with the Rx port number of the trigger frame. Only the first frame (TCRPSR[RX_CNT] = 0) captures the Rx timestamp.

For subsequent Rx trigger frames (TCRPSR[RX_CNT] > 0), only the TCRPSR[RX_CNT] register is incremented up to a maximum value of 3. This is an ingress indication that trigger frames were received faster than expected, faster than the rate at which the circuity can be re-armed.

On the transmission of the first trigger frame on a port (PTCMINLR[COUNT]=0), the TCRPIDR[TX_PORTn] register bit is set and its port registers PTCMINLR and PTCMAXLR are loaded with the latency (latency = current 1588 time - TCRPTSR).

For subsequent transmission of trigger frames on a port, its port register PTCMINLR[COUNT] is incremented up to a maximum value of 3. This is an egress indication that trigger frames were received faster than expected, faster than the rate at which the circuity can be re-armed.

When all the copies of the first trigger frame are transmitted, if enabled, the time capture interrupt will be generated. When the circuity is re-armed by software, the TCIDR, TCRPSR, PTCMINLR and PTCMAXLR registers are all cleared.

In the single arm mode, the PTCMINLR and PTCMAXLR registers will hold the same value.

53.4.2.4.6 Switch Statistics Counters

53.4.2.4.6.1 MAC Statistics Counters

For the MAC statistic counters, see section Ethernet MAC Statistics Counters for the Ethernet MAC statistics counters and section Pseudo MAC Statistics Counters for the pseudo MAC statistics counters.

53.4.2.4.6.2 Ingress Statistics Counters

The table below lists the available ingress traffic statistics counters.

Table 530. Ingress Traffic Statistics Counters

Counter	Description
Ingress Stream Count table - RX_COUNT	Received octets counter (ifInOctets) on a per stream basis
Rate Policer table - statistics counters	Bytes count on a per rate policer instance. Also available are marked/ remarked frame counts

Table continues on the next page...

Table 530. Ingress Traffic Statistics Counters (continued)

Counter	Description
Ingress Port Filter table - MATCH_COUNT	Ingress Port Filter entry matched count
Cut-through forwarding count - CTFCR	Cut-through frames counter of frames forwarded to at least one egress port

The table below lists the available ingress frame drops statistics counters.

Table 531. Ingress Frame Drops Statistics Counters

Counter	Description
PRXDCR	Frame drops count in the ingress datapath processing pipeline on a per port basis with the setting of the discard reason in the port's Rx discard count reason register 0/1 (PRXDCRR0/1)
Ingress Stream Count table - frame drops counters	Maximum SDU frame drops count, stream gate frame drops count and rate policer instance frame drops count on a per stream basis
Rate Policer table - DROP_FRAMES	Frame drops count on a per rate policer instance basis
BPDCR	Frame drops count in the bridge forwarding processing function on a per source port basis with the setting of the discard reason in the port's Rx discard count reason register 0/1 (BPDCRR0/1)

53.4.2.4.6.3 Egress Statistics Counters

The table below lists the available egress traffic statistics counters.

Table 532. Egress Traffic Statistics Counters

Counter	Description
Egress Count table - ENQ_FRM_CNT	Enqueued frames count onto ETM class queue(s)
ETM Class Queue table - DEQ_BYTE_CNT	Dequeued bytes count on a per ETM class queue basis
ETM Class Queue table - DEQ_FRM_CNT	Dequeued frames count on a per ETM class queue basis
Egress Sequence Recovery table - traffic statistic counters	In order packets counts, out of order packets counts, lost packets counts and tag-less packets counts

The table below lists the available egress frame drops statistics counters.

Table 533. Egress Frame Drops Statistics Counters

Counter	Description
PTXDCR	Frame drops count in the egress datapath processing pipeline on a per port basis with the setting of the discard reason in the port's Tx discard count reason register 0/1 (PTXDCRR0/1)
Egress Count table - REJ_FRM_CNT	Rejected frames count; rejected from attempting to enqueue onto ETM class queue
ETM Class Queue table - REJ_BYTE_CNT	Rejected bytes count on a per ETM class queue basis
ETM Class Queue table - REJ_FRM_CNT	Rejected frames count on a per ETM class queue basis
ETM Class Queue table - frame drops counts	Frame drops counts due to frame descriptor pointer error

Table continues on the next page...

Table 533. Egress Frame Drops Statistics Counters (continued)

Counter	Description
Egress Sequence Recovery table - ROGUE_PACKETS	Packet drops count by the vector recovery algorithm whose sequence number have fallen outside of the recovery history window
Egress Sequence Recovery table - DUPLICATE_PACKETS	Packet drops count due to a duplicate sequence number

53.4.2.4.7 Table Management Commands

Table management commands use the NTMP protocol. Familiarity with the basic NTMP concepts, described in the NETC Table Management Protocol (NTMP) section of this document, is needed to understand the material documented in this section.

Some functionality is configured and controlled using control messages sent to the switch using a BD ring interface . This BD ring interface is referred to as the command BD ring.

Control messages are primarily used when the underlying functionality being configured may be too large to configure using direct registers (e.g. large tables).

There are two switch command BD rings, with the format of the descriptor detailed in NTMP Request Message Header Format and in NTMP Response Message Header Format. Command BD ring selection amongst all NETC functions' command BD rings (i.e. the pair of switch rings plus the per-SI ENETC rings) is performed in a round robin manner. Each command BD ring is serviced (one command per round) once in each round of the robin. Each round considers all command BD rings defined amongst all NETC functions.

With respect to the pair of switch command BD rings, control messages may be issued to both rings in parallel. There is no ordering of command execution between the two rings. This mechanism is advantageous when a mix of short and long duration commands are issued. Short duration commands issued in one of the rings will interleave with and pass longer duration commands (e.g. table dump) executing in the other ring. NETC hardware provides periodic interleaving opportunities during execution of long duration commands such that a short command targeting a hardware resource that is also servicing a long command will not be excessively delayed. This interleaving mechanism is non-configurable.

The NETC serializes commands within a single ring. It is safe to pipeline commands A and B within a ring where command A must complete before command B begins. Any ordered processing must be done either using a single ring, or waiting until command A has completed before issuing command B.

Each command ring is configured as follows:

1. Configure the command ring base address registers CBDRaBAR0 and CBDRaBAR0, where a is the ring number. The address must be 128 byte aligned.
2. Configure the command ring producer index register CBDRaPIR. Software should initialize the index value at this address to 0 to reflect an empty ring. Optionally if the ring is pre-initialized with BDs the index values should reflect the number of BDs added.
3. Configure the command ring consumer index register CBDRaCIR. This index value indicates the next BD to be processed by the hardware. When the ring is re-initialized this register should be set to 0. The consumer index is later updated by the hardware during processing of the ring.
4. Configure the command ring size CBDRaLENR to indicate how many 32B entries, are allowed in the ring. There is no wrap bit to indicate full/empty; one entry is used to differentiate between full and empty. When producer index + 1 equals consumer index, the ring is considered full. When the producer/consumer indices match, the ring is always considered empty.
5. Enable the command ring CBDRaMR [EN]=1.

To add one or more buffer descriptors (or commands) to an enabled transmit ring, follow the procedure below. To add one or more buffer descriptors (or commands) to an enabled transmit ring, follow the procedure below.

1. Software checks to make sure the ring is not full by examining the consumer index (CI) register, CBDRaCIR. Note that maximum number of BDs allowed on a ring is one less than ring size.

2. Software adds one or more BDs to the ring. A memory barrier must be used to guarantee update to memory. If software requires an interrupt when a BD has been transmitted, set BD[CCI] =1 and enable the interrupt through CBDRaIER[CBDCIE].
3. When CBDRaCIR [BDR_INDEX] match CBDRaPIR [BDR_INDEX], the ring is empty. After one or more BDs have been processed, the consumer index will be updated by hardware.

Commands supported by the switch are described in the table below.

Table 534. Supported Switch Commands

Table ID	Table Name	Table Type
5	Time Gate Scheduling Table	Indexed table
10	Rate Policer Table	Indexed table
13	Ingress Port Filter Table	Ternary match table
15	FDB Table	Hash table
16	L2 IPV4 Multicast Filter Table	Hash table
18	VLAN Filter Table	Hash table
22	ETM Class Queue Table	Indexed table
23	ETM Class Scheduler Table	Indexed table
30	Ingress Stream Identification Table	Hash table
31	Ingress Stream Table	Indexed table
32	Ingress Stream Filter Table	Hash table
33	Egress Treatment Table	Indexed table
34	Ingress Sequence Generation Table	Indexed table
35	Egress Sequence Recovery Table	Indexed table
36	Stream Gate Instance Table	Indexed table
37	Stream Gate Control List Table	Indexed table
38	Ingress Stream Count Table	Indexed table
39	Egress Count Table	Indexed table
40	Frame Modification Table	Indexed table
41	Buffer Pool Table	Indexed table
42	Shared Buffer Pool Table	Indexed table
43	ETM Congestion Group Table	Indexed table
44	Frame Modification Data Table	Indexed table

53.4.2.4.7.1 Time Gate Scheduling Table

Table 535. Table ID 5 - Time Gate Scheduling Table Common Attributes

TABLE_ID	5

Table continues on the next page...

Table 535. Table ID 5 - Time Gate Scheduling Table Common Attributes (continued)

TABLE_VERSION	0
Table Type	Static bounded index table
Table Description	The Time Gate Scheduling table contains time gate scheduling configuration and operational information for a NETC function. There is one Time Gate Scheduling table for each ENETC instance and one Time Gate Scheduling table for the entire switch. For the switch, there is one entry for each switch port, whereby for an ENETC instance, there is a single entry for the entire ENETC instance. Each entry includes both an administrative gate control list and an operational gate control list, along with related configuration and status parameters. There is an internal memory that is used to store the administrative gate control list and the operational gate control list of each table entry. The number of words available for all entries in the Time Gate Scheduling table is specified in register TGSTCAPR[NUM_WORDS]. The memory is managed using a single free list of fixed equal size units (or words) of memory. Free memory units from the free list are available to be dynamically allocated to any gate control lists subject to the total memory available and maximum gate control list length (TGSTCAPR[MAX_GCL_LEN]. Each gate control list is comprised of a sequence of gate operation entries where each entry occupies one word of memory. Table management command operations Update and Query are supported. After reset, each entry is present with all fields cleared to zero; there is no administrative gate control list and operational gate control list, indicated by their gate control list length being set to 0. An administrative gate control list can only be added by an Update operation, on a entry that contains no administrative gate control list (length is set to 0). An existing administrative gate control list cannot be directly updated/modified. The administrative gate control list contained in the entry must be first removed by issuing an Update operation that sets the administrative gate control list length to zero, followed by another Update operation that adds the new administrative gate control list. An administrative gate control list cannot be removed if its config change time is 1 ms away. Therefore, before attempting to remove an administrative gate control list, a check must be performed to determine if the config change time minus the current time is less than 1 ms. If so, then the administrative gate control list can no longer be removed as it will become the operational gate control list. There are two ways to obtain the config change time: • config change time is returned in the STATUS field of a command response to a command configuring an administrative gate control list. • config change time can be retrieved by issuing a query operation against the Time Gate scheduling table entry. Once an operational gate control list is installed, it cannot be removed by a table management command. Disabling time gate scheduling on a port (PTGSCR[TGE]=0), will remove both the operational gate control list and the administrative gate control list from the corresponding table entry. When adding an administrative gate control list while there is a currently running gate control list (that is operational gate control list), the base time of the administrative gate control list (ADMIN_BASE_TIME value) must be set to a time in the future. The minimum future time is equal to: *CurrentTime* + *LookAheadTime* + *TableCmdProcessingTime* + (2 × *OperCycleTime*) Where: *CurrentTime* = 1588 (synchronized) time at which software is to issue the Time Gate Scheduling table update command *LookAheadTime* = E*a*TGSLR/S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET] *TableCmdProcessingTime* = Hardware processing time of the Time Gate Scheduling table update command 21,200 NETC clock cycles; for example, @240Mhz ~ 90µs *OperCycleTime* = Cycle time of the operational gate control list

Table continues on the next page...

Table 535. Table ID 5 - Time Gate Scheduling Table Common Attributes (continued)

	Thus, if there is a currently running gate control list and the base time of the administrative gate control list to be added is within the following range: *AdminBaseTime* < *CurrentTime* + *LookAheadTime* + *TableCmdProcessingTime* + (2 × *OperCycleTime*) Where: *AdminBaseTime* = Base time of the administrative gate control list Then software must adjust the base time of the administrative gate control list (ADMIN_BASE_TIME value) as follows: *Adjusted AdminBaseTime* = *AdminBaseTime* + (N × *AdminCycleTime*) where N is the smallest integer for which the relation *Adjusted AdminBaseTime* ≥ *CurrentTime* + *LookAheadTime* + *TableCmdProcessingTime* + (2 × *OperCycleTime*) would be TRUE. When the administrative gate control list is installed (by the hardware) as the operational gate control list, the gate control list itself is not copied, instead the gate control list is assigned as the operational gate control list. A query to the administrative gate control list will then return 0 for the length indicating that there is no administrative gate control list present in the table entry. However, note that ADMIN_ BASE_TIME, ADMIN_CYCLE_TIME and ADMIN_CYCLE_TIME_EXT values are preserved, until a new administrative gate control list is configured.			
Number of Entries	For the switch, the number of entries is equal to the number of switch ports; number of switch ports is indicated in register SCAPR0[NUM_PORT]. For ENETC, there is a one table entry per table.			
Default Reset Behavior	After reset, each entry is present with all fields cleared to zero; there is no administrative gate control list and operational gate control list, indicated by their gate control list length being set to 0			
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**

Table 541. Table ID 5 - Time Gate Scheduling Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
63-0	64	ADMIN_BASE_TIME	Administrative Base Time This field sets the base time, i.e., the start time, of the administrative gate control sequence. The time is expressed in units of nanoseconds. The field implements the AdminBaseTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 AdminBaseTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expects the time to be specified as a 64-bit integer number of nanoseconds. Therefore, if this field is to be set to a value which was obtained from a managed object using the IEEE 802.1Q-2018 PTP time format, the value must be converted by software from the IEEE 802.1Q-2018 format to the 64-bit integer number of nanoseconds.
95-64	32	ADMIN_CYCLE_TIME	Administrative Cycle Time Sets the cycle time of the administrative gate control list. This is the period of time over which the sequence of operations in a gate control list repeats. Command will be rejected if ADMIN_CYCLE_TIME=0. The time is expressed as an integer number of nanoseconds. The field implements the AdminCycleTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 AdminCycleTime parameter, which is a rational number in units of seconds (numerator and denominator). Instead of using the IEEE 802.1Q-2018 AdminCycleTime parameter format, the field expects the time to be specified as a 32-bit integer number of nanoseconds. Therefore, if this field is to be set to a value which was obtained from a IEEE 802.1Q-2018 managed object, the value must be converted by software from the IEEE 802.1Q-2018 format to the 32-bit integer number of nanoseconds. Note that if the cycle time is shorter than the sum of the time intervals (see ADMIN_TIME_INTERVAL_GE_i), the sequence of operations is truncated, which in turn could cause the undesirable effect of overrunning a next gate-close event.
127-96	32	ADMIN_CYCLE_TIME_EXT	Administrative Cycle Time Extension This is the maximum amount of time by which the ADMIN_CYCLE_TIME is permitted to be extended when a new gate control sequence is being installed. The cycle time extension is used to extend the last complete cycle so that it ends at the new base time,

Table continues on the next page...

Table 541. Table ID 5 - Time Gate Scheduling Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			or in other words, that the old and new cycles line up. Setting the cycle time extension to a value that extends the last complete cycle to complete before the new base time (too short), will result in undefined behavior of the time gate operation. The time is expressed as an integer number of nanoseconds.
143-128	16	ADMIN_CONTROL_LIST_LENGTH	Administrative Control List Length This field indicates the number of entries in the administrative gate control list. Valid values for N are 1 to TGSTCAPR[MAC_GCL_LEN] for creating a new administrative gate control list and 0 to remove the administrative gate control list. The command will be rejected if list length is invalid.
159-144	16	--	Reserved
(223 + 64i) - (160 + 64i)	32	ADMIN_TIME_INTERVAL_GE_i	Administrative Time Interval for Gate Entry i, where i = 0, ..., N-1 Specified in nanoseconds. A minimum of 2 gate entries must be specified. Restrictions (applies to any time interval entries): - Minimum gate time interval specified must not be less than (((TGP +2) * 4) + 20)/NETC clock frequency, where TGP is the number of NETC ports (ENETC and switch) where time gating is enabled.
	8	ADMIN_TC_STATES_GE_i	Administrative Traffic Class Gate States for Gate Entry i, where i = 0, ..., N-1. Bit 0: Gate state for traffic class 0. Bit 1: Gate state for traffic class 1. Bit 2: Gate state for traffic class 2. Bit 3: Gate state for traffic class 3. Bit 4: Gate state for traffic class 4. Bit 5: Gate state for traffic class 5. Bit 6: Gate state for traffic class 6. Bit 7: Gate state for traffic class 7. For each of the traffic classes above, the following values apply: 0b = Gate closed. 1b = Gate open.
	8	--	Reserved
	4	ADMIN_HR_CB_GE_i	Administrative gate operation type (as per IEEE 802.1Q-2018) field for gate control list entry i. 0x0: SetGateStates. HoldRequest is unchanged. 0x1: Set-And-Hold-MAC. HoldRequest is set to value hold (1). 0x2: Set-And-Release-MAC. HoldRequest is set to value release (0).
	12	--	Reserved

Table 543. Table ID 5 - Time Gate Scheduling Table OLSE_DATA Description

Bits	Width [bits]	Name	Description
63-0	64	CONFIG_CHANGE_TIME	This field specifies the time at which the administrative gate control list is to become active. The time is expressed in units of nanoseconds. The field implements the ConfigChangeTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 ConfigChangeTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expresses the time as a 64-bit integer number of nanoseconds. Therefore, if this field is to be queried from an IEEE 802.1Q-2018 managed object, the value must be converted by software from the 64-bit integer number of nanoseconds to the IEEE 802.1Q-2018 PTP time format.
127-64	64	CONFIG_CHANGE_ERROR	Count of the number of times that a configuration change (new schedule) has been requested with the old schedule still running and the requested base time was in the past.
191-128	64	OPER_BASE_TIME	Operational Base Time Indicates the base time, i.e., the start time, of the operational gate control sequence.

Table continues on the next page...

Table 543. Table ID 5 - Time Gate Scheduling Table OLSE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			The time is expressed in units of nanoseconds. The time indicated in the field is advanced by the amount of time specified in EaTGSLR/ S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]. The field implements the OperBaseTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 OperBaseTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expresses the time as a 64-bit integer number of nanoseconds. Therefore, if this field is to be queried from an IEEE 802.1Q-2018 managed object, the value must be converted by software from the 64-bit integer number of nanoseconds to the IEEE 802.1Q-2018 PTP time format.
223-192	32	OPER_CYCLE_TIME	Operational Cycle Time Indicates the cycle time of the operational gate control list. This is the period of time over which the sequence of operations in a gate control list repeats. Command will be rejected if ADMIN_CYCLE_TIME=0. The time is expressed as an integer number of nanoseconds.
255-224	32	OPER_CYCLE_TIME_EXT	Operational Cycle Time Extension This is the maximum amount of time by which the OPER_CYCLE_TIME is permitted to be extended when a new gate control sequence is being installed. The time is expressed as an integer number of nanoseconds.
271-256	16	OPER_CONTROL_LIST_LENGTH	Operational Control List Length This field indicates the number of entries in the operational gate control list.
287-272	16	--	Reserved
(351 + 64i) - (288 + 64i)	32	OPER_TIME_INTERVAL_GE_i	Operational Time Interval for Gate Entry i, where i = 0, ..., M-1 Specified in nanoseconds. Restrictions (applies to any time interval entries): - Minimum time interval time is the time required to transmit 128 bytes. - Time interval needs to be greater than the advance offset time configured in PTGATOR[ADV_TIME_OFFSET]. - The sum of any 15 consecutive time intervals must be greater than the advance offset time configured in EaTGSLR[MIN_LOOKAHEAD] / S0TGSLR[MIN_LOOKAHEAD] + PTGSATOR[ADV_TIME_OFFSET]. - An entries' time interval should be able to transmit the Traffic Classes' MAX_SDU when fusing.
	8	OPER_TC_STATES_GE_i	Operational Traffic Class Gate States for Gate Entry i, where i = 0, ..., M-1 Bit 0: Gate state for traffic class 0. Bit 1: Gate state for traffic class 1. Bit 2: Gate state for traffic class 2. Bit 3: Gate state for traffic class 3. Bit 4: Gate state for traffic class 4. Bit 5: Gate state for traffic class 5.

Bits	Width [bits]	Name	Description
			Bit 6: Gate state for traffic class 6. Bit 7: Gate state for traffic class 7. For each of the traffic classes above, the following values apply: 0b = Gate closed. 1b = Gate open.
	8	--	Reserved
	4	OPER_HR_CB_GE_i	Operational gate operation type (as per 802.1Q) field for gate control list entry i. 0x0: SetGateStates. HoldRequest is unchanged. 0x1: Set-And-Hold-MAC. HoldRequest is set to value hold (1). 0x2: Set-And-Release-MAC. HoldRequest is set to value release (0).
	12	--	Reserved

53.4.2.4.7.2 Rate Policer Table

Table 544. Table ID 10 - Rate Policer Table Common Attributes

TABLE_ID	10
TABLE_VERSION	0
Table Type	Dynamic bounded index table
Table Description	The Rate Policer table contains the rate policer configuration and operational information for a NETC function. There is one Rate Policer table for each ENETC instance and one Rate Policer table for the entire switch. Each table entry contains a set of parameters that defines a single rate policer instance. A rate policer instance controls the amount of traffic that is allowed to go through for a particular received flow of frames. A rate policer instance can be pointed to in the Ingress Port Filter, Ingress Stream, Ingress Stream Filter tables and storm control registers. Table entries used for storm control and table entries used for rate policing are mutual exclusive; these entries cannot be shared between these two distinct functions. Rate policers can be used across switch ports, and streams. In the case of bandwidth violations, a rate policer instance can change the drop resilience parameter associated with each frame and can discard frames on various basis such as the drop resilience of the frame. Table management command operations Add, Delete, Update and Query are supported. This table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. The entries are stored in contiguous manner in a common memory. For this table, each table entry occupies four words. Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers; S0RPITMAR[NUM_WORDS] for switch and EaRPITMAR[NUM_WORDS] for ENETC. These allocations can also be changed when the functions are initialized through their respective base function register RPITMAR[NUM_WORDS].
Number of Entries	Maximum number of entries is indicated in RPITCAPR[NUM_ENTRIES]. Number of entries in-use is indicated in RPITOR[NUM_ENTRIES].

Bits	Width [bits]	Name	Description
31-0	32	CIR	Committed Information Rate Expressed in units of 3.725 bits per second, this parameter limits the average rate of frames declared green by the rate policer instance.

Table continues on the next page...

Table 550. Table ID 10 - Rate Policer Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
63-32	32	CBS	Committed Burst Size Expressed in bytes, this is the maximum fill (number of bytes) allowed in the Committed (C) token bucket. This parameter limits the number of bytes allowed in a burst of frames that are declared green by the rate policer instance.
95-64	32	EIR	Excess Information Rate Expressed in units of 3.725 bits per second, this parameter limits the average rate of frames declared yellow by the rate policer instance.
127-96	32	EBS	Excess Burst Size Expressed in bytes, this is the maximum fill (number of bytes) allowed in the Excess (E) token bucket. This parameter limits the number of bytes allowed in a burst of frames that are declared yellow by the rate policer instance.
128	1	MREN	Mark All Frames Red Enable This field enables the rate policer blocking function called "mark all frames red". When the "mark all frames red" feature is enabled, any frames dropped because they were marked red or yellow (if drop on yellow is enabled) will cause all subsequent frames to be marked red and the MR bit to be set to 1 within the Policer State Element. Frames marked "red" are always dropped unless the NDOR field is set to 1, in which case the red frames are not dropped, but their DR is set to 3. The hardware will continue to mark red all frames arriving at this rate policer instance until the MR bit is cleared via an update command to the Policer State Element. 0b = The rate policer blocking function "mark all frames red" feature is disabled. 1b = The rate policer blocking function "mark all frames red" feature is enabled. Not valid when NDOR=1.
129	1	DOY	Drop on Yellow 0b = Frames marked as yellow by the rate policer instance are not dropped. 1b = Frames marked as yellow by the rate policer instance are dropped.
130	1	CM	Color mode 0b = Color blind; pre-color information (encoded in the Drop Resilience (DR)) is not taken into account by the rate policer instance. 1b = Color aware; pre-color information (encoded in the Drop Resilience (DR)) is taken into account by the rate policer instance.
131	1	CF	Coupling flag This field enables the feature of coupling the Committed (C) bucket and Excess (E) bucket. When the buckets are coupled, and the C bucket becomes full (C tokens = CBS), any overflow C tokens will be added to the E bucket, up to the max fill of the E bucket (EBS). 0b = C and E token buckets are not coupled. 1b = C and E token buckets are coupled.

Table continues on the next page...

Table 550. Table ID 10 - Rate Policer Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
132	1	NDOR	No Drop on Red. When this field is set to 1, the red frames from this rate policer instance, are not dropped, but their DR is set to 3. Frames marked red by the flow meter blocking feature "mark all frames red" (enable/disable via the MREN) will also not be dropped. When this field is set to 0, frames marked "red" are always dropped.
134-133	2	SDU_TYPE	Service Data Unit Type This field specifies the type of PDU/SDU (Protocol/Service Data Unit) for a frame received by this rate policer instance when performing flow meter calculations. Overhead values are specified by register PRXSDUOR. 00b = PPDU (Physical Layer PDU). 01b = MPDU (MAC PDU). 10b = MSDU (MAC SDU). All other values reserved.
143-135	9	--	Reserved

Table 552. Table ID 10 - Rate Policer Table FEE_DATA Description

Bits	Width [bits]	Name	Description
0	1	FEN	Functional Enable This field is used to enable/disable a rate policer instance. 0b = The rate policer instance is disabled, but the token buckets and statistics counters and other configuration information are left intact, to allow reading them after a policer instance has been disabled. Frames directed to a policer instance that is disabled are passed through (not discarded). 1b = The rate policer instance is enabled based on the configuration information within the Configuration Element. Enabling a rate policer instance consists of setting the committed (C) token bucket to its full value (which is CBS), setting the excess (E) token bucket to its full value (which is EBS), and clearing all of the statistics counters to 0. Note that the timer function must be configured and enabled before any rate policer instance is enabled. Either the default nanosecond timer or the 1588 timer can be used to generate the required nanosecond resolution time. The default nanosecond timer is configured and enabled by default out of reset. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer

Bits	Width [bits]	Name	Description
63-0	64	BYTE_COUNT	Number of bytes received by the rate policer instance. Refer to SDU_TYPE for the SDU type used for byte count updates..
95-64	32	DROP_FRAMES	Number of frames dropped by the rate policer instance.
159-128	32	DR0_GRN_FRAMES	Number of frames marked green with DR=0 by the rate policer instance.
223-192	32	DR1_GRN_FRAMES	Number of frames marked green with DR=1 by the rate policer instance.
287-256	32	DR2_YLW_FRAMES	Number of frames marked yellow with DR=2 by the rate policer instance.
351-320	32	REMARK_YLW_FRAMES	Number of frames re-marked from green to yellow by the rate policer instance. If CM=(color-blind mode), this will equal DR2_YLW_FRAMES.
415-384	32	DR3_RED_FRAMES	Number of frames marked red (DR=3) by the rate policer instance.
479-448	32	REMARK_RED_FRAMES	Number of frames re-marked from green or yellow to red by the rate policer instance. If CM=0 (color-blind mode), this will equal DR3_RED_FRAMES.

Table continues on the next page...

Table 556. Table ID 10 - Rate Policer Table STSE_DATA Description (continued)

Bits	Width [bits]	Name	Description
543-512	32	LTS	Last timestamp. This is the timestamp of the last frame (or periodic update) received by this rate policer instance. Frame timestamps in the receive datapath are applied at the MAC, and use the 32 lsb of the 64 bit 1588 time base, see also the TIMESTAMP field in the receive buffer descriptor.
575-544	32	BCI	Bucket Committed Integer (part) Indicates the integer part (32 bits) of the committed token bucket fill level, expressed in units of bytes.
606-576	31	BCF	Bucket Committed Fractional (part) Indicates the fractional part (31 bits) of the committed token bucket fill level, expressed in units of bytes.
607	1	BCS	Bucket Committed Sign-bit. Indicates the sign-bit value of the committed token bucket fill level. The committed token bucket fill level, expressed in units of bytes, is represented as a 64-bit 2’s complement value (BCI) with a 32-bits integer part and a 31-bits fractional part (BCF). The 2’s complement notation is used as the amount of tokens in the bucket can go negative (effectively borrowing future tokens) when forwarding cut-through frames. In cut-through mode, the amount of tokens required (and consumed initially) in the bucket for considering a frame ‘conforming’, is the initial segment size of the cut-through frame. Tokens then continue to get consumed as the rest of the cut-through frame is received, and then possibly resulting in the bucket going negative. The fractional part is mainly due to the replenishment of the bucket, as the replenishment rate is in units of 3.725 bits per second. Note that a fraction of a token (or byte) means from an algorithm perspective that the token is not considered available in the bucket.
639-608	32	BEI	Bucket Excess Integer (part) Indicates the integer part (32 bits) of the excess token bucket fill level, expressed in units of bytes.
670-640	31	BEF	Bucket Excess Fractional (part) Indicates the fractional part (31 bits) of the excess token bucket fill level, expressed in units of bytes.
671	1	BES	Bucket Excess Sign-bit. Indicates the sign-bit value of the excess token bucket fill level. The excess token bucket fill level, expressed in units of bytes, is represented as a 64-bit 2’s complement value with a 32-bits integer part (BEI) and a 31-bits fractional part (BEF). The 2’s complement notation is used as the amount of tokens in the bucket can go negative (effectively borrowing future tokens) when forwarding cut-through frames. In cut-through mode, the amount of tokens required (and consumed initially) in the bucket for considering a frame ‘conforming’, is the initial segment size of the cut-through frame. Tokens then continue to get consumed as the rest of the cut-through frame is received, and then possibly resulting in the bucket going negative. The

			fractional part is mainly due to the replenishment of the bucket, as the replenishment rate is in units of 3.725 bits per second. Note that a fraction of a token (or byte) means from an algorithm perspective that the token is not considered available in the bucket.

53.4.2.4.7.3 Ingress Port Filter Table

Table 557. Table ID 13 - Ingress Port Filter Table Common Attributes

TABLE_ID	13
TABLE_VERSION	0
Table Type	Hardware Managed Ternary Match table
Table Description	The Ingress Port Filter table contains a set of filters each capable of classifying incoming traffic using a mix of L2, L3, and L4 parsed and arbitrary field data. As a result of a filter match, several actions can be specified such as on whether to deny or allow a frame, overriding internal QoS attributes associated with the frame and setting parameters for the subsequent frame processing functions (e.g. stream identification, policing, ingress mirroring). Each entry corresponds to a filter. The Ingress Port Filter table is enabled per-port via PIPFCR[EN], when there is at least one entry added for that port. If disabled, or if no match is found, the frame is allowed and passed to the next frame processing function. The Ingress Port Filter entries are added using a precedence value. If a frame matches multiple entries, the entry with the higher precedence is used. The Ingress Port Filter table is implemented using a Ternary Content Addressable Memory (TCAM). TCAM provides deterministic and high-speed lookups, however they consume significant amount of die size area compared to other types of memories, and thus the need to optimize storage is important. As a result, a narrow (48-bit wide), but deep TCAM organization is used, where a table entry can occupy multiple sequential lines of the TCAM. The maximum number of TCAM lines occupied by an Ingress Port Filter entry is 14 lines. With the exception of the first TCAM line, TCAM lines for which all fields are masked out (their corresponding mask field set to all 0s) will not actually exist in the TCAM. However, if only the first line is not completely masked out, TCAM line 4 is added, where the reserved portion of the TCAM line (bits 47:40) are not masked out. As a result, an Ingress Port Filter entry may occupy from 2 lines to 14 lines, depending on how many TCAM lines are entirely don't cares. See IPF Entry Format for the Ingress Port Filter entry implementation format (that is, Ingress Port Filter table entry fields contained in each TCAM line). A maximum of 24 consecutive bytes can be used as payload data for a Ingress Port Filter entry. The per-port parser register PPCR is used to limit the amount of payload data needed, if no entries are added attempting to match the full 24B of payload. If the end of frame is received before the desired amount of payload has been extracted, then the payload data will be padded with zeros up to the next 6B multiple (TCAM line). There is a small opportunity for false matches, where the zero-padded payload matches an entry with actual payload data of zeros. However, since the payload is only padded to the next 6B boundary, the likelihood of false matches is reduced, since it only can false match an entry with zeros as the last few payload bytes, and the payload data ends at that 6B boundary. For example, if 16B of payload is required, and the end of frame happens after extracting 12B of payload, there will be no zero padding, since the payload data extracted ended on a 6B boundary. If the end of frame occurs after extracting 14B, then there will be 4B of zero padding, to complete that TCAM line. In this case, only the first 2B of zero padding will have a valid mask, the last 2B of padding will have a mask of "don't care" since we only care about 16B of payload data.

Table continues on the next page...

Table 557. Table ID 13 - Ingress Port Filter Table Common Attributes (continued)

	Software adds entries using the "Add followed by Query" operation and the Ternary Match Key Element Match Access Method. The PRECEDENCE value is used to insert the entry. Hardware automatically moves entries with lower PRECEDENCE values when adding a new entry. The ENTRY_ID assigned to the entry is returned as part of the response to the Query operation. Software can issue a Search operation to dump entries that have been added along with their ENTRY_ID values. A query operation cannot be performed using the Key Element (KEYE_DATA). If the entry being added is too large for the available memory, an error will be returned. The IPFTMOR per-function register can be used to help determine the current usage. When deleting entries, Software provides the ENTRY_ID of the entry to be deleted. Hardware will find the entry specified, delete all lines associated to the entry, and shift entries up to close the gap (if any). When software performs a Query operation, and requests the Key Element of a ternary match (TCAM) table to be returned, the Key Element information in the Response Data Buffer may not precisely match the data which was used when an Add operation was issued. Ternary match tables perform a lossy compression when storing the key element data within the key element and thus, when querying a ternary match table's key element, software must be aware of the following behavior: for any data bits which had their associated mask bit set to 0 (don't care), the resulting data bit in the query response will be 0 regardless of how that bit was set in the key element data when adding or updating the key element. The precedence value within a Key Element will be returned precisely upon query. The Search Access Method can only be used to dump the Ingress Port Filter table entries for a given function (i.e. match all entries for a given ENETC, or the Switch as a whole). Table management operations Add, Delete, Update and Query are supported.		
Number of Entries	Maximum number of words is indicated in IPFTCAPR[NUM_WORDS]. Number of words in-use is indicated in IPFTMOR[NUM_WORDS]. Note: Port Filter entries can vary in size, from 2 to 14 words.		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x6 = Query, followed by Update.
	Exact Match Key Element Match (KEY_ELEMENT)	No	--
	Ternary Match Key Element Match (KEY_ELEMENT)	Yes	Following table management command operation is supported: 0xC = Add followed by a Query. When adding multiple entries with the same Key Element,

Table 563. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			Precedence value of an entry. When adding an entry, the existing entries are walked until an entry is found with a lower or equal Relative Priority value. The new entry will be inserted at that point. In the case of an equal Relative Priority value, the new entry will have precedence over the existing entry.
63-16	48	--	Reserved.
79-64	16	FRM_ATTR_FLAGS	Frame Attribute Flags The frame attribute flags to match. Bit 0: Switch port masquerading (Switch function) 0b = Switch port is not masqueraded. 1b = Switch port is masqueraded. Applicable only if the incoming port is designated as a switch management port. There is the option on per frame basis, to indicate to the switch to process the frame as it was received from a specified switch port other than the switch management port. This option is referred to as the switch port masquerading option. Bit 0: Reserved (ENETC function) Bit 1: Reserved. Bit 2: Outer VLAN Present. The outer VLAN tag is considered present if VLAN classification has deemed the outer VLAN tag valid and the VLAN tag wasn't taken from the port VLAN configuration register. 0b = Outer VLAN is not present. 1b = Outer VLAN is present. Bit 3: Inner VLAN Present. The inner VLAN tag is considered present if VLAN classification has deemed the inner VLAN tag valid and the VLAN tag wasn't taken from the port VLAN configuration register. 0b = Inner VLAN is not present. 1b = Inner VLAN is present. Bits 6-4: Sequence Tag Code. 000b = R-TAG/HSR tag is not present. 001b = 802.1CB draft 2.0 R-TAG is present. 010b = 802.1CB R-TAG is present. 011b = HSR Tag is present. 100b ... 111b = Reserved. Bit 7: IP Header Present. 0b = IP header is not present. 1b = IP header is present.

Table continues on the next page...

Table 563. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			Bit 8: IP Version. 0b = IPv4. 1b = IPv6. Bit 9: IPv4 option / IPv6 extension present. 0b = IPv4 option / IPv6 extension is not present. 1b = IPv4 option / IPv6 extension is present. Bits 11-10: L4 Code. 00b = Other L4. The L4 Header is considered as other L4 if it is not one of the following L4 Headers. 01b = TCP header is present. 10b = UDP header is present. 11b = SCTP header is present (not supported for NETC 3.0 and 3.1). Bit 12: Wake-on-LAN Magic Packet Present. 0b = WoL magic packet is not present. 1b = WoL magic packet is present. Note: Valid if IPFCAPR[WOL]=1. Reserved for Switch function. Bits 15-13: Reserved. Note: When adding an entry, all fields and masks must be correctly set, regardless of the value of this field. i.e. if Bit 8 indicates this entry is for IPv4, the IP address masks must be set for the IPv4 bits only.
95-80	16	FRM_ATTR_FLAGS_MASK	Frame Attribute Flags Mask This field is used to mask the FRM_ATR_FLAGS field when determining matches.
101-96	6	DSCP	Differentiated Services Code Point This field is matched against the differentiated services code point (DSCP) of the received frame.
107-102	6	DSCP_MASK	Differentiated Services Code Point Mask This field is used to mask the DSCP field when hardware is matching this entry.
111-108	4	--	Reserved.
116-112	5	SRC_PORT	Source Port ID This field is matched against the Source port ID. Note: this field is reserved for ENETC.
121-117	5	SRC_PORT_MASK	Source Port ID Mask This field is used to mask the SRC_PORT field when hardware is matching this entry. Note: this field is reserved for ENETC.

Table continues on the next page...

Table 563. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
127-122	6	--	Reserved.
143-128	16	OUTER_VLAN_TCI	Outer VLAN Tag Control Information This field is matched against the outer VLAN tag TCI of the received frame. TCI includes 3-bit Priority Code Point (PCP), 1-bit Drop Eligibility (DEI) and 12-bit VLAN ID (VID). This field is defined in network byte order (big-endian). Most significant byte of the TCI is stored at the lowest byte offset of this field.
159-144	16	OUTER_VLAN_TCI_MASK	Outer VLAN Tag Control Information Mask This field is used to mask the OUTER_VLAN_TCI field when hardware is matching this entry.
207-160	48	DMAC	Destination MAC Address This field is matched against the destination MAC address of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the destination MAC address is stored at the lowest byte offset of this field.
255-208	48	DMAC_MASK	Destination MAC Address Mask This field is used to mask the DMAC field when hardware is matching this entry.
303-256	48	SMAC	Source MAC Address This field is matched against the source MAC address of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the source MAC address is stored at the lowest byte offset of this field.
351-304	48	SMAC_MASK	Source MAC Address Mask This field is used to mask the SMAC field when hardware is matching this entry.
367-352	16	INNER_VLAN_TCI	Inner VLAN Tag Control Information This field is matched against the inner VLAN tag TCI of the received frame. TCI includes 3-bit Priority Code Point (PCP), 1-bit Drop Eligibility (DEI) and 12-bit VLAN ID (VID). This field is defined in network byte order (big-endian). Most significant byte of the TCI is stored at the lowest byte offset of this field.
383-368	16	INNER_VLAN_TCI_MASK	Inner VLAN Tag Control Information Mask This field is used to mask the INNER_VLAN_TCI field when hardware is matching this entry.
399-384	16	ETHERTYPE	EtherType This field is matched against the 2-byte EtherType after VLAN tag(s)/R-TAG/HSR tag (if any), of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the EtherType is stored at the lowest byte offset of this field.

Table continues on the next page...

Table 563. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
415-400	16	ETHERTYPE_MASK	EtherType Mask This field is used to mask the ETHERTYPE field when hardware is matching this entry.
423-416	8	IP_PROTOCOL	IP Protocol Indicates which L4 protocol is encapsulated. This field is matched against the IPv4 Protocol or the IPv6 Next Header (upper layer) field of the received frame.
431-424	8	IP_PROTOCOL_MASK	IP Protocol Mask This field is used to mask the IP_PROTOCOL field when hardware is matching this entry.
543-432	112	--	Reserved.
671-544	128	IP_SRC_ADDR	IP Source Address This field is matched against the IP source address of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the IP address is stored at the lowest byte offset of this field. If this IP address defines an IPv6 address, then: Bits 127-0: IPv6 source address. If this IP address defines an IPv4 address, then: Bits 95-0: Reserved. Bits 127-96: IPv4 source address .
735-672	64	--	Reserved.
863-736	128	IP_SRC_ADDR_MASK	IP Source Address Mask This field is used to mask the IP_SRC_ADDR field when hardware is matching this entry. Note: If the IP_SRC_ADDR is intended to match an IPv4 frame, then bits 95-0 of this field must be 0.
879-864	16	L4_SRC_PORT	L4 Source Port This field is matched against the L4 destination port of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the port number is stored at the lowest byte offset of this field.
895-880	16	L4_SRC_PORT_MASK	L4 Source Port Mask This field is used to mask the L4_SRC_PORT field when hardware is matching this entry.

Table continues on the next page...

Table 563. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
927-896	32	--	Reserved.
1055-928	128	IP_DEST_ADDR	IP Destination Address This field is matched against the IP destination address of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the IP address is stored at the lowest byte offset of this field. If this IP address defines an IPv6 address, then: Bits 127-0: IPv6 destination address. If this IP address defines an IPv4 address, then: Bits 95-0: Reserved. Bits 127-96: IPv4 destination address .
1119-1056	64	--	Reserved.
1247-1120	128	IP_DEST_ADDR_MASK	IP Destination Address Mask This field is used to mask the IP_DEST_ADDR field when hardware is matching this entry. Note: If the IP_DEST_ADDR is intended to match an IPv4 frame, then bits 95-0 of this field must be 0.
1263-1248	16	L4_DEST_PORT	L4 Destination Port This field is matched against the L4 destination port of the received frame. This field is defined in network byte order (big-endian). Most significant byte of the port number is stored at the lowest byte offset of this field.
1279-1264	16	L4_DEST_PORT_MASK	L4 Destination Port Mask This field is used to mask the L4_DEST_PORT field when hardware is matching this entry.
1311-1280	32	--	Reserved.
1319-1312	8	PLD_DATA_BYTE_0	Payload Byte 0 This field is matched against the most significant byte (or first byte) of the payload data of the received frame. Payload data starting position in the received frame is dependent at which point of the frame the parser has ended. - When no IP header is present, the payload data starts immediately after the payload EtherType. The payload EtherType is located immediately after the source MAC address or VLAN tag(s)/R-TAG/HSR tag (if any).

Table continues on the next page...

Table 563. Table ID 13 - Ingress Port Filter Table KEYE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			- When IP header is present and no TCP or UDP header is present, payload data starts immediately after the IP header except when IPv4 options or IPv6 extensions are present. For the latter, payload data starts at the beginning of the IPv4 Options/IPv6 Extensions header. - When TCP or UDP header is present, the payload data starts immediately after the TCP/UDP Ports.
1327-1320	8	PLD_MASK_BYTE_0	Payload Mask for Byte 0 This field is used to mask the PLD_DATA_BYTE_0 field when hardware is matching this entry.
1335-1328	8	PLD_DATA_BYTE_1	Payload Byte 1 This field is matched against the second-most significant byte (or second byte) of the payload data of the received frame.
1343-1336	8	PLD_MASK_BYTE_1	Payload Mask for Byte 1 This field is used to mask the PLD_DATA_BYTE_1 field when hardware is matching this entry.
...	...	...	...
1671-1664	8	PLD_DATA_BYTE_22	Payload Byte 22 This field is matched against the second-least significant byte (or second last byte) of the payload data of the received frame.
1679-1672	8	PLD_MASK_BYTE_22	Payload Mask for Byte 22 This field is used to mask the PLD_DATA_BYTE_22 field when hardware is matching this entry.
1687-1680	8	PLD_DATA_BYTE_23	Payload Byte 23 This field is matched against the least significant byte (or last byte) of the payload data of the received frame.
1695-1688	8	PLD_MASK_BYTE_23	Payload Mask for Byte 23 This field is used to mask the PLD_DATA_BYTE_23 field when hardware is matching this entry.

Table 564. Table ID 13 - Ingress Port Filter Table CFGE_DATA Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Offset

FLTA_TGT																																0x4

Table 565. Table ID 13 - Ingress Port Filter Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
3-0	4	IPV	Internal Priority Value New IPV to be assigned to frame, if OIPV is set. The least significant 3 bits are used, most significant bit is reserved.
4	1	OIPV	Override Internal Priority Value (IPV) 0b = Don't override frame IPV. 1b = Override frame IPV with value in IPV field of this entry.
6-5	2	DR	Drop Resilience New DR to be assigned to frame, if ODR is set.
7	1	ODR	Override Drop Resilience (DR) 0b = Don't override frame DR. 1b = Override frame DR with value in DR field of this entry.
9-8	2	FLTFA	Filter Forwarding Action (Switch function) 00b = Discard. 01b = Permit. 10b = Redirect frame to switch management port without any frame modification, along with Host Reason metadata set to the value configured in the HR field of this entry. Rate policing function will be applied to the frame if enabled (i.e. FLTA = 01b). Ingress Stream and 802.1Q bridge forwarding functions are by-passed. 11b = Copy frame to switch management port without any frame modification, along with Host Reason metadata set to the value configured in the HR field of this entry. Frame forwarding action not impacted. Filter Forwarding Action (ENETC function) 00b = Discard. 01b = Permit. 10b, 11b = Reserved.
10	1	--	Reserved.
11	1	IMIRE	Ingress Mirroring Enable 0b = No ingress mirroring action specified in this entry. 1b = The frame is mirrored to the mirror destination specified in the IMDCR0 register. Note: Not applicable to ENETC function.
12	1	WOLTE	Wake-on-LAN Trigger Enable 0b = WoL trigger is disabled. 1b = WoL trigger is enabled. When this field is set to 1b (WoL trigger is enabled), FLTA should be set to 11b (setting a pre L2 filtering SI bitmap) and optionally Override Internal Priority Value (IPV) and Override Drop Resilience (DR). Other actions should not be specified. Note: Valid if IPFCAPR[WOL]=1. Reserved for the Switch function.

Table continues on the next page...

Table 565. Table ID 13 - Ingress Port Filter Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
14-13	2	FLTA	Filter Action (Switch function) 00b = No action. 01b = Rate action with the Rate Policer Entry ID (RP_EID) set to the value configured in the FLTA_TGT field of this entry. 10b = Ingress stream identification action where the Ingress Stream Entry ID (IS_EID) is set to the value configured in the FLTA_TGT field of this entry. 11b = Reserved. Filter Action (ENETC function) 00b = No action. 01b = Rate policing action with the Rate Policer Entry ID (RP_EID) set to the value configured in the FLTA_TGT field of this entry. 10b = Ingress stream identification action where the Ingress Stream Entry ID (IS_EID) is set to the value configured in the FLTA_TGT field of this entry. 11b = Setting a pre L2 filtering SI bitmap that will be used by the L2 filtering function to determine the final SI bitmap. The value of pre L2 filtering SI bitmap is set to the value configured in the FLTA_TGT field of this entry.
16-15	2	RPR	Relative Precedent Resolution This field is used to select the final Ingress Stream Entry ID (IS_EID) when more than one table lookup can yield an IS_EID. This field specifies the precedence/priority of this table lookup entry relative to other table lookups that can yield the IS_EID. (IS_EID) Precedence Value for this entry. 00b = Highest precedence. 01b = Precedence is between ISIDKC0CR0 & ISIDKC1CR0 Ingress Stream Identification exact match lookup. Note that ISIDKC0CR0 lookup match has higher precedence value than ISIDKC1CR0's lookup match. 10b = Lowest precedence. 11b = Reserved. Valid if FLTA = 10b.
17	1	CTD	Cut through disable. 0b = No action. 1b = Cut-through is disabled for a frame matching this entry with this bit set. Valid when FLTFA = 01b. Note: Not applicable to ENETC function.
21-18	4	HR	Host Reason. This field specifies the Host Reason metadata when frame is redirected/copied to the switch management port (i.e. FLTFA = 10b or 11b). Value specified has to be a software defined Host Reason (8-15). See Switch Management Port for details. Note: Not applicable to ENETC function.
22	1	TIMECAPE	Timestamp Capture Enable 0b = No change to the timestamp.

Table continues on the next page...

Table 565. Table ID 13 - Ingress Port Filter Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			1b = Timestamp is to be captured; valid if FLTFA = 01b. Note: Not applicable to ENETC function.
31-23	9	--	Reserved.
63-32	32	FLTA_TGT	Target For Selected Filter Action (Switch function) If FLTA = 01b, this is a RP_EID (Rate Policer Table Entry ID). 0x0..RPITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); rate policing function is by-passed Other values are reserved If FLTA = 10b, this is an IS_EID (Ingress Stream Table Entry ID). 0x0..ISITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); stream filtering function is by-passed Other values are reserved Target For Selected Filter Action (ENETC Function) If FLTA = 01b, this is a RP_EID (Rate Policer Table Entry ID). 0x0..RPITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); rate policing function is by-passed Other values are reserved If FLTA = 10b, this is an IS_EID (Ingress Stream Table Entry ID). 0x0..ISITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); stream filtering function is by-passed Other values are reserved If FLTA = 11b, this is a pre L2 filtering SI bitmap. Each bit of the bitmap corresponds to an SI on a given port. Least significant bit of the bitmap corresponds to the smallest SI number. The SIs to which the frame is to be delivered, are identified by having their corresponding bit set to 1 in the bitmap. Bits 0-15: Bit wise setting of bitmap. LSB is the lowest order of SI. Bits 16-31: Reserved.

See Table 562 for the description of the fields in the above table.

53.4.2.4.7.4 FDB Table

Table 571. Table ID 15 - FDB Table Common Attributes

TABLE_ID	15
TABLE_VERSION	0
Table Type	Hash Table
Table Description	The FDB table contains forwarding and/or filtering information about MAC addresses. The FDB table is used for MAC learning lookups and MAC forwarding lookups. Each table entry includes information such as a FID and MAC address that may be unicast or multicast and a forwarding destination field containing a port bitmap identifying the associated port(s) with the MAC address. FDB table entries can be static or dynamic. Static entries are added from software whereby dynamic entries are added either by software or by the hardware as MAC addresses are learned in the datapath. The FDB is implemented as a hash table optionally augmented with a CAM for guaranteed FDB entries (see register FDBHTCAPR). Entries are added as a hash entry first (hash space), and if an entry (static or dynamic) is unable to be added due to collision chain length having reached its maximum length, defined in the register HBTCAPR[MAX_COL], it will be added to the CAM and its associated indexed table. An entry will not be added to the hash space or CAM/indexed table if an entry limit has been hit (for example, the number of hash entries in-use across all switch hash tables, has reached the limit specified in the register HTMCAPR[NUM_WORDS])). Table management command operations Add, Delete, Update and Query are supported.
Number of Entries	The memory allotment to store the hash entries is shared across all switch hash tables. The maximum amount of memory words available to store all switch hash tables entries, is indicated in register HTMCAPR[NUM_WORDS]). If the number of memory words in-use to store hash table entries for the switch has reached this limit, the Add operation will fail, regardless of the fill level of the CAM. The number of memory words in-use by the switch for hash table entries is indicated in register HTMOR[AMOUNT]. Note that CAM-based FDB table entries are not counted in register HTMOR[AMOUNT]. The total amount of words available to store the CAM-based FDB table entries, is indicated in register GHTEMCAPR[NUM_WORDS]. The number of FDB entries in-use in the CAM is indicated in register FDBHTOR0[NUM_GENTRIES]. The amount of dynamic entries is limited to the limit configured in the per-port register BPCR[DYN_LIMIT]. When an Add operation is issued, for every port that has its bit set in the Destination Port Bitmap, hardware will check if its maximum number of dynamic entries allowed has been reached (BPCR[DYN_LIMIT]). If any port has reached its limit, then the entry is not added. If the entry is added, the BPOR[NUM_DYN] value for each port that has its bit set, will be incremented. When an Update operation is issued, for every port that has its bit changing from 0 to 1 in the Destination Port Bitmap, hardware will check if its maximum number of dynamic entries allowed has been reached (BPCR[DYN_LIMIT]). If any port has reached its limit, then the entry is not updated. If the entry is updated, the BPOR[NUM_DYN] value for each port that has its bit changing from 0 to 1 will be incremented and for each port that has its bit changing from 1 to 0, will be decremented. The amount of dynamic entries for the entire switch is limited to the limit configured in the register FDBHTMCR[DYN_LIMIT].

Table continues on the next page...

Table 571. Table ID 15 - FDB Table Common Attributes (continued)

	Number of static FDB entries in-use (hash-based and CAM-based entries) is indicated in register FDBHTOR0[STATIC_ENTRIES]. Number of dynamic FDB entries in-use (hash-based and CAM-based entries) is indicated in register FDBHTOR1[DYN_ENTRIES].			
Default Reset Behavior	There are no entries in the table by default.			
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**	
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x6 = Query, followed by Update.	
	Exact Match Key Element Match (KEY_ELEMENT)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x6 = Query, followed by Update. 0x8 = Add. 0xC = Add, followed by a Query.	
	Ternary Match Key Element Match (KEY_ELEMENT)	No	None.	
	Search (SEARCH_CRITERIA)	Yes	Not supported for Add operations. In the event of a search command requiring multiple iterations (see RESUME_ENTRY_ID), the user must not delete any entries in the table between iterations of that search.	
Data Buffer Component Attributes	**Name**	**Description**	**Size [bytes]**	**Alignment [bytes]**
	ENTRY_ID	Entry Id (L2FDB_EID)	4	4
	ACCESS_KEY	Access Key	32	4
	ACTE_DATA	Activity Element	1	1
	KEYE_DATA	Key Element	12	4
	CFGE_DATA	Configuration Element	12	4
Entry Alignment [bytes]	4			
Entry ID Management	Hardware assigns entry IDs.

Table 575. Table ID 15 - FDB Table Response Data Buffer Description

Bits	Width [bits]	Name	Description
31-0	32	STATUS	Status Bits 31-0: RESUME_ENTRY_ID - An Entry ID which can be used as the RESUME_ENTRY_ID value within the ACCESS_KEY of a subsequent search to continue the search. When RESUME_ENTRY_ID is returned as the NULL Entry ID, this indicates that the search was completed successfully and no further iterations are required. Note: A NULL Entry ID is 0xFFFF_FFFF. Note: This field is valid only in responses for commands which use the Search as the Access Method. For all other Access Methods, this field is reserved. For generic details on the STATUS field, see Status. For generic details on the Search Access Method, see Search Access Method.
63-32	32	ENTRY_ID [1]	Entry ID Entry ID value generated by hardware, used to access existing entries. When an unassigned entry ID is used to access an entry, H/W needs to process the command as if the entry were not found. Note: A NULL Entry ID is 0xFFFF_FFFF. For generic details on the Entry ID field, see Entry ID Management.
159-64	96	KEYE_DATA[1]	Key Element Data See KEYE_DATA_Format.
255-160	96	CFGE_DATA[1]	Configuration Element Data See CFGE_DATA_Format.
263-256	8	ACTE_DATA[1]	Activity Element Data See ACTE_DATA_Format.
287-264	24	--	Reserved.

1. This component is present only for commands which perform a query. For more generic details on the element data blocks, see Element Data Blocks.

Bits	Width [bits]	Name	Description
23-0	24	PORT_BITMAP	Destination Port Bitmap This field identifies the destination port(s) to which the frame is to be forwarded. The destination port(s) are represented as a bitmap, where each bit of the bitmap corresponds to a port on the switch. Least significant bit of the bitmap corresponds to

Table continues on the next page...

Table 579. Table ID 15 - FDB Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			the smallest port number; i.e. bit offset 0 of the bitmap corresponds to port numbered 0, bit offset 1 to port numbered 1, and so on. The port(s) to which the frame are to be forwarded, are identified by having their corresponding bit set to 1 in the bitmap. Valid bits in the bitmap are from 0..SCAPR0[NUM_PORT]-1 Bits beyond the valid range will be ignored.
31-24	8	--	Reserved.
33-32	2	OETEID	Override ET_EID Option This field is used to convey the egress packet processing actions to be applied to packets matching this entry. The egress packet processing actions are specified in the Egress Treatment table, where each table entry contains the egress packet processing actions to be applied to a scope of packets (e.g. packets matching a particular 802.1Q bridge forwarding entry) exiting on a particular egress port of the switch. The means by which one specifies the Egress Treatment table entries to be accessed, is through the Egress Treatment group. Within the hardware, an Egress Treatment group is determined by a base index (first Egress Treatment table entry of the group) and an applicability port bitmap (a bitmap corresponding to all ports of the switch) which indicates (with a 1) which ports have Egress Treatment table entries present. For more details, see Egress Treatment table access. Specifically, this field specifies how to derive the applicability port bitmap of the primary Egress Treatment group being assigned to packets matching this entry. The base index is specified in the ET_EID field of this entry. 00b = No egress packet processing actions specified. Do not override ET_EID (and associated applicability port bitmap). 01b = Single-port Egress Treatment table access. Only one port requires egress packet processing. That port identifier is specified in the EPORT field of this entry. The applicability port bitmap is set with a 1 for the port that is been identified in the EPORT field of this entry. For other ports, the applicability port bitmap is set to 0. The group assigned to packets matching this entry will have a single Egress Treatment table entry, for the port identified in the EPORT field of this entry. 10b = Multi-port packed Egress Treatment table access. Applicability port bitmap is set to the port bitmap specified in PORT_BITMAP field of this entry. The group assigned to packets matching this entry will have an Egress Treatment table entry for each port set to 1 in the applicability port bitmap. 11b = Multi-port absolute Egress Treatment table access. Applicability port bitmap is set with 1 for all ports. The group assigned to packets matching this entry will have Egress Treatment table entries for all ports on the switch.
38-34	5	EPORT	Egress Port This field specifies the identifier of the port requiring egress packet processing when

Table continues on the next page...

Table 579. Table ID 15 - FDB Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			the Override ET_EID Option field is set to 01b (single-port Egress Treatment table access option). The port is expressed as an integer value, and must correspond to a port that is set in the destination port bitmap. Range: {0..SCAPR0[NUM_PORT]-1} Valid if OETEID=1 or CTD=1.
39	1	IMIRE	Ingress Mirroring Enable 0b = No ingress mirroring action specified in this entry. 1b = The frame is mirrored to the mirror destination specified in the IMDCR0 register.
40	1	--	Reserved.
42-41	2	CTD	Cut-Through Disable 00b = Do not override cut-through state. 01b = Disable cut-through for the outgoing port specified in the EPORT. Cut-through is not disabled for the other ports specified in destination port bitmap. 10b = Disable cut-through for all ports specified in the destination port bitmap. 11b = Reserved. Note: Cut-through should be disabled for any outgoing port where its Egress Treatment table entry specifies an Egress Sequence Recovery action. i.e.: Configuration Element Data ESQA field in the Egress Treatment table entry is set to 2.
43	1	DYNAMIC	Static or Dynamic Entry This field determines whether the entry is static or dynamic. 0b = Static entry. 1b = Dynamic entry. This field can be used in the aging software process as part of the decision as to whether the entry can be aged or not. Software can set this field to static or dynamic. When an entry is created by hardware (via the MAC learning function), this field is set to 1 (dynamic entry).
44	1	TIMECAPE	Timestamp Capture Enable when set. 0b = No change to the timestamp. 1b = Timestamp is to be captured.
63-45	19	--	Reserved.
95-64	32	ET_EID	Egress Treatment Table Entry ID This field specifies the index (or base index) to be used when accessing the Egress Treatment table. This field is valid if the Override ET_EID Option field is set to value other than 00b. 0x0..ETTCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL) Other values are reserved

53.4.2.4.7.5 L2 IPV4 Multicast Filter Table

Table 584. Table ID 16 - L2 IPv4 Multicast Filter Table Common Attributes

TABLE_ID	16		
TABLE_VERSION	0		
Table Type	Hash table		
Table Description	The L2 IPV4 Multicast Filter table contains forwarding and/or filtering information about IPv4 multicast addresses. The L2 IPv4 Multicast Filter table is used for Source Specific Multicast (SSM) and Any Source Multicast (ASM) lookups. Each table entry includes information such as a FID and IPv4 multicast address and a forwarding destination field containing a port bitmap identifying the associated port(s) with the IPv4 multicast address. The lookup is performed using the FID from VLAN Filtering, and the IP addresses of the frame (SA and DA for SSM, DA for ASM). Table management command operations Add, Delete, Update and Query are supported.		
Number of Entries	The memory allotment to store the hash entries is shared across all switch hash tables. The maximum amount of memory words available to store all switch hash tables entries, is indicated in register HTMCAPR[NUM_WORDS]). If the number of memory words in-use to store hash table entries for the switch has reached this limit, the Add operation will fail. The number of memory words in-use by the switch for hash table entries is indicated in register HTMOR[AMOUNT].		
Default Reset Behavior	No entries in the table by default.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x6 = Query, followed by Update.
	Exact Match Key Element Match (KEY_ELEMENT)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x6 = Query, followed by Update. 0x8 = Add. 0xC = Add, followed by a Query.
	Ternary Match Key Element Match (KEY_ELEMENT)	No	--
	Search (SEARCH_CRITERIA)	Yes	Not supported for Add operations. In the event of a search command requiring multiple iterations (see RESUME_ENTRY_ID), the user

53.4.2.4.7.6 VLAN Filter Table

Table 589. Table ID 18 - VLAN Filter Table Common Attributes

TABLE_ID	18		
TABLE_VERSION	0		
Table Type	Hash table		
Table Description	This table contains configuration and control information for each VLAN configured on the switch. Each VLAN entry includes the VLAN port membership, which FID to use in the FDB lookup, which spanning tree group to use, the egress frame modification actions to apply to a frame exiting form this VLAN, and various configuration and control parameters for this VLAN. The Search Access Method can only be used to dump the VLAN Filter table (match all entries). Table management command operations Add, Delete, Update and Query are supported.		
Number of Entries	The memory allotment to store the hash entries is shared across all switch hash tables. The maximum amount of memory words available to store all switch hash tables entries, is indicated in register HTMCAPR[NUM_WORDS]). If the number of memory words in-use to store hash table entries for the switch has reached this limit, the Add operation will fail. The number of memory words in-use by the switch for hash table entries is indicated in register HTMOR[AMOUNT].		
Default Reset Behavior	No entries in the table by default. There is a default entry configured in registers: VFHTDECR<0..2>		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query.
	Exact Match Key Element Match (KEY_ELEMENT)	Yes	Following table management command operations are supported: 0x1 = Delete.

Table continues on the next page...

Table 593. Table ID 18 - VLAN Filter Table Response Data Buffer Description

Bits	Width [bits]	Name	Description
31-0	32	STATUS	Status Bits 31-0: RESUME_ENTRY_ID - An Entry ID which can be used as the RESUME_ENTRY_ID value within the ACCESS_KEY of a subsequent search to continue the search. When RESUME_ENTRY_ID is returned as the NULL Entry ID, this indicates that the search was completed successfully and no further iterations are required. Note: A NULL Entry ID is 0xFFFF_FFFF. Note: This field is valid only in responses for commands which use the Search as the Access Method. For all other Access Methods, this field is reserved. For generic details on the STATUS field, see Status. For generic details on the Search Access Method, see Search Access Method.
63-32	32	ENTRY_ID [1]	Entry ID Entry ID value generated by Hardware, used to access existing entries. When an unassigned entry ID is used to access an entry, hardware needs to process the command as if the entry were not found. Note: A NULL Entry ID is 0xFFFF_FFFF. For generic details on the Entry ID field, see Entry ID Management.
79:64	16	KEYE_DATA[1]	Key Element Data See KEYE_DATA_Format.
95:80	16	--	Reserved. Alignment padding.
223-96	128	CFGE_DATA[1]	Configuration Element Data See CFGE_DATA_Format.

1. This component is present only for commands which perform a query. For more generic details on the element data blocks, see Element Data Blocks.

Table 597. Table ID 18 - VLAN Filter Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
23-0	24	PORT_MEMBERSHIP	Port Membership Bitmap This field specifies the ports that are member of this VLAN. The VLAN membership ports are represented as a bitmap, where each bit of the bitmap corresponds to a port on the switch. Least significant bit of the bitmap corresponds to the smallest port number; i.e. bit offset 0 of the bitmap corresponds to port numbered 0, bit offset 1 to port numbered 1, and so on. The port(s) that are member of this VLAN, are identified by having their corresponding bit set to 1 in the bitmap. Received frames from a port that is not a member of this VLAN will be dropped. A port is not member of this VLAN if its bit in the port membership bitmap field is set to 0. Note: Bits beyond the valid range of switch ports will be ignored.
27-24	4	STG_ID	Spanning Tree Group Member ID This field specifies the spanning tree protocol group to which this VLAN belongs. The

Table continues on the next page...

Table 597. Table ID 18 - VLAN Filter Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			value in this field is expressed as an integer and is used to index the spanning tree protocol per-port state register (BPSTGSR) to obtain the port spanning tree protocol state. The BPSTGSR register maintains spanning tree protocol port states for every spanning tree protocol group. The information retrieved from this register is used to perform spanning tree protocol (STP) port state checking during ingress VLAN filtering processing and egress VLAN filtering processing. In the case of ingress VLAN filtering processing, the source port ID and spanning tree protocol group ID are used to access register (BPSTGSR) to obtain the spanning tree protocol port state. Disabled - Frames will be discarded. Learning - Learn SMAC, but do not forward the frame. Forwarding - Both MAC learning and forwarding functions are executed. In the case of egress VLAN filtering processing, for each port that has its bit set in the destination port bitmap, the destination port ID and spanning tree protocol group ID are used to access register (BPSTGSR) to obtain the spanning tree protocol port state Disabled - Frames will be discarded. Learning - Frames will be discarded. Forwarding - Frames will be forwarded.
31-28	4	--	Reserved.
43-32	12	FID	Filtering ID The Filtering ID (FID) is a locally significant identifier (global to the switch), that is used as a key value when hardware performs a lookup into the FDB table and the L2 IPV4 Multicast Filter table. The FID is used to identify a set of VIDs, which in turn allows sharing of the same address (MAC, IP) between multiple VIDs during lookups into the FDB table and L2 IPV4 Multicast Filter table. This allows the support of the independent and shared learning modes.
47-44	4	--	Reserved.
50-48	3	MLO	MAC Learning Options 000b = Reserved. 001b = Disable MAC learning. MAC learning function is not performed during the forwarding processing. 010b = Hardware MAC learning is performed. 011b = Software MAC learning secure. A MAC learning lookup is performed into the FDB table. If there is no match, no attempt is made to add a new entry, and the frame is redirect to the switch management port. If there is match, and the entry's port number does not match frame ingress port number, the frame is redirected to the switch management port if station move is allowed, otherwise the frame is discarded. 100b = Software MAC learning unsecure. A MAC learning lookup is performed into the FDB table. If there is no match, no attempt is made to add a new entry, and a copy of the frame is sent to the switch management port. If there is match, and the entry's port number does not match frame ingress port number, the frame is copied to the switch

Table continues on the next page...

Table 597. Table ID 18 - VLAN Filter Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			management port if station move is allowed, otherwise the frame is discarded. 101b = Disable MAC learning with SMAC validation. A MAC learning lookup is performed into the FDB table. If there is no match or there is a match but the ingress port is not a member of the FDB entry, the frame is discarded and counted against the bridge port discard count register (BPDCR) with discard reason BPDCRR0[MACLNFDR] set to 1. All other values reserved.
52-51	2	MFO	MAC Forwarding Options 00b = Reserved. 01b = No FDB lookup is performed, the frame is flooded. 10b = FDB lookup is performed, and if there is no match, the frame is flooded. 11b = FDB lookup is performed, and if there is no match, the frame is discarded.
53	1	--	Reserved.
54	1	IPMFE	IP Multicast Filtering Enable This field specifies whether IP multicast filtering is to be performed. IP multicast filtering is accomplished by executing one or two exact match lookups: Source Specific Multicast (SSM) exact match lookup (if at least one entry added) utilizing both source IP address and destination IP address, and if there is no match, followed by Any Source Multicast (ASM) exact match lookup (if at least one entry added) utilizing destination IP address only. If an entry is found, the frame is forwarded according to the matched table entry. If no entry is found, then the frame will be forwarded according to IPMFLE. 0b = No IP multicast filtering is performed. 1b = If the frame is identified as a multicast IP packet, then IP multicast filtering is performed. If the frame is not identified as an IP multicast packet, the IP multicast filtering is not performed. A frame is identified as a multicast IP packet if the destination IP address falls under the following address range: IPv4: 224.0.1.0-238.255.255.255
55	1	IPMFLE	IP Multicast Flooding Enable If IP multicast filtering is performed (IPMFE = 1b, and the frame is identified as a multicast IP packet), and there was no match found, then the frame is forwarded according to this field. 0b = IP Multicast Flooding disabled, frame is discarded. 1b = IP Multicast Flooding enabled, frame is flooded. If IP multicast filtering is disabled (IPMFE = 0b), this field is ignored by hardware.
63-56	8	--	Reserved.

Table continues on the next page...

Table 597. Table ID 18 - VLAN Filter Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
87-64	24	ETA_PORT_BITMAP	Egress Treatment Applicability Port Bitmap This field specifies the Egress Treatment applicability port bitmap. See BASE_ET_EID field for more details. All ports that have their bit set to 1 in the Egress Treatment applicability port bitmap must member of this VLAN. Valid if BASE_ET_EID is not NULL. Note: Bits beyond the valid range of switch ports will be ignored.
95-88	8	--	Reserved.
127-96	32	BASE_ET_EID	Base Egress Treatment Entry ID This field is used to convey the egress packet processing actions to be applied to packets matching this entry. The egress packet processing actions are specified in the Egress Treatment table, where each table entry contains the egress packet processing actions to be applied to a scope of packets (e.g. packets from a particular VLAN) exiting on a particular egress port of the switch. The means by which one specifies the Egress Treatment table entries to be accessed, is through the Egress Treatment group. Within the hardware, an Egress Treatment group is determined by a base index (first Egress Treatment table entry of the group) and an applicability port bitmap (a bitmap corresponding to all ports of the switch) which indicates (with a 1) which ports have Egress Treatment table entries present. For more details, see Egress Treatment table access. Specifically, this field specifies the base index of the secondary Egress Treatment group being assigned to packets matching this entry. The applicability port bitmap is set to the port bitmap specified in ETA_PORT_BITMAP field of this entry. The group assigned to packets matching this entry will have an Egress Treatment table entry for each port set to 1 in the applicability port bitmap. 0x0..ETTCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); egress treatment processing is by-passed Other values are reserved

53.4.2.4.7.7 ETM Class Queue Table

Table 600. Table ID 22 - ETM Class Queue Table Common Attributes

TABLE_ID	22		
TABLE_VERSION	0		
Table Type	Static bounded index table		
Table Description	The ETM Class Queue table contains class queue configuration and operational information. Each entry corresponds to a class queue on given switch port (multiple class queues per port). After reset all class queues are initialized and enabled by hardware, and thereafter remain operational. Class queues are always present and enabled.		
Number of Entries	Number of entries is equal to the total number of class queues on the switch. Total number of class queues is equal to the number of switch ports (SCAPR0[NUM_PORT]) multiplied by the number of class queues per port (8).		
Default Reset Behavior	After reset all class queues (or entries) are initialized and enabled by hardware, with the CQ2CG_MAP field set equal to the CQ number within the port, so that each class queue is associated with a dedicated congestion group; consecutive class queue numbers contain consecutive congestion group numbers.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x2 = Update. 0x4 = Query. 0x6 = Query, followed by Update.
	Exact Match Key Element Match (KEY_ELEMENT)	No	--
	Ternary Match Key Element Match (KEY_ELEMENT)	No	--
	Search (SEARCH_CRITERIA)	No	--

Table 615. Table ID 23 - ETM Class Scheduler Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
3-0	4	CQ_ASSG	Class Queue Assignment Class queue assignment to scheduler inputs. The class queue scheduler as 16 inputs numbered from 0 to 15. Input 0 to 7 are weighted fair whereby input 8 to 15 are strict priority. Strict priority input with a larger numeric value will be served before another with a smaller numeric value, Class queue 7 can be assigned to any of the scheduler inputs numbered from 8 to 15. Preceding queues are then assigned automatically in a contiguous downwards manner till the maximum number of class queues is reached (i.e. 8). For example, when class queue 7 is assigned to input 15 (the default value), all class queues (0 to 7) within the channel are treated as strict priority. When class queue 7 is assigned to input 7, all class queues (0 to 7) are treated as weighed fair queueing. Any assignment of the class queue 7 in between inputs 8 and 15 will result in some queues as strict priority and some with weighed fair queueing. If the assignment is to an input numerically lower than 7, then the behavior is that of the input 15 setting. Assignment of CQ 7 (CQ_ASSG) is coded as follows: 0: Scheduler input 15 1: Scheduler input 14 2: Scheduler input 13

Table 615. Table ID 23 - ETM Class Scheduler Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			3: Scheduler input 12 4: Scheduler input 11 5: Scheduler input 10 6: Scheduler input 9 7: Scheduler input 8 8: Scheduler input 7 After reset, this field is initialized to all 0.
15-4	12	--	Reserved
26-16	11	OAL	Overhead Accounting Length This value is an 11-bit unsigned number, and is added to the actual length of each frame when performing class scheduler WBFS calculations. After reset this field is set to 0. The overall effect of the frame modification actions that will be applied to each frame is automatically added to the actual frame length, and thus does not need to be accounted for in the OAL value.
31-27	5	--	Reserved
39-32	8	WBFS_WEIGHT_0	Weight for Scheduler Input 0 Weight for scheduler input 0 in the channel being configured. These weights are used by the weighted scheduling (WBFS) algorithm in the ETM class schedulers. Each 8-bit weight code is formatted as Bits 7-3: weight code y value Bits 2-0: weight code x value And the formula for converting weight code to effective weight is: $(2^x)/(1-(y/64))$. After reset, this field is initialized to all 0.
47-40	8	WBFS_WEIGHT_1	Weight for scheduler input 1 Weight for scheduler input 1 in the channel being configured. These weights are used by the weighted scheduling (WBFS) algorithm in the ETM class schedulers. Each 8-bit weight code is formatted as described in the WBFS_WEIGHT_0 field. After reset, this field is initialized to all 0.
55-48	8	WBFS_WEIGHT_2	Weight for scheduler input 2 Weight for scheduler input 2 in the channel being configured. These weights are used by the weighted scheduling (WBFS) algorithm in the ETM class schedulers. Each 8-bit weight code is formatted as described in the WBFS_WEIGHT_0 field. After reset, this field is initialized to all 0.
63-56	8	WBFS_WEIGHT_3	Weight for scheduler input 3 Weight for scheduler input 3 in the channel being configured. These weights are used by the weighted scheduling (WBFS) algorithm in the ETM class schedulers. Each 8-bit weight code is formatted as described in the WBFS_WEIGHT_0 field. After reset, this field is initialized to all 0.

Table continues on the next page...

Table 615. Table ID 23 - ETM Class Scheduler Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
71-64	8	WBFS_WEIGHT_4	Weight for scheduler input 4 Weight for scheduler input 4 in the channel being configured. These weights are used by the weighted scheduling (WBFS) algorithm in the ETM class schedulers. Each 8-bit weight code is formatted as described in the WBFS_WEIGHT_0 field. After reset, this field is initialized to all 0.
79-72	8	WBFS_WEIGHT_5	Weight for scheduler input 5 Weight for scheduler input 5 in the channel being configured. These weights are used by the weighted scheduling (WBFS) algorithm in the ETM class schedulers. Each 8-bit weight code is formatted as described in the WBFS_WEIGHT_0 field. After reset, this field is initialized to all 0.
87-80	8	WBFS_WEIGHT_6	Weight for scheduler input 6 Weight for scheduler input 6 in the channel being configured. These weights are used by the weighted scheduling (WBFS) algorithm in the ETM class schedulers. Each 8-bit weight code is formatted as described in the WBFS_WEIGHT_0 field. After reset, this field is initialized to all 0.
95-88	8	WBFS_WEIGHT_7	Weight for scheduler input 7 Weight for scheduler input 7 in the channel being configured. These weights are used by the weighted scheduling (WBFS) algorithm in the ETM class schedulers. Each 8-bit weight code is formatted as described in the WBFS_WEIGHT_0 field. After reset, this field is initialized to all 0.

53.4.2.4.7.9 Ingress Stream Identification Table

Table 616. Table ID 30 - Ingress Stream Identification Table Common Attributes

TABLE_ID	30
TABLE_VERSION	0
Table Type	Hash table
Table Description	The Ingress Stream Identifier table contains a set of entries each capable of classifying incoming traffic using a mix of L2 parsed and arbitrary data fields, into streams. As a result of an entry match, an Ingress Stream Entry ID is provided, which is a locally significant identifier (global to the switch), that identifies a stream within an ENETC instance or the switch. The Ingress Stream Identification table can be used to support the IEEE 802.CB stream identification functions. The Ingress Stream Identifier table is an exact match table where four logical tables can be defined using four different L2 parsed and arbitrary data fields key (key construction types). The key construction type (defined in registers) is included in the key element of an entry, to identify to which of the four logical tables the entry belongs to. The datapath can perform two exact match lookups, each against different Ingres Stream Identifier logical table. The two logical tables (or key construction type) to be used is configurable on per port basis. Table management command operations Add, Delete, Update and Query are supported.

Table continues on the next page...

Table 616. Table ID 30 - Ingress Stream Identification Table Common Attributes (continued)

Number of Entries	The memory allotment to store the hash entries is shared across all of the (ENETC instance/ switch) function hash tables. The maximum amount of memory words available to store all of the function hash tables entries, is indicated in the register HTMCAPR[NUM_WORDS]). If the number of memory words in-use to store hash table entries for the function has reached this limit, the Add operation will fail. The number of memory words in-use by the function for hash table entries is indicated in the register HTMOR[AMOUNT].			
Default Reset Behavior	No entries in the table by default.			
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**	
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query.	
	Exact Match Key Element Match (KEY_ELEMENT)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x8 = Add. 0xC = Add, followed by a Query.	
	Ternary Match Key Element Match (KEY_ELEMENT)	No	--	
	Search (SEARCH_CRITERIA)	Yes	Only supported when command operation = 0x4 (Query). In the event of a search command requiring multiple iterations (see RESUME_ENTRY_ID), the user must not delete any entries in the table between iterations of that search.	
Data Buffer Component Attributes	**Name**	**Description**	**Size [bytes]**	**Alignment [bytes]**

53.4.2.4.7.10 Ingress Stream Table

Table 627. Table ID 31 - Ingress Stream Table Common Attributes

TABLE_ID	31
TABLE_VERSION	0
Table Type	Dynamic bounded index table
Table Description	The Ingress Stream table contains configuration and operational information about streams identified by the stream identification function. Each entry includes the actions (or functions) that are to be applied to frames belonging to a particular stream, such as: • Whether a frame is accepted or discarded • Specifies the PSFP (IEEE 802.1Qci) filtering and policing actions. To support a PSFP (IEEE 802.1Qci) stream filtering function that uses the 3-bit PCP value (priority) of the received frame and the stream handle (i.e. Ingress Stream Entry ID) to select a stream filter, an additional lookup (i.e. Ingress Stream Filter table lookup) can be specified in the Ingress Stream table entry. • FREF (IEEE 802.1CB) sequence generation function (switch only) • Stream forwarding function; the 802.1Q bridge forwarding function is by-passed, instead the Ingress Stream table provides the port(s) to which the frame should be output to (switch only) • Ingress frame modification in addition to adding a sequence tag (switch only)

10-9	2	DR	Drop Resilience New Drop Resilience (DR) to be assigned to the frame, if ODR is 1.
11	1	ODR	Override Drop Resilience (DR) 0b = Do not override frame DR. 1b = Override frame DR with value configured in DR field of this entry.
12	1	IMIRE	Ingress Mirroring Enable 0b = No ingress mirroring action specified in this entry. 1b = Frame is mirrored to the mirror destination specified by IMDCR0 register. Note: Not applicable to ENETC function
13	1	TIMECAPE	Timestamp Capture Enable 0b = No change to the timestamp. 1b = Timestamp is to be captured. Note: Not applicable to ENETC function
14	1	--	Reserved.
15	1	SPPD	Source Port Pruning Disable. This field is used to enable/disable source port pruning. Source port pruning ensures that frames do not get forwarded back to the port they originated from. Once the final destination ports have been determined, source pruning when enabled, will set the port from which the frame originated from, to 0 in the destination port bitmap. This field is valid only if the FA field of this entry is set 010b or 100b (stream forwarding) and will overwrite any previous configuration/setting for source pruning. 0b = Source port pruning enabled. 1b = Source port pruning disabled. Note: Not applicable to ENETC function.
17-16	2	ISQA	Ingress Sequence Action This field specifies whether the Frame Replication and Elimination for Reliability (FRER) sequence generation function (or action) is to be performed. Sequence generation consists of tagging a frame with a sequence number, following which the frame can be replicated and transmitted along multiple paths for redundancy. Implemented as per the IEEE 802.1CB. 00b = FRER sequence generation function is not performed. 01b = FRER sequence generation function is performed. 10b, 11b = Reserved. Note: Sequence Generation action is not applicable for ENETC function.
18	1	ORP	Override Rate Policer (instance) ID. 0b = Rate policer instance ID not overridden. 1b = Rate policer instance ID overridden.

Table continues on the next page...

Table 633. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			If ORP = 1, RP_EID specified in this entry overrides the default RP_EID (which is NULL) or PR_EID specified in Port filter.
19	1	OSGI	Override Stream Gate Instance Entry ID 0b = Stream Gate Instance Entry ID not overridden. 1b = Stream Gate Instance Entry ID overridden if OSGI = 1, specified SGI_EID in this entry overrides the default NULL SGI_EID.
23-20	4	HR	Host Reason This field specifies the Host Reason metadata when frame is redirected to the switch management port or copied to the switch management port (i.e. FA = 01b, 100b or 101b). Value specified has to be a software defined Host Reason (8-15). See Switch Management Port for details. Note: Not applicable to ENETC function.
26-24	3	FA	Forwarding Actions Switch function 000b = Discard. 001b = Re-direct frame to switch management port without any frame modification, along with Host Reason metadata set to the value configured in the HR field of this entry. Policing function will be applied to the frame if enabled. Stream and 802.1Q bridge forwarding functions are by-passed. 010b = Stream forwarding. It by-passes the 802.1Q bridge forwarding function. Frame is forwarded to the port(s) specified in the EGRESS_PORT_BITMAP field of this entry. 011b = 802.1Q bridge forwarding (VLAN processing and L2 forwarding). 100b = Copy to switch management port with specified HR and stream forwarding (stream forwarding action is as specified in FA = 010b). 101b = Copy to switch management port with specified HR and Bridge forwarding (Bridge forwarding action is as specified FA = 011b). All other values reserved. ENETC function 00b = Discard; 01b = Allow without setting the pre L2 filtering SI bitmap. 10b = Allow with setting the pre L2 filtering SI bitmap to the value configured in the SI_MAP field of this entry. If the pre L2 filtering SI bitmap was already set up by the ingress port filtering function, the pre L2 filtering SI bitmap is overwritten with the value configured in the SI_MAP field of this entry, The pre L2 filtering SI bitmap is used by the L2 filtering function to determine the final SI bitmap. All other values reserved.
28-27	2	SDU_TYPE	Service Data Unit type to use for MSDU (Maximum Service Data Unit) field. Overhead values are specified by register PRXSDUOR. 00b = PPDU (Physical Layer PDU). 01b = MPDU (MAC PDU).

Table continues on the next page...

Table 633. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			10b = MSDU (MAC SDU). All other values reserved. Note: This field has to be valid if MSDU field is not 0.
31-29	3	--	Reserved.
47-32	16	MSDU	Maximum Service Data Unit This field specifies the maximum service data unit size allowed for packets received on this stream. This is part of IEEE 802.1Qci (Per-Stream Filtering and Policing) specification. If the received frame length exceeds this value, the frame is discarded. A value of zero in this field, disables the maximum service data unit check. Note: This check is not performed for cut-through frames.
54-48	7	IFME_LEN_CHANGE	Ingress Frame Modification Entry Frame Length Change This field represents the effective frame length change of the ingress frame modification actions which are configured in the ingress frame modification entry (IFM_EID) referred by this entry. This frame length change value is used to adjust the frame length metadata, which in turn is passed along the frame processing pipeline, and used by the egress scheduling and management function to determine the actual length of the frame on the transmission link. Note that the egress queue scheduling and management function is executed prior to applying the frame modification actions to the frame, and thus the need to know of the frame length change resulting from the frame modification actions since it requires knowledge of the exact length of a frame transmitted on a link. Specifying explicitly the frame length change avoids having the hardware to read the ingress frame modifications entry and compute the frame length change itself. Fame length change is specified in unit of bytes using a 2's complement notation. Supported range is -4 bytes (removing one VLAN tag) to +4 bytes (adding one VLAN tag). This field is ignored by hardware if the IFM_EID field is set to NULL. Note: Not applicable to ENETC function.
59-55	5	EPORT	Egress Port This field specifies the identifier of the port requiring egress packet processing when the OETEID field of this entry is set to 01b (single-port Egress Treatment table access option). The port is expressed as an integer value. Switch Range: {0..SCAPR0[NUM_PORT]-1} Note: Not applicable to ENETC function.
61-60	2	OETEID	Override ET_EID This field is used to convey the egress packet processing actions to be applied to packets belonging to the stream associated with this entry. The egress packet

Table continues on the next page...

Table 633. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			processing actions are specified in the Egress Treatment table, where each table entry contains the egress packet processing actions to be applied to a scope of packets (e.g. stream) exiting on a particular egress port of the switch. The means by which one specifies the Egress Treatment table entries to be accessed, is through the Egress Treatment group. Within the hardware, an Egress Treatment group is determined by a base index (first Egress Treatment table entry of the group) and an applicability port bitmap (a bitmap corresponding to all ports of the switch) which indicates (with a 1) which ports have Egress Treatment table entries present. For more details, see Egress Treatment table access. Specifically, this field specifies how to derive the applicability port bitmap of the primary Egress Treatment group being assigned to packets belonging to the stream associated with this entry. The base index is specified in the ET_EID field of this entry. 00b = No egress packet processing actions specified. 01b = Single-port Egress Treatment table access. Only one port requires egress packet processing. That port identifier is specified in the EPORT field of this entry. The applicability port bitmap is set with a 1 for the port that is been identified in the EPORT field of this entry. For other ports, the applicability port bitmap is set to 0. The group assigned to packets belonging to the stream associated with this entry will have a single Egress Treatment table entry, for the port identified in the EPORT field of this entry. 10b = Multi-port packed Egress Treatment table access. Applicability port bitmap is set to the port bitmap specified in EGRESS_PORT_BITMAP field of this entry. The group assigned to packets belonging to the stream associated with this entry will have an Egress Treatment table entry for each port set to 1 in the applicability port bitmap. 11b = Multi-port absolute Egress Treatment table access. Applicability port bitmap is set with 1 for all ports. The group assigned to packets belonging to the stream associated with this entry will have Egress Treatment table entries for all ports on the switch. Valid if FA = 010b..101b and ET_EID is not NULL. Note: Not applicable to ENETC function.
63-62	2	CTD	Cut-Through Disable 00b = Do not override cut-through state. 01b = Disable cut-through for the outgoing port specified in the EPORT field. Cut-through is not disabled for the other ports specified in destination port bitmap (i.e. EGRESS_PORT_BITMAP field of this entry). 10b = Disable cut-through for all ports specified in the destination port bitmap (i.e. EGRESS_PORT_BITMAP of this entry). 11b = Reserved. Valid if FA = 010b .. 101b. All other values reserved.

Table continues on the next page...

Table 633. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			Note: Not applicable to ENETC function.
95-64	32	ISQ_EID	Ingress Sequence Generation Entry ID This field specifies the Ingress Sequence Generation Entry ID to be used as an index into the Ingress Sequence Generation table. Valid only when ISQA is set to 1. 0x0..ISQGITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); ingress sequence generation function is by-passed Other values are reserved Note: Not applicable to ENETC functions.
127-96	32	RP_EID	Rate Policer Entry ID This field specifies the Rate Policer Entry ID to be used as an index into the Rate Policer table. Valid if ORP is set to 1. Override Rate Policer Entry ID with this value when ORP =1. 0x0..RPITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); rate policing function is by-passed Other values are reserved
159-128	32	SGI_EID	Stream Gate Instance Entry ID This field specifies the Stream Gate Instance Entry ID to be used as an index into the Stream Gate Instance table. 0x0..SGIITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); stream gating function is by-passed Other values are reserved
191-160	32	IFM_EID	Ingress Frame Modification Entry ID This field specifies the Ingress Frame Modification Entry ID which is encoded either as an index into the Frame Modification table or encoded as a set of frame modification actions. For the latter, there is no need to access the Frame Modification table as the actions are encoded in the Ingress Frame Modification Entry ID itself. If IFM_EID is set to 0xFFFF_FFFF (NULL), no ingress frame modification is performed. If IFM_EID is not set to NULL, bits 15-0 are used for IFM_EID, upper bits are ignored. Refer to Table Frame Modification Entry Definition for IFM_EID format. Note: Not applicable to ENETC function
223-192	32	ET_EID	Egress Treatment Entry ID This field specifies the index (or base index) to be used when accessing the Egress Treatment table. This field is valid if FA field is set to 010b .. 101b, and the OETEID field is set to value other than 00b. 0x0..ETTCAPR[NUM_ENTRIES]-1

Table continues on the next page...

Table 633. Table ID 31 - Ingress Stream Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			0xFFFF_FFFF (NULL); egress treatment processing is by-passed Other values are reserved Note: Not applicable to ENETC function.
255-224	32	ISC_EID	Ingress Stream counter Index Index to a set of counters in common memory that will be updated for this Stream. 0x0..ICITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); no Ingress Stream Count table counters are updated Other values are reserved
279-256	24	EGRESS_PORT_BITMAP	Egress Port bitmap For FA = 010b, 100b (stream forwarding), this field identifies the destination port(s) to which the frame is to be forwarded for this stream. For FA = 011b, 101 (802.1Q bridge forwarding), this field identifies destination ports to which egress packet processing is required. The destination port(s) are represented as a bitmap, where each bit of the bitmap corresponds to a port on the switch. Least significant bit of the bitmap corresponds to the smallest port number; i.e. bit offset 0 of the bitmap corresponds to port numbered 0, bit offset 1 to port numbered 1, and so on. The port(s) to which the frame are to be forwarded (stream forwarding) and/or egress packet processing is required (VLAN/FDB), are identified by having their corresponding bit set to 1 in the bitmap. Valid bits in the bitmap is from 0..CAPR0[NUM_LINKS]-1 Bits beyond the valid range will be ignored. Note: Not applicable to ENETC function.
287-280	8	--	Reserved.
303-288	16	SI_MAP	Station Interface Map This field specifies a pre L2 filtering SI bitmap. Each bit of the bitmap corresponds to an SI on a given port. Least significant bit of the bitmap corresponds to the smallest SI number. The SIs to which the frame is to be delivered, are identified by having their corresponding bit set to 1 in the bitmap. Bit wise setting of Station Interface map. LSB is the lowest order of SI which is the primary SI, rest are VSIs. Number of VSIs are specified in CAPR0[NUM_VSI]. Bits beyond the valid range will be ignored. Note: This field is only valid for ENETC function when FA field is set to 10b.

53.4.2.4.7.11 Ingress Stream Filter Table

Table 634. Table ID 32 - Ingress Stream Filter Table Common Attributes

TABLE_ID	32
TABLE_VERSION	0

Table continues on the next page...

Table 634. Table ID 32 - Ingress Stream Filter Table Common Attributes (continued)

Table Type	Hash table			
Table Description	The Stream Filter table contains PSFP (IEEE 802.1Qci) stream filter information for stream filters selected based on the 3-bit PCP value (priority) of the received frame and the stream handle (i.e. Ingress Stream Entry ID). Table management command operations Add, Delete, Update and Query are supported.			
Number of Entries	The memory allotment to store the hash entries is shared across all of the (ENETC instance/ switch) function hash tables. The maximum amount of memory words available to store all of the function hash tables entries, is indicated in the register HTMCAPR[NUM_WORDS]). If the number of memory words in-use to store hash table entries for the function has reached this limit, the Add operation will fail. The number of memory words in-use by the function for hash table entries is indicated in the register HTMOR[AMOUNT].			
Default Reset Behavior	No entries in the table by default.			
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**	
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query.	
	Exact Match Key Element Match (KEY_ELEMENT)	Yes	Following commands are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x8 = Add. 0xC = Add, followed by a Query.	
	Ternary Match Key Element Match (KEY_ELEMENT)	No	--	
	Search (SEARCH_CRITERIA)	Yes	Only supported when command operation = 0x4 (Query). In the event of a search command requiring multiple iterations (see RESUME_ENTRY_ID), the user must not delete any entries in the table between iterations of that search.	
Data Buffer Component Attributes	**Name**	**Description**	**Size [bytes]**	**Alignment [bytes]**

Bits	Width [bits]	Name	Description
3-0	4	IPV	Internal Priority Value New Internal Priority Value (IPV) to be assigned to the frame, if OIPV is set to 1. The least significant 3 bits are used, most significant bit is reserved.
4	1	OIPV	Override Internal Priority Value (IPV) 0b = Don't override frame IPV. 1b = Override frame IPV with value configured in IPV field of this entry.
6-5	2	DR	Drop Resilience New Drop Resilience (DR) to be assigned to the frame, if ODR is set 1.
7	1	ODR	Override Drop Resilience (DR) 0b = Don't override frame DR. 1b = Override frame DR with value configured in DR field of this entry.
8	1	IMIRE	Ingress Mirroring Enable 0b = No ingress mirroring action specified in this entry. 1b = The frame is mirrored to the mirror destination specified in the IMDCR0 register. Note: Not applicable to ENETC function.
9	1	TIMECAPE	Timestamp Capture Enable 0b = No change to the timestamp. 1b = Timestamp is to be captured. Note: Not applicable to ENETC function.
10	1	OSGI	Override Stream Gate Instance Entry ID 0b = Stream Gate Instance Entry ID not overridden 1b = Stream Gate Instance Entry ID overridden; specified SGI_EID in this entry overrides the default null SGI_EID or SGI_EID specified in Ingress Stream table.
11	1	CTD	Cut-Through Disable 00b = Do not override cut-through state.

Table continues on the next page...

Table 642. Table ID 32 - Ingress Stream Filter Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			01b = Disable cut-through for all destined ports. Note: Not applicable to ENETC function.
12	1	ORP	Override Rate Policer (instance) ID 0b = Rate policer instance ID not overridden 1b = Rate policer instance ID overridden If the rate policer instance was already set by a match in the Ingress Port Filter table or Ingress Stream table and if ORP is set to 1, the rate policer instance value is overwritten with the value configured in the RP_EID field of this entry.
14:13	2	SDU_TYPE	Service Data Unit type to use for MSDU (Maximum Service Data Unit) field. Overhead values are specified by register PRXSDUOR. 00b = PPDU (Physical Layer PDU). 01b = MPDU (MAC PDU). 10b = MSDU (MAC SDU). All other values reserved. Note: This field has to be valid if MSDU field is not 0.
15	1	--	Reserved.
31-16	16	MSDU	Maximum Service Data Unit This field specifies the maximum service data unit size defined for the stream. This is part of IEEE 802.1Qci (Per-Stream Filtering and Policing) specification. If the received frame length exceeds this value, the frame is discarded. A value of zero in this field, disables the maximum SDU check. This field overrides the maximum SDU check field specified in the previous matched Ingress Stream table entry. Note: This check is not performed for cut-through frames.
63-32	32	RP_EID	Rate Policer Entry ID This field specifies the Rate Policer Entry ID to be used as an index into the Rate Policer table. Valid if ORP is set to 1. Override Rate Policer Entry ID with this value when ORP = 1. 0x0..RPITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); rate policing function is by-passed Other values are reserved
95-64	32	SGI_EID	Stream Gate Instance Entry ID This field specifies the Stream Gate Instance Entry ID to be used as an index into the Stream Gate Instance table. Stream Gating action will be performed if SGI_EID is not null. Valid if OSGI is set to 1. 0x0..SGIITCAPR[NUM_ENTRIES]-1 0xFFFF_FFFF (NULL); stream gating function is by-passed Other values are reserved

Bits	Width [bits]	Name	Description
31-0	32	RESUME_ENTRY_ID	Resume Entry ID When starting a search, pass the NULL Entry ID. To continue a search, pass the RESUME_ENTRY_ID value returned in the CBD Response of the previous search command. Note: A NULL Entry ID is 0xFFFF_FFFF

53.4.2.4.7.12 Egress Treatment Table

Table 645. Table ID 33 - Egress Treatment Table Common Attributes

TABLE_ID	33
TABLE_VERSION	0
Table Type	Dynamic bounded index table
Table Description	Each entry in the Egress Treatment table contains the egress packet processing actions to be applied to a grouping or scope of packets exiting on a particular egress port of the switch. A scope of packets, for example could be the packets exiting a particular VLAN, matching a particular 802.1Q bridge forwarding entry or belonging to a stream identified at ingress. The Egress Treatment table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. Egress Treatment Entry ID (ET_EID) is used as an index to an entry in this table. For this table, each table entry occupies 8 bytes. Note that when software performs a Query operation, and requests the Configuration Element data to be returned, the Configuration Element data in the Response Data Buffer may not precisely match the data which was used when an Add operation was issued. If EFM_MODE=00b

Table continues on the next page...

Table 645. Table ID 33 - Egress Treatment Table Common Attributes (continued)

	then the value of EFM_DATA_LEN is always returned as 0x0. If EFM_MODE=01b or EFM_MODE=10b then the value of EFM_LEN_CHANGE is always returned as 0x0.			
Number of Entries	Maximum number of entries is indicated in ETTCAPR. Number of entries in-use is indicated in ETTOR[NUM_ENTRIES]. Entry size is 8 bytes.			
Default Reset Behavior	No entries in the table by default.			
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**

Table 651. Table ID 33 - Egress Treatment Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
1-0	2	EFM_MODE	Egress Frame Modification Mode This field is used to determine how the EFM_LEN_CHANGE or EFM_DATA_LEN field is used to get the effective length of the frame, after modifications. See the description of these fields for more details. 00b = Normal/Default mode. The EFM_LEN_CHANGE field is used to make adjustments to the frame size. 01b = When EFM_EID[L2_ACT]=01b. The EFM_DATA_LEN field represents the new size of the frame. 10b = When EFM_EID[PLD_ACT]=001b. The EFM_DATA_LEN field represents the size of the Ethernet payload plus any changes to the L2 Header. 11b = Reserved.
3-2	2	--	Reserved
5-4	2	ESQA	Egress Sequence Actions 00b = No Sequence Action required. 01b = Reserved. 10b = Sequence Recovery action. See ESQA_TGT_EID. 11b = Reserved.
8-6	3	ECA	Egress Counter Action 000b = Do not increment egress frame counter. 001b = Increment egress frame counter. See EC_EID. 010b ..111b = Reserved.
15-9	7	EFM_LEN_CHANGE	Egress Frame Modification Length Change This field specifies the frame length change that represents the effective frame length change of the egress frame modification actions configured in the EFM_EID field of this entry. This frame length change value is used to adjust the frame length meta data, which in turn is passed to the egress scheduling and management functions to represent the actual length of the frame on the transmission link. Specifying explicitly the frame length change avoids having the hardware to read the egress frame modifications entry and compute the frame length change itself.

Table continues on the next page...

Table 651. Table ID 33 - Egress Treatment Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			Frame Length change is specified in units of bytes using a 2's complement notation. Supported range is -10 bytes (removing one VLAN tag and one R-TAG/HSR) to +6 bytes (adding one VLAN tag and replacing a 4-byte 802.1CB draft 2.0 R-TAG with 6-byte 802.1CB R-TAG or HSR tag). This field is ignored by hardware if the EFM_EID field is set to null, or if EFM_MODE != 00b. As a result, when performing a Query operation the value returned may not precisely match the value used when the Add operation was issued.
26-16	11	EFM_DATA_LEN	Egress Frame Modification Data Length The value specified in this field is used to adjust the frame length meta data, which in turn is passed to the egress scheduling and management functions to represent the actual length of the frame on the transmission link. When EFM_MODE=01b, this field must be set to mirror the value held in EFM_EID[FMD_BYTES]. When EFM_MODE=10b, this field must be set to the value held in EFM_EID[FMD_BYTES] plus or minus any change to the L2 header due to egress L2 header frame modifications. For example, if a VLAN is being added, this field would be set to EFM_EID[FMD_BYTES]+4. EFM_EID[FMD_BYTES] minus the L2 header size decrease due to the egress L2 header modification actions specified, must be higher than 0. For example, if a VLAN tag is being removed, the minimum number of bytes that can be specified in EFM_EID[FMD_BYTES] is 5 bytes. Hardware uses the value of this field, to compute what would be the length of the frame on the transmission link, by first adding the value specified in this field to the size of the L2 header in the received frame. The resulted frame length is then adjusted for any ingress L2 header modifications. The Data Length field is specified in units of bytes. Supported range is 1 to 2047 bytes. Support for payload/frame creation when EFM_MODE=01b or 10b, not payload replacement. This field is ignored by hardware if the EFM_EID field is set to null, or if EFM_MODE != 01b or 10b. As a result, when performing a Query operation the value returned may not precisely match the value used when the Add operation was issued.
31-27	5	--	Reserved.
63-32	32	EFM_EID	Egress Frame Modification Entry Id. This field specifies the Egress Frame Modification Entry ID which is encoded either as

Table continues on the next page...

Table 651. Table ID 33 - Egress Treatment Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			an index into the Frame Modification table or encoded as a set of frame modification actions. For the latter, there is no need to access the frame modification table as the actions are encoded in the Egress Frame Modification Entry ID itself. If EFM_EID is set to 0xFFFF_FFFF (NULL), no egress frame modification is performed. If EFM_EID is not set to NULL, bits 15-0 are used for EFM_EID, upper bits are ignored. Refer to Frame Modification Entry Definition for EFM_EID format.
95-64	32	EC_EID	Egress Count Table Entry ID Index to a set of egress counters in common memory that will be updated. Valid if ECA not set 0 Valid Range: {0..ECTCAPR[NUM_WORDS]-1} Note: If EC_EID is not Null, bits 15-0 are used for EC_EID, upper bits are ignored, and as a result only 2 bytes of memory are used to store the EC_EID.
127-96	32	ESQA_TGT_EID	Egress Sequence Actions Target Entry ID Valid if ESQA=2, it then represent the ESQR_EID Valid Range: {0..ESQACAPR[NUM_WORDS]-1} Note: If ESQA_TGT_EID is not Null, bits 15-0 are used for ESQA_TGT_EID, upper bits are ignored, and as a result only 2 bytes of memory are used to store the ESQA_TGT_EID.

53.4.2.4.7.13 Ingress Sequence Generation Table

Table 652. Table ID 34 - Sequence Generation Table Common Attributes

TABLE_ID	34
TABLE_VERSION	0
Table Type	Dynamic bounded index table
Table Description	The Ingress Sequence Generation table provides the tag type to be inserted and the next sequence number value to be used in that tag. This table is used to implement the IEEE 802.1CB sequence generation function which consists of tagging a frame with a sequence number, following which the frame can be replicated and transmitted along multiple paths for redundancy. The Ingres Sequence Generation table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. The entries are stored in contiguous manner in the common memory. Ingress Sequence Generation Entry ID (ISQ_EID) is used as an index to an entry in this table. The Ingress Sequence Generation Entry ID is specified in the Ingress Stream table entry. For this table, there are 8 entries per word. Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) register S0ISQGITMAR[NUM_WORDS]. This allocation can also be changed when the function is initialized through its respective base function register ISQGITMAR[NUM_WORDS]. Table management command operations Add, Delete, Update and Query are supported.

Bits	Width [bits]	Name	Description
15-0	16	SQG_NUM	Sequence Generation Number. This field specifies the next sequence number value to be used in the tag to be added to the frame. Initialized to 0 when entry is added or reset is performed. SQG_NUM is incremented by one after each packet that passes through the sequence generation function. This field rolls over to 0 when maximum value of 0xFFFF is reached.

53.4.2.4.7.14 Egress Sequence Recovery Table

Table 661. Table ID 35 - Egress Sequence Recovery Table Common Attributes

TABLE_ID	35		
TABLE_VERSION	0		
Table Type	Static bounded index table		
Table Description	The Egress Sequence Recovery table contains one entry per FRER recovery function (implemented as per 802.1CB), and each entry contains a number of configuration elements, whose value is set when the table entries are configured, and operational elements, which are managed by the hardware and can be queried by software. Whether or not a FRER recovery function is to be performed is specified in the Egress Treatment table, and if so then the Egress Treatment table also provides an index into a Egress Sequence Recovery table. The Egress Sequence Recovery table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. The entries are stored in contiguous manner in a dedicated memory. Egress Sequence Actions Target Entry ID (ESQA_TGT_EID) is used as an index to an entry in this table. The ESQA_TGT_EID is specified in the Egress Treatment table.		
Number of Entries	Number of entries is indicated in ESQRTCAPR[NUM_ENTRIES].		
Default Reset Behavior	After reset all table fields are cleared to 0.		
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported:

Table 667. Table ID 35 - Egress Sequence Recovery Table CFGE_DATA Description

Bits	Width [bits]	Name	Description
2-0	3	SQ_TAG	Sequence Tag This field is optional, and can be used to specify the expected sequence tag type in the frame. The default setting of 0 causes sequence recovery to be performed on any tag type, with frames treated as tagless only if no sequence tag is present. If SQ_TAG is non-zero, then this fields specifies the expected sequence tag type in the frame, sequence recovery is performed if the sequence tag type in the frame matches SQ_TAG, otherwise the frame is treated as tagless. 000b = Accept any incoming tag type. 001b = 802.1CB draft 2.0 R-TAG. 010b = 802.1CB R-TAG. 011b = HSR Tag 100b ... 111b = Reserved.
3	1	SQR_TNSQ	Sequence Recovery Take No Sequence This field specifies the action taken (accept or discard) on frames passing through a FRER recovery function that are tag-less, A frame is considered tagless if it has no sequence tag, or if SQ_TAG is not 0 and the tag type in the frame does not match the tag type specified in SQ_TAG. 0b = Discard frame and count in both the TAGLESS_PACKETS counter and in the port's PTXDCR register along with the setting of the SQRTNSQDR flag to 1 in the port's PTXDCRR0 register. 1b = Accept frame and do not perform recovery function. Note: Driver adds TaglessPackets to frerCpsSeqRcvyDiscardedPackets if SQR_TNSQ=1.
4	1	SQR_ALG	Sequence Recovery Algorithm This field specifies the recovery function algorithm. 0b = Vector algorithm. The vector recovery algorithm starts by always accepting the first received frame as valid. After the first frame has been accepted, all subsequent frames whose sequence number is in the window (last sequence number accepted +/- (recovery history length-1)) are checked against the recovery history to see if a previous frame with the same sequence number has already been accepted, and if

Table continues on the next page...

Table 667. Table ID 35 - Egress Sequence Recovery Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			so the current frame is rejected, otherwise it is accepted and the recovery history is updated to indicate the newly accepted sequence number. Frames whose sequence number falls outside of the recovery history window are rejected and counted as rogue frames. 1b = Match algorithm. The match recovery algorithm starts by always accepting the first received frame as valid, same as vector recovery. After the first frame has been accepted, all subsequent frames either match the last frame number accepted, and are therefore discarded, or do not, in which case they are accepted. The recovery history (SQR_HL) and the future window length (SQR_FWL) are not used by the match recovery algorithm.
5	1	SQR_TYPE	Sequence Recovery Function type This field specifies the type of recovery function supported: 0b = Sequence recovery function. For a sequence recovery function, the stored frame timestamp is updated only for accepted frames, it is not updated for rejected frames. This means that a sequence recovery function that is out of step and is continually rejecting frames will be reset after the timeout period is reached, allowing it to resume sending frames. 1b = Individual recovery function. For an individual recovery function, the stored frame timestamp is updated for all frames. This means that an individual recovery function will not timeout even if all received frames are rejected, and can only timeout if frames stop arriving for a long time (timeout period or greater), and then start arriving again.
7-6	2	--	Reserved.
14-8	7	SQR_HL	Sequence Recovery History Length This field specifies how many bits are used in the SQR History operational variable. The history length is equal to SQR_HL + 1. Valid if SQR_ALG = 0 Range: 1..ESQRCAPR[SQR_MAX_HL] Any attempt to set a history length larger than the maximum supported will result in the history length being set to its maximum. Any frame whose sequence number is less than or equal to SQR_NUM - history length (SQR_HL + 1) is rejected and counted as a rogue packet.
15	1	--	Reserved.
27-16	12	SQR_FWL	Sequence Recovery Future Window Length This field specifies the length of the recovery window for frames whose sequence number is greater than the last seen highest sequence number SQR_NUM. Valid if SQR_ALG = 0 The future window length is set to SQR_FWL + 1, so the default value is 1. Any frame whose sequence number is greater than or equal to SQR_NUM + SQR_FWL + 1 is rejected and counted as a rogue packet. Note this field is not part of the 802.1CB standard, to achieve behavior compliant to the standard the user should set SQR_FWL = SQR_HL.

Table continues on the next page...

Table 667. Table ID 35 - Egress Sequence Recovery Table CFGE_DATA Description (continued)

Bits	Width [bits]	Name	Description
31-28	4	--	Reserved.
43-32	12	SQR_TP	Sequence Timeout Period This field specifies the recovery timeout period in increments of 1.048576 milliseconds. A value of 0 disables recovery timeout. Each recovery function stores a timestamp of the last frame accepted (for sequence recovery) or the last frame seen (for individual recovery). Each time a frame passes through the recovery function, the time that has expired since the last frame timestamp (current time minus last frame time) is calculated, and if the expired time exceeds the configured recovery timeout period, then the recovery function is reset.
63-44	20	--	Reserved.

Table 669. Table ID 35 - Egress Sequence Recovery Table STSE_DATA Description

Bits	Width [bits]	Name	Description
63-0	64	IN_ORDER_PACKETS	In Order Packets Count of packets that have passed the sequence recovery algorithm in a sequence order. Standard: frerCpsSeqRcvyPassedPackets = InOrderdPackets + OutOfOrderPackets + TaglessPackets (if SQR_TNSQ=1)

Table continues on the next page...

Table 669. Table ID 35 - Egress Sequence Recovery Table STSE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			Note: tsnCpsSidInputPackets = frerCpsSeqRcvyPassedPackets + frerCpsSeqRcvyDiscardedPackets
127-64	64	OUT_OF_ORDER_PACKETS	Out of Order Packets Incremented once for each packet accepted out-of-order by the Egress Sequence Recovery Algorithm. Count of packets that are out-of-order meaning that their sequence number is not one more than the one of the previous received packet. Standard: frerCpsSeqRcvyOutOfOrderPackets
191-128	64	ROGUE_PACKETS	Rogue Packets Count of packets discarded by the vector recovery algorithm whose sequence number have fallen outside of the recovery history window. The port's PTXDCR register is also incremented along with the setting of the SQRRDR flag to 1 in the port's PTXDCRR0 register. Standard: frerCpsSeqRcvyRoguePackets
255-192	64	DUPLICATE_PACKETS	Duplicate Packets Count of packets discarded due to a duplicate sequence number. The port's PTXDCR register is also incremented along with the setting of the SQRDDR flag to 1 in the port's PTXDCRR0 register. Standard: frerCpsSeqRcvyDiscardedPackets=RoguePackets + DuplicatePackets + TaglessPackets (if SQR_TNSQ=0) + EnqueueDiscardPackets
319-256	64	LOST_PACKETS	Lost Packets Count of packets lost by the vector recovery algorithm. A packet is counted as lost if its sequence number is not received on any ingress port. Standard: frerCpsSeqRcvyLostPackets
383-320	64	TAGLESS_PACKETS	Tag-Less Packets Count of packets received by the recovery function that have no sequence_number, or whose sequence tag type does not match SQ_TAG if SQ_TAG is non-zero. If the frame is discarded (SQR_TNSQ = 0), then the port's PTXDCR register is also incremented along with the setting of the SQRTNSQDR flag to 1 in the port's PTXDCRR0 register. Standard: frerCpsSeqRcvyTaglessPackets and frerCpsSeqEncErroredPackets
415-384	32	SREC_RESETS	Sequence Recovery Resets Count is incremented each time the sequence recovery function is reset due to recovery timeout. Standard: frerCpsSeqRcvyResets

Table 670. Table ID 35 - Egress Sequence Recovery Table SRSE_DATA Format

SQR_HISTORY																																0x10

Table 671. Table ID 35 - Egress Sequence Recovery Table SRSE_DATA Description

Bits	Width [bits]	Name	Description
15-0	16	SQR_NUM	Sequence Recovery Number This field holds the highest sequence number value received so far by the recovery function, or 0xFFFF after reset of the recovery function. The sequence number is an unsigned integer that rolls over from maximum to 0, therefore at the rollover boundary sequence number 0 is treated as larger than sequence number 0xFFFF.
16	1	TAKE_ANY	Take Any This field is set to 1 when the recovery function is reset, and cleared after the first frame is received. The recovery function always accepts the first frame after reset, which updates SQR_NUM and SQR_HISTORY. All subsequent frames are then accepted or rejected based on their sequence number and the recovery algorithm used. Operational Element field which when set causes recovery algorithm to accept the next packet, no matter the value of its sequence number.
17	1	LCE	Lost Count Enable This field is reset to 0 and disables lost packet counting when the recovery function is reset. This bit is set to 1 the first time that the history window is moved and a 1 is detected in the history bits that are shifted out, i.e. there has been at least one sequence number received and shifted out of the history. Then lost packet counting will begin at the next history window move.
29-18	12	SQR_TS	Sequence Recovery Timestamp This field stored the timestamp of the last frame accepted (for sequence recovery) or the last frame seen (for individual recovery.
31-30	2	--	Reserved.
159-32	128	SQR_HISTORY	Recovery History This is a bit vector that maintains a history of the sequence numbers of recently received packets, with each bit corresponding to sequence numbers from SQR_NUM down to

Table continues on the next page...

Table 671. Table ID 35 - Egress Sequence Recovery Table SRSE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			SQR_NUM - SQR_HL + 1. A 1 in a history bit indicates that a packet with that sequence number has been previously received, a 0 indicates that no packet with that sequence number has yet been received.

53.4.2.4.7.15 Stream Gate Instance Table

Table 672. Table ID 36 - Stream Gate Instance Table Common Attributes

TABLE_ID	36
TABLE_VERSION	0
Table Type	Dynamic bounded index table
Table Description	The Stream Gate Instance (SGI) table contains the stream gate configuration and operational information for a NETC function. There is one SGI table for each ENETC instance and one SGI table for the entire switch. Each entry contains a set of parameters that defines a single stream gate instance. The stream gate instance parameters includes an administrative stream gate control list and an operational stream gate control list, along with related configuration and status parameters. A stream gate control list (SGCL) is used to specify time gates or time slots during which incoming frames from one or more streams will be accepted. This table is implemented as a linear array of entries accessed using an index (0, 1, 2, ..., n) that uniquely identifies an entry within the array. The entries are stored in contiguous manner in the common memory. For this table, each table entry occupies one word (one to one corresponding between words and entries). Allocation of this table is first performed at pre-boot initialization time based on the setting of the Integrated Endpoint Register Block (IERB) registers; S0SGIITMAR[NUM_WORDS] for switch and EaSGIITMAR[NUM_WORDS] for ENETC. These allocations can also be changed when the functions are initialized through their respective base function registers SGIITMAR[NUM_WORDS]. The index to access this table, is obtained earlier on, via lookups in the Ingress Stream or in the Ingress Stream Filter table. An SGI can hold two SGCLs, one as operational and the other as administrative. An administrative SGCL becomes operational at Config Change Time as defined in the IEEE 802.1Qci standard and remains operational till another SGCL is installed. An administrative SGCL is added to a SGI using the Add or Update operations. The actual SGCLs are stored in a separate table called the Stream Gate Control List table, with references to these SGCLs (that is, entry IDs) specified in the SGI table. It is recommended that the entry ID for each of these two SGCLs be predetermined and known by software, and persist till the SGI is no longer in use. Take the following into consideration when accessing the SGI table[1]: • **Initialization** - The 1588 timer must be initialized and configured before adding any SGCL to an SGI. See IEEE 1588 timer module, for information on how to initialize and configure the 1588 timer. After the 1588 timer is in normal operation, any change to the 1588 timer configuration (for example TMROFF_H/L), except for TMR_ADD updates, requires that all SGIs with an operational SGCL be deleted, and for SGIs that have no operational SGCLs, that the administrative SGCL, if present, be removed from the SGI. • **Stream association -** An SGI can be associated with only one switch port. Streams from different switch ports cannot use the same SGI.

Table continues on the next page...

Table 672. Table ID 36 - Stream Gate Instance Table Common Attributes (continued)

	• **Config Change Time** - Note that when Config Change Time has been reached, the actual installation of a new SGCL, will occur at the next event that will cause the operational SGCL to be traversed; that is reception of a frame or expiry of the refresh timestamp timer. For any SGI command processed by hardware prior to this event, the administrative SGCL is considered to be still pending although the Config Change Time may have been reached. • **Add operation** - When an ADMIN_SGCL_EID is specified in the Add operation, the SGI will operate with the initial SGI configuration till the ADMIN_SGCL_EID is installed at Config Change Time. An SGI can operate without an SGCL and with just the initial SGI configuration. To operate in this mode, specify a NULL ADMIN_SGCL_EID in the Add operation. • **Update operation** - This operation is used to add a new administrative SGCL to an existing SGI or to remove an administrative SGCL from an SGI. For the details on how to add a new administrative SGCL, refer to the sequence described below in Adding an administrative SGCL to an SGI. For the details on how to remove an administrative SGCL, refer to the sequence described below in Removing an administrative SGCL from an SGI. Note that if the operational SGCL is present, it will continue to operate as normal. • **Delete operation** - Perform the following steps to delete an SGI table entry: 1. Remove, if present in the SGI, the administrative SGCL by means of an SGI command containing an Update operation to the SGI's Admin Configuration Element with ADMIN_SGCL_EID set to NULL. 2. Issue a Delete operation against the SGI table entry that is to be deleted. 3. If needed, delete the SGCLs from the Stream Gate Control List table. Since there are two possible SGI_EIDs, which the deleted SGI may have used, software can then safely issue SGCL commands containing a Delete operation to those two SGCLs. A Delete operation to an SGCL has not been added before or has been already deleted, will execute with no error; that is, the Delete operation is not performed, and the response message indicates that no entry has been found (NUM_MATCHED in Response Message Header is set to 0). ***Adding an administrative SGCL to a SGI*** Follow these steps to add an administrative SGCL to an SGI: 1. Since software has only two possible SGCLs (and therefore, SGCL_EIDs) to use, software must first verify that at least one of them is unused by the hardware, and therefore, "free" to be configured and associated to the SGI. This procedure is started by issuing a query on the SGI to record the presence of both the administrative and operational SGCLs (found in SGISE_DATA[STATE]), and the SGCL_EIDs (found in ACFGE_DATA[ADMIN_SGCL_EID] and SGISE_DATA[OPER_SGCL_EID]), respectively, if valid, based on the value of SGISE_DATA[STATE]. • **Case 0** - Neither SGCL is present. An administrative SGCL may be configured and associated to the SGI. Proceed to Step 3. • **Case 1** - An administrative SGCL only is present. Execute the sequence described below in Removing an administrative SGCL from an SGI, but starting at step 2 (as step 1 has already performed in this sequence), to remove the administrative SGCL and then retry this sequence.

Table continues on the next page...

Table 672. Table ID 36 - Stream Gate Instance Table Common Attributes (continued)

	• **Case 2** - An administrative SGCL and an operational SGCL is present. Both SGCLs are currently in use; a new one may not be configured. Execute the sequence described below in Removing an administrative SGCL from an SGI, but starting at step 2 (as step 1 has already performed in this sequence), to remove the administrative SGCL and then retry this sequence. • **Case 3** - An operational SGCL only is present. An administrative SGCL can be configured and associated to the SGI. Proceed to Step 2. 2. Ensure that any stale SGCL is deleted from the SGCL table; a stale SGCL is an operational SGCL that ceased to be operational as it was replaced by a new SGCL. a. Since there are two possible SGI_EIDs which this SGI may use, any of the two lists which are not present, may be deleted. The SGI_EID(s) present in the SGI is indicated based on the combination of SGISE_DATA[STATE] and ACFGE_DATA[ADMIN_SGCL_EID]/SGISE_DATA[OPER_SGCL_EID]. b. Software can then safely issue SGCL commands containing a Delete operation to those SGCLs. A Delete operation to an SGCL has not been added before or has been already deleted, will execute with no error; i.e. the Delete operation is not performed, and the response message indicates that no entry has been found (NUM_MATCHED in Response Message Header is set to 0). 3. Software may chose an SGCL from its pool of two SGCLs for this SGI which is currently unused by the hardware (or not present) and issue a command containing an Add operation to SGCL table, to add the new administrative SGCL. 4. The new added SGCL may now be associated with the SGI by means of an SGI command containing an Update operation to the SGI's Admin Configuration Element with the new SGCL (e.g. setting ADMIN_SGCL_EID to new added SGCL_EID). ***Removing an administrative SGCL from an SGI*** Follow these steps to remove an administrative SGCL from an SGI: 1. This procedure is started by issuing a query on the SGI. Software records the presence of both the administrative and operational SGCLs (found in SGISE_DATA[STATE]), and the SGCL_EIDs (found in ACFGE_DATA[ADMIN_SGCL_EID] and SGISE_DATA[OPER_SGCL_EID]), respectively, if valid, based on the value of SGISE_DATA[STATE]. 2. Remove the administrative SGCL by means of an SGI command containing an Update operation to the SGI's Admin Configuration Element with ADMIN_SGCL_EID set to NULL. 3. Query the SGI again. a. If the query response indicates that no administrative SGCL is present, and if the “operational SGCL” encoding from SGISE_DATA[STATE] and SGISE_DATA[OPER_SGCL_EID] (if operational SGCL is present) are matching the queried values from Step 1, this indicates that the administrative SGCL was successfully removed from the SGI. Proceed to Step 4. b. If software finds that either an operational SGCL is now present when it did not in the Step 1 query, or if the SGCL_EID of the operational SGCL is different from the one in the Step 1 query, this indicates that the update command in Step 2 was processed by the hardware only after the administrative SGCL (which software was attempting

Table continues on the next page...

Table 672. Table ID 36 - Stream Gate Instance Table Common Attributes (continued)

	to uninstall) had become operational. In this case, software must not proceed to delete the SGCL. Do not proceed to step 4. 4. The administrative SGCL was successfully removed from the SGI, it is now safe to issue a SGCL command containing a Delete operation to the administrative SGCL.			
Number of Entries	Maximum number of entries is indicated in SGIITCAPR[NUM_ENTRIES]. Number of entries in-use is indicated in SGIITOR[NUM_ENTRIES].			
Default Reset Behavior	No entries in the table by default.			
Access Method (ACCESS_METHOD)	**Access Method**	**Supported**	**Restrictions**	
	Entry ID Match (ENTRY_ID)	Yes	Following table management command operations are supported: 0x1 = Delete. 0x2 = Update. 0x4 = Query. 0x8 = Add.	
	Exact Match Key Element Match (KEY_ELEMENT)	No	--	
	Ternary Match Key Element Match (KEY_ELEMENT)	No	--	
	Search (SEARCH_CRITERIA)	No	--	
Data Buffer Component Attributes	**Name**	**Description**	**Size [bytes]**	**Alignment [bytes]**
	ENTRY_ID	Entry Id (SGI_EID)	4	4
	ACCESS_KEY	Access Key	4	4
	ACFGE_DATA	Admin Configuration Element	16	4
	ICFGE_DATA	Initial Configuration Element	1	1
	CFGE_DATA	Configuration Element	1	1
	SGISE_DATA	Stream Gate Instance State Element	13	4
Entry Alignment [bytes]	4			

Table continues on the next page...

Table 672. Table ID 36 - Stream Gate Instance Table Common Attributes (continued)

Entry ID Management	Software assigns entry IDs
Response STATUS Applicable	No
ERROR codepoints specific to this table	0x000 = no errors 0x001-0x07F = reserved 0x080-0x0FF = Generic codepoints; see ERROR field description. 0x2C0 = SGCL_EID specified in out of range for Add or Update operation. Valid SGCL_EID values are {0..SGCLITCAPR[NUM_WORDS]-1}, NULL (0xFFFF_FFFF). 0x2C1 = SDU_TYPE is specified is invalid for Add or Update operation. 0x2C2 = Either the SGCL_EID specified as admin gate control list in Add or Update operation has not been allocated or SGCL_EID is not the first entry in gate control list, or the reference count in SGCL entry is not 0. 0x2C3 = SGCL_EID specified for Update operation is in invalid. When update is performed for an existing Admin control list, SGCL_EID specified in Update operation has to match that in the Stream Gate Instance. An Admin list exist in the Stream gate Instance if STATE in SGISE_DATA element = 2 or 3. 0x2C4 = ADMIN_BASE_TIME specified for Add or Update operation is more than 2^30ns in the past. (that is, current time - ADMIN_BASE_TIME is <2 ^30ns) 0x2C5 = Cumulated time value of CYCLE_TIME in Stream gate Control list plus CYCLE_TIME_EXT specified in Add or Update operation is >=2^30ns or CYCLE_TIME specified is 0.

1. The command sequences described in these considerations, assume that the entry ID for each of the two SGCLs be predetermined and known by software

ADMIN_BASE_TIME																																0x8
ADMIN_CYCLE_TIME_EXT																																0xC

Table 678. Table ID 36 - Stream Gate Instance Table ACFGE_DATA Description

Bits	Width [bits]	Name	Description
31-0	32	ADMIN_SGCL_EID	Administrative Stream Gate Control List Entry ID This field specifies the Entry ID in the Stream Gate Control List table (expressed in units of words) of the administrative stream gate control list to be used for this stream gate instance. 0x0..SGCLITCAPR[NUM_WORDS]-1 0xFFFF_FFFF (NULL); implies no Gate Control List specified. Other values are reserved
95-32	64	ADMIN_BASE_TIME	Admin Base Time This field sets the base time, that is, the start time, of the administrative gate control sequence. The time is expressed in units of nanoseconds. The field implements the PSFPAdminBaseTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 PSFPAdminBaseTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expects the time to be specified as a 64-bit integer number of nanoseconds. Therefore, if this field is to be set to a value which was obtained from a managed object using the IEEE 802.1Q-2018 PTP time format, the value must be converted by software from the IEEE 802.1Q-2018 format to the 64-bit integer number of nanoseconds. This field is reserved when ADMIN_SGCL_EID is NULL.
127-96	32	ADMIN_CYCLE_TIME_EXT	Admin Cycle Time Extension The value supplied in this field is equivalent with the 802.1.Qci definition of "Cycle Time Extension". When the administrative stream gate control list becomes operational, this is the maximum amount of time by which the cycle time is permitted to be extended before a new administrative stream gate control list takes effect. The time is expressed as an integer number of nanoseconds. Only least significant 30 bits are valid. Upper two bits are ignored. It is required that CYCLE_TIME in Stream gate control list + ADMIN_CYCLE_TIME_EXT must be < 2^{30} -1. This field is reserved when ADMIN_SGCL_EID is NULL.

Table 680. Table ID 36 - Stream Gate Instance Table ICFGE_DATA Description

Bits	Width [bits]	Name	Description
3-0	4	IPV	Internal Priority Value (IPV) This field specifies the IPV that will be assigned to frames before the first administrative stream gate control list takes affect, otherwise the IPV value is determined by the stream gate control list entry. Valid if OIPV of this entry is set to 1. The least significant 3 bits are used, most significant bit is reserved.
4	5	OIPV	Override Internal Priority Value (IPV) 0b = Don't override frame IPV. 01 = Override frame IPV with the value configured in the IPV field of this entry if the first administrative stream gate control list hasn't taken effect, otherwise overwrite with the IPV value stored in the stream gate control list.
5	1	GST	Gate State This field specifies the gate state to use before the administrative stream gate control list takes affect. 0b = Closed; frames are not permitted to pass through. 1b = Open; frames are permitted to pass through.
6	1	CTD	Cut Through Disabled This field specifies whether to disable cut-through before the administrative stream gate control list takes affect. 0b = No action. 1b = Cut-through is disabled. Note: Not applicable to ENETC function.
7	1	--	Reserved.

Bits	Width [bits]	Name	Description
1	1	IRXEN	Invalid Receive Enable 0b = "Gate Closed Due To Invalid Rx" function is disabled. 1b = "Gate Closed Due To Invalid Rx" function is enabled. See IRX for status of this function.
3-2	2	SDU_TYPE	Specifies the type of PDU/SDU (Protocol/Service Data Unit) for Interval Octets Maximum check for Gate Entry. Refer to IOM_GE field in SGCL table) Overhead values are specified by register PRXSDUOR. 00b = PPDU (Physical Layer PDU). 01b = MPDU (MAC PDU). 10b = MSDU (MAC SDU). All other values reserved.
7-4	4	--	Reserved.

Table 684. Table ID 36 - Stream Gate Instance Table SGISE_DATA Description

Bits	Width [bits]	Name	Description
31-0	32	OPER_SGCL_EID	Operational Stream Gate Control List Entry ID This field indicates the Entry ID in the Stream Gate Control List table (expressed in units of words) of the stream gate control list that is currently operational. Set to NULL (0xFFFF_FFFF) if there is no Operational Stream Gate Control List.
95-32	64	CONFIG_CHANGE_TIME	Configuration Change Time If an administrative gate control list is pending, this is the time at which administrative gate control list is to become operational (implements the PSFPConfigChangeTime parameter as defined by IEEE 802.1Q-2018). If there is no administrative gate control

Table 684. Table ID 36 - Stream Gate Instance Table SGISE_DATA Description (continued)

Bits	Width [bits]	Name	Description
			list and if an operational gate control list exists then this is the time the operational list became active. The actual value stored by hardware (and thus available to query) is expressed in units of nanoseconds. If this field is to be queried from an IEEE 802.1Q-2018 managed object, the value must be converted by software from the 64-bit integer number of nanoseconds to the IEEE 802.1Q-2018 PTP time format.
159:96	64	OPER_BASE_TIME	Operational Base Time The base time (start time) of the operational stream gate control sequence. The actual value stored by hardware (and thus available to query) is expressed in units of nanoseconds. The field implements the PSFPOperBaseTime parameter as defined by IEEE 802.1Q-2018, however, the field does not use the time format defined for the IEEE 802.1Q-2018 PSFPOperBaseTime parameter, which is the PTP time format, consisting of a 48-bit integer number of seconds and a 32-bit integer number of nanoseconds. Instead of using the PTP time format, the field expresses the time as a 64-bit integer number of nanoseconds. Therefore, if this field is to be queried from an IEEE 802.1Q-2018 managed object, the value must be converted by software from the 64-bit integer number of nanoseconds to the IEEE 802.1Q-2018 PTP time format.
191-160	32	OPER_CYCLE_TIME_EXT	Oper Cycle Time Extension The value supplied in this field is equivalent with the 802.1.Qci definition of "Cycle Time Extension". If Operational Gate Control List is active, this is the maximum amount of time by which the cycle time is permitted to be extended before a new Admin Gate Control List takes effect. Only least significant 30 bits are valid. Upper two bits are ignored.
192	1	OEX	Octets Exceeded Flag 0b = Normal operation. 1b = Gate closed permanently due to octets exceed. If OEXEN = 1, detection of octets received exceeding INTERVAL_OCTET_MAX in a gate interval results in the stream gate being permanently set to closed. OEX can be cleared by performing Stream Gate State Element Update (SGISEU) action.
193	1	IRX	Invalid Receive Flag 0b = Normal operation. 1b = Gate closed permanently due to invalid receive. If IRXEN=1, detection of incoming frames during time periods when the stream gate is in the closed state results in the stream gate being permanently set to closed state. IRX can be cleared by performing Stream Gate State Element Update (SGISEU) action.
195-194	3	STATE	Current Gate Instance State 000b = Reserved. 001b = Gate instance is operational but no stream gate control list specified. Default Gate Instance parameters are applied to received frame. 010b = New administrative stream gate control list pending. Default Gate Instance
