i.MX RT1180 Reference Manual

Contents

Chapter 1
About This Manual

1.1 Audience

The reference manual is intended for the board-level product designers and product software developers. This manual assumes that the reader has a background in computer engineering and/or software engineering and understands the concepts of the digital system design, microprocessor architecture, input/output (I/O) devices, industry standard communication, and device interface protocols.

1.2 Organization

This manual has two main sets of chapters.

- Chapters in the first set contain information that applies to all components on the chip.
- Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
  - Examples of these groupings are clocking, timers, and communication interfaces.
  - Each grouping includes chapters that provide a technical description of individual modules.

1.2.1 Attachments

This manual includes key information in the files attached to it. For example, memory map and I/O details. Use the content in these attachments in conjunction with this manual's content.

NOTE

Select the paperclip icon on the left side of the PDF window to see the list of attachments.

1.3 General Information

The following documentation provides useful background information about the ARM Cortex processor.

For information about the ARM Cortex processor see:

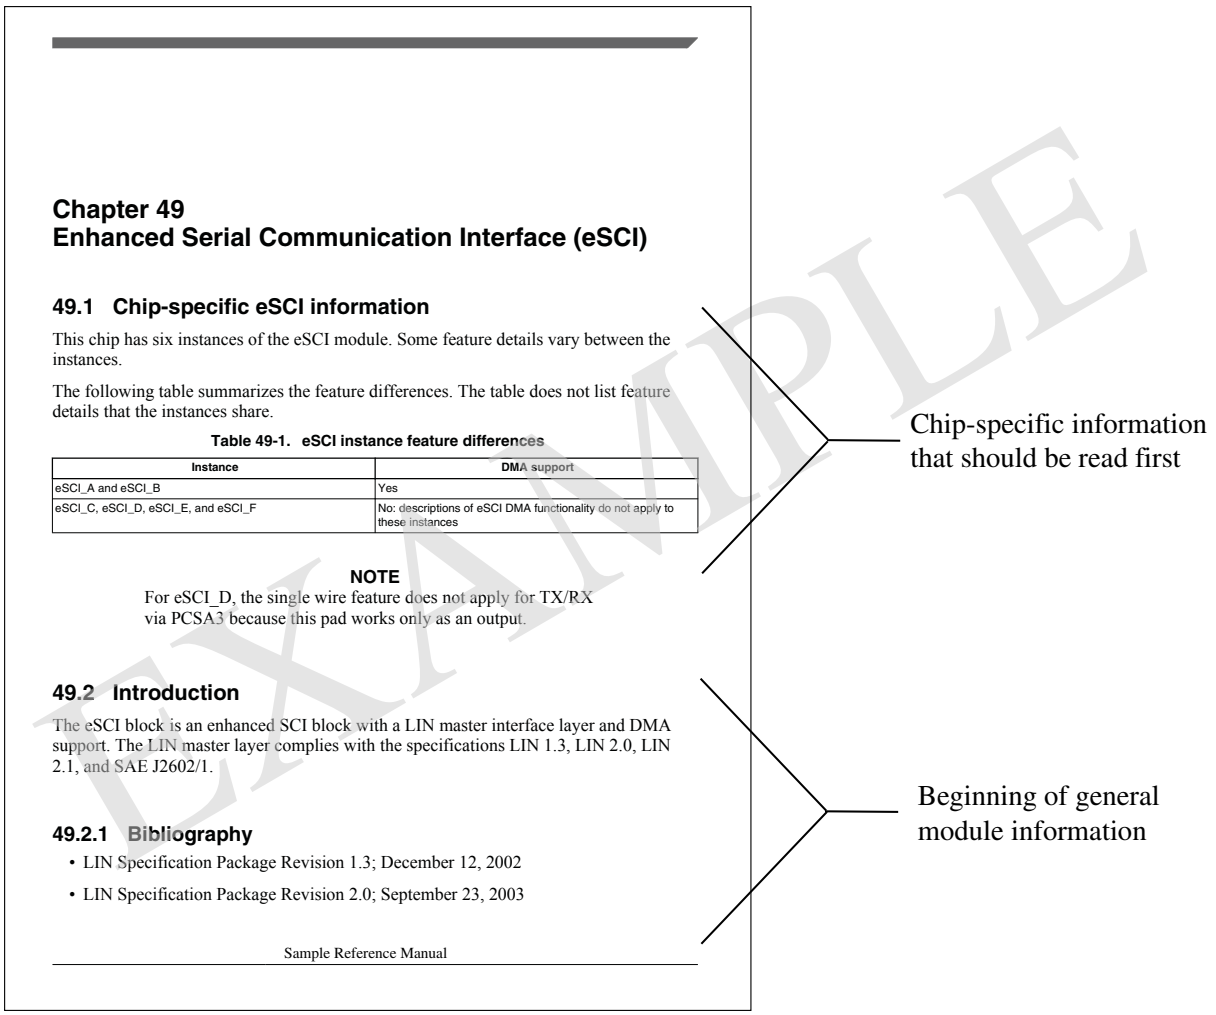
- http://infocenter.arm.com

1.4 Module descriptions

Each module chapter has two main parts:

- The first section, *chip-specific [module name]* information, provides details such as the number of module instances on the chip and connections between that module and the other ones. Read this section *first* because its content is crucial for understanding the information in the other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

The following figure shows you an example of this demarcation.



Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	DMA support
eSCI_A and eSCI_B	Yes
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	No: descriptions of eSCI DMA functionality do not apply to these instances

NOTE
For eSCI_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 Bibliography

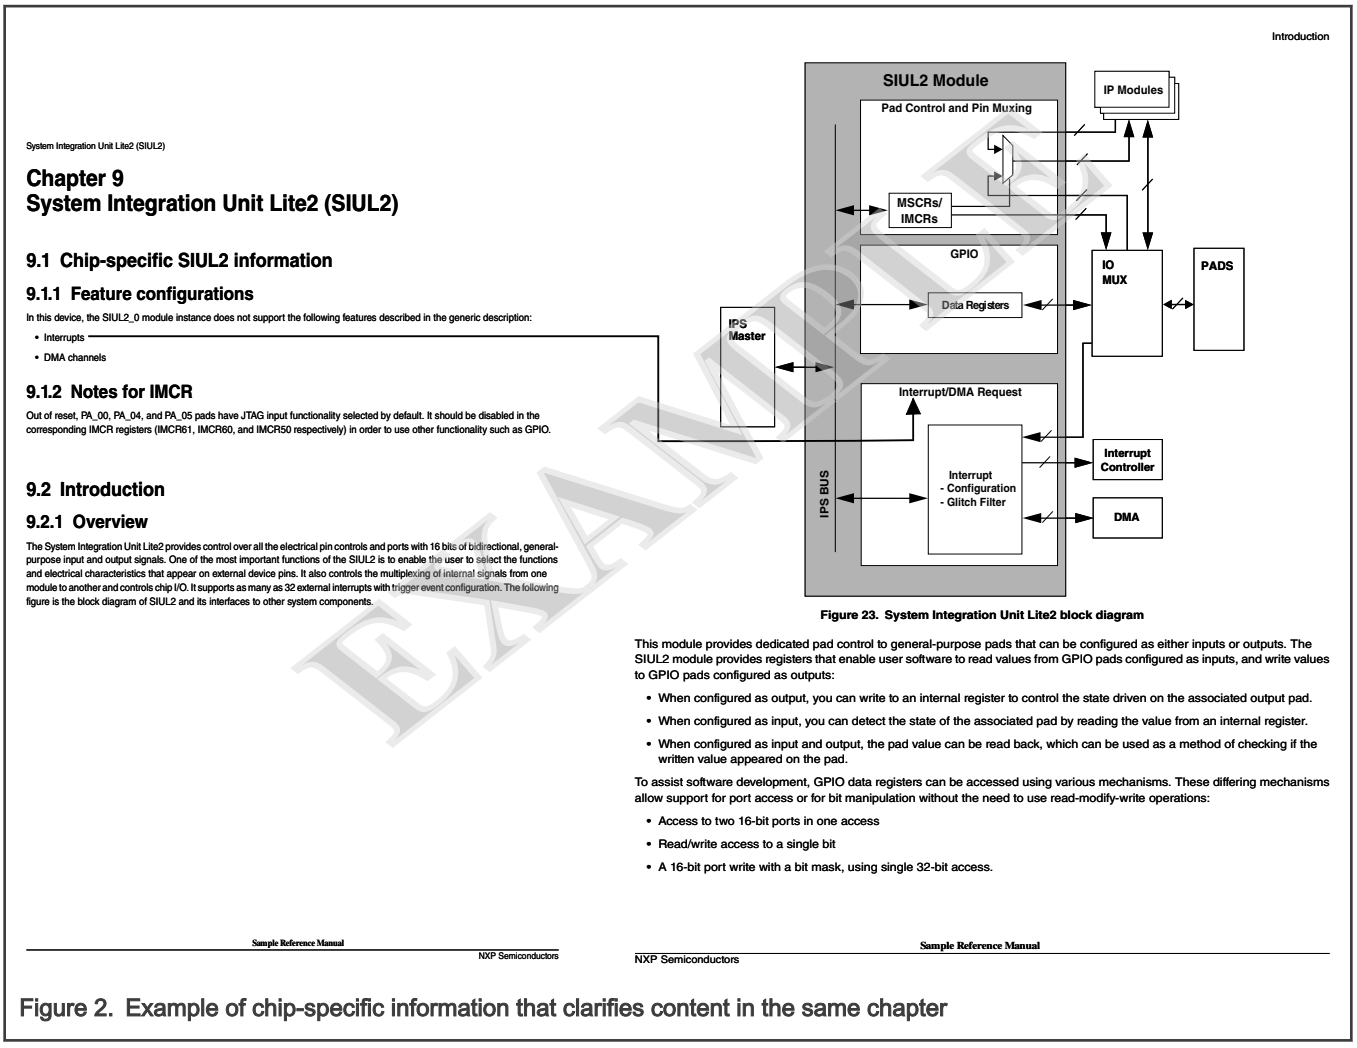
- LIN Specification Package Revision 1.3; December 12, 2002
- LIN Specification Package Revision 2.0; September 23, 2003

Sample Reference Manual

Figure 1. Example of chapter chip-specific information and general module information

1.4.1 Chip-specific information that clarifies content in the same chapter

The following figure shows an example of chip-specific information that clarifies general module information presented later in the chapter. In this case, the chip-specific register reset values supersede the reset values that appear in the register diagram.



Introduction

System Integration Unit Lite2 (SIUL2)

Chapter 9
System Integration Unit Lite2 (SIUL2)

9.1 Chip-specific SIUL2 information

9.1.1 Feature configurations

In this device, the SIUL2_0 module instance does not support the following features described in the generic description:

- Interrupts
- DMA channels

9.1.2 Notes for IMCR

Out of reset, PA_00, PA_04, and PA_05 pads have JTAG input functionality selected by default. It should be disabled in the corresponding IMCR registers (IMCR61, IMCR60, and IMCR50 respectively) in order to use other functionality such as GPIO.

9.2 Introduction

9.2.1 Overview

The System Integration Unit Lite2 provides control over all the electrical pin controls and ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is to enable the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls chip I/O. It supports as many as 32 external interrupts with trigger event configuration. The following figure is the block diagram of SIUL2 and its interfaces to other system components.

Figure 23. System Integration Unit Lite2 block diagram

This module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations:

- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access.

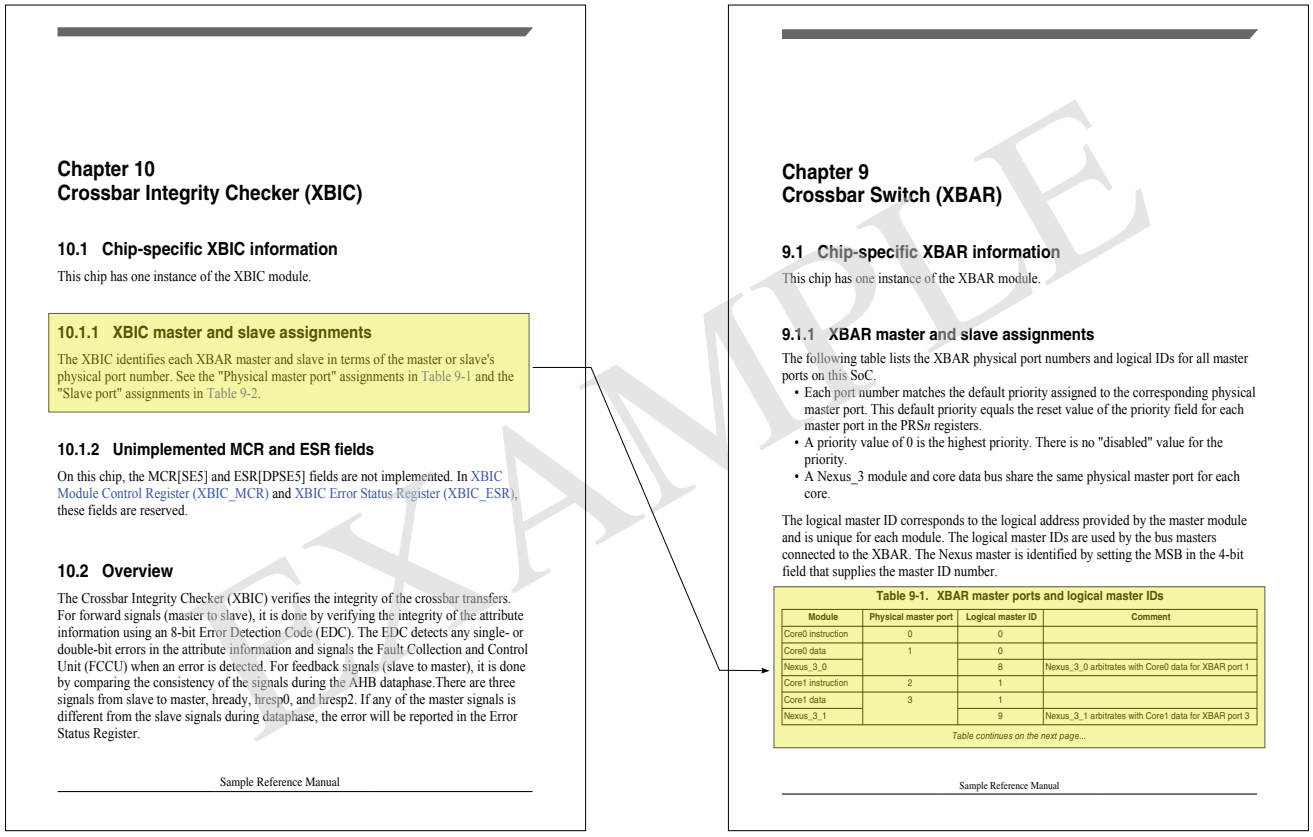
Figure 2. Example of chip-specific information that clarifies content in the same chapter

1.4.2 Chip-specific information that refers to a different chapter

Related chip-specific information may be provided in different chapters of the manual. The following figure shows an example of two such connected pieces of information. In this case, read both before you proceed.



Chapter 10
Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC master and slave assignments

The XBIC identifies each XBAR master and slave in terms of the master or slave's physical port number. See the "Physical master port" assignments in Table 9-1 and the "Slave port" assignments in Table 9-2.

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In XBIC Module Control Register (XBIC_MCR) and XBIC Error Status Register (XBIC_ESR), these fields are reserved.

10.2 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comparing the consistency of the signals during the AHB dataphase.There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

Sample Reference Manual

Chapter 9
Crossbar Switch (XBAR)

9.1 Chip-specific XBAR information

This chip has one instance of the XBAR module.

9.1.1 XBAR master and slave assignments

The following table lists the XBAR physical port numbers and logical IDs for all master ports on this SoC.

- Each port number matches the default priority assigned to the corresponding physical master port. This default priority equals the reset value of the priority field for each master port in the PRS*n* registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical master port for each core.

The logical master ID corresponds to the logical address provided by the master module and is unique for each module. The logical master IDs are used by the bus masters connected to the XBAR. The Nexus master is identified by setting the MSB in the 4-bit field that supplies the master ID number.

Table 9-1. XBAR master ports and logical master IDs

Module	Physical master port	Logical master ID	Comment
Core0 instruction	0	0	
Core0 data	1	0	
Nexus_3_0		8	Nexus_3_0 arbitrates with Core0 data for XBAR port 1
Core1 instruction	2	1	
Core1 data	3	1	
Nexus_3_1		9	Nexus_3_1 arbitrates with Core1 data for XBAR port 3

Table continues on the next page...

Sample Reference Manual

Figure 3. Example of chip-specific information that refers to a different chapter

1.5 Register descriptions

Module chapters present register information in the following:

- Memory maps, which contain:
  - An offset from the module's base address
  - The mnemonic and name of each register
  - The width of each register (in bits)
  - The reset value of each register
- Register figures
- Field-description tables
- Associated text

The following figure shows register figure conventions used throughout the manual.

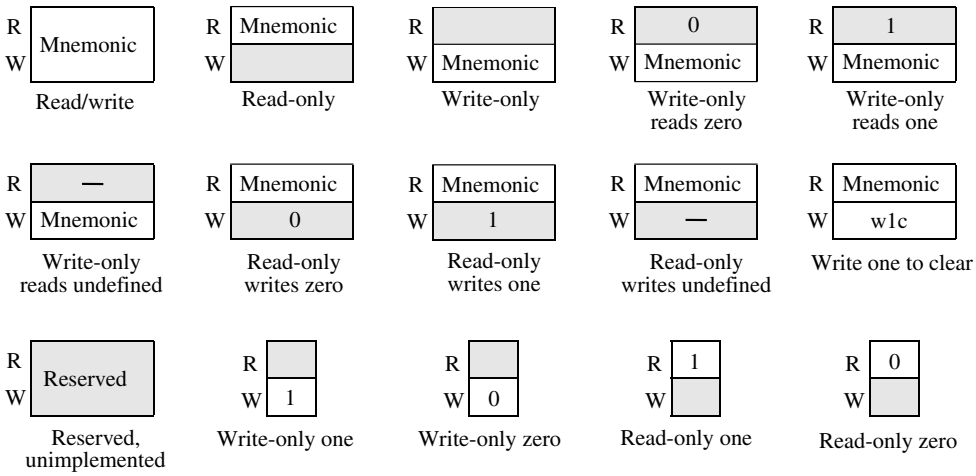


Figure 4. Register figure conventions

NOTE

Reset values of reserved locations documented in this manual are subject to change and must not be used for diagnostic purposes.

1.6 Conventions

1.6.1 Notes and cautions

Specific information is provided as part of notes and cautions throughout this manual.

NOTE

Emphasizes information that deserves extra attention.

CAUTION

Informs you of situations that could lead to highly undesirable outcomes—such as damage to the chip or irreversible malfunction.

1.6.2 Numbering systems

The following suffixes identify different numbering systems:

Table 1. Numbering systems

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is mentioned as 101b. In some cases, *0b* is prefixed to binary numbers.
d	Decimal number. Decimal numbers are followed by this suffix only when there is a possibility of confusion. In general, decimal numbers are used without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is mentioned as 3Ch. In some cases, *0x* is prefixed to hexadecimal numbers.

1.6.3 Typographic notation

The following typographic notations are used throughout this document:

Table 2. Typographic notation

Example	Description
x and other italicized text	The italicized, lowercase *x* is used as a placeholder for replaceable numbers. In general, italicized text is used for titles of publications and for emphasis. Additionally, italics could be used for metasymbols in syntax descriptions. Plain lowercase letters are used as placeholders for single letters and numbers.
`code font`	Fixed-width font (such as Courier) used for code. It is used for a letter, word, or phrase that you want the user to type. For example, "Type `Read` and press Enter." This type of font is also used for instruction mnemonics, directives, symbols, subcommands, parameters, operators, computer-language elements, code listings, commands that appear in running text, and for sample code. Instruction mnemonics and directives in text and tables are mentioned in all caps; for example, BSR.
SR[SCM]	A mnemonic in square brackets represents the name of a register field. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets that are separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6-4 that are part of the COREREV field occupying bits 6-0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7-0 of the XAD bus.
MOD.REG	A period separates the elements of a hierarchy: subsystem.module.register. For example: • SWT.TO means that the TO register is located in the SWT module. • SMU.XRDC.CR means that the CR register is located in the XRDC module within the SMU subsystem.

1.6.4 Special terms

The following terms have special meanings.

Table 3. Special terms

Term	Meaning
Asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
Deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
Reserved	Refers to memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. You must:

Table continues on the next page...

Table 3. Special terms (continued)

Term	Meaning
	• Not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved. • Not use the reset values of reserved locations documented in this manual for diagnostic purposes. They are subject to change.
Write 1 to clear (w1c)	Refers to the access type of a register field that is used to clear the field by writing the value 1 to it.
Undefined (u)	Refers to undefined reset values

1.7 Editorial changes

Each new release of this document includes editorial improvements such as:

- Spelling
- Grammar
- Punctuation
- Voice
- Tense
- Capitalization
- Formatting
- Presentation
- Navigation

1.8 Acronyms and Abbreviations

The table below contains acronyms and abbreviations used in this document.

Acronyms and Abbreviated Terms

Term	Meaning
ACMP	Analog Comparator
ADC	Analog-to-Digital Converter
AHB	Advanced High-performance Bus
AIPS	Arm IP Bus
ALU	Arithmetic Logic Unit
AMBA	Advanced Microcontroller Bus Architecture
AON	Always On domain

Table continues on the next page...

Table continued from the previous page...

Term	Meaning
APB	Advanced Peripheral Bus
ASRC	Asynchronous Sample Rate Converter
AXI	Advanced eXtensible Interface
BBNSM	Battery Backed Non-Secure Module
BBSM	Battery Backed Secure Module
CAN	Controller Area Network
CCM	Clock Controller Module
CM7	Arm Cortex M7 Core
CPU	Central Processing Unit
CSI	CMOS Sensor Interface
CTI	Cross Trigger Interface
D-cache	Data cache
DAP	Debug Access Port
DDR	Double data rate
DMA	Direct memory access
DPLL	Digital phase-locked loop
DRAM	Dynamic random access memory
ECC	Error correcting codes
LPSPI	Low-power SPI
EDMA	Enhanced Direct Memory Access
EIM	Error Injection Module
ENET	Ethernet
EPROM	Erasable Programmable Read-Only Memory
ETF	Embedded Trace FIFO
ETM	Embedded Trace Macrocell
FIFO	First-In-First-Out
GIC	General Interrupt Controller
GPC	General Power Controller
GPIO	General-Purpose I/O

Table continues on the next page...

Table continued from the previous page...

Term	Meaning
GPR	General-Purpose Register
GPS	Global Positioning System
GPT	General-Purpose Timer
GPV	Global Programmers View
HAB	High-Assurance Boot
I-cache	Instruction cache
I2C or I^2C	Inter-Integrated Circuit
IC	Integrated Circuit
IEEE	Institute of Electrical and Electronics Engineers
IOMUX	Input-Output Multiplexer
IP	Intellectual Property
IrDA	Infrared Data Association
JTAG	Joint Test Action Group (a serial bus protocol usually used for test purposes)
LDO	Low-Dropout
LSB	Least-Significant Byte
LUT	Look-Up Table
LVDS	Low Voltage Differential Signaling
MAC	Medium Access Control
MCM	Miscellaneous Control Module
MMC	Multimedia Card
MSB	Most-Significant Byte
OCRAM	On-Chip Random-Access Memory
OCOTP	On-Chip One-Time Programmable Controller
PCI	Peripheral Component Interconnect
PCIe	PCI express
PIC	Programmable Interrupt Controller

Table continues on the next page...

Table continued from the previous page...

Term	Meaning
PMU	Power Management Unit
POR	Power-On Reset
PSRAM	Pseudo-Static Random Access Memory
PWM	Pulse Width Modulation
QoS	Quality of Service
RISC	Reduced Instruction Set Computing
ROM	Read-Only Memory
RTOS	Real-Time Operating System
Rx	Receive
SAI	Synchronous Audio Interface
SD	Secure Digital
SDIO	Secure Digital Input/Output
SDMA	Smart DMA
SIM	Subscriber Identification Module
SoC	System-on-Chip
SPDIF	Sony Philips Digital Interface
SPI	Serial Peripheral Interface
SRAM	Static Random-Access Memory
SRC	System Reset Controller
TPIU	Trace Port Interface Unit
Tx	Transmit
UART	Universal Asynchronous Receiver/Transmitter
USB	Universal Serial Bus
USDHC	Ultra Secured Digital Host Controller
WDOG	Watchdog
WLAN	Wireless Local Area Network

Chapter 2
Introduction

2.1 Overview

The i.MX RT1180 is a high-performance networking crossover MCU, which features a main computer Arm® Cortex®-M7 at 800 MHz, and a power efficient Arm Cortex-M33 at 240 MHz. The i.MX RT1180 includes an integrated Gbps Time Sensitive Networking (TSN) switch.

This device also has an EtherCAT Device Controller to support multiple Industrial networking protocols, bridging the communications between real-time Ethernet and Industry 4.0 systems.

The i.MX RT1180 integrates advanced power management that reduces complexity of an external power supply and simplifies power sequencing. The i.MX RT1180 also provides various memory interfaces and a wide range of peripherals.

2.1.1 Block Diagram

The functional block diagram is shown in the figure below. This diagram provides a view of the chip's major functional components and core complexes.

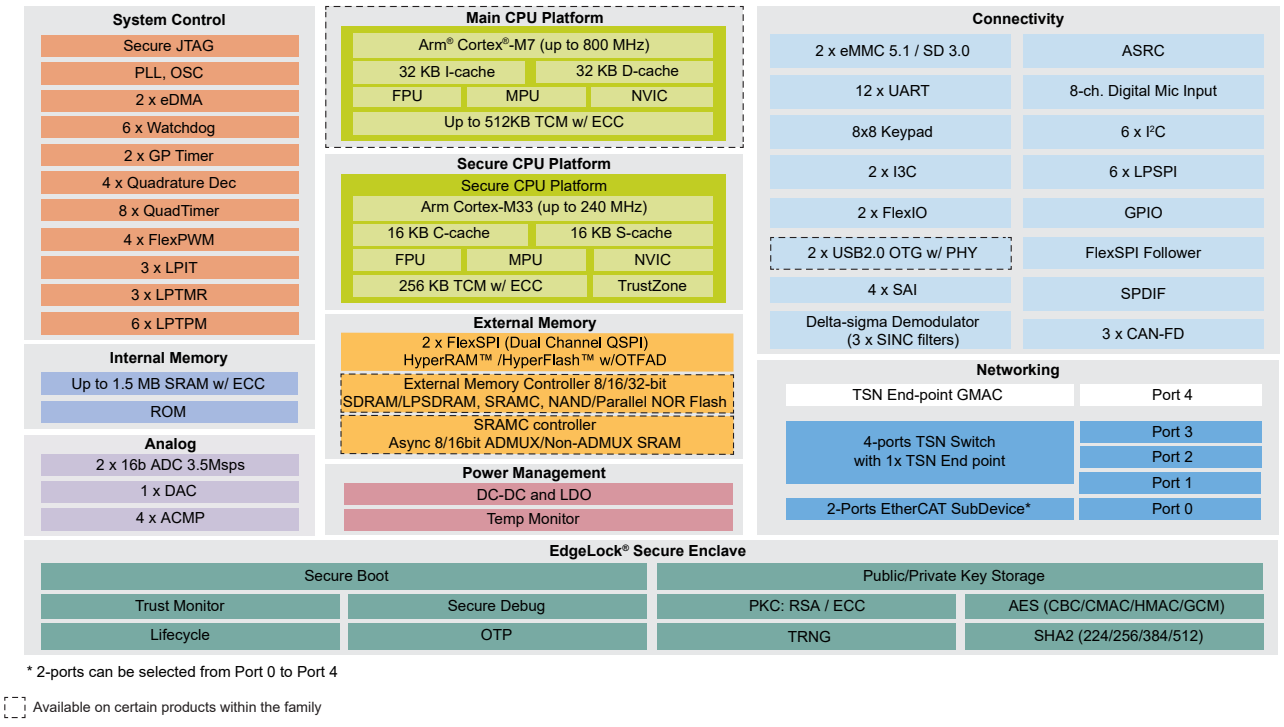

Figure 5. Simplified Block Diagram

2.1.2 System Bus Diagram

The system bus diagram is shown below.

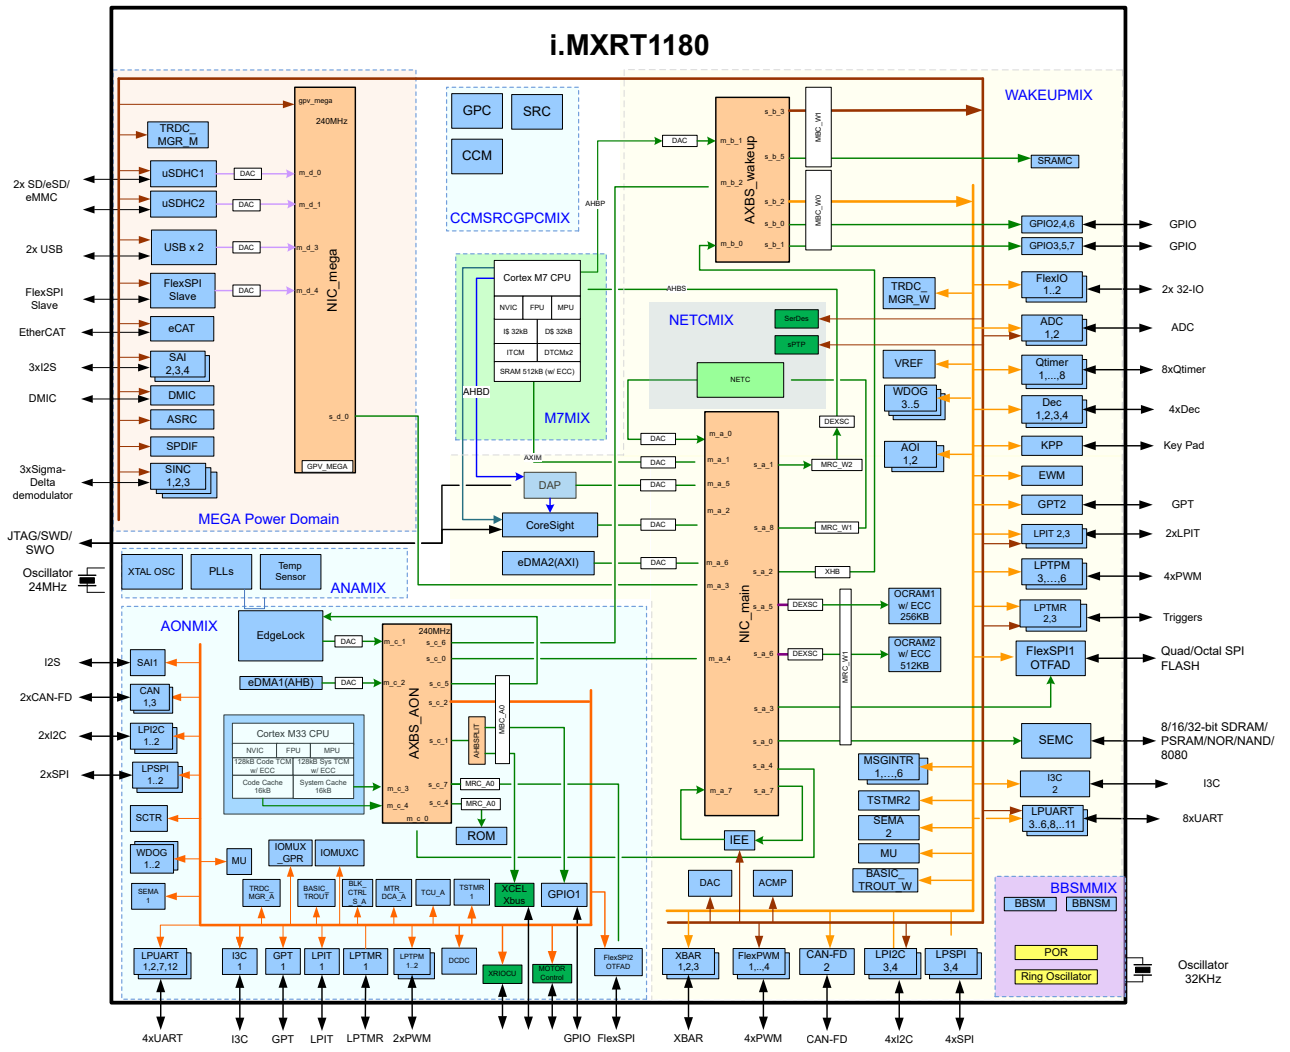

Figure 6. System Bus Diagram

2.1.3 Features

The i.MX RT1180 processor is based on Arm Cortex-M7 Platform and Arm Cortex-M33 which have the following features:

Arm Cortex-M7 Platform:

- Arm Cortex-M7 Processor:
  - 32 KB L1 Instruction Cache
  - 32 KB L1 Data Cache
  - Full featured Floating Point Unit (FPU) with support of the VFPv5 architecture
  - Support the ARMv7-M Thumb instruction set, defined in the ARM v7-M architecture
- Integrated Memory Protection Unit (MPU), up to 16 individual protection regions
- Up to 512 KB I-TCM and D-TCM in total
- Target frequency of 800 MHz at 1.1 V (over voltage) with Forward Body Biasing (FBB)
- ECC support for cache and TCM

Arm Cortex®-M33 Platform:

- Microcontroller available both for boot and for customer application
- Arm Cortex®-M33 Processor:
  - 16KB L1 Instruction Cache
  - 16KB L1 System Cache
  - 256 KB TCM, also accessible as SRAM by the rest of the system
- Target frequency of 240MHz at 1.0V without body biasing
- ECC support for both cache and TCM

Security:

- TRDC – Trusted Resource Domain Controller
  - Supports up to 16 resource domains
- Arm TrustZone® (TZ) architecture
- Secure and trusted access control
- Battery Backed Security Module (BBSM)
  - Monotonic counter - Secure real-time clock (RTC) - Zeroized Master Key
- Inline Encryption Engine (IEE)
  - External memory encryption/decryption
  - I/O direct encrypted storage and retrieval (Stream Support)

System Debug:

- Arm CoreSight® debug and trace architecture
- Trace Port Interface Unit (TPIU) to support off-chip real-time trace
- Support for 5-pin (JTAG) and SWD debug interfaces

On Chip Memory:

- Boot ROM (160KB)
- 512KB Tightly Coupled RAM (TCM) for CM7, with ECC
- 256KB Tightly Coupled RAM (TCM) for CM33, with ECC
- Dedicated 768KB OCRAM, with ECC

External Memory Interfaces:

- Smart External Memory Controller (SEMC)
  - 8/16/32-bit SDRAM interface, 4 Chip Select (CS) and each CS up to 512Mb
  - 8/16-bit NAND FLASH interface, with hardware ECC
  - 8/16-bit NOR flash interface
  - SRAM Interface
- FlexSPI with support for XIP and support for either one Octal SPI, or parallel read mode of two identical Quad SPI FLASH devices
  - OTFAD is supported for decryption with 0 cycle delay
- SRAMC Interface (FPGA I/F)

Audio:

- SPDIF Input and Output
- 4x Synchronous Audio Interface (SAI) modules supporting I2S, AC97, TDM, and Codec/DSP interfaces
- Digital microphone input, 8-channel PDM
- 1x Asynchronous Sample Rate Converter (ASRC)

Connectivity:

- 2x USB 2.0 OTG controller with integrated PHY interfaces
- 2x Ultra Secure Digital Host Controller (uSDHC) interfaces
  - uSDHC1 with boot support for eMMC 5.1 compliance with HS400 DDR signaling to support up to 400 MB/sec
  - uSDHC2 with boot support for SD/SDIO 3.0 compliance with 200 MHZ SDR signaling to support up to 100 MB/sec
  - Support for SDXC (extended capacity)
- EtherCAT®
- 12x Low-power Universal asynchronous receiver/transmitter (LPUARTs) modules
- 6x LPSPI modules
- 6x I2C modules
- 2x I3C modules
- 3x CAN-FD modules
- 2x FlexIO modules
- Advanced and flexible Ethernet:
  - Port virtualization support on ENETC1 MAC for dual Access (CM33/CM7)
  - Extended support of TSN standards over flexible architecture
  - 1x independent 1Gbps TSN MAC end point
  - 5-Ports (4 external + 1 internal) TSN Switch with 1Gbps TSN MAC
  - OPC UA Frame Summation HW acceleration integrated in switch
  - Maximum 5 RGMII/MII/RMII external ports
- 1x FlexSPI follower, 4/8 bit, 133MHz

Timers and PWMs:

- 2x General Programmable Timer (GPT)
  - 4-channel generic 32-bit resolution timer each
  - Each support standard capture and compare operation
- 3x Low Power Periodical Interrupt Timer (LPIT)
  - 4 channel
  - 4 external trigger source
  - Generic 32-bit resolution timer
  - Periodical interrupt generation
- 6x Timer/PWM module (TPM)
  - Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
  - 32-bit counter, support free-running counter or modulo counter mode, counting up or down

  - Includes 4 channels that can be configured for input capture, output compare, edge-aligned PWM mode, or center-aligned PWM mode
- 8x Quad Timer (TMR)
  - 4-channel generic 16-bit resolution timer each
  - Each support standard capture and compare operation
  - Quadrature decoder integrated
- 4x FlexPWM
  - Maximum 8 individual PWM channels per each
  - 16-bit resolution PWM suitable for Motor Control applications
- 4x Quadrature Decoder

GPIO and Pin Multiplexing:

- General-purpose input/output (GPIO) modules with interrupt capability
- Input/output multiplexing controller (IOMUXC) to provide centralized pad control

Analog:

- 2x 16-bit dual-channel SAR ADC, 3.5Msps, 30-channels
- 4x Analog Comparators (CMP)
- 1x 12-bit Digital-Analog-Converter (DAC)
- 3x SINC filter(4-ch) to interface to external sigma-delta ADC

Power Management:

- Full PMIC integration, including on-chip DCDC and LDO
- Temperature sensor with programmable trim points
- GPC hardware power management controller

2.2 Target Applications

The i.MX RT1180 can be used but not limited to applications such as:

- Industrial
- IoT

2.3 Endianness Support

The chip supports only the Little Endian mode.

Chapter 3
Memory Maps

3.1 Memory system overview

This section introduces the memory architecture of the chip.

NOTE

Accessing the reserved memory regions can result in unpredictable behavior.

NOTE

The first 16k OCRAM is reserved as a rom patch area and cannot be safely used by application images.

3.2 System memory map (CM7)

The table below shows the CM7 memory map. There are both Non-Secure (NS) and Secure (S) access possibilities.

Table 4. System memory map (CM7)

Start address	End address	Size (KB)	Description
E010_0000 (NS)	FFFF_FFFF (NS)	523264	Reserved
E004_4000 (NS)	E00F_FFFF (NS)	752	M7 Private Peripheral Bus
E000_0000 (NS)	E004_3FFF (NS)	272	M7 Private Peripheral Bus
D000_0000 (NS)	DFFF_FFFF (NS)	262144	SEMC (offset 1.25 GB)
C000_0000 (NS)	CFFF_FFFF (NS)	262144	SEMC (offset 1 GB)
B000_0000 (NS)	BFFF_FFFF (NS)	262144	SEMC (offset 768 MB)
A000_0000 (NS)	AFFF_FFFF (NS)	262144	SEMC (offset 512 MB)
9000_0000 (NS)	9FFF_FFFF (NS)	262144	SEMC (offset 256 MB)
8000_0000 (NS)	8FFF_FFFF (NS)	262144	SEMC0 (offset 0 MB)
6100_0000 (NS)	7FFF_FFFF (NS)	507904	Reserved
6000_0000 (NS)	60FF_FFFF (NS)	16384	NETC register

3.4 AIPS-1 Memory Map

The table below shows the AIPS-1 memory map. The peripherals have both Non-Secure (NS) and Secure (S) access possibilities.

The start address of AIPS1 Peripherals for non-secure access is 0x4400_0000

The start address of AIPS1 Peripherals for secure access is 0x5400_0000

Table 6. AIPS-1 memory map

3.5 AIPS-2 Memory Map

The table below shows the AIPS-2 memory map. The peripherals have both Non-Secure (NS) and Secure (S) access possibilities.

The start address of AIPS2 Peripherals for non-secure access is 0x4200_0000

The start address of AIPS2 Peripherals for secure access is 0x5200_0000

3.6 AIPS-3 Memory Map

The table below shows the AIPS-3 memory map. The peripherals have both Non-Secure (NS) and Secure (S) access possibilities.

The start address of AIPS3 Peripherals for non-secure access is 0x4280_0000

The start address of AIPS3 Peripherals for secure access is 0x5280_0000

Table 8. AIPS-3 memory map

Chapter 4
Interrupt, DMA Events, and XBAR Assignments

4.1 Overview

This section provides information on the assignments of the interrupts, DMA, and XBARs.

4.2 System interrupts

The Nested Vectored Interrupt Controller (NVIC) collects interrupt request sources and provides an interface to the Cortex-M cores. The IRQ Mask is shown below.

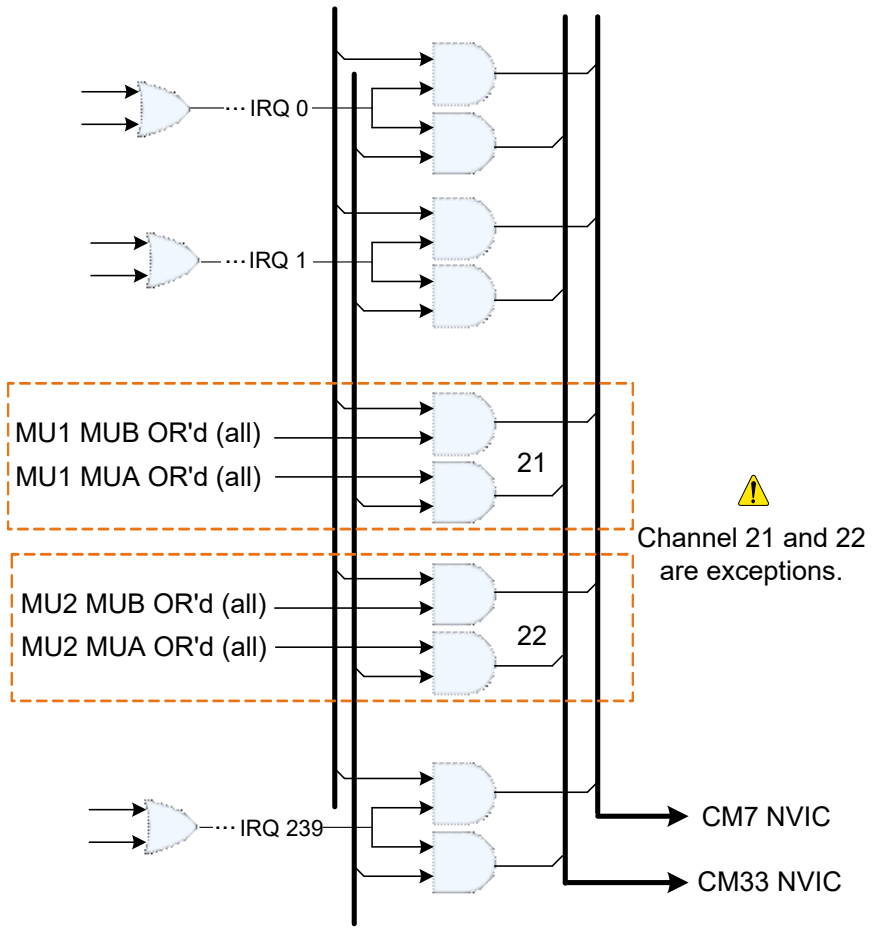

Figure 7. IRQ Mask

The table below describes the interrupt sources:

Table 11. System interrupt summary

IRQ	Module	LOGIC	Description
0	TMR1	OR	TMR Channel 0 interrupt
0		OR	TMR Channel 1 interrupt
0		OR	TMR Channel 2 interrupt

Table continues on the next page...

5.2 Overview

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

5.2.1 Block diagram

Figure 9 illustrates the components of the eDMA system, including the eDMA module (engine).

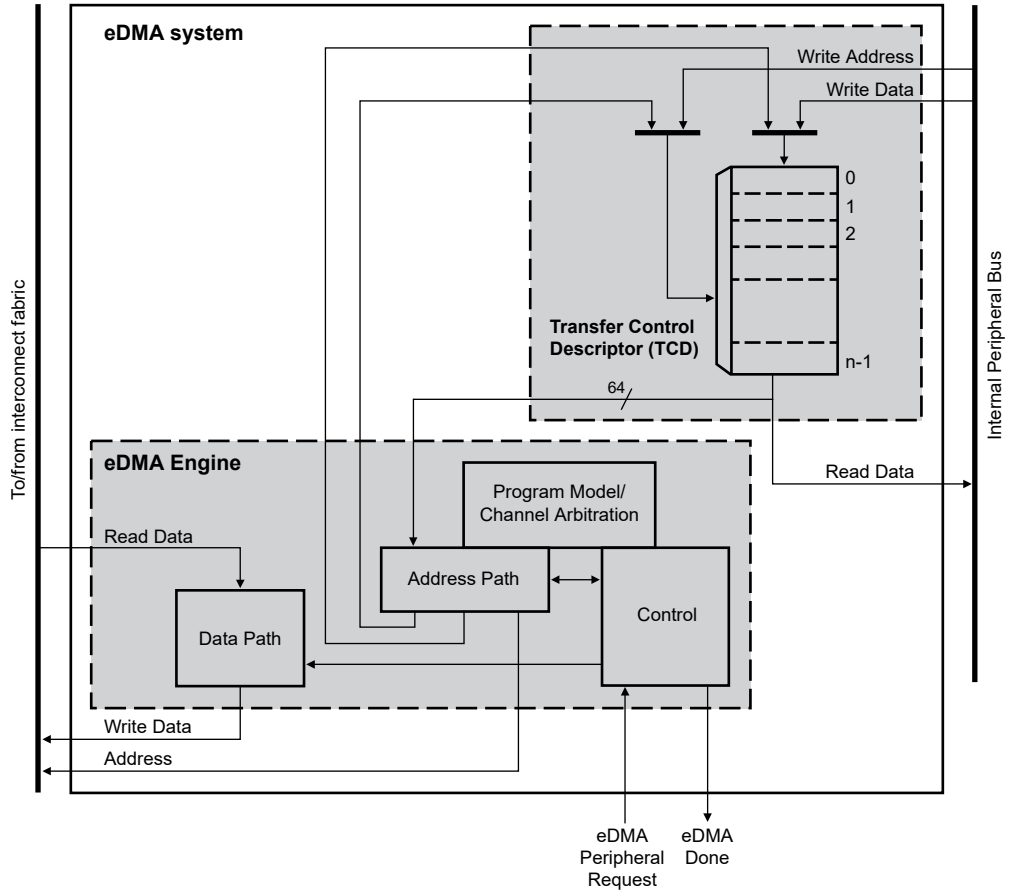

Figure 9. Block diagram

5.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 17. eDMA engine submodules

Submodule	Function
Address path	This block: • Implements a primary channel and secondary (preempt) channel • Manages all master bus-address calculations All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution.

Table continues on the next page...

Table 17. eDMA engine submodules (continued)

Submodule	Function
	When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details.
Data path	This block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write.

The transfer control descriptor local memory is further partitioned into:

Table 18. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. In simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

5.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and is not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers

  - Connections to the crossbar switch for bus mastering the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

5.3 Functional description

The operation of eDMA is described in the following subsections.

5.3.1 Modes of operation

The eDMA operates in the following modes:

Table 19. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared to 0, eDMA continues to operate. • If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires.

5.3.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

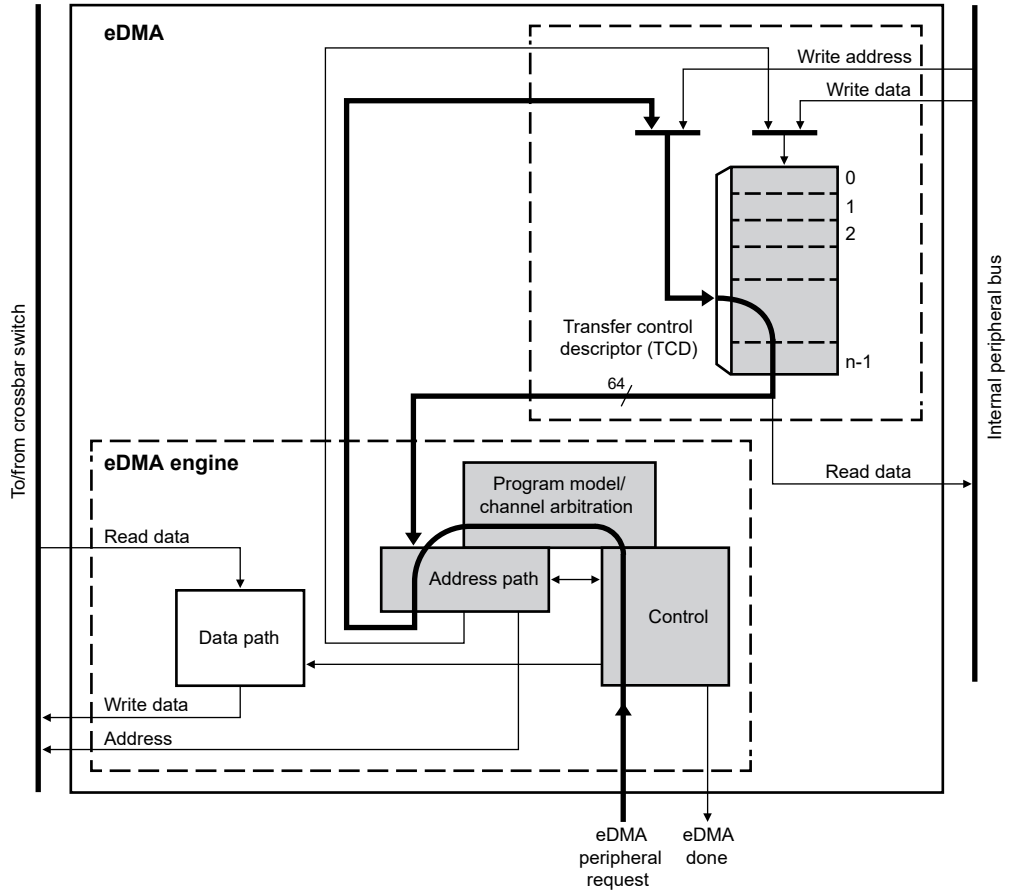

Figure 10. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

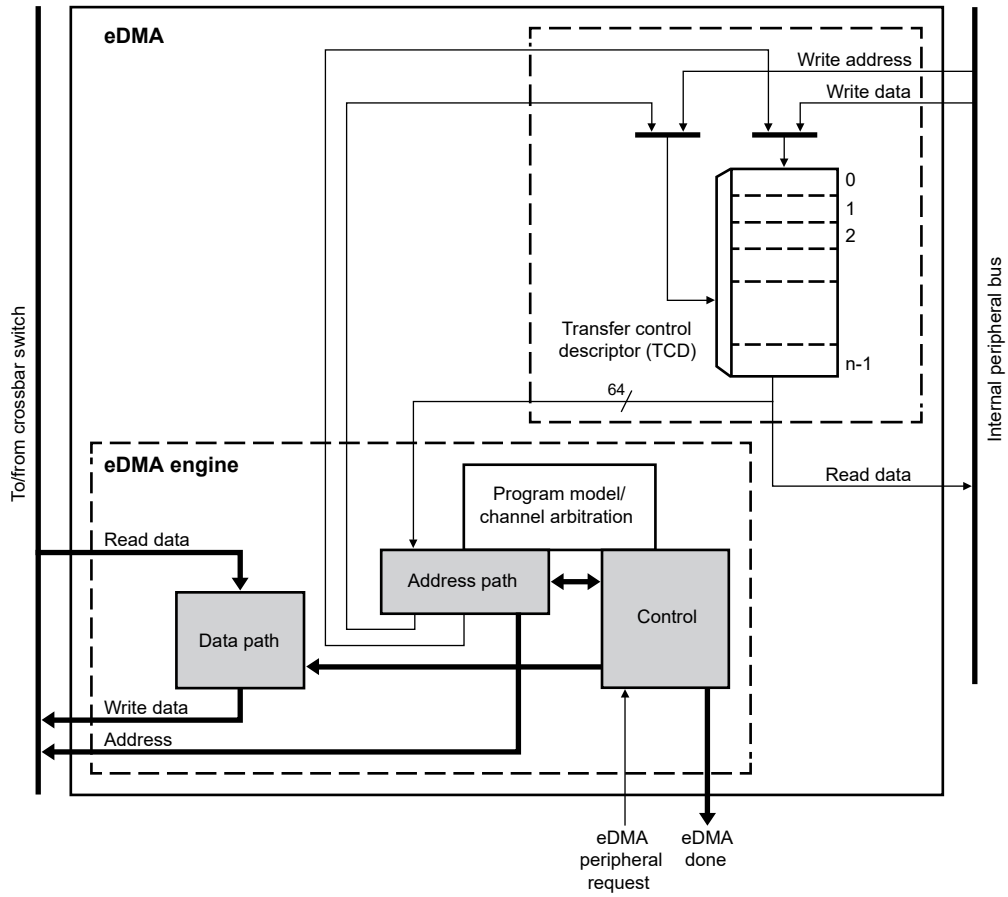

Figure 11. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

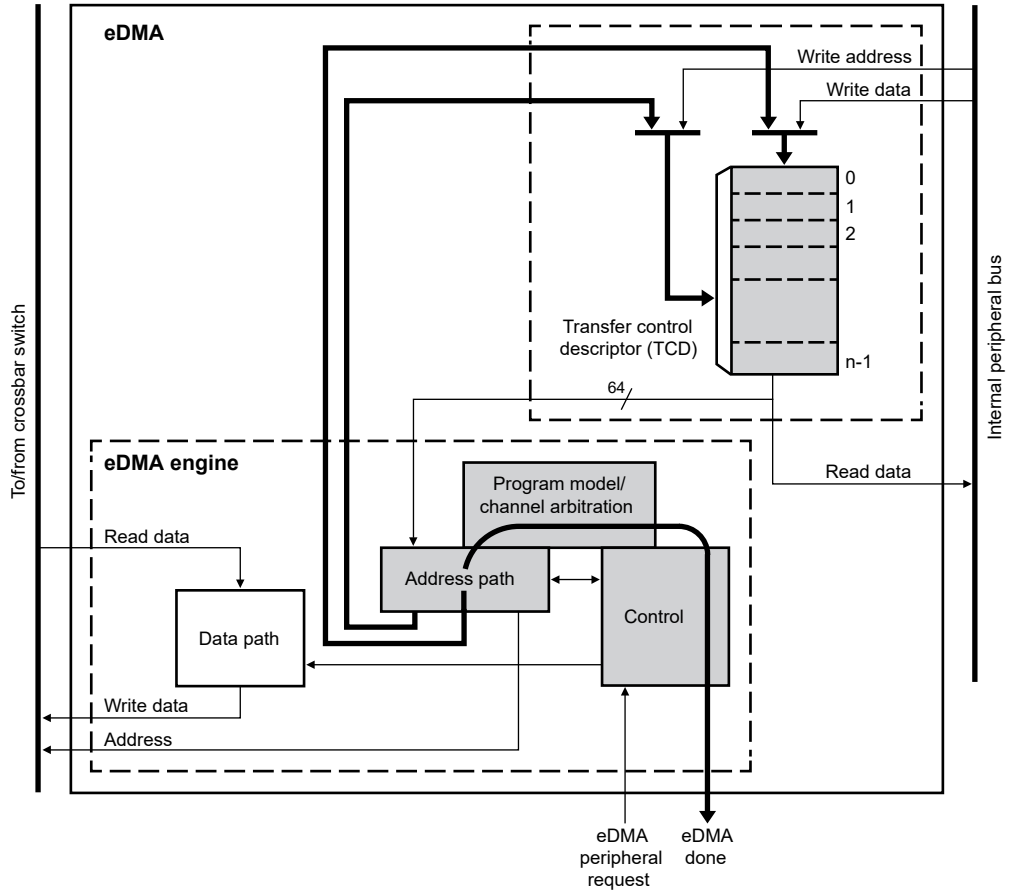

Figure 12. eDMA operation, part 3

5.3.3 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_ES) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- An error termination to a bus master read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

NOTE

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (TCDn_DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. CHn_ES[ERR] is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved all errors and cleared all of the error interrupt fields, the MP_ES[VLD] is cleared to 0 but the cause of the last error is still indicated.

5.3.4 Channel preemption

The eDMA uses a priority vector value to determine the highest priority channel requesting service.

The priority vector is a combination of:

1. the channel's group priority, CHn_GRPRI
2. the channel's priority level, CHn_PRI[APL]
3. the channel number

Priority vector = ((CHn_GRPRI << 8) + (CHn_PRI[APL] << 5) + CHn_*)

A channel requesting service with the highest priority vector value will receive the next execution slot.

An execution slot is available:

1. immediately if the eDMA is idle
2. when an active channel retires
3. when valid preemption conditions exist

NOTE

Preemption is strictly priority based. Preemption is not bound by a specific group number as defined by CHn_GRPRI.

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel's preempt ability is disabled, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower-priority channel's ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

5.3.5 Clocking

This module has no clocking considerations.

5.3.6 Interrupts

Software can enable the interrupt for each channel for the following events:

1. The major loop is half complete (INTHALF)
2. The major loop is complete (INTMAJOR)
3. A configuration error occurs (EEI)

5.4 External signals

This module has no external signals.

5.5 Initialization

The following sections discuss initialization of the eDMA and programming considerations.

5.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the MP_CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.
3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 20, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 20. TCD control and status (TCDn_CSR) fields

TCDn_CSR field name	Description
START	Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
EEOP	Control field to enable end-of-packet processing
ESDA	Control field to enable storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
BWC	Control field for throttling the bandwidth control of a channel
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable interrupt when major loop is half-complete
INTMAJOR	Control field to enable interrupt when major loop completes

Table 21. Channel control and status (CHn_CSR) fields

CHn_CSR field name	Description
ACTIVE	Status field indicating the channel is currently in execution
DONE	Status field indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control field to enable error interrupts
EARQ	Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field
ERQ	Control field to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

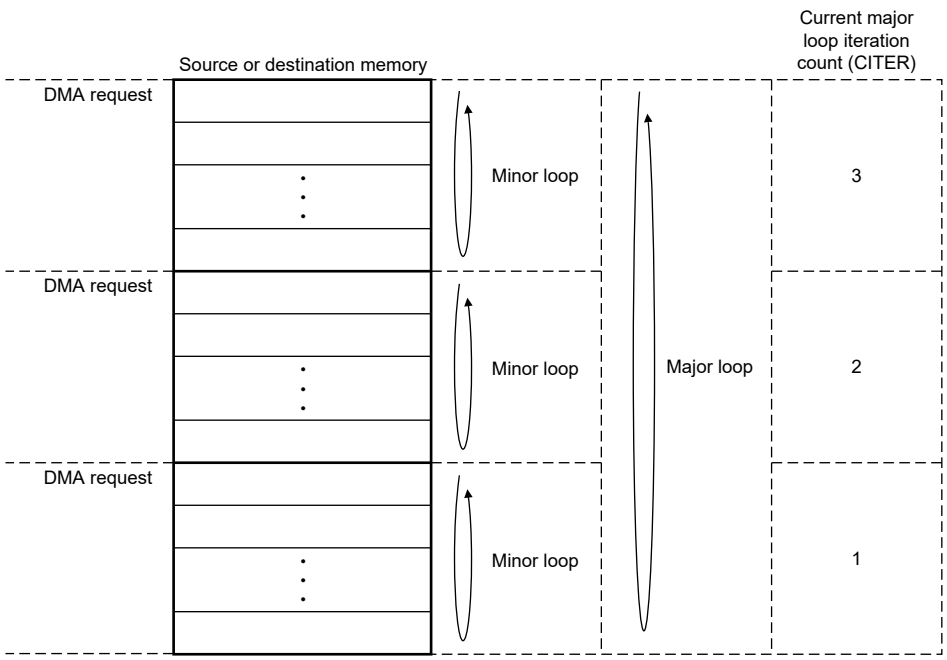

Figure 13. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

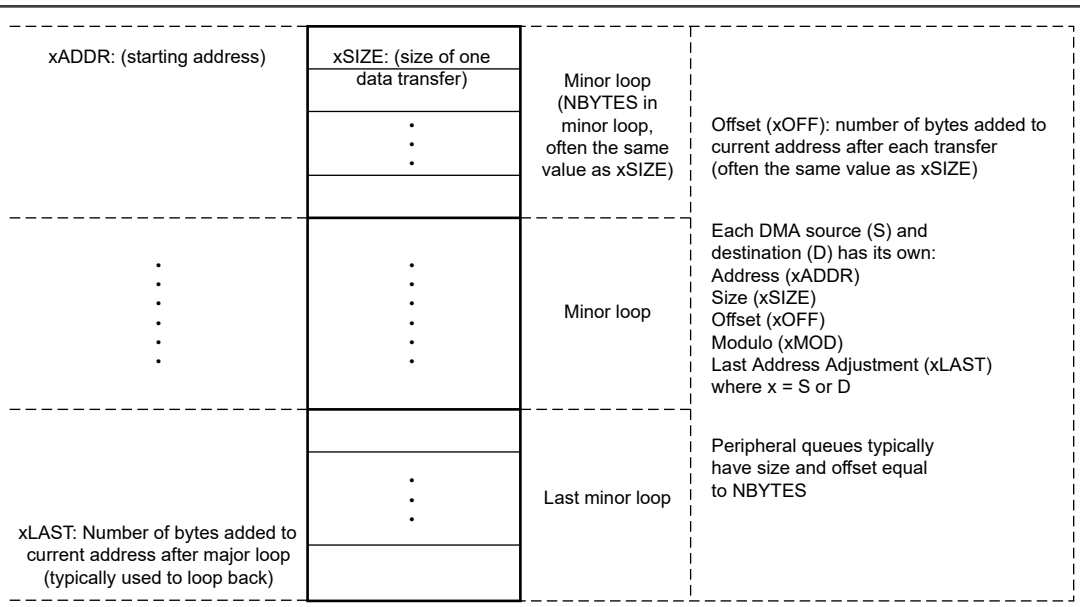

Figure 14. Memory array terms

5.5.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

Table 22. eDMA arbitration priorities

Priority	Scheme	Description
1 (Highest)	Arbitration group priority	Each channel is assigned an arbitration group via the CHn_GRPRI registers. Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default).
2	Channel priority	Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three.
3	Channel number	When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is given to the highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4 (Lowest)	Round-robin	When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the MP_CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels.

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

5.5.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_ES). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent recurrence of the error.

5.5.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

5.5.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

5.5.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

5.5.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

5.5.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
```

```
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

5.5.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:

a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
h. Write 32 bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

5.5.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a 2^4 byte (16 byte) queue size.

Table 23. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

5.5.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

5.5.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	1	0	0	Initiate channel service request via software.
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	0	0	0	Initiate channel service request via hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

5.5.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

5.5.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

5.5.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field

2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 24. Channel linking parameters

Wanted link behavior	TCD control field name	Description
Link at end of minor loop	TCDn_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCDn_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	TCDn_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCDn_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

5.5.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

5.5.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

5.5.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.

2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

5.5.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[MAJORELINK] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

5.5.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.

- If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
- If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

5.5.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

5.5.9 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, you must follow a specific procedure. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (SPI), Sigma Delta Analog to Digital Convertor (SDADC), or other module.

5.5.9.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status (MP_HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the SPI is set as a master for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure there is no DMA service request from the SPI by verifying that MP_HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

5.5.9.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

5.6 Memory map/register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.
3. The third part corresponds to the local TCD memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits. See DMA TCD register descriptions for details.

TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

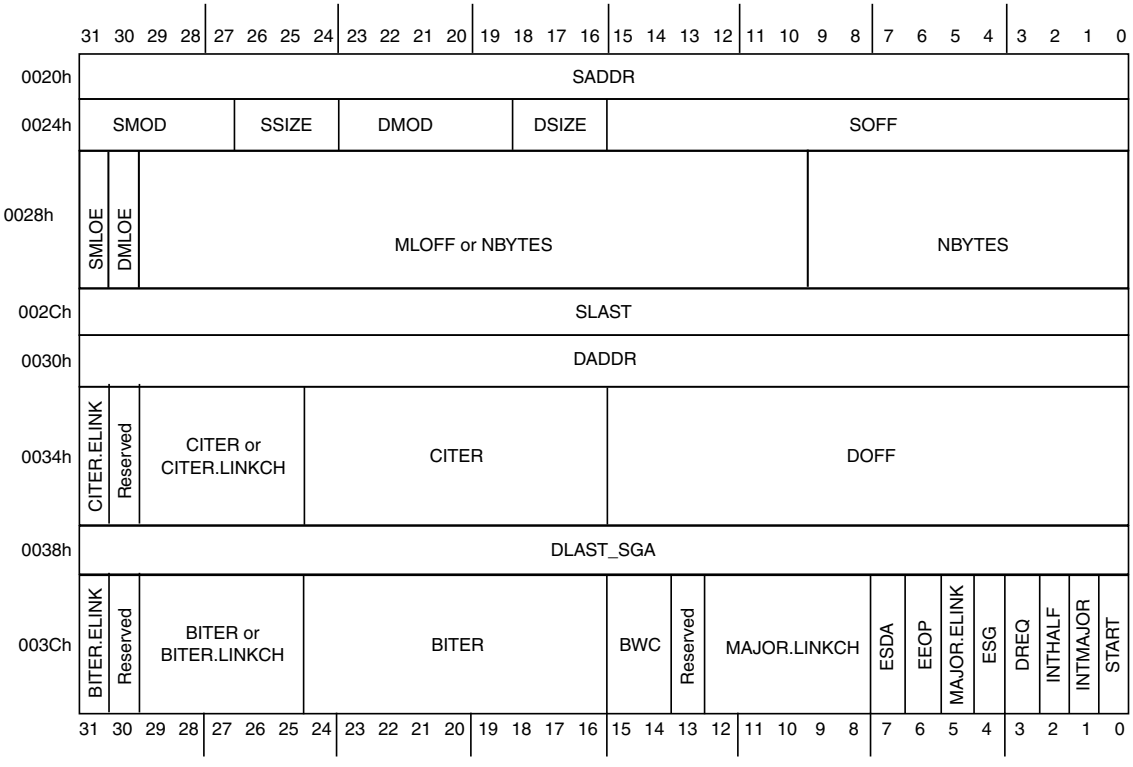

Figure 15. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.

- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

5.6.1 DMA MP register descriptions

5.6.1.1 MP memory map

DMA3.MP base address: 4400_0000h

NOTE

For registers in the following table with *Protection*, see the REG_PROT details for more information.

Offset	Register	Width (In bits)	Access	Reset value	Protection
0h	Management Page Control (MP_CSR)	32	RW	0031_0000h	Yes
4h	Management Page Error Status (MP_ES)	32	R	0000_0000h	No
8h	Management Page Interrupt Request Status (MP_INT)	32	R	0000_0000h	No
Ch	Management Page Hardware Request Status (MP_HRS)	32	R	0000_0000h	No
100h - 17Ch	Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI)	32	RW	0000_0000h	Yes

5.6.1.2 Management Page Control (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

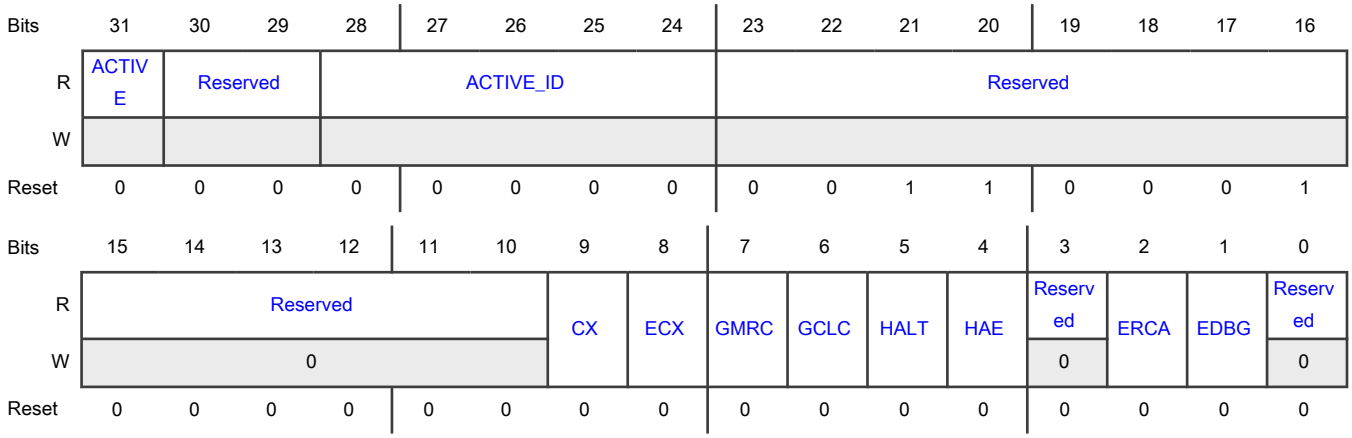
The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

Diagram



Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle 1b - eDMA is executing a channel
30-29 —	Reserved
28-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0b - Normal operation 1b - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to

Table continues on the next page...

Table continued from the previous page...

Field	Function
	cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (MP_ES) and generating an optional error interrupt. 0b - Normal operation 1b - Cancel the remaining data transfer
7 GMRC	Global Master ID Replication Control **NOTE** If master ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Master ID replication disabled for all channels 1b - Master ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6 GCLC	Global Channel Linking Control 0b - Channel linking disabled for all channels 1b - Channel linking available and controlled by each channel's link settings
5 HALT	Halt DMA Operations This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0b - Normal operation 1b - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0b - Normal operation 1b - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0b - Round-robin channel arbitration disabled. Fixed priority arbitration used for channel selection within each group 1b - Round-robin channel arbitration enabled. Round-robin arbitration used for channel selection within each group
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Debug mode disabled. When in debug mode, the DMA continues to operate 1b - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

5.6.1.3 Management Page Error Status (MP_ES)

Offset

Register	Offset
MP_ES	4h

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM
- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Field	Function
31	Valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
VLD	Logical OR of all CHn_ES[ERR] status fields. 0b - No CHn_ES[ERR] fields are set to 1 1b - At least one CHn_ES[ERR] field is set to 1, indicating a valid error exists that software has not cleared
30-29 —	Reserved
28-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the CHn_ES[ERR] field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was a bus error on a destination write

5.6.1.4 Management Page Interrupt Request Status (MP_INT)

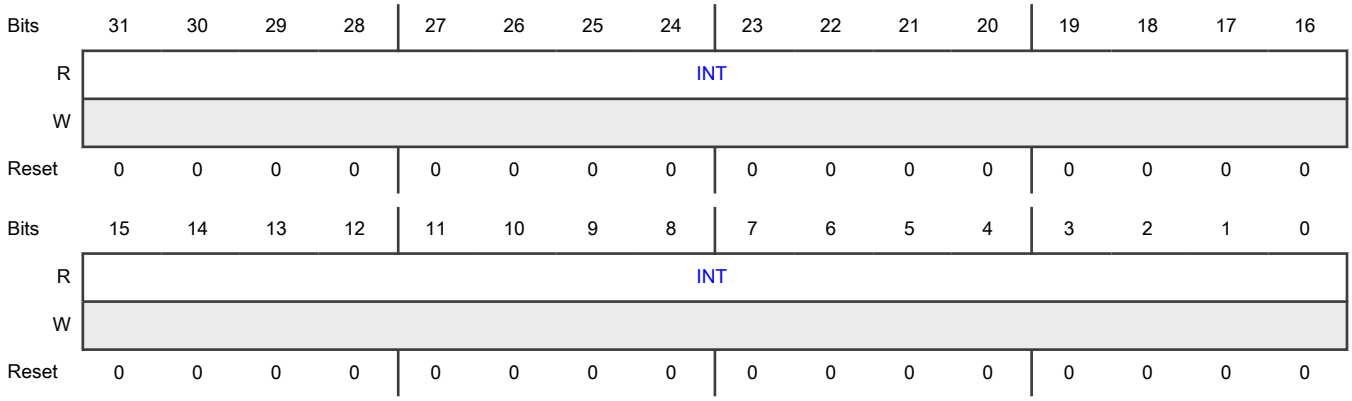
Offset

Register	Offset
MP_INT	8h

Function

This register shows the current state of the interrupt service requests for all eDMA channels.

Diagram



Fields

Field	Function
31-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

5.6.1.5 Management Page Hardware Request Status (MP_HRS)

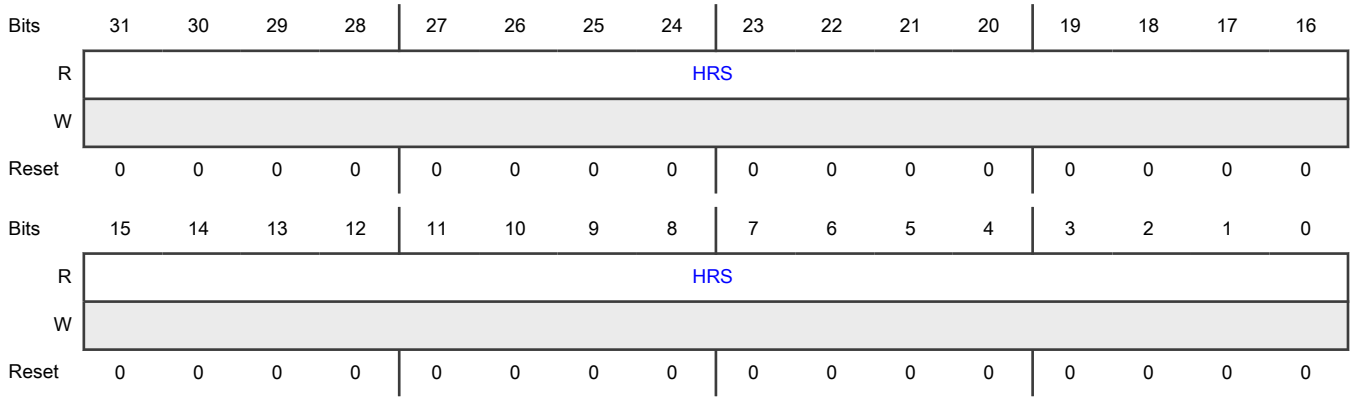
Offset

Register	Offset
MP_HRS	Ch

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

Diagram



Fields

Field	Function
31-0 HRS	Hardware Request Status The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. 0b - Hardware service request for corresponding channel is not present 1b - Hardware service request for corresponding channel is present

5.6.1.6 Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI)

Offset

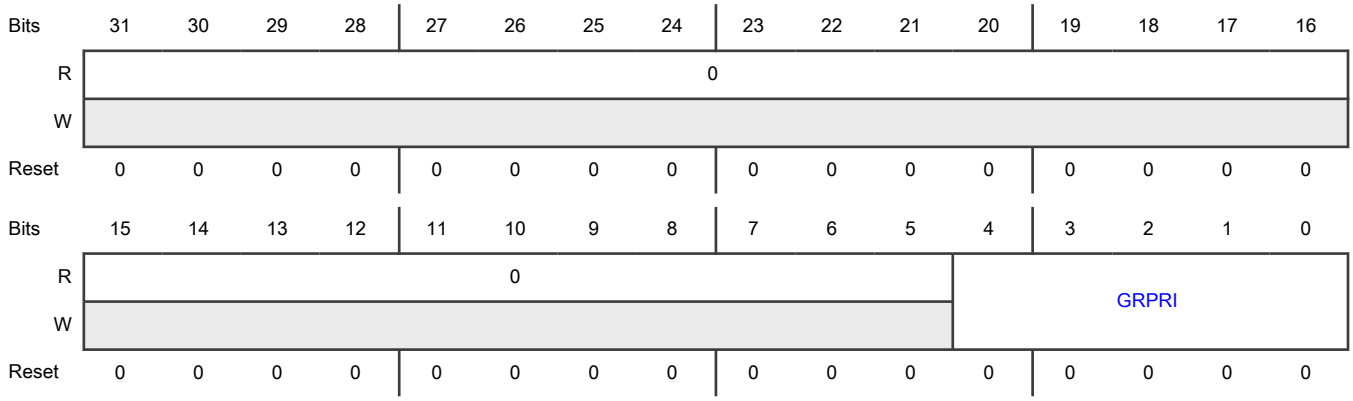
For n = 0 to 31:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Function

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 GRPRI	Arbitration Group For Channel n Fixed-priority arbitration group number.

5.6.2.2 Channel Control and Status (CH0_CSR - CH31_CSR)

Offset

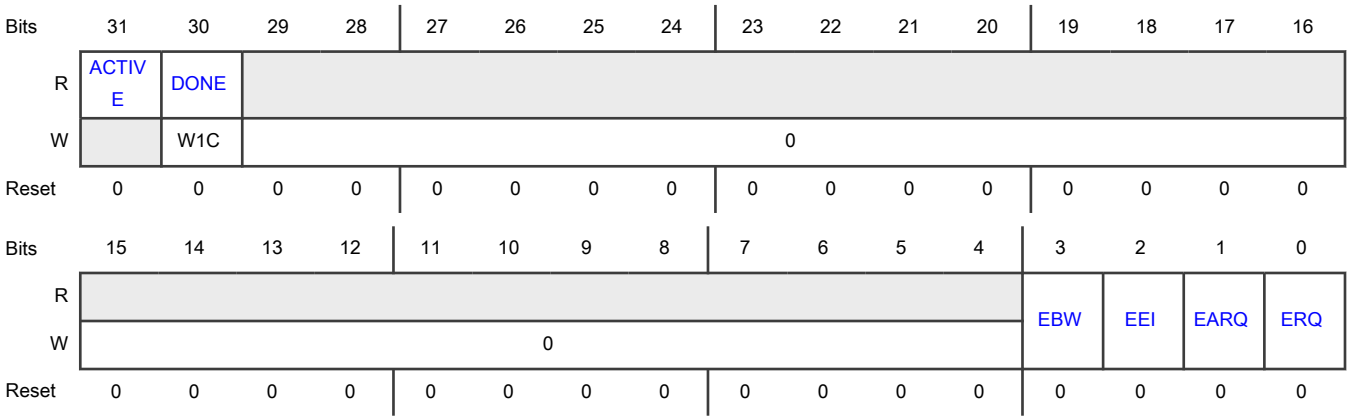
For n = 0 to 31:

Register	Offset
CHn_CSR	0h + (n × 1_0000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3	Enable Buffered Writes

Table continues on the next page...

Table continued from the previous page...

Field	Function
EBW	When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled 1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt 1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

5.6.2.3 Channel Error Status (CH0_ES - CH31_ES)

Offset

For n = 0 to 31:

Register	Offset
CHn_ES	4h + (n × 1_0000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor

- An error termination to a bus master read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller.

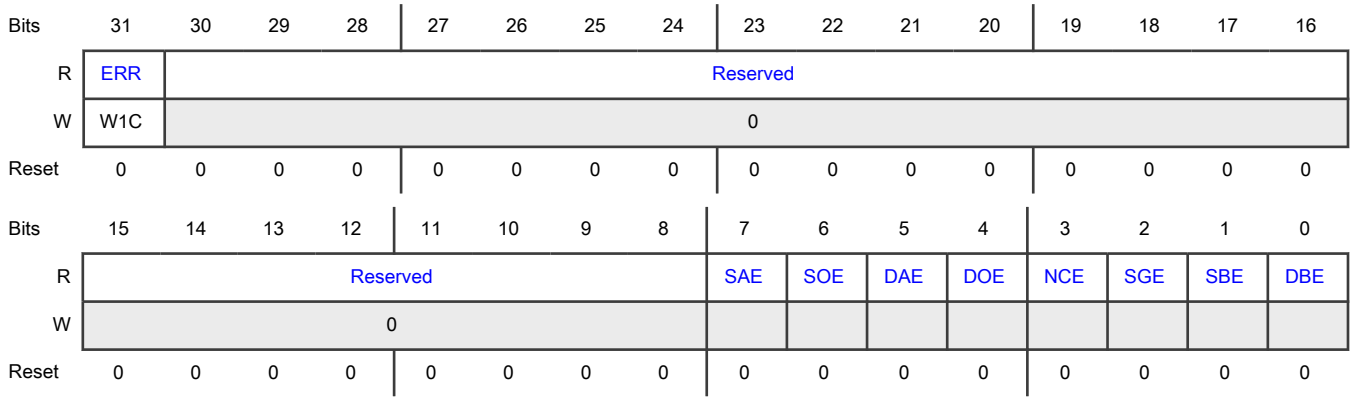
During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 ERR	Error In Channel 0b - An error in this channel has not occurred 1b - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6	Source Offset Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
SOE	TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

5.6.2.4 Channel Interrupt Status (CH0_INT - CH31_INT)

Offset

For n = 0 to 31:

Register	Offset
CHn_INT	8h + (n × 1_0000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

5.6.2.5 Channel System Bus (CH0_SBR - CH31_SBR)

Offset

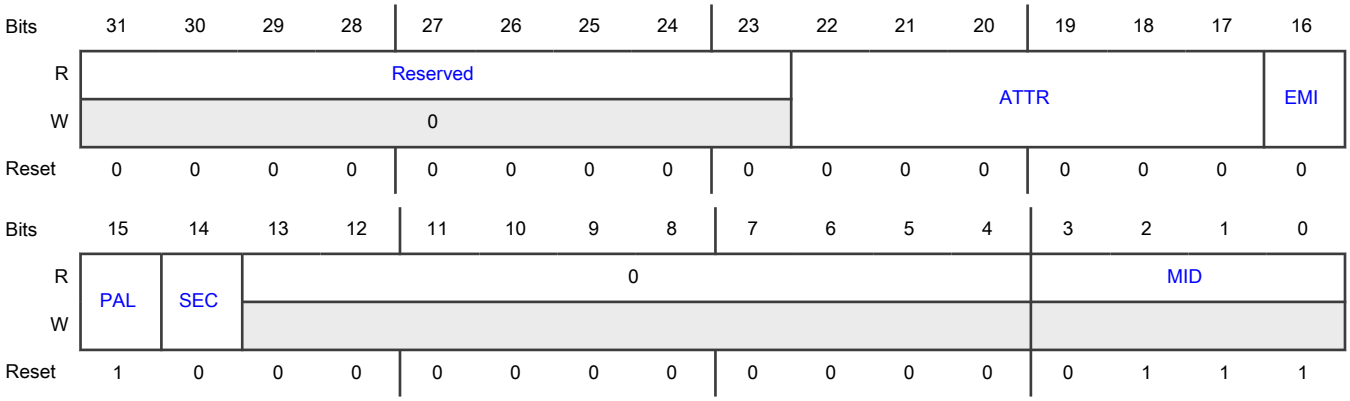
For n = 0 to 31:

Register	Offset
CHn_SBR	Ch + (n × 1_0000h)

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-17 ATTR	Attribute Output DMA's system bus attribute output value.
16 EMI	Enable Master ID Replication The eDMA master ID replication field allows the eDMA to use the same protection level and system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA uses the master ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a master (for example a core) programs a TCD, its master ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Master ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If master ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Master ID replication is disabled 1b - Master ID replication is enabled
15	Privileged Access Level

Table continues on the next page...

Table continued from the previous page...

Field	Function
PAL	This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13-4 —	Reserved
3-0 MID	Master ID This field controls the DMA's master ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the master ID of the core or other master writing the channel's security attributes, TCD*n*_SBR[SEC].

5.6.2.6 Channel Priority (CH0_PRI - CH31_PRI)

Offset

For n = 0 to 31:

Register	Offset
CHn_PRI	10h + (n × 1_0000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI).

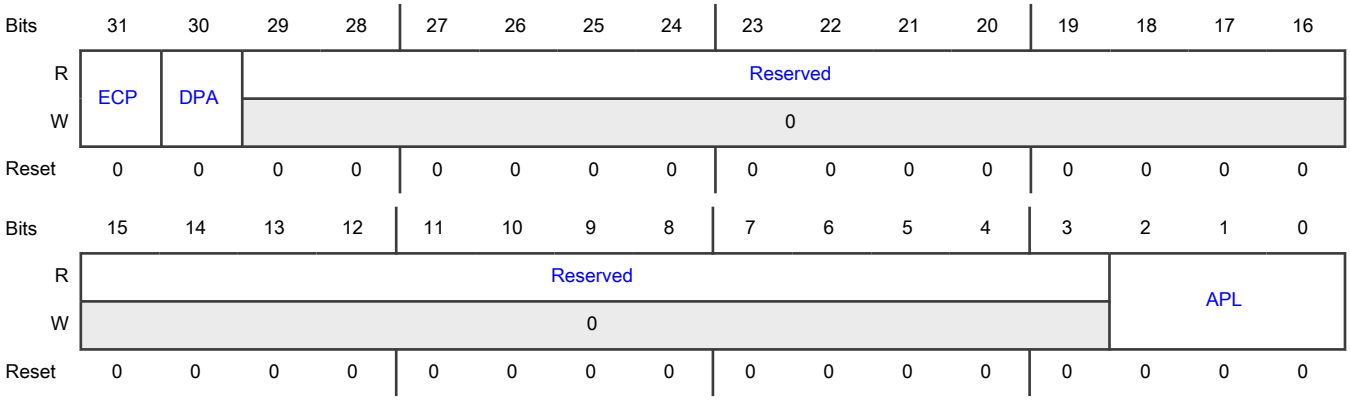
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

5.6.2.7 Channel Multiplexor Configuration (CH0_MUX - CH31_MUX)

Offset

For n = 0 to 31:

Register	Offset
CHn_MUX	14h + (n × 1_0000h)

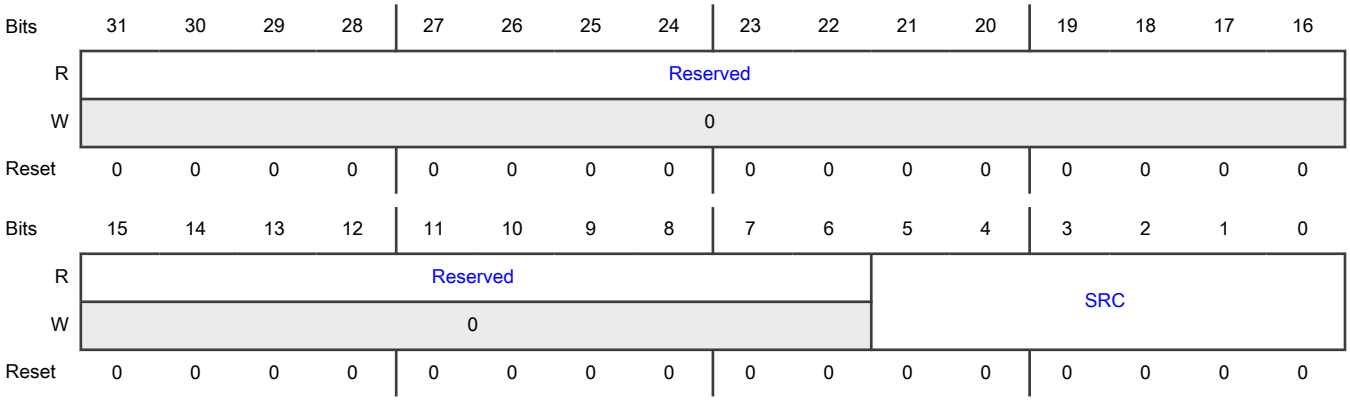
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by any channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-6 —	Reserved
5-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

5.6.2.8 TCD Source Address (TCD0_SADDR - TCD31_SADDR)

Offset

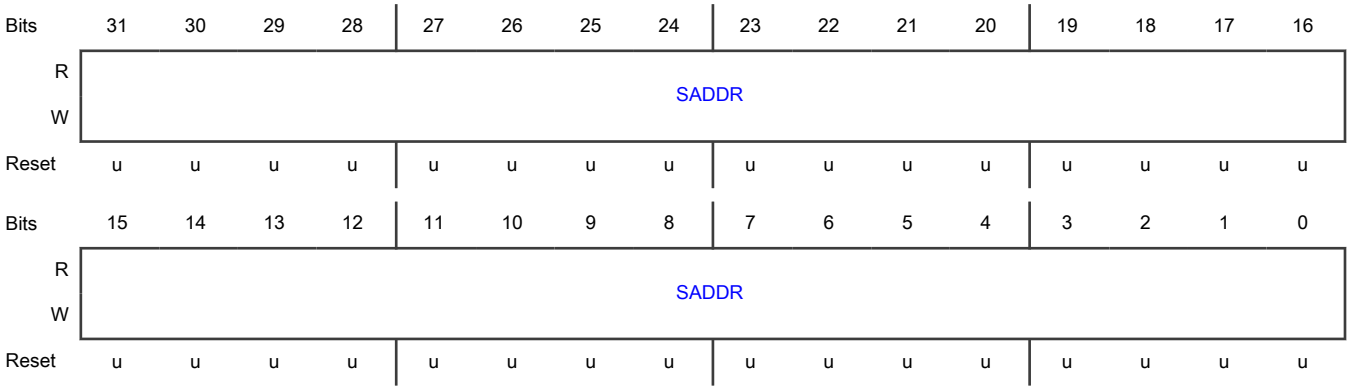
For n = 0 to 31:

Register	Offset
TCDn_SADDR	20h + (n × 1_0000h)

Function

This register contains the address for the read transactions.

Diagram



Fields

Field	Function
31-0 SADDR	Source Address Memory address pointing to the source data.

5.6.2.9 TCD Signed Source Address Offset (TCD0_SOFF - TCD31_SOFF)

Offset

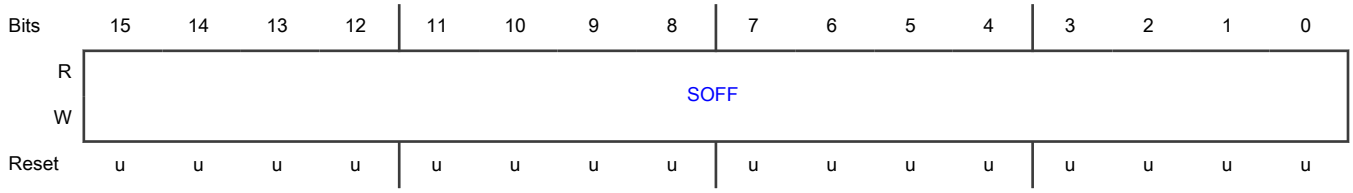
For n = 0 to 31:

Register	Offset
TCDn_SOFF	24h + (n × 1_0000h)

Function

This register contains the sign-extended value added to Source Address register after each read transaction.

Diagram



Fields

Field	Function
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

5.6.2.10 TCD Transfer Attributes (TCD0_ATTR - TCD31_ATTR)

Offset

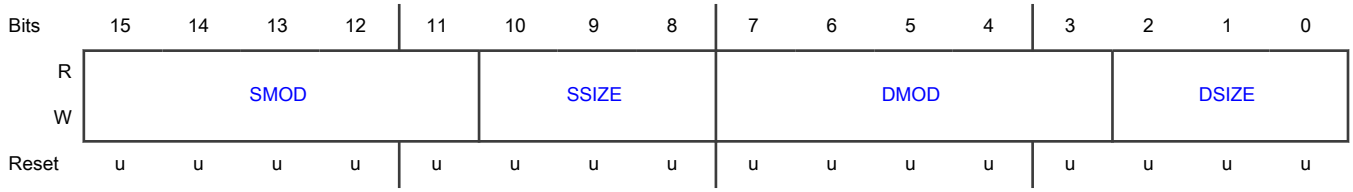
For n = 0 to 31:

Register	Offset
TCDn_ATTR	26h + (n × 1_0000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled 0_0001b - Source address modulo feature enabled for any non-zero value [1-31]
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - 64-byte 111b - Reserved
7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

5.6.2.11 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD31_NBYTES_MLOFFNO)

Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1_0000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

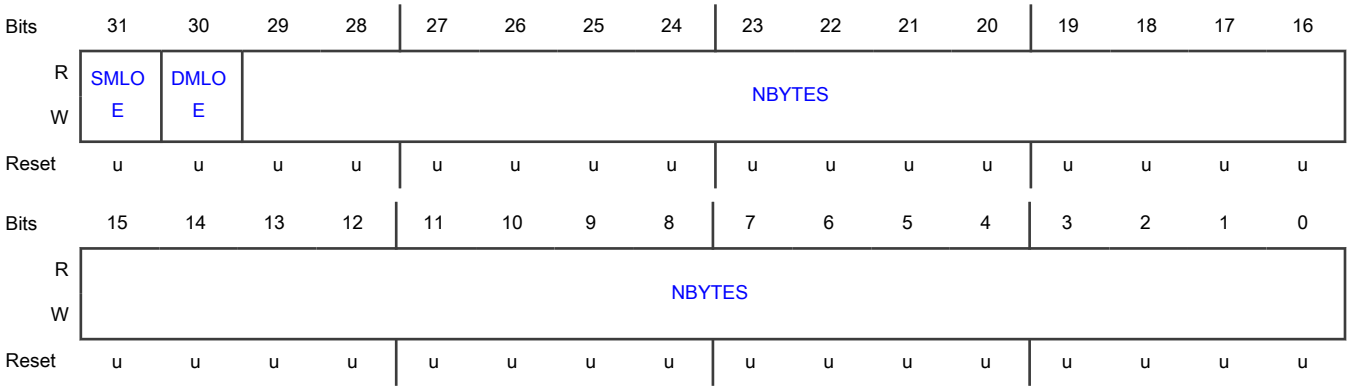
The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR

29-0	Number of Bytes To Transfer Per Service Request

Table continues on the next page...

Table continued from the previous page...

Field	Function
NBYTES	Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

5.6.2.12 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD31_NBYTES_MLOFFYES)

Offset

For n = 0 to 31:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1_0000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

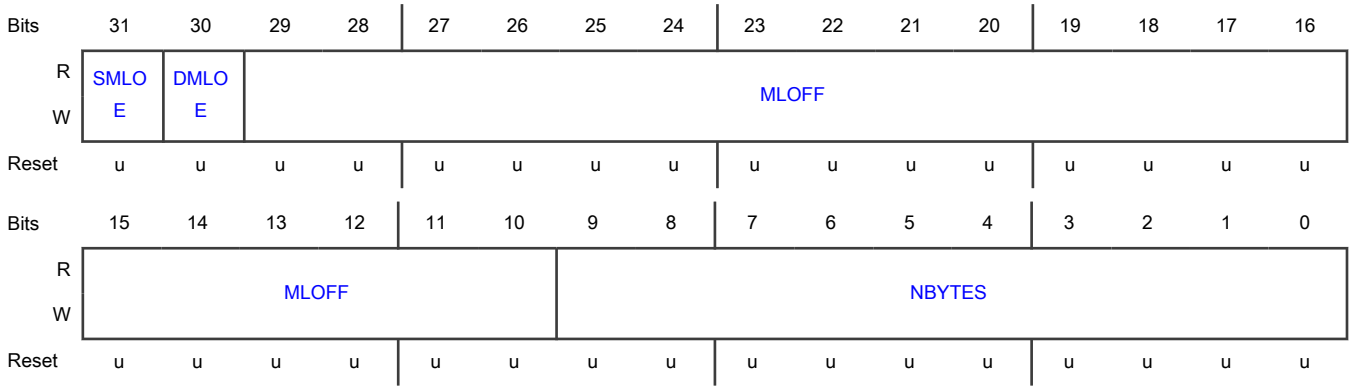
When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

5.6.2.13 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD31_SLAST_SDA)

Offset

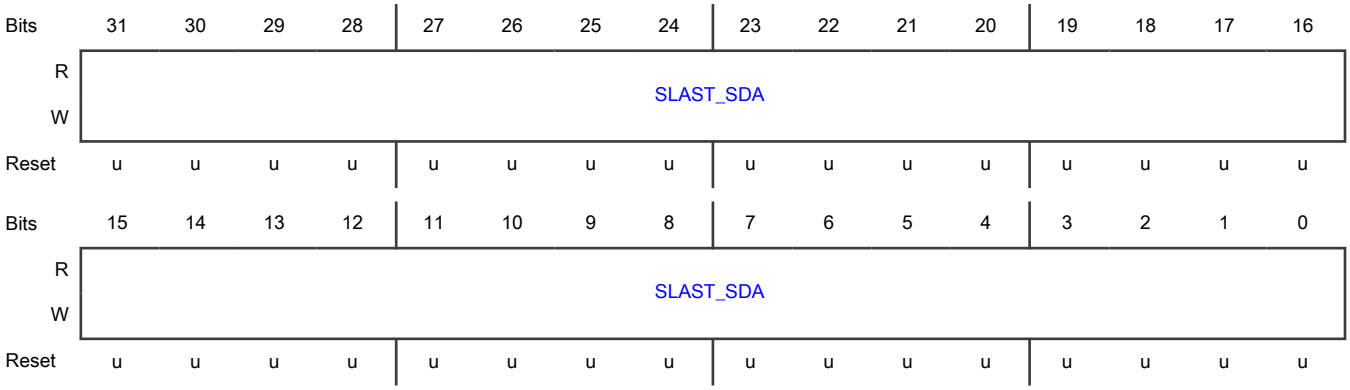
For n = 0 to 31:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1_0000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

5.6.2.14 TCD Destination Address (TCD0_DADDR - TCD31_DADDR)

Offset

For n = 0 to 31:

Register	Offset
TCDn_DADDR	30h + (n × 1_0000h)

Function

This register contains the address for the write transactions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	DADDR															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

5.6.2.15 TCD Signed Destination Address Offset (TCD0_DOFF - TCD31_DOFF)

Offset

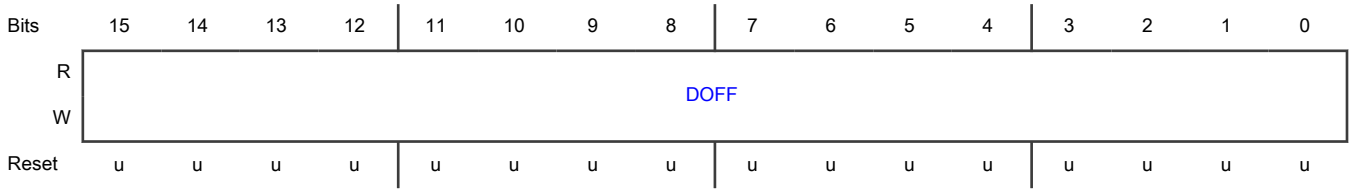
For n = 0 to 31:

Register	Offset
TCDn_DOFF	34h + (n × 1_0000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram



Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

5.6.2.16 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD31_CITER_ELINKNO)

Offset

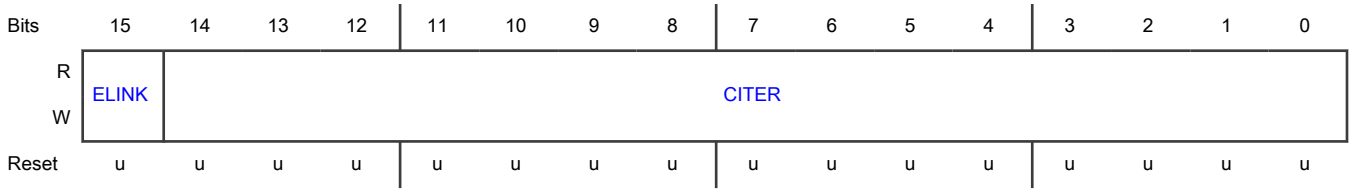
For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1_0000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

5.6.2.17 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD31_CITER_ELINKYES)

Offset

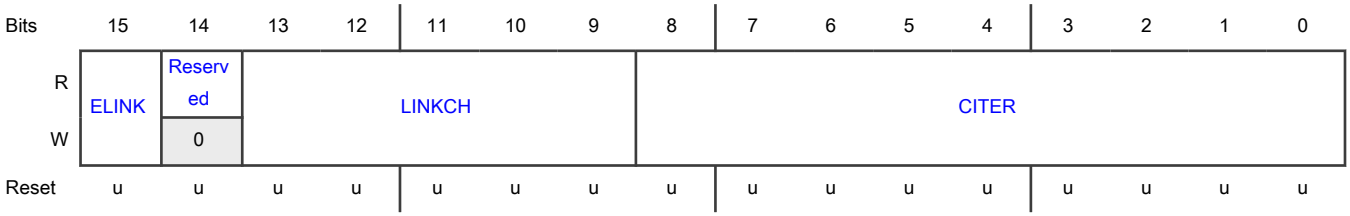
For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1_0000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14 —	Reserved
13-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

5.6.2.18 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD31_DLAST_SGA)

Offset

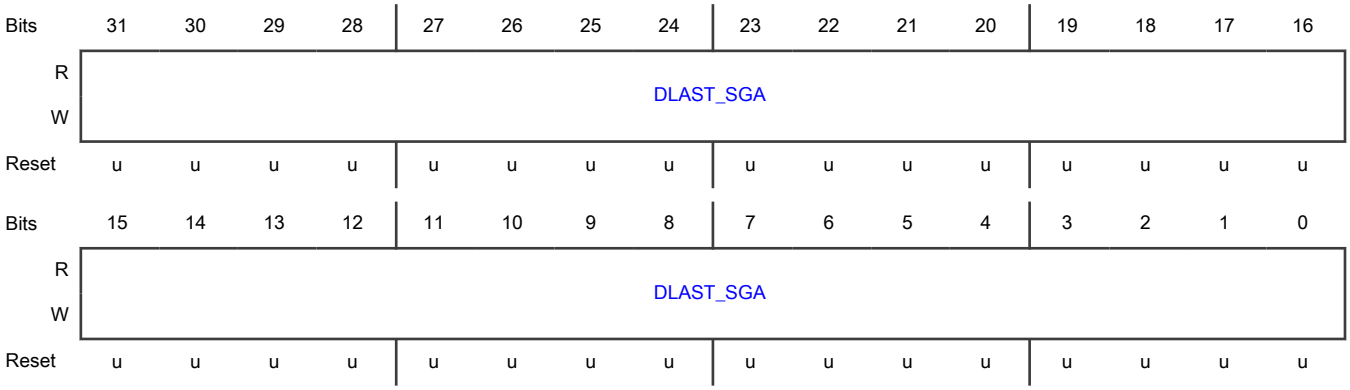
For n = 0 to 31:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1_0000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

5.6.2.19 TCD Control and Status (TCD0_CSR - TCD31_CSR)

Offset

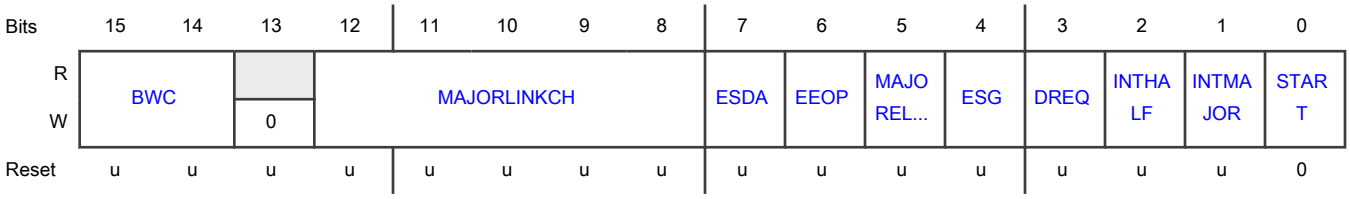
For n = 0 to 31:

Register	Offset
TCDn_CSR	3Ch + (n × 1_0000h)

Function

This register is used to enable optional features.

Diagram



Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13 —	Reserved
12-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the last DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled 1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2 INTHALF	Enable Interrupt If Major Counter Half-complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

5.6.2.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD31_BITER_ELINKNO)

Offset

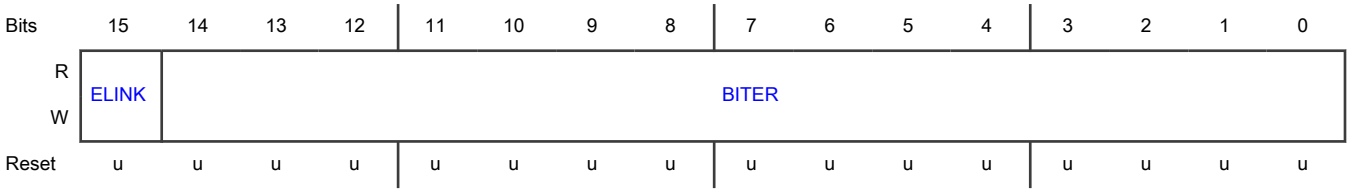
For n = 0 to 31:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1_0000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

5.6.2.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD31_BITER_ELINKYES)

Offset

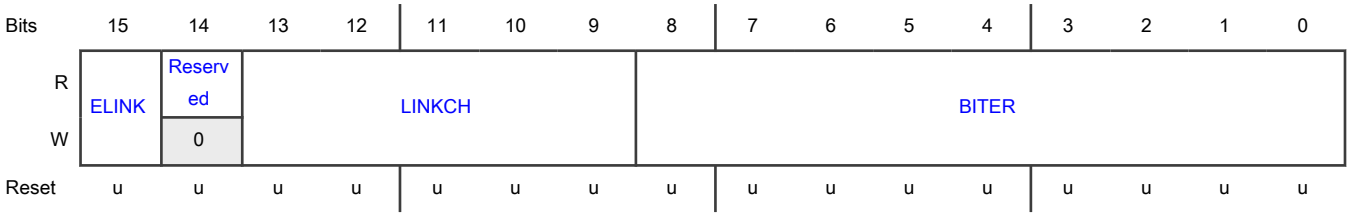
For n = 0 to 31:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1_0000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14 —	Reserved
13-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.

6.2 Overview

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 64 channels

6.2.1 Block diagram

Figure 16 illustrates the components of the eDMA system, including the eDMA module ("engine").

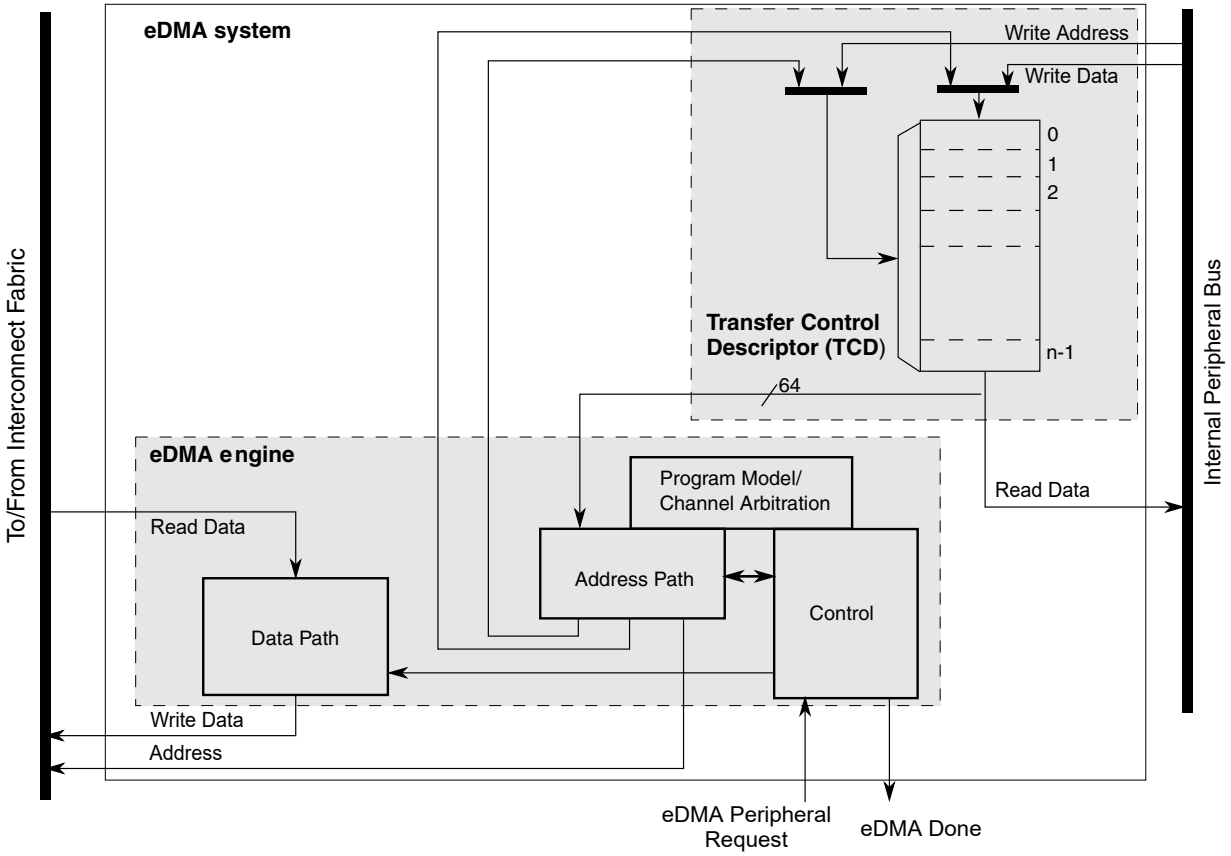

Figure 16. Block diagram

6.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 26. eDMA engine submodules

Submodule	Function
Address path	This block implements registered versions of two channel transfer control descriptors, a primary channel and secondary (preempt) channel, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates,

Table continues on the next page...

Table 26. eDMA engine submodules (continued)

Submodule	Function
	reloading the TCD*n*_CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned into:

Table 27. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

6.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination plus a write-only initialization mode
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 64-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support large multibyte transfers
  - Connections to the interconnect fabric for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count

  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

6.3 Functional description

The operation of the eDMA is described in the following subsections.

6.3.1 Modes of operation

The eDMA operates in the following modes:

Table 28. Modes of operation

Mode	Description
Normal	In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared, the eDMA continues to operate. • If CSR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.

6.3.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

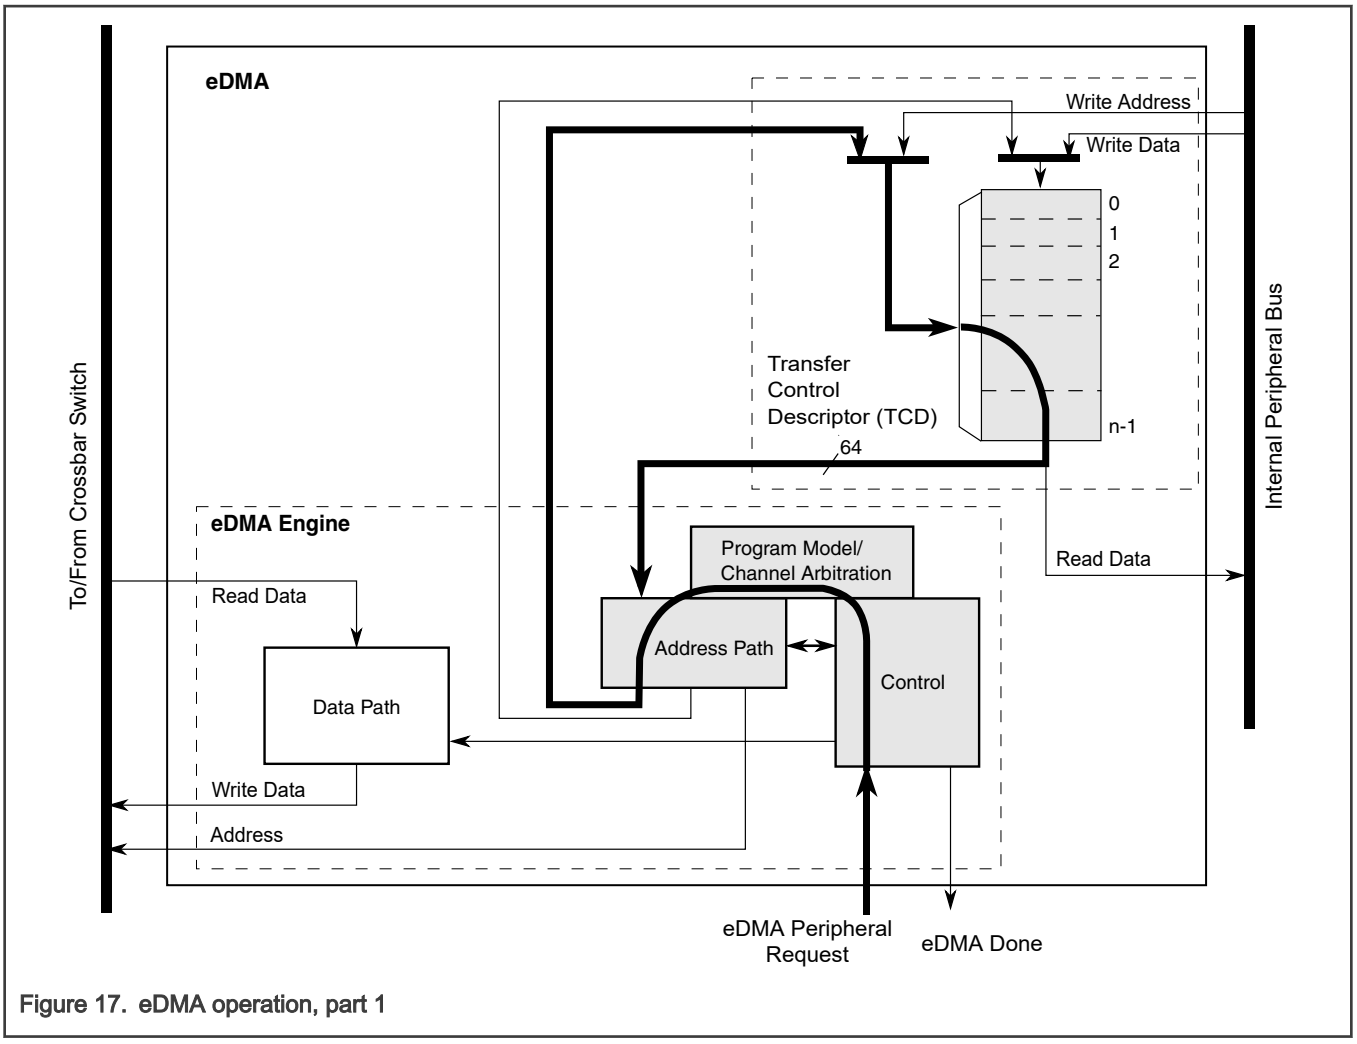

Figure 17. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

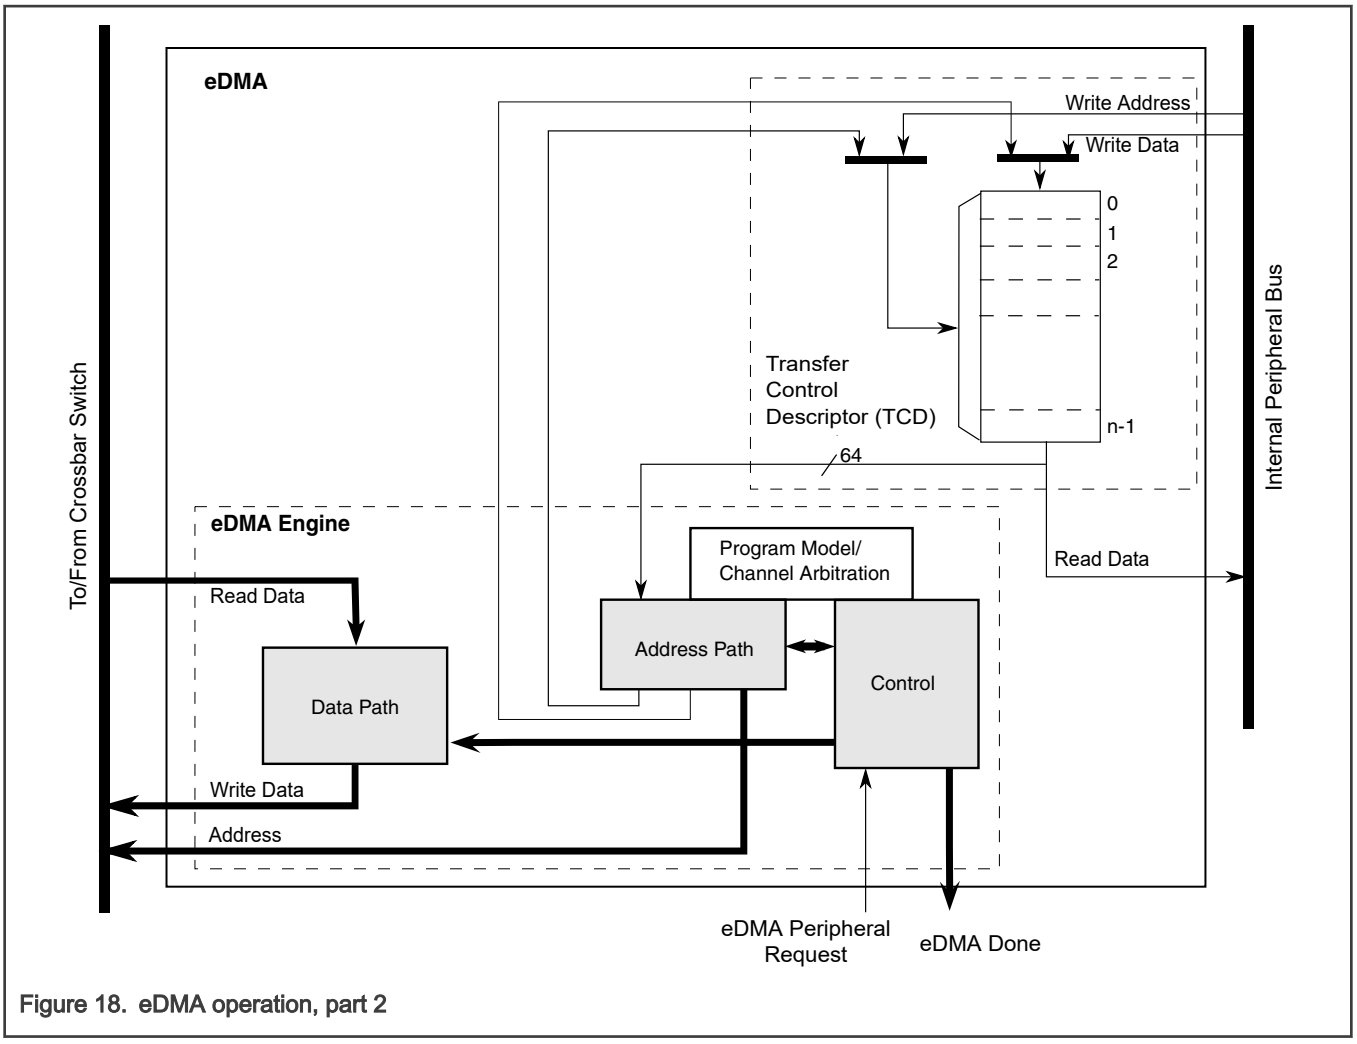

Figure 18. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

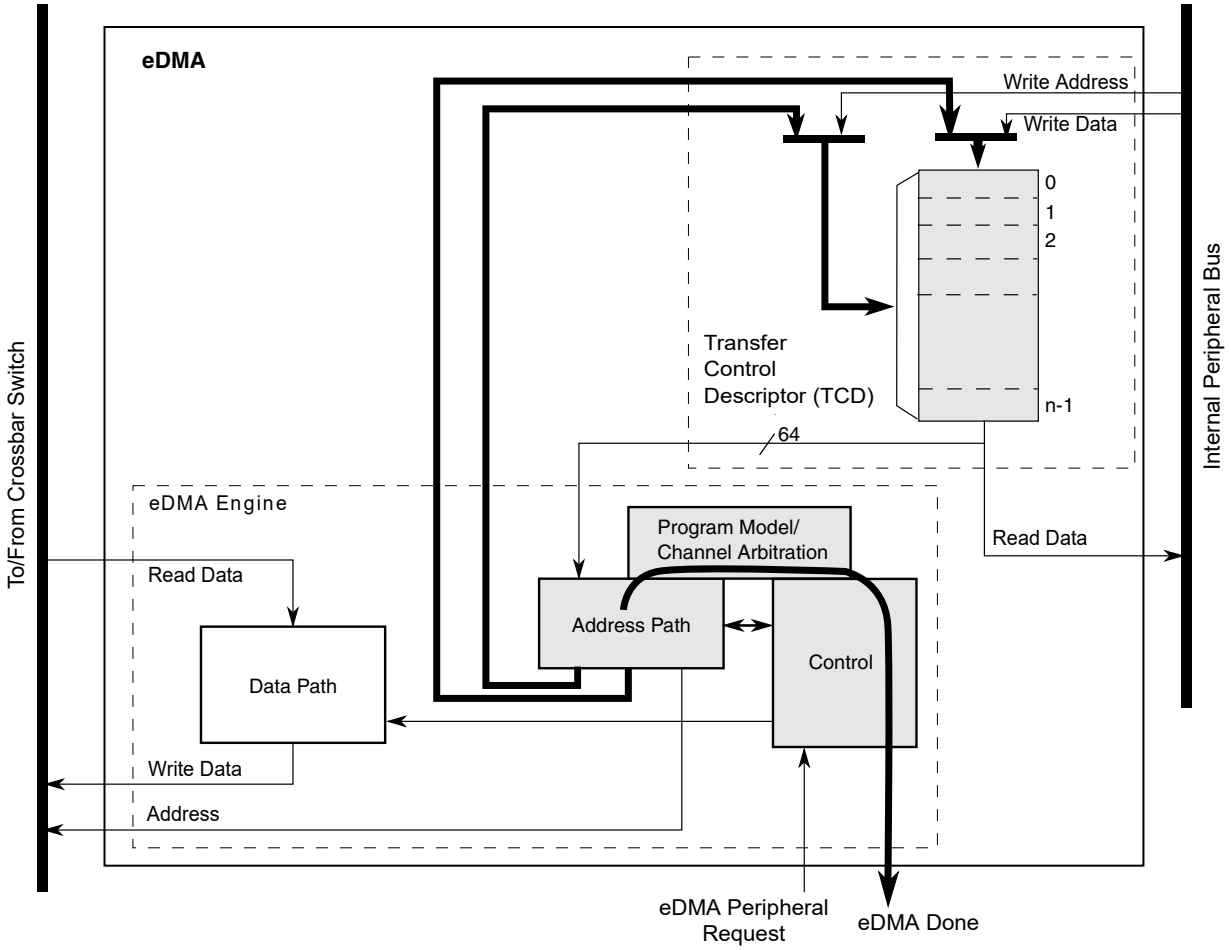

Figure 19. eDMA operation, part 3

6.3.3 Fault reporting and handling

Channel errors are reported in the Error Status register (ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor, or
- An active channel canceled via a "cancel transfer with error" software request, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.

NOTE

To aid in debug, set the Halt After Error bit in the DMA's Control Status Register, CSR[HAE]. Upon any error condition, the DMA will be halted after the error is recorded. The DMA will remain halted and will not process any channel service requests. Once the error is fixed, the DMA may be enabled again by clearing the Halt bit, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] bit does not equal the TCDn_BITER[ELINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request if enabled. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates processing. Due to pipeline effect, transfers already in progress when the bus error is received by the eDMA are not aborted. Bus errors are imprecise. The source and destination addresses stored in the TCD after a bus error may not be the address that caused the error.

A transfer may be cancelled by software with the CSR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. Transactions in flight are allowed to finish. If the cancel occurs on the last sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into the Management Page ES[ERRCHN], and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

NOTE

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The cancel transfer is an imprecise operation. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is automatically disabled from hardware service requests. If a channel is terminated by an error, its CHn_CSR[ERQ] enable hardware requests bit is cleared thus preventing continuous errors from a peripheral's service request.

The error status bits are read-only. These error indicators are sticky and cannot be cleared. They will show the last recorded error until the DMA is reset. The valid bit (VLD) can be used to determine is a new error condition exists. This bit is the logical OR of each channel's error interrupt bit (ERR). Once the software has resolved any errors and cleared all of the error interrupt bits, the valid bit will be cleared, but the cause of the last error will still be indicated.

6.3.4 Channel preemption

The eDMA uses a priority vector value to determine the highest priority channel requesting service.

The priority vector is a combination of:

1. the channel's group priority, CHn_GRPRI
2. the channel's priority level, CHn_PRI[APL]

3. the channel number

Priority vector = ((CHn_GRPRI << 8) + (CHn_PRI[APL] << 5) + CHn_*)

A channel requesting service with the highest priority vector value will receive the next execution slot.

An execution slot is available:

1. immediately if the eDMA is idle
2. when an active channel retires
3. when valid preemption conditions exist

NOTE

Preemption is strictly priority based. Preemption is not bound by a specific group number as defined by CHn_GRPRI.

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel. When Round-Robin channel arbitration mode is enabled, CSR[ERCA] = 1, any channel with a priority level equal to zero, CHn_PRI[APL] = 0, has preemption disabled and will not preempt another channel.

6.3.5 Clocking

This module has no clocking considerations.

6.3.6 Interrupts

This module has no interrupts.

6.4 External signals

This module has no external signals.

6.5 Initialization

The following sections discuss initialization of the eDMA and programming considerations.

6.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CSR if a configuration other than the default is desired.
2. Write the channel priority levels to the CH_PRI registers and group priority levels to the MP_GPRI registers if a configuration other than the default is desired.
3. Enable error interrupts in the CH_CSR[EEI] registers if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CH_CSR[ERQ] registers.

6. Request channel service via either:
   - Software: setting the TCD_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD*n*_SADDR, to the destination, as defined by TCD*n*_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 29. TCD Control and Status (TCD_CSR) fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
EEOP	Control bit to enable End-Of-Packet processing
ESDA	Control bit to enable the storing of the destination address to system memory after the major loop completes
DREQ	Control bit to disable hardware initiated DMA service requests after major loop completion
BWC	Control bits for throttling bandwidth control of a channel
ESG	Control bit to enable scatter-gather feature
INTHALF	Control bit to enable interrupt when major loop is half complete
INTMAJ	Control bit to enable interrupt when major loop completes

Table 30. Channel Control and Status (CH_CSR) fields

TCD*n*_CSR field name	Description
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control bit to enable error interrupts
EARQ	Control bit to enable external, asynchronous wake-up event in conjunction with the ERQ bit
ERQ	Control bit to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

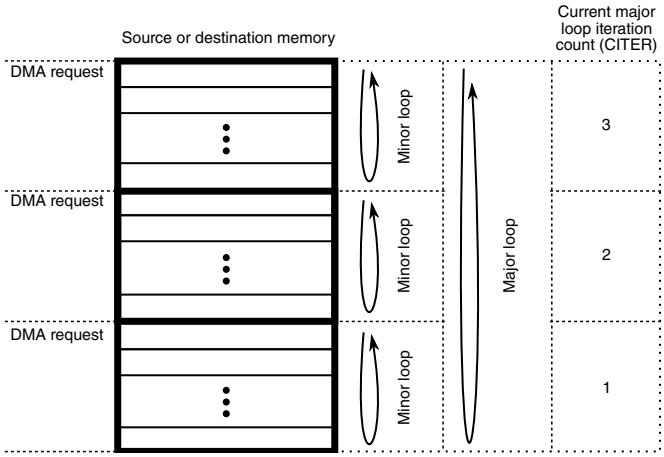

Figure 20. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

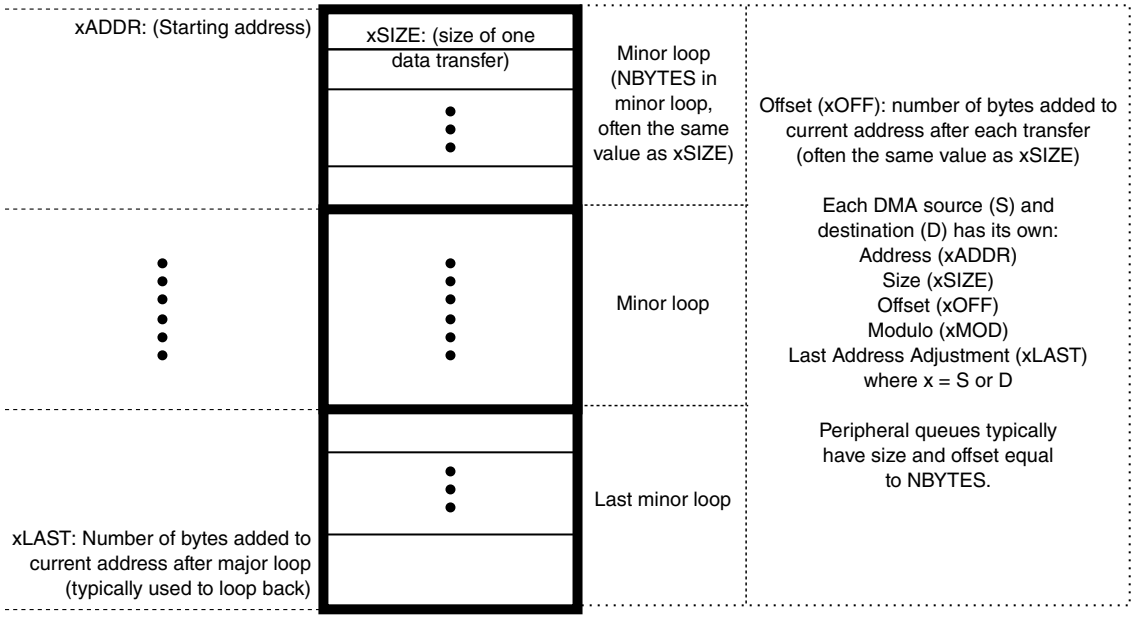

Figure 21. Memory array terms

6.5.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed priority arbitration scheme with an optional, round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

1. Highest

   Arbitration Group Priority. Each channel is assigned an arbitration group via the MP_GRPI registers. Priority is given the to highest value (31 being the highest possible value) down to the lowest value (zero, the default).

2. Channel Priority. Each channel is assigned a channel priority level via the CH_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (7 being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group do not have to be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in item 3.

3. Channel Number. When two or more channels have the same arbitration group priority and channel priority, the channel number (CH_NUM) is used to determine the highest priority. Priority is giver to the highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4. Lowest

   When round robin is enabled, any channel configured for round robin operation has lowest priority within an arbitration group. Round robin is enabled be setting the CSR[ERCA] bit. Once enabled, channels with a channel priority of zero (CH_PRI=0) will use round robin arbitration. Round robin arbitration will rotate the channel selection amongst the channel's requesting service with CH_PRI=0 within the arbitration group. Any nonzero channel within the arbitration group will continue to use fixed priority arbitration and if requesting service, will be selected over any round robin channels.

For fixed arbitration, the overall priority can be consider a number composed of three concatenated priority levels- MP_GRPI:CH_PRI:CH_NUM. The largest number will have the highest priority and the lowest number will have the lowest priority.

For round robin arbitration, the priority number is- MP_GRPI:0:X. The CH_PRI=0 channels requesting service are rotated through without regard to priority amongst these channels. Any channel within the arbitration group with a CH_PRI > 0 will be serviced before the round robin channels.

6.5.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again. Setting the halt after error bit, CSR[HAE], will halt the DMA and prevent the recurrence of the error.

6.5.4 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

6.5.4.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within a high priority group have a high number of request or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower priority groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

6.5.4.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to zero, the highest channel number requesting service is selected and then rotating through to the lowest channel number requesting service. The round-robin channel arbitration may provide a fairness mechanism to lower priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, Fixed channel arbitration, but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

6.5.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

6.5.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
    a. Continuously read data from the source addresses by issuing read transactions and adjusting the source address via the source address offset value after each transaction.
    b. Continuously write data to the destination addresses after sufficient data has been buffered. Adjust the destination address via the destination address offset after each transaction.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

6.5.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CH_CSR[ERQ] register bit, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
    a. Continuously read data from the source addresses by issuing read transactions and adjusting the source address via the source address offset value after each transaction.
    b. Continuously write data to the destination addresses after sufficient data has been buffered. Adjust the destination address via the destination address offset after each transaction.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
    a. Continuously read data from the source addresses by issuing read transactions and adjusting the source address via the source address offset value after each transaction.
    b. Continuously write data to the destination addresses after sufficient data has been buffered. Adjust the destination address via the destination address offset after each transaction.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

6.5.5.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567*x*) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2^4 byte (16-byte) size queue.

Table 31. Modulo example

Transfer number	Address
1	0x12345670

Table continues on the next page...

Table 31. Modulo example (continued)

Transfer number	Address
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

6.5.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

6.5.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the CH*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the CH*n*_CSR[ACTIVE] bit only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CH_CSR and TCD_CSR status bits execute the following sequence for a software activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)

Table continues on the next page...

Table continued from the previous page...

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the CH*n*_CSR[DONE] bit.

The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

6.5.6.2 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher priority request becomes active. When Round-Robin channel arbitration mode is enabled, all channels with their channel priority set to zero lose their preempt ability. Channel priorities of zero are treated as equal, that is, constantly rotating, when Round-Robin arbitration mode is enabled.

The CH*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two CH*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

6.5.7 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done→ set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[ELINK] = 1), the TCD*n*_CITER[CITER] field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[ELINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCD*n*_CITER[ELINK] bit and the TCD*n*_BITER[ELINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e, use another channel's TCD, at the end of a loop.

Table 32. Channel Linking Parameters

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	TCD_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCD_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	TCD_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCD_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

6.5.8 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] and TCDn_CSR[MAJORLINKCH] fields during channel execution. This bits are read from the TCD profile at the end of channel execution, thus allowing the user to enable the feature during channel execution. When attempting a dynamic channel link, the user must write the TCDn_CSR[MAJORELINK] and TCDn_CSR[MAJORLINKCH] in a single write transaction; that being a write size of at least 16 bits to the TCDn_CSR register.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD_CSR[MAJORELINK] bit at the same time the eDMA engine is retiring the channel. The TCD_CSR[MAJORELINK] would be set in the programmer’s model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] bit.
2. Read back the TCDn_CSR[MAJORELINK] bit.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

The TCD local memory controller forces the TCDn_CSR[MAJORELINK] bit to zero on any writes to a channel’s TCDn_CSR after that channel’s CHn_CSR[DONE] bit is set, indicating the major loop is complete.

NOTE

The user must clear the CHn_CSR[DONE] bit before writing the TCDn_CSR[MAJORELINK] bit. The CHn_CSR[DONE] bit is cleared automatically by the eDMA engine after a channel begins execution.

6.5.9 Suspend/resume a DMA channel with active hardware service requests

The DMA allows the user to move data from memory or peripheral registers to another location in memory or peripheral registers without CPU interaction. Once the DMA and peripherals have been configured and are active, it is rare to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, a specific procedure must be followed. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module.

6.5.9.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status Register (DMA_HRSn) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ bit on appropriate DMA channel.

For example, assume the SPI is set as a master for transmitting data via a DMA service request when the DSPI_TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If the user needs to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure there is no DMA service request from the SPI by verifying that DMA_HRS[HRS*n*] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ bit. If a service request is present, wait until the request has been processed and the HRS bit reads zero.

6.5.9.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting the its ERQ bit.
2. Enable the DMA service request at the peripheral.

6.6 Memory map/register definition

The eDMA's programming model is partitioned into three parts:

- The first part defines a number of registers providing overall control functions: the management page
- The second part corresponds to the channel (CH) control, status, and configuration
- The third part corresponds to the local transfer control descriptor (TCD) memory

TCD memory

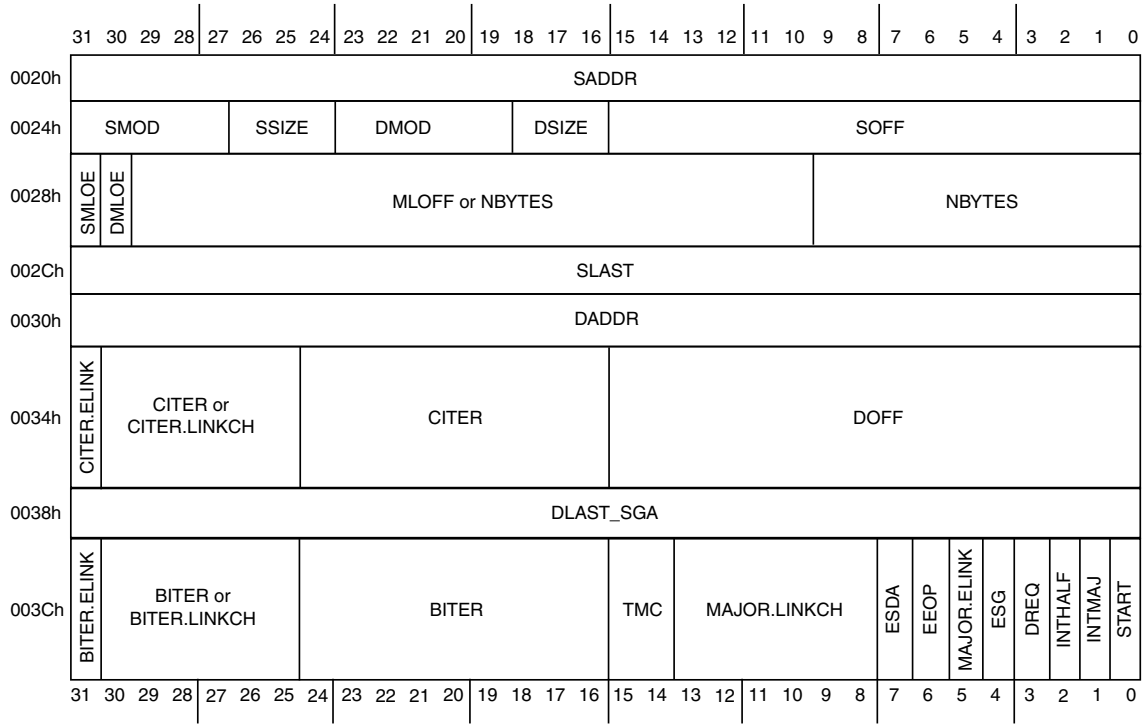
Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 63.

This table provides a 32-bit view of the eDMA's memory map.

TCD initialization

The TCD memory is in an unknown state after reset. Only the TCD START bit is initialized to 0. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure



Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

6.6.1 DMA MP register descriptions

6.6.1.1 MP memory map

DMA4.MP base address: 4200_0000h

6.6.1.2 Management Page Control Register (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

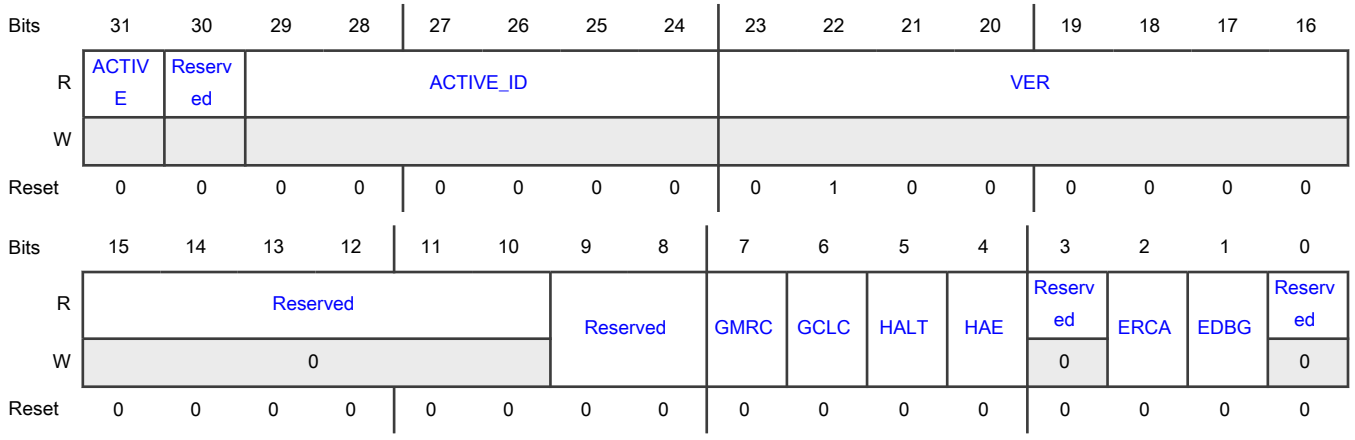
The Management Page Control Register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. Each channel is assigned a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, the highest priority channel requesting service in the highest priority arbitration group is selected to execute. The channel priority registers assign the relative priorities within each arbitration group; see the CH *n* _PRI registers. All channels with a non-zero CH *n* _PRI value use fixed-priority arbitration. When round-robin arbitration is enabled, any channel with its channel priority set to zero does not have a priority and, of these channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CH *n* _PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in the management page group priority registers (MP_GRPRI).

NOTE

For correct operation, changes to the CSR[ERCA, GCLC, GMRC] bits must be performed when the DMA channels are inactive; that is, when CSR[ACTIVE] bit is cleared.

Diagram



Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle. 1b - eDMA is executing a channel.
30 —	Reserved
29-24 ACTIVE_ID	Active channel ID
23-16 VER	eDMA version
15-10 —	Reserved
9-8 —	Do not change the value of this field.
7 GMRC	Global Master ID Replication Control **NOTE** If master ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Master ID replication is disabled for all channels. 1b - Master ID replication is available and is controlled by each channel's CHn_SBR[EMI] setting.
6 GCLC	Global Channel Linking Control 0b - Channel linking is disabled for all channels. 1b - Channel linking is available and controlled by each channel's link settings.
5 HALT	Halt DMA Operations 0b - Normal operation 1b - Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
4 HAE	Halt After Error 0b - Normal operation 1b - Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2 ERCA	Enable Round Robin Channel Arbitration 0b - Round robin channel arbitration is disabled. Fixed priority arbitration is used for channel selection within each group . 1b - Round robin channel arbitration is enabled. Round robin arbitration is used for channel selection within each group .
1 EDBG	Enable Debug 0b - Debug mode is disabled. When in debug mode, the DMA continues to operate. 1b - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.
0 —	Reserved

6.6.1.3 Management Page Error Status Register (MP_ES)

Offset

Register	Offset
MP_ES	4h

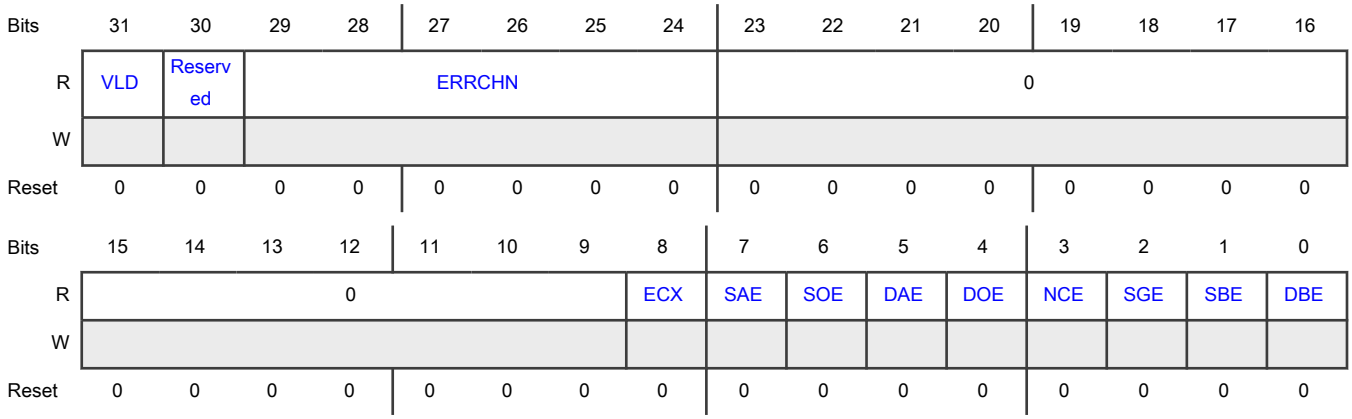
Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer-control descriptor
- An error termination to a bus master read or write cycle
- An uncorrectable error occurred while the device was accessing the TCD SRAM
- A cancel transfer with error request was made via the corresponding cancel transfer bit or input signal

Upon any error condition, the software must initialize the errant channel's TCD as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 VLD	Valid Logical OR of all ERR status bits. 0b - No ERR bits are set. 1b - At least one ERR bit is set indicating a valid error exists that has not been cleared.
30 —	Reserved
29-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a Management Page function. When employed, the targeted channel's CH_ES register will report an unspecified error; only the ERR bit is set. The Management Page has full view of the error condition. 0b - No canceled transfers 1b - The last recorded entry was a canceled transfer by the error cancel transfer input.
7 SAE	Source Address Error 0b - No source address configuration error. 1b - The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
6 SOE	Source Offset Error 0b - No source offset configuration error

Table continues on the next page...

Table continued from the previous page...

The eDMA channel interrupt requests are routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit in the channel’s interrupt request register, CHn_INT, thus negating the interrupt request. • 0 - An interrupt request for the corresponding channel is not present. • 1 - An interrupt request for the corresponding channel is present.

6.6.1.6 Management Page Hardware Request Status Register - Low (MP_HRS_LOW)

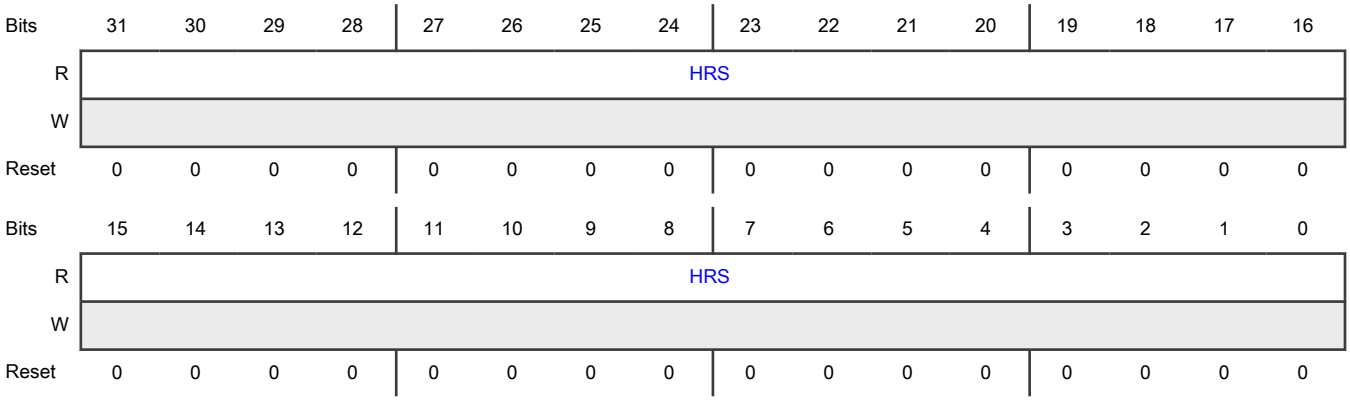
Offset

Register	Offset
MP_HRS_LOW	10h

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by the eDMA's arbitration logic.

Diagram



Fields

Field	Function
31-0 HRS	Hardware Request Status for channels 31 - 0 The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. After the request is completed and channel is free, the HRS bit is automatically cleared by hardware. 0000_0000_0000_0000_0000_0000_0000_0000b - A hardware service request for the channel is not present 0000_0000_0000_0000_0000_0000_0000_0001b - A hardware service request for channel 0 is present

6.6.1.7 Management Page Hardware Request Status Register - High (MP_HRS_HIGH)

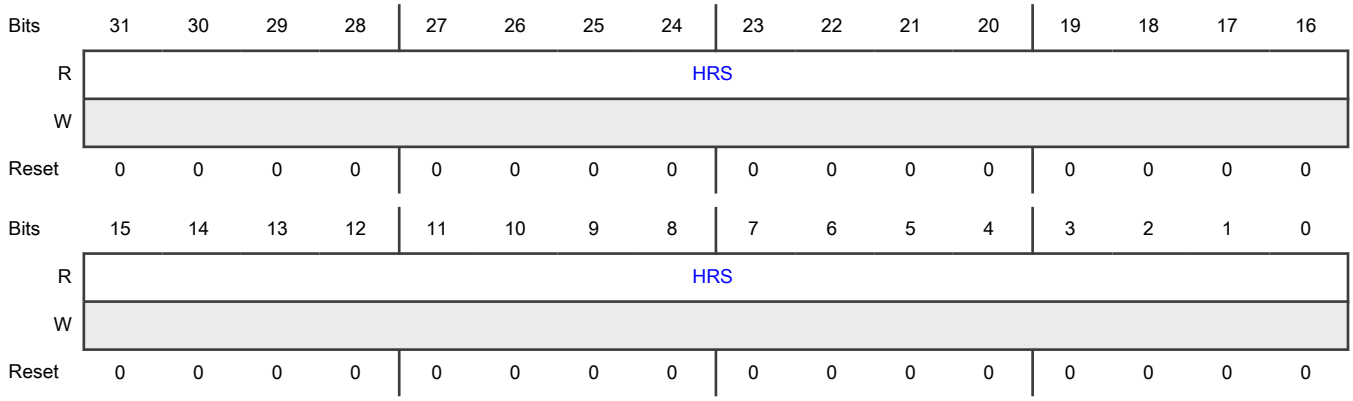
Offset

Register	Offset
MP_HRS_HIGH	14h

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by the eDMA's arbitration logic.

Diagram



Fields

Field	Function
31-0 HRS	Hardware Request Status for channels 63-32 The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. After the request is completed and channel is free, the HRS bit is automatically cleared by hardware. 0000_0000_0000_0000_0000_0000_0000_0000b - A hardware service request for the channel is not present 0000_0000_0000_0000_0000_0000_0000_0001b - A hardware service request for channel 0 is present

6.6.1.8 Channel Arbitration Group Register (CH0_GRPRI - CH63_GRPRI)

Offset

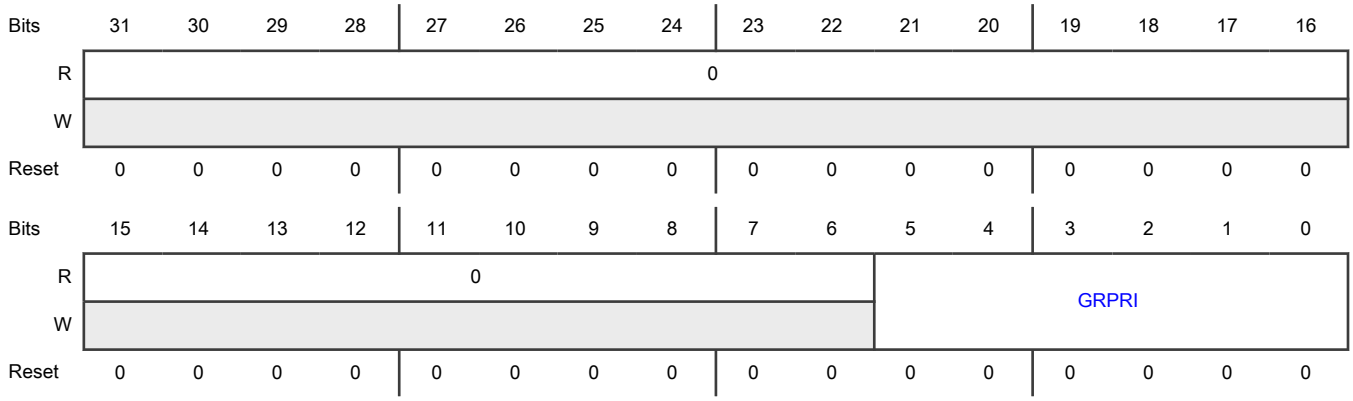
For n = 0 to 63:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Function

The contents of this register defines the arbitration group associated with each channel. Using fixed-priority group arbitration scheme, the arbitration group priorities are evaluated by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority, CH *n* _PRI, assignment determines the highest priority channel.

Diagram



Fields

Field	Function
31-6 —	Reserved
5-0 GRPRI	Arbitration group per channel. Fixed-priority arbitration group number.

6.6.2.2 Channel Control and Status Register (CH0_CSR - CH63_CSR)

Offset

For n = 0 to 63:

Register	Offset
CHn_CSR	0h + (n × 8000h)

Function

The DMA hardware request input signal and the enable request bit (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request bit does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ bit does not affect the channel's START bit.

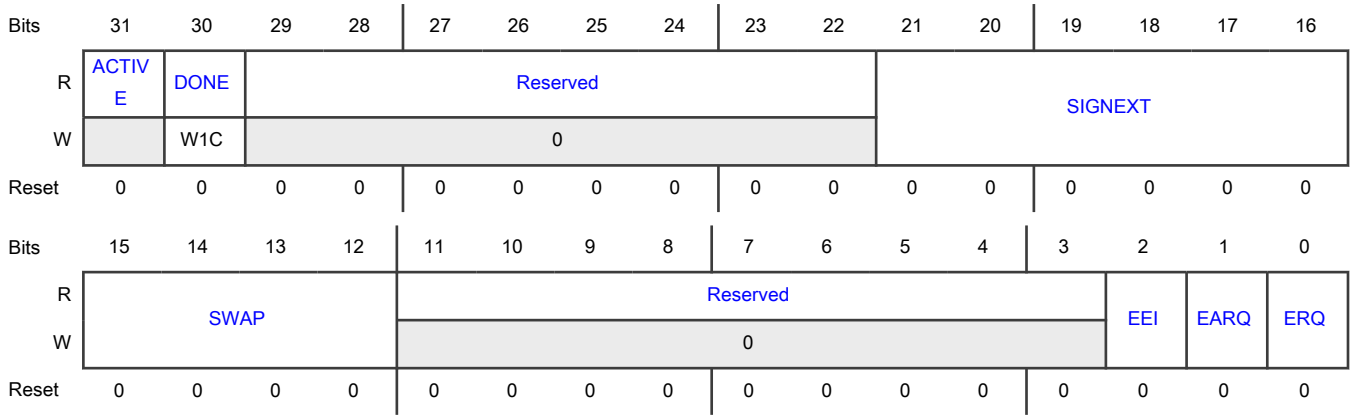
The enable asynchronous DMA request bit (EARQ) does not affect DMA operations. When set, this bit allows the hardware service request enable bit (ERQ) to propagate out of the DMA to the power controller. When cleared, this bit masks the hardware service request enable bit to the power controller.

The EEI register bit enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

The DONE register bit indicates the channel has completed the major loop. If enabled, the eDMA will generate an interrupt request corresponding to this completed channel.

The ACTIVE register bit indicates the channel was selected by arbitration and is executing the prescribed transfers. Except for dynamic channel linking, the Transfer Control Descriptor should not be modified while a channel is active .

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active This flag indicates the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.
30 DONE	Channel Done This flag indicates the eDMA has completed the major loop. The eDMA engine sets this bit as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated. **NOTE** This bit must be cleared to write a 1 to the MAJORELINK bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
29-22 —	Reserved
21-16 SIGNEXT	Sign Extension The data written on each transaction will be sign extended at the bit specified in this field. If 0, sign extension is disabled. 00_0000b - disabled 00_0001b - A non-zero value specifying the sign extend bit position
15-12 SWAP	Swap size Swap data elements within the specified transfer. Swap occurs with respect to the specified transfer size (SSIZE or DSIZE). 0000b - disabled 0001b - read with 8-bit swap 0010b - read with 16-bit swap 0011b - read with 32-bit swap 0100b-1000b - reserved 1001b - write with 8-bit swap 1010b - write with 16-bit swap 1011b - write with 32-bit swap 1100b-1111b - reserved
11-3 —	Reserved
2 EEI	Enable Error Interrupt 0b - The error signal for corresponding channel does not generate an error interrupt 1b - The assertion of the error signal for corresponding channel generates an error interrupt request
1 EARQ	Enable Asynchronous DMA Request 0b - Disable asynchronous DMA request for the channel. 1b - Enable asynchronous DMA request for the channel.
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ bit. 0b - The DMA hardware request signal for the corresponding channel is disabled. 1b - The DMA hardware request signal for the corresponding channel is enabled.

6.6.2.3 Channel Error Status Register (CH0_ES - CH63_ES)

Offset

For n = 0 to 63:

Register	Offset
CHn_ES	4h + (n × 8000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer-control descriptor,
- An error termination to a bus master read or write cycle

The ERR bit signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected. The contents of this ERR register bit can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI mask. The state of any given channel's error indicators is affected by writes to this register. On writes to the ERR bit, a one clears the channel's error status. A zero has no affect on the channel's current error status.

An unspecified error, where only the ERR bit is set, indicates a transfer was cancelled with an error . The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

6.6.2.4 Channel Interrupt Status Register (CH0_INT - CH63_INT)

Offset

For n = 0 to 63:

Register	Offset
CHn_INT	8h + (n × 8000h)

Function

The INT register bit signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion . The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no affect on the channel's current interrupt status.

Diagram

6.6.2.5 Channel System Bus Register (CH0_SBR - CH63_SBR)

Offset

For n = 0 to 63:

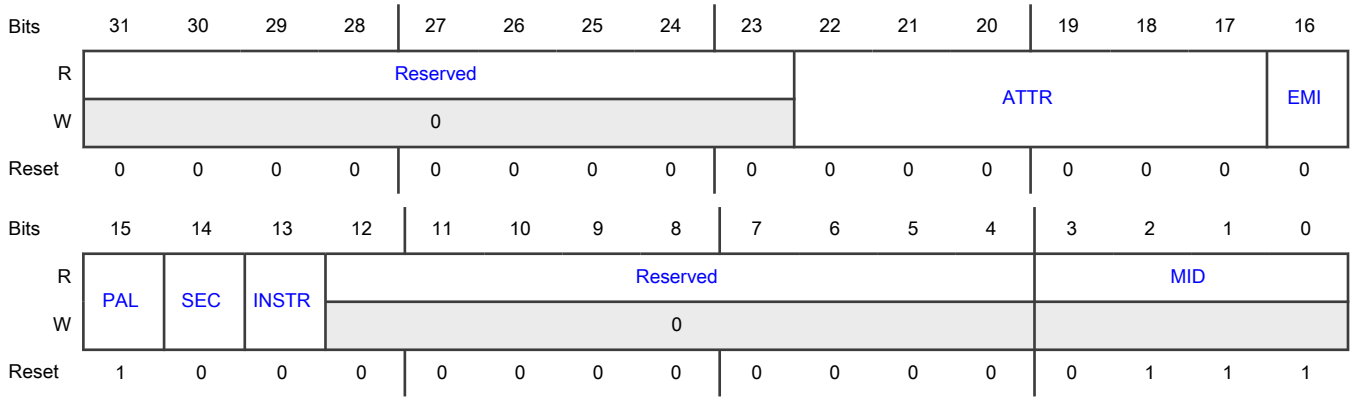
Register	Offset
CHn_SBR	Ch + (n × 8000h)

Function

The System Bus Register places identification and protection information on the system bus interface for the eDMA.

The ATTR register outputs the registers values onto the system bus interface for further decode by the security system.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-17 ATTR	Attribute Output DMA's system bus attribute output value.
16 EMI	Enable Master ID replication The eDMA master ID replication register allows the eDMA to use the same protection level and system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA uses the master ID and protection level stored in the SBR registers instead of the eDMA's default values. When a master, for example a core, programs a TCD, its master ID is captured when the TCD *n* _CSR control is written. The protection and security levels are captured when the CH *n* _SBR security attributes are written. A scatter/gather operation does not affect the CH *n* _SBR registers. The EMI bit may be written only if Management Page CSR[GMRC] = 1, Global Master ID Replication Control is enabled; otherwise, the EMI will be forced to zero.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If master ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Master ID replication is disabled 1b - Master ID replication is enabled
15 PAL	Privileged Access Level DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH *n* _SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH *n* _SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13 INSTR	Instruction/Data Access DMA's transactions type on the system bus when the channel is active. 0b - Data access for DMA transfers 1b - Instruction access for DMA transfers
12-4 —	Reserved
3-0 MID	Master ID DMA's master ID on the system bus when the channel is active. **NOTE** When master ID replication is enabled, the ID captured in this register reflects the master ID of the core or other master writing the channel's control attributes, lower byte of TCD *n* _CSR.

6.6.2.6 Channel Priority Register (CH0_PRI - CH63_PRI)

Offset

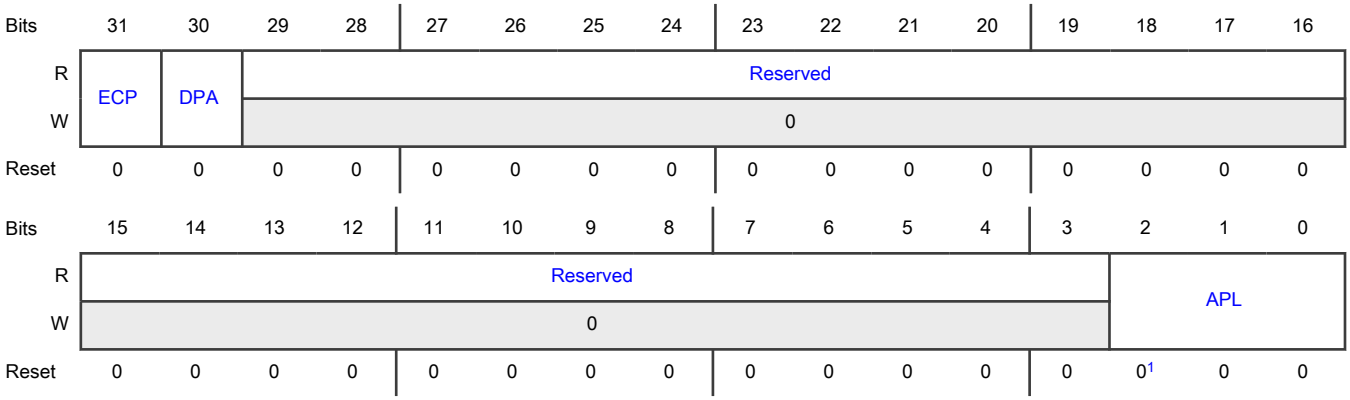
For n = 0 to 63:

Register	Offset
CHn_PRI	10h + (n × 8000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via the group priority registers MP_GRPRI. The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority. If more than one channel in a group has an Arbitration Priority Level value of zero, then the arbitration mode bit MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group. When round-robin channel arbitration is enabled (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme which will rotate among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group. When fixed-priority channel arbitration is enabled (MP_CSR[ERCA] = 0), channels with APL=0 will be selected based on channel number with the higher channel number having higher priority.

Diagram



1. See bit field description.

Fields

Field	Function
31 ECP	Enable Channel Preemption. 0b - The channel cannot be suspended by a higher priority channel's service request. 1b - The channel can be temporarily suspended by the service request of a higher priority channel.
30 DPA	Disable Preempt Ability.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - The channel can suspend a lower priority channel. 1b - The channel cannot suspend any other channel, regardless of channel priority.
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group

6.6.2.7 Channel Multiplexor Configuration (CH0_MUX - CH63_MUX)

Offset

For n = 0 to 63:

Register	Offset
CHn_MUX	14h + (n × 8000h)

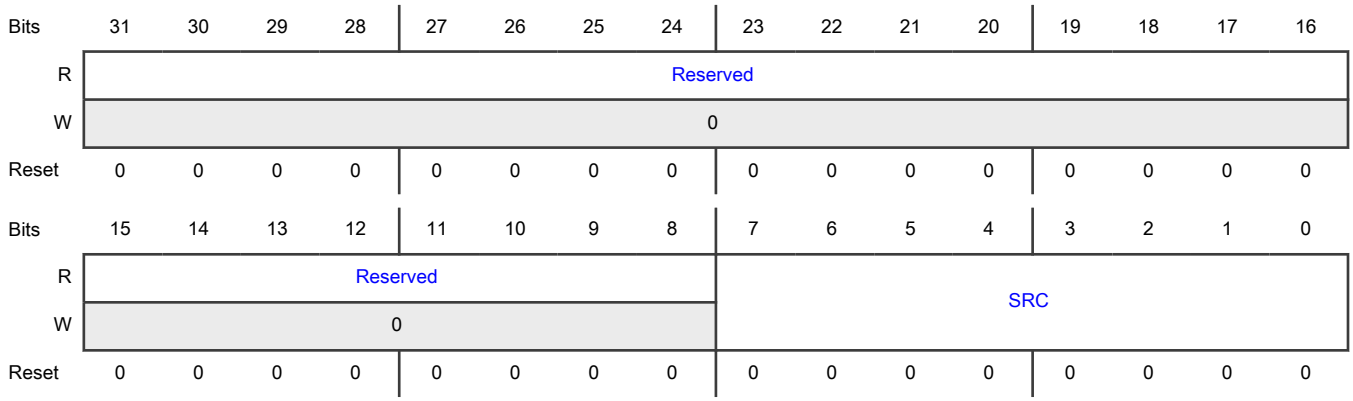
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by another channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

6.6.2.8 Memory Attributes Register (CH0_MATTR - CH63_MATTR)

Offset

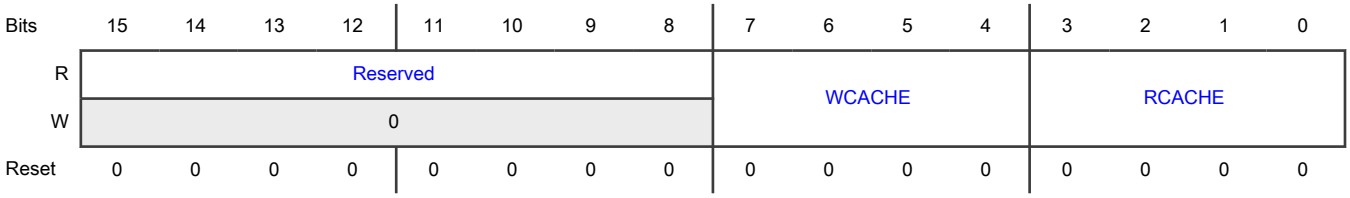
For n = 0 to 63:

Register	Offset
CHn_MATTR	18h + (n × 8000h)

Function

The Memory Attributes Register defines a set of transaction attributes for memory and peripherals. The cache attributes specify how a transaction progresses through the system and how they are handled.

Diagram



Fields

Field	Function
15-8 —	Reserved
7-4 WCACHE	Write Cache Attributes This field defines the attributes associated with a write transaction. • [7] 0b0 no write allocate, 0b1 write-allocate • [6] 0b0 no read allocate, 0b1 read-allocate

3-0 RCACHE	Read Cache Attributes This field defines the attributes associated with a read transaction. • [3] 0b0 no write allocate, 0b1 write-allocate • [2] 0b0 no read allocate, 0b1 read-allocate • [1] 0b0 non-cacheable, 0b1 cacheable • [0] 0b0 non-bufferable, 0b1 bufferable

6.6.2.9 TCD Source Address Register (TCD0_SADDR - TCD63_SADDR)

Offset

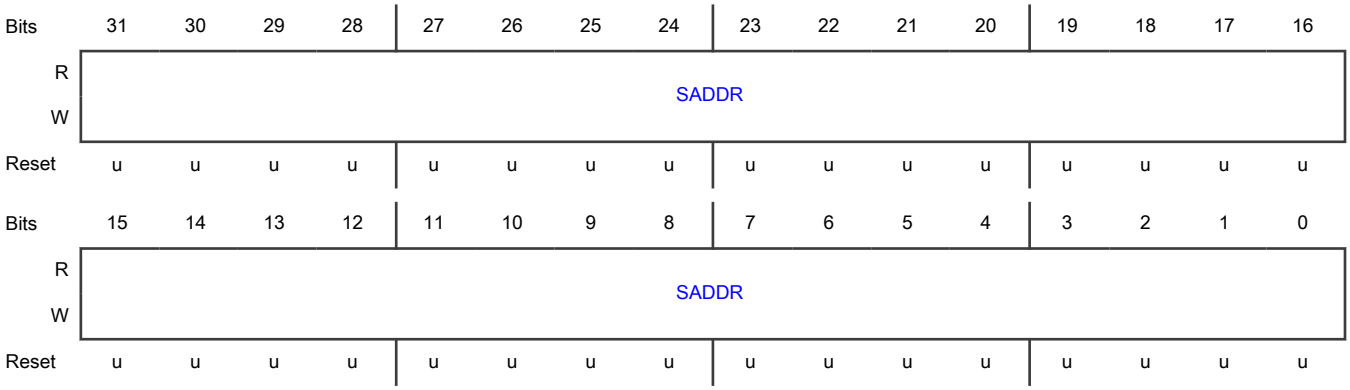
For n = 0 to 63:

Register	Offset
TCDn_SADDR	20h + (n × 8000h)

Function

This register contains the address for the read transactions.

Diagram



Fields

Field	Function
31-0 SADDR	Source Address Memory address pointing to the source data.

6.6.2.10 TCD Signed Source Address Offset Register (TCD0_SOFF - TCD63_SOFF)

Offset

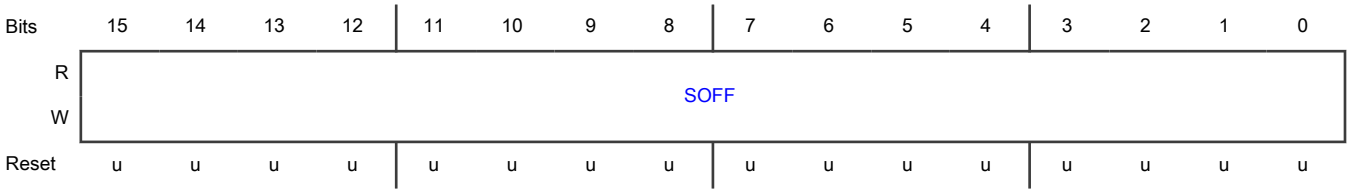
For n = 0 to 63:

Register	Offset
TCDn_SOFF	24h + (n × 8000h)

Function

This register contains the sign-extended value added to Source Address register after each read transaction.

Diagram



Fields

Field	Function
15-0 SOFF	Source address signed offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

6.6.2.11 TCD Transfer Attributes Register (TCD0_ATTR - TCD63_ATTR)

Offset

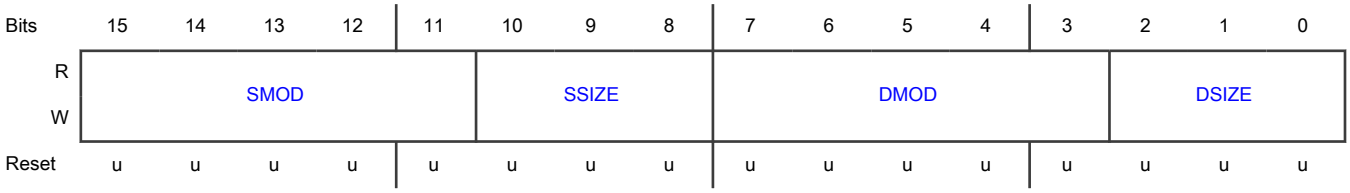
For n = 0 to 63:

Register	Offset
TCDn_ATTR	26h + (n × 8000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source address modulo This field defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature is disabled 0_0001b - Source address modulo feature is enabled for any non-zero value [1-31]
10-8 SSIZE	Source data transfer size This field specifies the size of each read transaction on the system bus. **NOTE** NBYTES must be an integer multiple of the source transfer size. 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - 64-byte 111b - 128-byte
7-3 DMOD	Destination address modulo See the SMOD definition
2-0 DSIZE	Destination data transfer size This field specifies the size of each write transaction on the system bus. **NOTE** NBYTES must be an integer multiple of the destination transfer size.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - 64-byte 111b - 128-byte

6.6.2.12 TCD Transfer Size without Minor Loop Offsets Register (TCD0_NBYTES_MLOFFNO - TCD63_NBYTES_MLOFFNO)

Offset

For n = 0 to 63:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 8000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDa word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCD word 2 is defined as follows if:

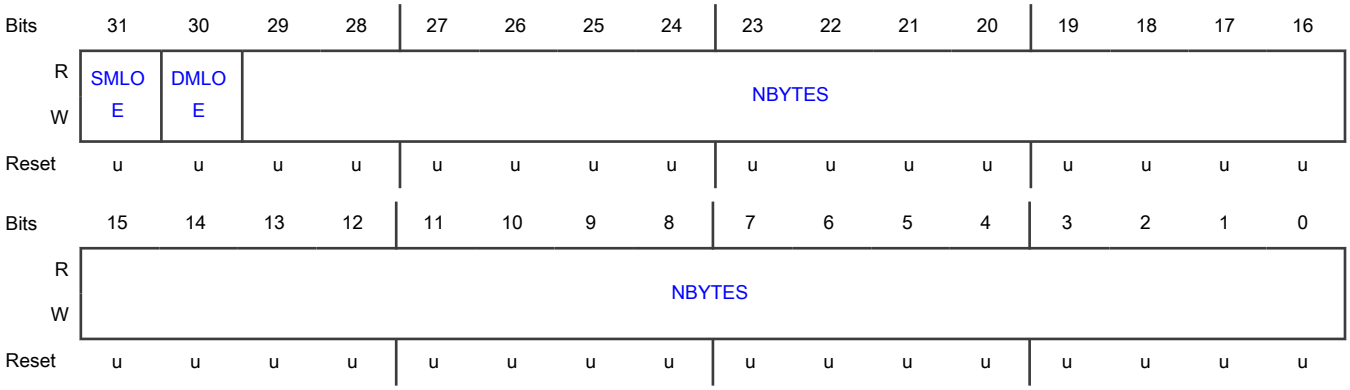
- SMLOE = 0 and DMLOE = 0

If either SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description.

NOTE

NBYTES must be an integer multiple of the source transfer size and an integer multiple of the destination transfer size.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - The minor loop offset is not applied to the SADDR 1b - The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - The minor loop offset is not applied to the DADDR 1b - The minor loop offset is applied to the DADDR
29-0 NBYTES	Number of Bytes to transfer per service request Number of bytes to be transferred for each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the byte transfer count has transferred. This is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is completed, additional processing is performed.

6.6.2.13 TCD Transfer Size with Minor Loop Offsets Register (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES)

Offset

For n = 0 to 63:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 8000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE). The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) should be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) should be applied to the destination address (TCDn_DADDR) upon minor loop completion. If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When the minor loop offset overlay is enabled (either SMLOE or DMLOE is 1), TCDn_NBYTES_* is redefined. A portion of TCDn_NBYTES_* is used to specify the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When enabled, the minor loop offset must be aligned to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_ is defined as follows if:

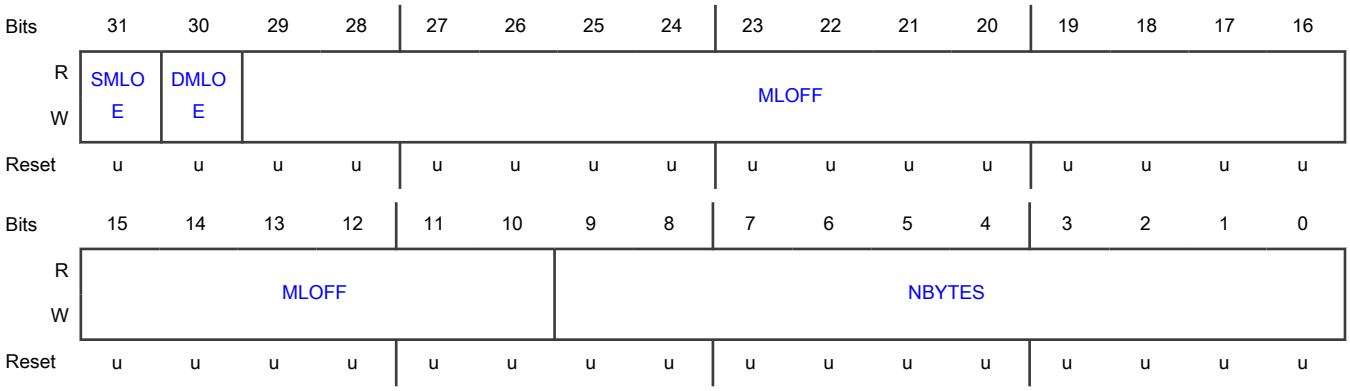
- Either minor loop offset is enabled (SMLOE or DMLOE = 1), then refer to the TCD_NBYTES_MLOFFYES register description.

If SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description.

NOTE

NBYTES must be an integer multiple of the source transfer size and an integer multiple of the destination transfer size.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - The minor loop offset is not applied to the SADDR 1b - The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - The minor loop offset is not applied to the DADDR 1b - The minor loop offset is applied to the DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes to transfer per service request Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

6.6.2.14 TCD Last Source Address Adjustment / Store DADDR Address Register (TCD0_SLAST_SDA - TCD63_SLAST_SDA)

Offset

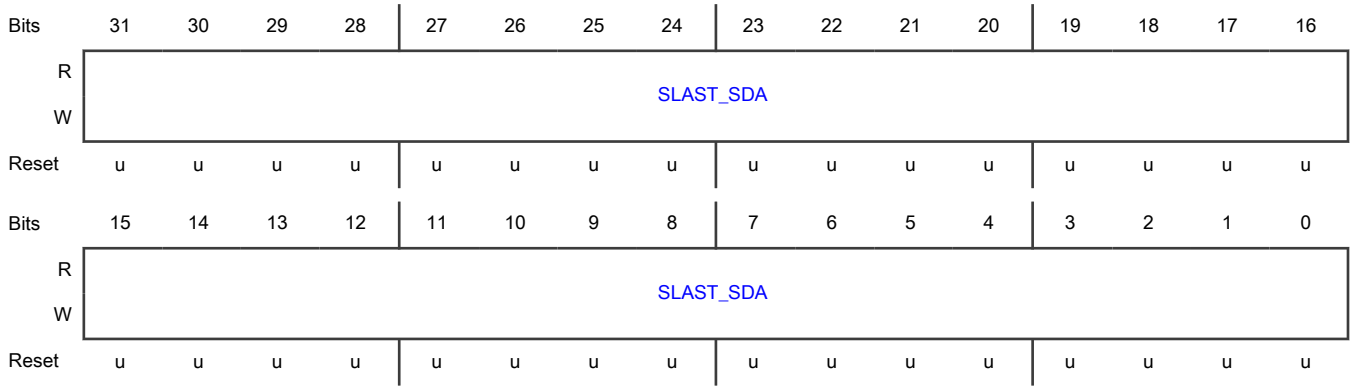
For n = 0 to 63:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 8000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

6.6.2.15 TCD Destination Address Register (TCD0_DADDR - TCD63_DADDR)

Offset

For n = 0 to 63:

Register	Offset
TCDn_DADDR	30h + (n × 8000h)

Function

This register contains the address for the write transactions.

Diagram

Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

6.6.2.16 TCD Signed Destination Address Offset Register (TCD0_DOFF - TCD63_DOFF)

Offset

For n = 0 to 63:

Register	Offset
TCDn_DOFF	34h + (n × 8000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DOFF															
W																
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed.

6.6.2.17 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) Register (TCD0_CITER_ELINKNO - TCD63_CITER_ELINKNO)

Offset

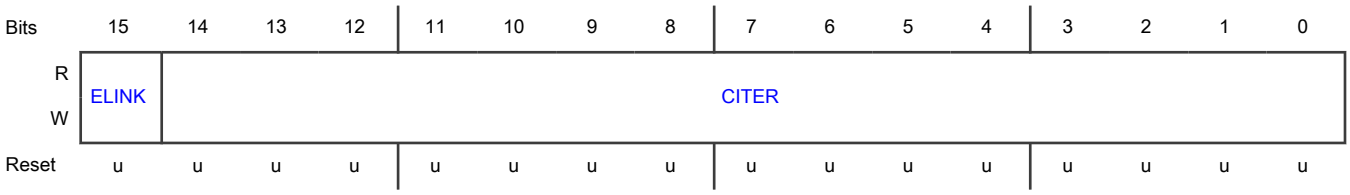
For n = 0 to 63:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 8000h)

Function

If TCDn_CITER[ELINK] is cleared, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0b - The channel-to-channel linking is disabled 1b - The channel-to-channel linking is enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field for the proper operation of the optional TCDn_CSR[INTHALF] interrupt. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

6.6.2.18 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) Register (TCD0_CITER_ELINKYES - TCD63_CITER_ELINKYES)

Offset

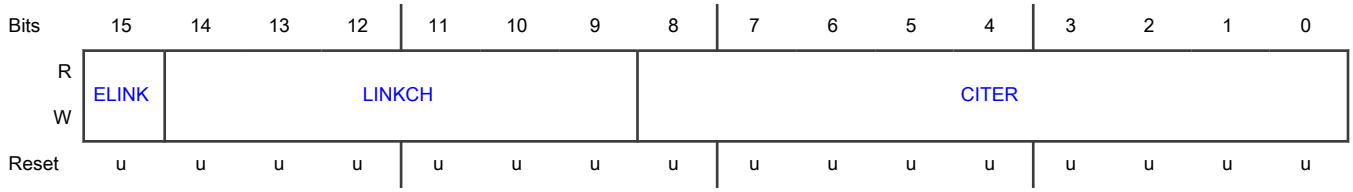
For n = 0 to 63:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 8000h)

Function

If TCDn_CITER[ELINK] is set, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] bit of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0b - The channel-to-channel linking is disabled 1b - The channel-to-channel linking is enabled
14-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field for the proper operation of the optional TCDn_CSR[INTHALF] interrupt. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

6.6.2.19 TCD Last Destination Address Adjustment / Scatter Gather Address Register (TCD0_DLAST_SGA - TCD63_DLAST_SGA)

Offset

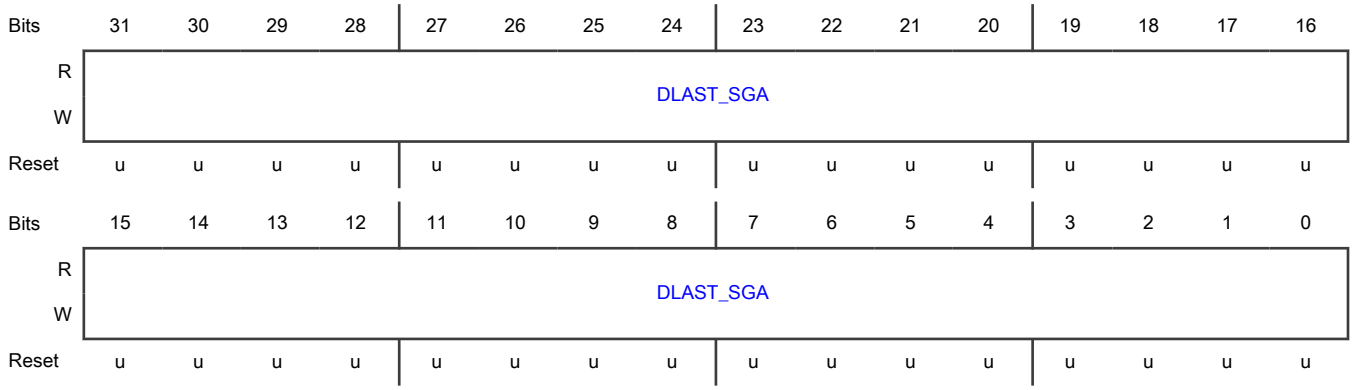
For n = 0 to 63:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 8000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Final Destination Address Adjustment / Scatter Gather Address Destination final address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (Scatter/Gather). If (TCDn_CSR[ESG] = 0), then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can be used to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported.

6.6.2.20 TCD Control and Status Register (TCD0_CSR - TCD63_CSR)

Offset

For n = 0 to 63:

Register	Offset
TCDn_CSR	3Ch + (n × 8000h)

Function

This register is used to enable optional features.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TMC		MAJORLINKCH						ESDA	EEOP	MAJO REL...	ESG	DREQ	INTHA LF	INTMA JOR	STAR T
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	0

Fields

Field	Function
15-14 TMC	Transfer Mode Control Transfer Mode Control specifies the direction the DMA will transfer data. For normal data movement operation, Read/Write mode reads from the source address and writes to the destination address. For Read Only mode, data is read from the source address and discarded. Read Only mode may be useful for calculating CRC values on a block of memory. For Write Only mode, the source address is read once and all subsequent writes to the destination uses the data from the first and only read. Write only mode may be used to initialize a block of memory to a specific value. 00b - Read/Write 01b - Read Only 10b - Write Only 11b - Reserved
13-8 MAJORLINKCH	Major loop link channel number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
7 ESDA	Enable store destination address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to zero or by receiving an enabled end-of-packet signal,, this bit enables writing the destination address (DADDR) to the address pointed to by the SLAST_SDA field. When the SDA bit is set, the SLAST_SDA contains the write pointer instead of the final source address offset. The value written to system memory pointed by SLAST_SDA is different for two cases: • For a normal successful transfer: the value is the last DADDR value prior to the DLAST_SGA offset being applied or overwritten by an enabled scatter/gather operation. **NOTE** Software can also compute this value using the TCD information. • For a transfer that was ended early by EOP: the value written to the memory is the last destination address that was written with the last good read data before EOP was issued. 0b - The store destination address to system memory operation is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - The store destination address to system memory operation is enabled.
6 EEOP	Enable end-of-packet processing When enabled by the EEOP bit, a end-of-packet hardware input signal directs the eDMA to discontinue executing the active channel and to treat the shutdown as major loop completed. If the EEOP bit is set, the end-of-packet signal from supported peripherals will be accepted. If the EEOP bit is cleared, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA saved destination address) minus the software-saved initial (DADDR) reflects the total amount of data transferred. For the aforementioned calculation, the destination offset (DOFF) must match the natural boundary of the destination transfer size DSIZE. For example, if DSIZE = 32-bit, DOFF = 4. 0b - The end-of-packet operation is disabled. 1b - The end-of-packet hardware input signal is enabled.
5 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. This field and the MAJORLINKCH must be written at the same time when attempting a dynamic channel link. 0b - The channel-to-channel linking is disabled. 1b - The channel-to-channel linking is enabled.
4 ESG	Enable Scatter/Gather processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **NOTE** Any changes made to this field while the channel is executing will not be recognized until the next time the channel is activated. 0b - The current channel's TCD is normal format. 1b - The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
3 DREQ	Disable request If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero. 0b - No operation. The channel's ERQ {H,L} bit is not affected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Clear the ERQ bit upon major loop completion, thus disabling hardware service requests. The channel's ERQ {H,L} bit is cleared when the major loop is complete.
2 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF. Use INTMAJOR instead. 0b - The half-point interrupt is disabled. 1b - The half-point interrupt is enabled.
1 INTMAJOR	Enable an interrupt when major iteration count completes. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count (CITER) reaches zero. 0b - The end-of-major loop interrupt is disabled. 1b - The end-of-major loop interrupt is enabled.
0 START	Channel Start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. 0b - The channel is not explicitly started. 1b - The channel is explicitly started via a software initiated service request.

6.6.2.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) Register (TCD0_BITER_ELINKNO - TCD63_BITER_ELINKNO)

Offset

For n = 0 to 63:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 8000h)

Function

If the TCDn_BITER[ELINK] bit is cleared, the TCDn_BITER register is defined as follows.

Diagram

Fields

Field	Function
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0b - The channel-to-channel linking is disabled 1b - The channel-to-channel linking is enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field should be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field for the proper operation of the optional TCDn_CSR[INTHALF] interrupt. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

6.6.2.22 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) Register (TCD0_BITER_ELINKYES - TCD63_BITER_ELINKYES)

Offset

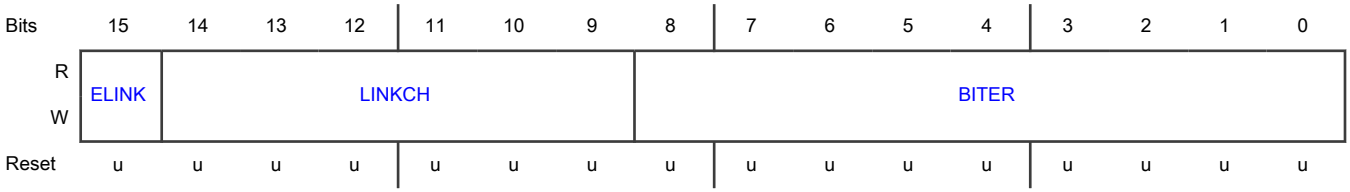
For n = 0 to 63:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 8000h)

Function

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0b - The channel-to-channel linking is disabled 1b - The channel-to-channel linking is enabled
14-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit. **NOTE** As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.
8-0 BITER	Starting major iteration count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field for the proper operation of the optional TCDn_CSR[INTHALF] interrupt. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

Chapter 7
Security Overview

7.1 Security features

Protecting customers' assets is at the core of the chip's security architecture. Valuable assets comprise intellectual property, confidential data, device integrity, service availability, as well as company's reputation. By controlling access to the device as well as providing trusted computing environment, the chip offers various security features and tools that allow customers to protect their assets. Some of the basic features include:

- **Secure boot** ensuring that only authentic entity is allowed to access the device or execute code on it.
- **Secure debug** allowing customers to securely develop and debug software while the device is at manufacturing or deployed in the field.
- **Secure life cycle management** guaranteeing that security mechanisms are enforced, and device reaches its highest security level after it has been deployed or returned to NXP for failure analysis.
- **Hardware Security Module (HSM)** and cryptographic services ensuring that cryptographic keys remain hidden from the application in all circumstances.

This chapter provides an overview of security-relevant SoC components, explaining the main purpose and features of each of them.

- **EdgeLock secure enclave (ELE)** acts as a Root of Trust for platform security. It manages the SoC life cycle, enforces secure boot, controls debug access, and provides full key management and key isolation from the rest of SoC.
- **Trusted Resource Domain Controller (TRDC)** is essential in enabling isolation between various processes running within the SoC. It is used to define and enforce separation between security critical and other processes by introducing the notion of domain IDs, as well as enforcing the trusted execution environment defined by ARM TrustZone.
- **On The Fly AES Decryption (OTFAD)** protects the confidentiality of code stored in external memory using AES in CTR mode. The key used for decryption is securely handled by ELE and delivered to OTFAD using a dedicated private bus, ensuring that the key is not observable by any application running on the SoC. Two instances of OTFAD are available, interfacing FlexSPI1 and FlexSPI2. OTFAD supports up to four independent memory contexts, each having a unique 128-bit decryption key.
- **Inline Encryption Engine (IEE)** uses AES-128 in CTR mode for decryption only and AES-128 XTS mode for encryption and decryption of code and data stored in external memory. Decryption only is supported through FlexSPI interface and is meant to be used for code stored in FLASH (similar to OTFAD), while the content stored in SDRAM can be both encrypted and decrypted using IEE in AES-128 XTS mode. IEE supports up to eight independent memory contexts, each having a unique 128-bit key.
- **Battery Backed Secure Memory (BBSM)** is used as a non-volatile storage of security parameters including general purpose registers, run-time counter with a wake-up alarm, monotonic counters, as well as tamper detection inputs.

Building on security-relevant SoC components a number of security features emerge which, altogether, serve to protect the valuable assets.

7.1.1 Edgelock Enclave (ELE)

The Edgelock Enclave (ELE) is asynchronous to the rest of the AON Domain, so that the ELE can be in complete control of its clock root, regardless of what clock is used for other IP in the AON Domain.

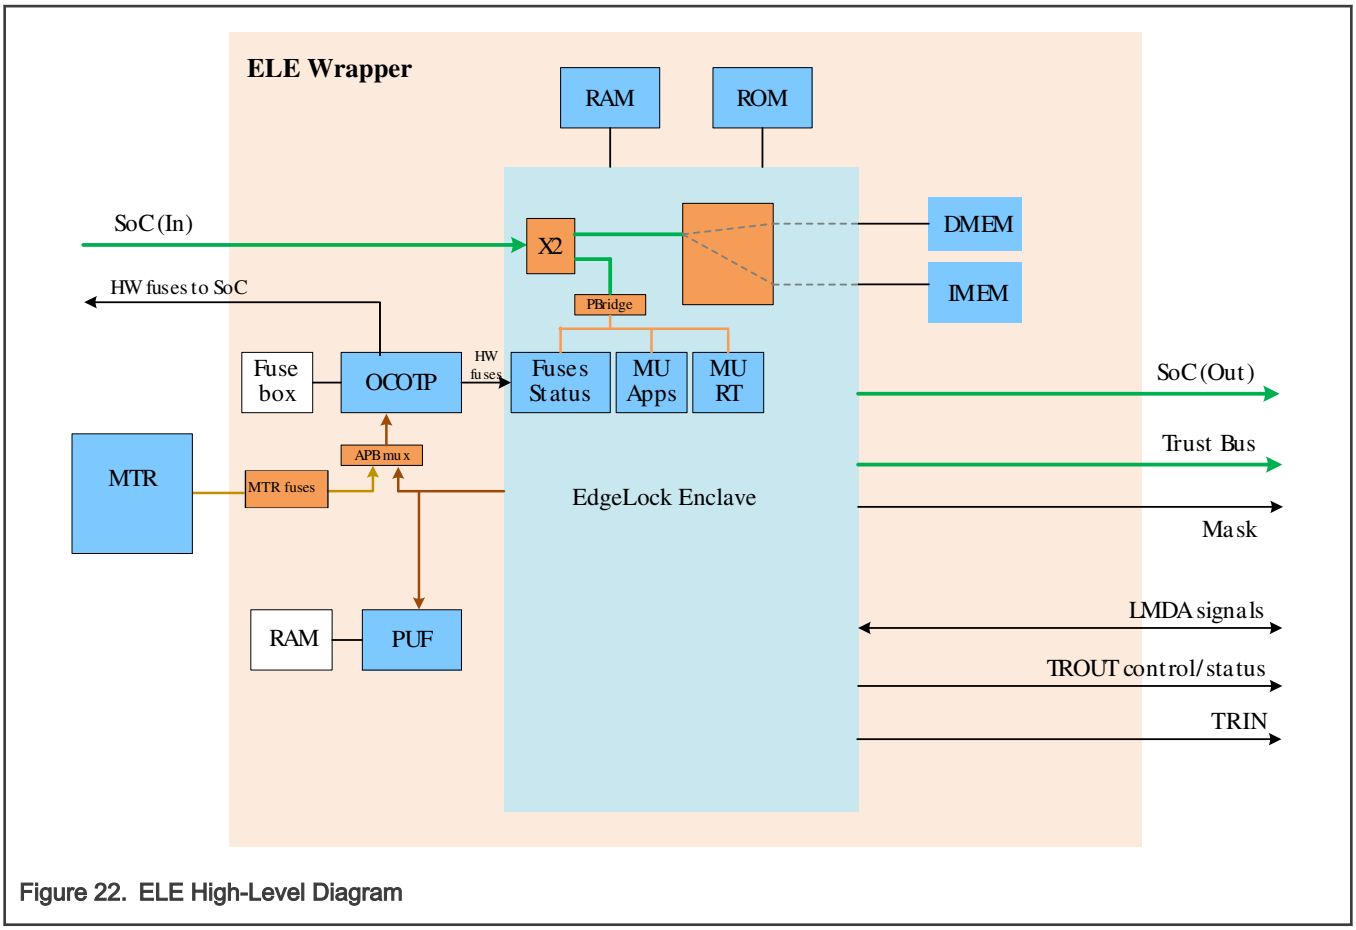


Figure 22. ELE High-Level Diagram

Name	Description
SoC Out	External Memory Accesses
SoC In	Communicate to MUs, and fast boot port to load FW
Trust Bus	Dedicated SoC security paths, security configurations and load keys
TRIN/TROUT	SoC security state machine interface
LMDA	System control
HW Fuses	Hardware only fuses
MTR	Memory Test Repair

ELE has a 32-bit bus with access to the SoC. The ELE has multiple MU instances, and private buses (Trust Bus and TROUT) to connect to security components outside ELE, such as BBSM and FlexSPI's OTFAD.

ELE has its own internal WDOG timer to ensure operation and frequency detect logic to ensure that the CM33 clock root frequency is no faster than the ELE clock root frequency.

NOTE

The ELE is not customer programmable. To use the ELE provided services, the ELE and SoC domains requesting (requestor) ELE services communicate using one of the available Messaging Units (S3MU). Refer to the EdgeLock Enclave (ELE) API Reference Guide for the complete list of available ELE services and details on the messaging protocol. For details on the S3MU, refer to the S3MU chapter in this manual.

7.1.1.1 ELE active timer

Every day (24 hours), a SoC application needs to kick the ELE Active Timer by exercising the PING request. If the SoC application does not handle this, ELE will reset the chip.

See the *EdgeLock Secure Enclave (ELE) ROM API Guide* for more information on the PING command.

7.1.2 On-Chip OTP Controller (OCOTP_CTRL)

The OCOTP_CTRL block is within the Edgelock subsystem and is used to control the OTP fuses. Access to fuses by the rest of the SoC is handled through Edgelock.

OCOTP supports:

- Load fuse into shadow registers
  - Hardware load: fuse will load into shadow registers automatically after power-on reset (POR)
  - Software load: fuse will reload into shadow registers after SW register configuration
- Register interface to allow SW to read, override or program the fuse.
- Flexible permission control to the fuse, including read-protect, override-protect, program-protect, lock, etc.
- Programming sequence to allow single bit to be programmed individually, and also allow the non-programmed bit to be programmed later.

7.1.3 Battery Backed Secure / Non-Secure Module (BBSM/BBNSM)

The BBSM and BBNSM is in the low power section VDD_BBSM_IN domain, which can be battery backed. This enables it to keep this data valid and continue to increment the time counter when the power goes down in the rest of the device. The always-powered up part of the module is isolated from the rest of the logic to ensure that it does not get corrupted when the device is powered down.

The BBSM and BBNSM are designed to comply with Digital Rights Management (DRM) and other security application rules and requirements. The BBSM incorporates a security monitor that checks for various security conditions. If a security violation is detected, it zeroizes the secret data and issues an interrupt request. The BBSM can also be configured to ignore specific violation inputs, so it can be used by systems that do not require security.

7.1.3.1 Monotonic Counter

- The counter can only increment.
- The counter does not roll over.
- The counter value is invalidated if there is loss of power to the VDD_BBSM_IN domain.
- The counter maintains state as long as the VDD_BBSM_IN is powered, even when SoC power is off.

7.1.3.2 Secure Real Time Clock

- Can be driven by an independent clock source (other than the clock that the SoC uses).
- Clock counter does not roll over. The RTC Alarm Register in BBSM represents the number of seconds, and in theory supports time alarm as high as ~140 years.
- Has a programmable timed interrupt. The RTC Alarm (from BBSM/BBNSM) are mapped as interrupt to NVIC and (where present) GIC. As per other interrupts in the i.MX RT1180, the RTC alarm is also a wake-up source from any low power modes.
- The Secure Real Time Clock continues counting when SoC power is off.

7.1.3.3 Tamper Detection

The chip supports up to 10 tamper pins: 5 of which are configurable to be either input or output, and 5 of which are statically input-only. It is SoC-specific how many tamper pins are connected in a given SoC.

7.1.4 TrustZone

TrustZone-M (TZ-M) is a feature on the Cortex M33, which provides segmentation of memory arrays and peripherals into either Secure (S) or Non-Secure (NS). This feature allows the M33 core to execute in either S or NS mode, and provides a secure separation between various application software.

The TrustZone® security architecture is supported. TrustZone-M is always enabled, as this is an integral feature of the Cortex-M33 BootROM and system security. For on-chip RAM, all of OCRAM/OCRAM_S have TrustZone® access control support. One region with configurable address range of the OCRAM/OCRAM_S can be set to TZ access only. The TrustZone memory region protection of DRAM is supported through TRDC.

The majority of system initiators in the SoC do not natively support TrustZone (and more specifically, do not support a concept of AxPROT[0] indicating controllable privileged vs normal access or AxPROT[1] indicating non-secure vs TrustZone secure access). Therefore, the TRDC DAC provides controls to override IP initiator's AxPROT[1:0] inputs to the subsystem NICs. However, initiators which do have concept of these AxPROT[1:0] signals, do not have their signals overridden by the TRDC DAC.

7.1.5 Trusted Resource Domain Control (TRDC)

The chip uses a domain based resource control architecture for the memory/peripheral resource sharing and isolation between the Cortex®-M7 core, Cortex®-M33 core, and other bus masters. A key feature of this architecture is that it must be possible for either Cortex-M7 platform or the Cortex-M33 platform to program the resource domain control access lists to implement a customer-defined policy. Another key feature is that any peripheral can be assigned to any domain. The TRDC supports multiple regions with flexible access permission control for each memory space.

7.1.6 Inline Encryption Engine (IEE)

The IEE provides for encryption and decryption in different contexts including multiple key sizes, encryption modes and algorithms. It can be used for code or data, volatile or non-volatile storage. It supports multiple regions where each region may have its own context. The context for each region is configured in the IEE and then each region is associated to a context in an upstream Memory Region Checker (MRC) on each master bus.

It provides the following features:

- SDRAM encryption/decryption
- FlexSPI decryption only
- Secure scan
- Secure on-chip key loading
- I/O direct encrypted storage and retrieval (Stream Support)

7.1.7 On-the-Fly AES Decryption (OTFAD)

The OTFAD provides decryption on the fly through the FLEXSPI interface, to decrypt the code and data fetched from the external flash memory.

It provides the following features:

- AES-128 Counter Mode On-the-Fly Decryption
  - 128-bit key and 128-bit data sizes
  - Receives 64-bit encrypted data from FlexSPI
- Hardware support for unwrapping key blobs
- Hardware support for 4 independent decryption segments, known as memory contexts

7.1.8 Block Control Secure (BLK_CTRL_S_AON)

The chip includes a block called BLK_CTRL_S_AON which contains assorted configuration controls that can potentially have security implications. The BLK_CTRL_S_AON registers are reset only by POR (when Edgelock is reset). These registers can only be accessed by TrustZone Secure World.

BLK_CTRL_S_AON has the following functions:

- AXBS_AON priority and arbitration controls.
- Cortex-M NVIC Interrupt Masking.
- WDOG Timer output masking for combined watchdog timer SoC output pin.

Chapter 8
System Debug

8.1 Overview

The chip debug architecture is based on Arm CoreSight technology, with support for the Cortex-M7, Cortex-M33, and Edgelock cores.

8.1.1 Block Diagram

The block diagram for the system level debug architecture is provided below.

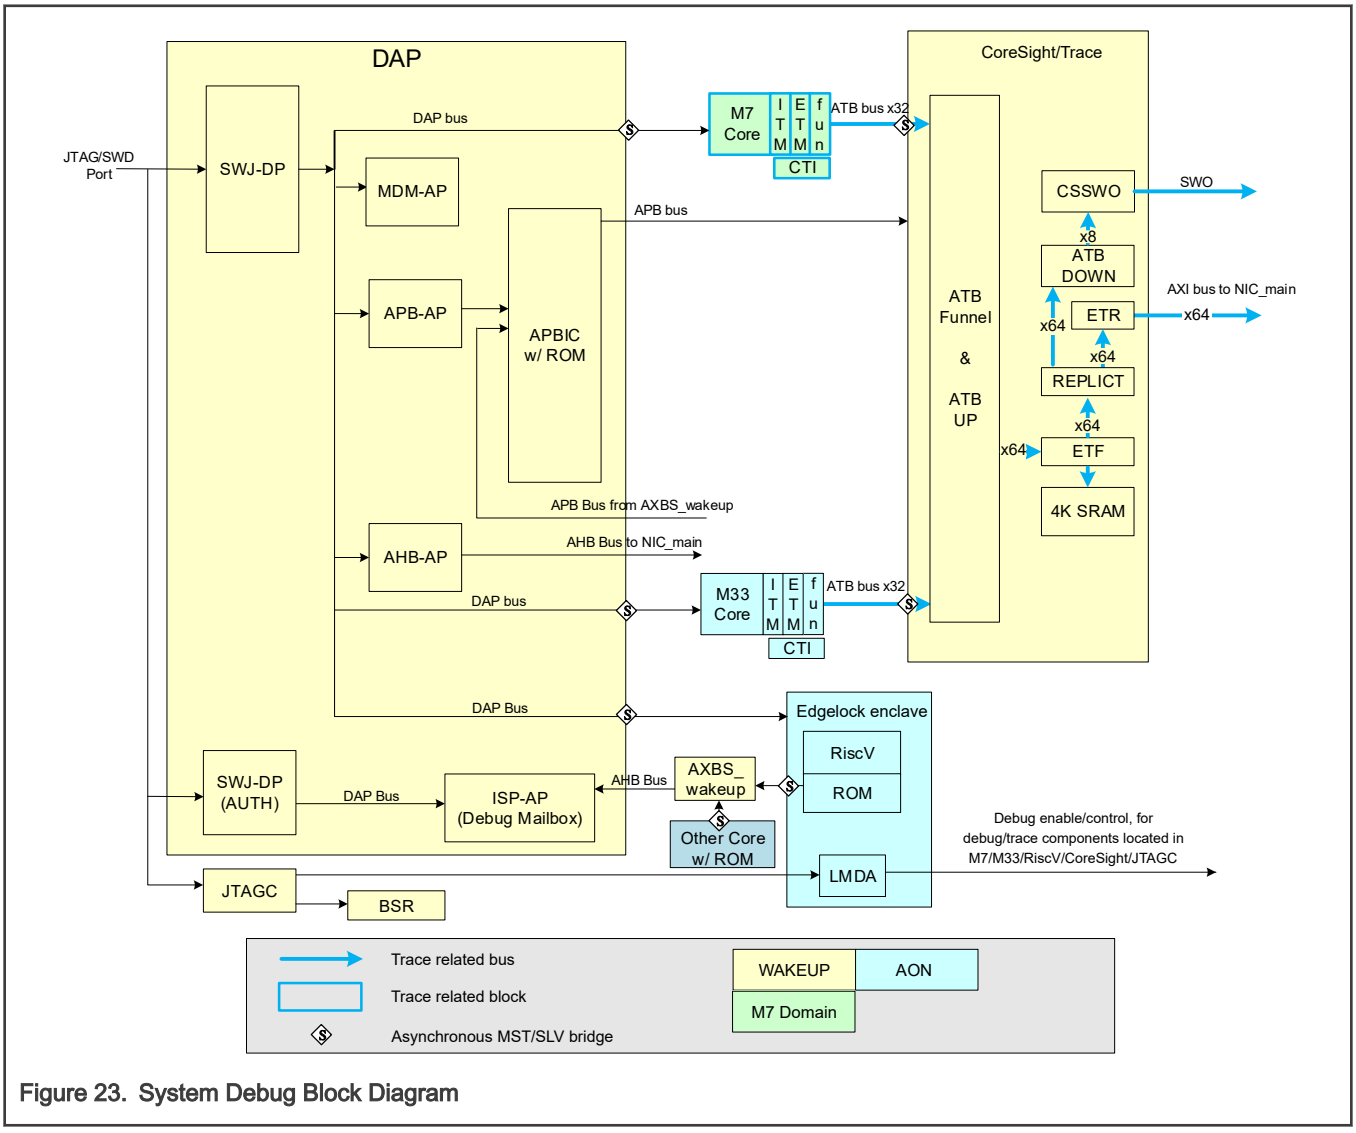

Figure 23. System Debug Block Diagram

The debug/trace components are listed below:

- Debug Access Port (DAP) - Has Serial Wire port (SWJ-DP) which interprets the data coming in and routes to appropriate Access Port (AP).
- Serial Wire port (SWJ-DP) - Consists of a wrapper around the JTAG-DP and SW-DP. It selects JTAG or SWD as the connection mechanism and enables either JTAG-DP or SW-DP as the interface to the various on chip debug/trace components. It is enabled only after debug is authenticated.

- SWJ-DP (AUTH) is another SWJ-DP instance dedicated for ISP-AP. It is enabled only when debug authentication is required, means it will be disabled if debug is authenticated.
- JTAGC
  - JTAGC and DAP/SWJ-DP share the same JTAG interface from PAD.
  - Achieve boundary scan testing, with an external BSR connected.
  - Supports Challenge-response authentication, with LMDA in Edgelock.
  - Supports IEEE 1149.6/AC JTAG.
- Debug Access port for Cortex-M7 platform.
- Debug Access port for CoreSight.
- Cortex-M33 DAP-AP - Debug Access port for M33 core.
- RISC-V DAP-AP - Debug Access port for RISC-V core in Edgelock.
- ISP-AP - Debug Access port for Debug Mailbox, to allow the debugger to communicate with onboard ROM code.
- MDM-AP registers for debugger to control multi-core halt/resume cores.
- CoreSight components.
- Cross-Trigger Interface (CTI) and Cross-Trigger Matrix (CTM).

8.1.2 Features

The key features of the debug system include:

- Supports 1149.1/ARM SWD interface. Supports both 5-pins (JTAG) and 2-pins (SWD) interfaces, to make efficient use of package pins, serial wire shares the JTAG pins use an auto-detect mechanism.

NOTE

1149.7 Compact JTAG is NOT supported.

- Supports both non-intrusive and halt-mode trace/debug options
- Supports trace for various cores, including a trace Memory Controller (TMC) to enable capturing trace
  - 4KB ETF in SOC trace block
  - ETR (4G memory range, 64-bit wide) to allow routing trace data to system memory
  - CoreSight Serial Wire Output
- Supports cross trigger between the Cortex-M7 and Cortex-M33
- MDM-AP registers for debugger to control multi-core halt/resume cores
- Supports narrow timestamp for trace components
- Supports ISP-AP (Debug Mailbox), allowing the debugger to communicate with onboard ROM code, providing debug authentication based on messages
- Supports challenge-response authentication

NOTE

Arm ELA-500 and CoreSight SoC-600 are not supported.

8.2 Functional description

8.2.1 Debug Access Port (DAP) TAP

DAP is a standard Arm component, comprising of several components. These components are used to access the DAP from an external debugger and Access Ports to access on-chip debug system resources. The DAP supports 1149.1/Arm SW-DP interface, which means that the JTAG interface can be operate in standard 5-pin JTAG-DP interface or in 2-pin SW-DP interface. The following figure shows the connectivity between the DAP and the pads.

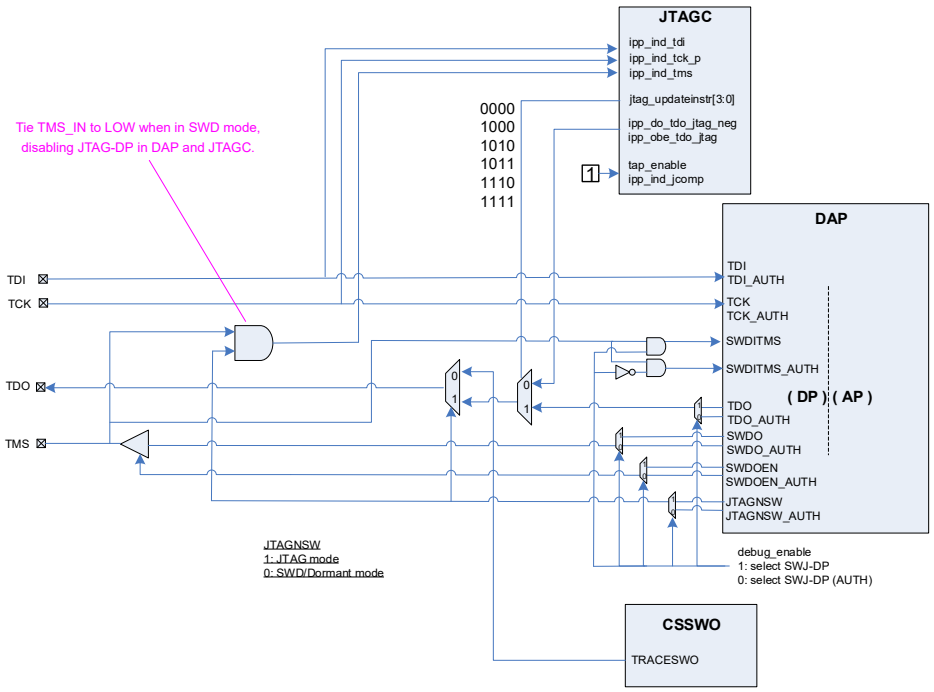

Figure 24. JTAG Pad Connectivity

For PAD descriptions, see External Signals.

8.2.2 JTAGC and JTAG mux

The JTAGC and SWJ-DP/SWJ-DP (AUTH) share the same 5-pin JTAG interface from PAD. SWJ-DP and SWJ-DP (AUTH) will not be enabled at the same time, controlled by the authentication status from LMDA.If debug is authenticated, select SWJ-DP, otherwise select SWJ-DP (AUTH).

SW-DP pins (TCK,TMS) are connected directly from and to SoC pins.

- When SW-DP is enabled, both JTAGC and JTAG-DP will be disabled.
- When SW-DP is disabled, the output to TDO from JTAGC and JTAG-DP will be selected by a mux and that mux is controlled by decode of the IR inside the JTAGC (JTAGC output port jtag_updateinstr[4:0]), and then connected to SoC pins for debug and/or test purposes.

Selection is based on the following table of decodes.

Table 33. Instruction Register

Instruction	Value	Module
EXTEST (Arm)	4'b0000	Arm JTAG-DP
IDCODE (JTAGC)	4'b0001	JTAGC
SAMPLE/PRELOAD	4'b0010	JTAGC

Table continues on the next page...

Table 33. Instruction Register (continued)

Instruction	Value	Module
SAMPLE	4'b0011	JTAGC
EXTEST (JTAGC)	4'b0100	JTAGC
TEST_LEAKAGE	4'b0101	JTAGC
ENABLE_TEST_CTRL	4'b0110	JTAGC
ABORT (Arm)	4'b1000	Arm JTAG-DP
HIGHZ	4'b1001	JTAGC
DPACC (Arm)	4'b1010	Arm JTAG-DP
APACC (Arm)	4'b1011	Arm JTAG-DP
CLAMP	4'b1100	JTAGC
IDCODE (Arm)	4'b1110	Arm JTAG-DP
BYPASS (Arm)	4'b1111	Arm JTAG-DP

Partial of TARGETID[31:0] input for SWJ-DP should also be connected to JTAGC, for coherence, as below:

Table 34. JTAG TARGETID

JTAGC	SWJ-DP	description
jtagc_pin_plug[9:0]	TARGETID[21:12]	Part Identification Number
jtagc_prn_plug[3:0]	TARGETID[31:28]	Part Revision Number
jtagc_jcomp_plug[0:J-1]	1'b1 (J=1)	JTAG JCOMP value

8.2.3 AP Select Decoding

The recommendation for AP selects decoding is provided in the following table.

NOTE

SWJ-DP (AUTH) has only one DAP slot (the first DAP slot) targeting ISP-AP, so it has no DAPBUSIC decoding logic.

The DAP BUS interconnect (DAPBUSIC) in the table below is only for SWJ-DP rather than SWJ-DP (AUTH).

Table 35. Address Decoding for DAPBUSIC

Destination	DAPBUSIC_AP_SEL[31:24]
AHB-AP to System Bus	8'h00 (M0)
APB-AP0 to CoreSight System	8'h01 (M1) See Address decoding for APBIC
DAP-AP to M7	8'h02 (M2)
DAP-AP to M33	8'h03 (M3)
DAP-AP to Edgelock enclave RISC-V core	8'h04 (M4)

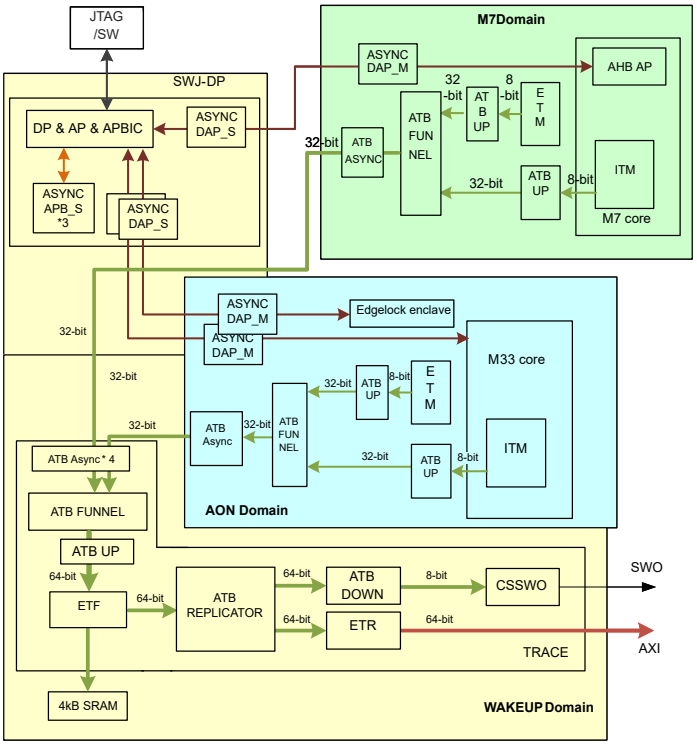
8.2.4 Trace

The debug and trace implementation for the Cortex-M7 and Cortex-M33 is shown in the following figure.



Note: APB/DAP/ATB ASYNC means couples of MST/SLV bridges located in corresponding domains.

Figure 25. Trace Diagram

- Trace sources include ETM in Cortex-M7 and ITM/ETM in Cortex-M33.
- One Embedded Trace FIFO (ETF, can operate as ETB, programmable), 4KB size as 128x256 (width x depth) with single port of SRAM.
- ATB funnel can capture trace data from Cortex-M7, Cortex-M33 ETM and Cortex-M33 ITM.
- ETR - Routing trace to system enabling to reuse SoC resources. (4G memory range, 64-bit wide).

NOTE

SRC_SCR_BT_RELEASE_M7 bit should be set for dual core parts when CM33 trace activity is proceeded.

8.2.5 Embedded Cross Trigger (ECT)

The ECT for CoreSight consists of a few CTIs and CTM. The diagram below shows the structure of the ECT. The ECT enables subsystems to interact, that is cross trigger with each other. It is used for multiple core run control and trace cross trigger.

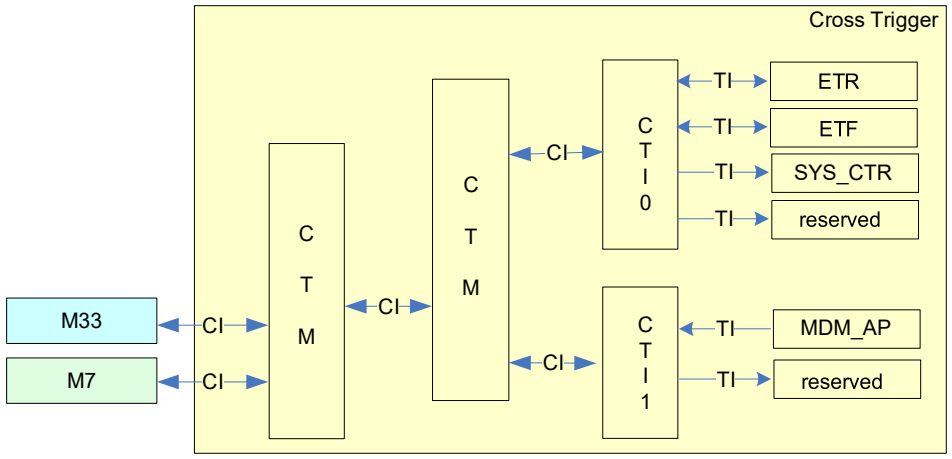


Figure 26. Embedded Cross Trigger Diagram

8.2.6 Timestamp Generation

There is no Arm CoreSight Timestamp Generator in the system, and instead the System Counter is the source of the time used by all of the following components:

- System Counter internal counters and comparators.
- Cortex-M7 timestamp value (for trace).
- Cortex-M33 timestamp value (for trace).
- TSTMR1 and TSTMR2 read-only timestamp snapshot registers.

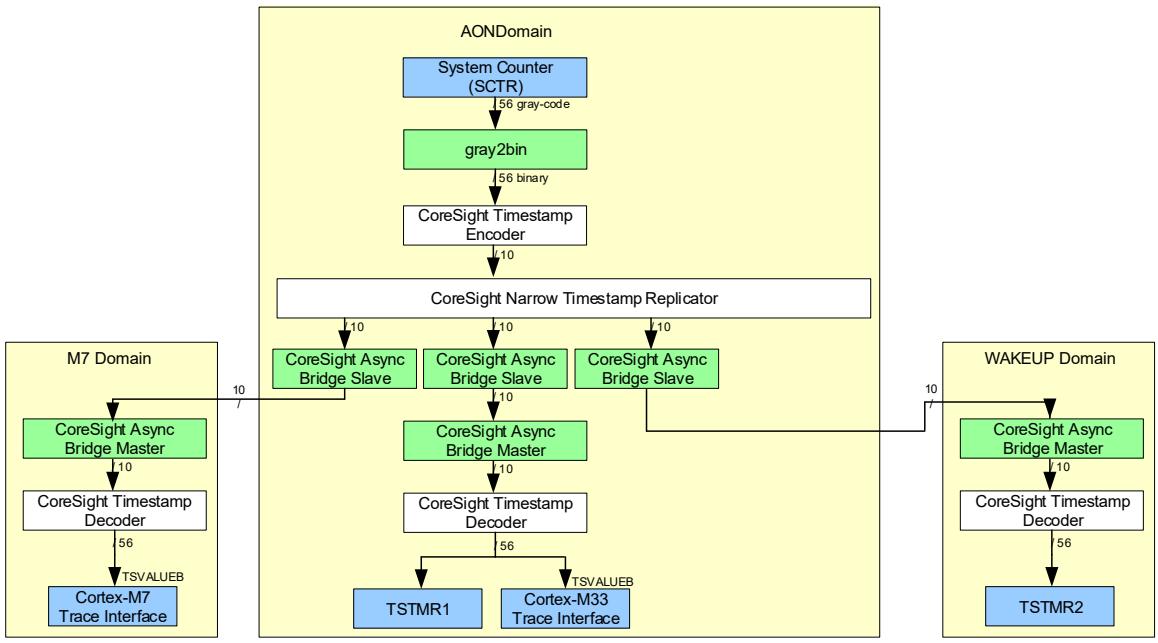

Figure 27. Timestamp Distribution

8.2.7 JTAG IDCODE

The JTAG_IDCODE (JTAG ID) is a 32-bit identifier that identifies the chip silicon for the purpose of both debug and boundary scan access.

Table 37. JTAG_IDCODE

Device	JTAG_IDCODE
i.MX RT1180	0x1892_001D

8.3 External Signals

The JTAG signals are outlined in the following table.

Table 38. External signals

Name	I/O	JTAG	SWD	Pullup (PU) / Pulldown (PD)
TMS/SWDIO	I/IO	Mode selection	Data In/Out	PU
TCLK/SWCLK	I	Clock	Clock	PD
TDI	I	Data input	-	PU
TDO	O	Data output	-	NC

This device has one instance of the JTAGC module.

The initialization sequence is needed before running the boundary scan test. Please send the JTAG instruction "ENABLE_TEST_CTRL" and then configure the corresponding JTAG data register 5'b00001. Please make sure no JTAG reset is triggered after the initialization sequence.

9.2 JTAC instructions

See Table 33 of the System Debug chapter for the instruction set for this device.

9.3 Overview

JTAGC allows you to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from JTAGC is communicated in serial format.

9.3.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information within this chapter as well as Register description for more information about the JTAGC registers.

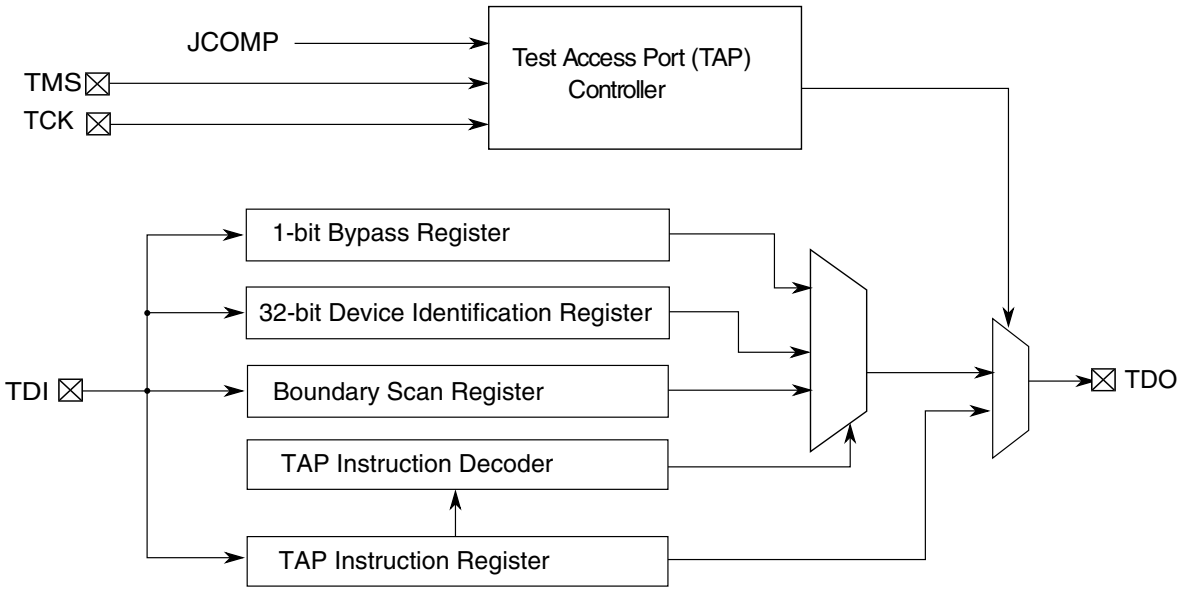

Figure 28. JTAG (IEEE 1149.1) block diagram

9.3.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 TAP interface
  - Four pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see JTAGC block instructions for a list of supported instructions).
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

9.4 Functional description

9.4.1 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

9.4.1.1 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS

- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

9.4.1.2 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

9.4.2 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

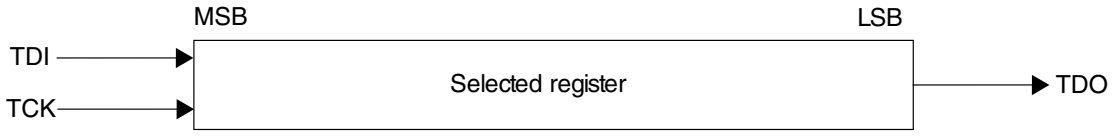

Figure 29. Shifting data through a register

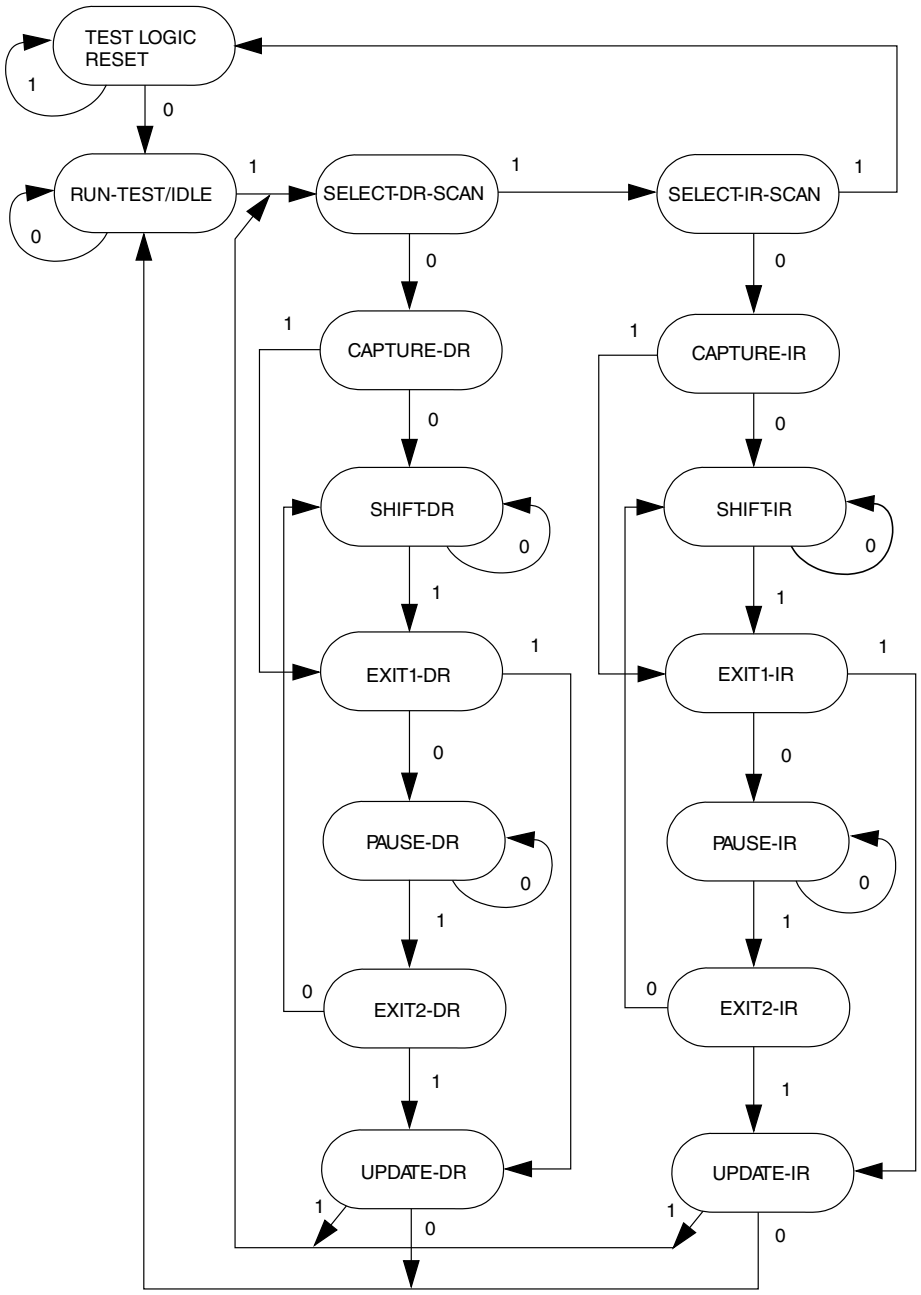
9.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 30. IEEE 1149.1-2001 TAP controller finite state machine

9.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

9.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

9.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions. See the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

NOTE

See the chip specific information JTAGC block instructions for applicable to your device.

9.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

9.4.4.2 PRELOAD instruction

The PRELOAD instruction has two functions:

- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

9.4.4.3 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

9.4.4.4 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

9.4.4.5 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

9.4.4.6 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the system logic operates normally.

9.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

9.4.6 Clocking

There is one clock for this module. For more information See External signals.

9.4.7 Interrupts

This module has no interrupts.

9.4.8 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- JCOMP is negated
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

9.4.8.1 JTAGC reset configuration

When in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

9.5 External signals

JTAGC includes a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 40. JTAG signal properties

Name	I/O	Function	Reset state
TCK	Input	Test clock	Weak pulldown
TDI	Input	Test data in	Weak pullup
TDO	Output	Test data out	High Z[1]
TMS	Input	Test mode select	Weak pullup
JCOMP	Input	JTAG compliance	Weak pulldown

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

9.5.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

9.5.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

9.5.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

9.5.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

9.5.5 JCOMP JTAG compliance

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding—otherwise the JTAGC TAP controller remains in reset.

9.6 Initialization

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller.
2. Load the appropriate instruction for the test or action to be performed.

9.7 Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

9.8 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

9.8.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the

Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

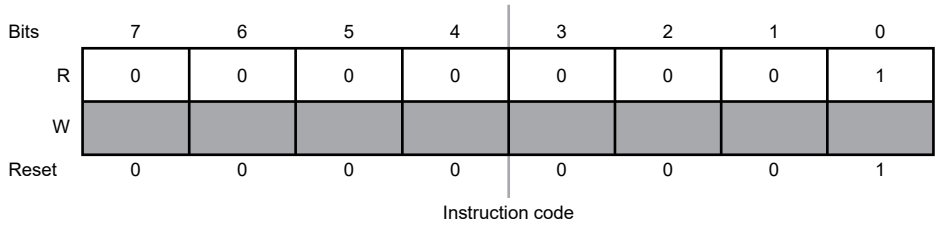


Figure 31. Instruction register

9.8.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

9.8.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

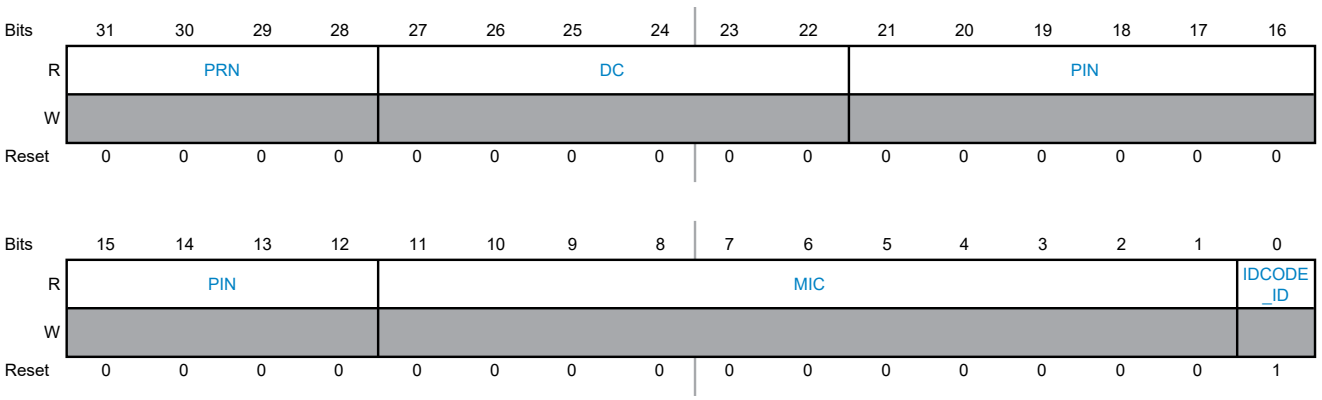

Figure 32. Device identification register

The following table describes the device identification register functions. The device identification register values are described in the chip-specific JTAGC information.

Table 41. Device identification register field descriptions

Field	Function
PRN	Part revision number Contains the revision number of the part.
DC	Design center Indicates the design center.
PIN	Part identification number Contains the part number of the device.
MIC	Manufacturer identity code Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID .
IDCODE ID	IDCODE register ID Identifies this register as the device identification register and not the bypass register. Always set to 1.

9.8.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

Chapter 10
System Counter (SYS_CTR)

10.1 Chip-specific SYS_CTR Information

Table 42. Reference links to related information

Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

10.2 Overview

SYS_CTR is a programmable system counter that provides you with a shared time base to multiple processors. It is intended for applications in which the counter is always powered on and supports multiple unrelated clocks.

10.2.1 Block diagram

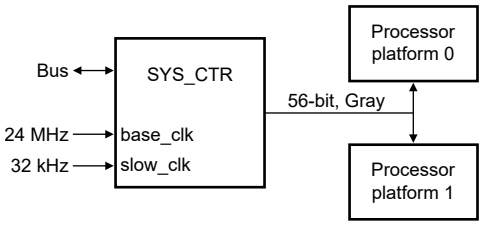

Figure 33. Block diagram

10.2.2 Features

- Two counter clock frequencies:
  - Base clock for normal operation
  - Alternate slow clock for low-power operation

- 56-bit counter width
- Gray-coded counter output for distribution to the processor timers
- Two compare frames, with each frame:
  - Containing a 64-bit compare value
  - Supporting a programmable interrupt generation

10.3 Functional description

SYS_CTR inputs two counter clock sources and outputs a gray-coded counter value and interrupt signals (one per compare frame) to the platform's interrupt controller.

10.3.1 Modes of operation

Table 43. Modes of operation

Mode	Function
Normal	The counter increments on the rising edge of the selected clock when enabled in Normal mode.
Debug	You can configure the SYS_CTR debug operation via Counter Control (CNTCR): • If CNTCR[HDBG] = 0, SYS_CTR continues to operate. • If CNTCR[HDBG] = 1, SYS_CTR halts when its debug input signal is asserted.

10.3.2 Operation

After reset, SYS_CTR is disabled with the count value reset to 0 and base frequency selected. After the counter is enabled, it increments the appropriate value on each rising edge of the selected clock. Because SYS_CTR handles a 56-bit count value across multiple clock domains, synchronization is necessary. SYS_CTR provides synchronization mechanisms between the various clock domains.

After the system switches the counter's clock source, there is a short pause while the clock multiplexer is handling the clock transition. To maintain an accurate count value, the clock control logic employs two offset counters: one for base-to-slow transition and the other one for slow-to-base transition. These offset counters only operate during the clock transition time to compensate for the idled source clock. Both counters run off the base clock. The transition offset values are added to the system count value at an appropriate time after the counter's clock is restored.

NOTE

Both the base clock and alternate clock must be running when changing frequencies.

10.3.3 Clocks

Table 44. Clocks

Clock	Description
base_clk	Base clock This clock is used during normal operation.
slow_clk	Slow clock This clock is used during low-power mode. It is internally divided by 64 before use.

10.3.4 Interrupts

Each SYS_CTR compare frame (SYS_CTR_COMPARE) is capable of generating one maskable interrupt.

10.4 External signals

This module has no external signals.

10.5 Initialization

To initialize SYS_CTR:

1. Write an initial value to Counter Count Value Low (CNTCV0) and Counter Count Value High (CNTCV1), if a different value is desired.
2. Write 1 to CNTCR[EN] to enable the counter.

10.6 Application information

To use a compare frame:

1. Write the desired count value into Compare Count Value Low (CMPCVL0 - CMPCVL1) and Compare Count Value High (CMPCVH0 - CMPCVH1).
2. Enable interrupts using CMPCR0[IMASK], if required.
3. Write 1 to CMPCR0[EN] to enable the compare function.
4. Read CMPCR0[ISTAT] to check whether the count value is reached.

10.7 Programming model

SYS_CTR contains three programming model sections. Each section has an independent module enable to allow individual secure access control. See the following table for details.

Table 45. Programming model

Programming model	Description
Control	Controls the counter frequency, enable, debug, and count value. This model also contains the frequency-modes table that supplies control and status for the frequency of SYS_CTR.
Read	Allows you to read the count value.
Compare	Controls the compare value frequency, enable, interrupt mask, and interrupt status for each compare frame.

10.8 Memory map and register definition

10.8.1 SYS_CTR_CONTROL register descriptions

NOTE

Write or read access to reserved locations does not generate a transfer error.

NOTE

All 32-bit registers allow only 32-bit wide write operations, and are aligned to 32 bits.

10.8.1.1 SYS_CTR_CONTROL memory map

SYS_CTR_CONTROL base address: 4429_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Counter Control (CNTCR)	32	RW	0000_0000h

FD0h	Counter ID (CNTID0)	32	R	0000_0000h

10.8.1.2 Counter Control (CNTCR)

Offset

Register	Offset
CNTCR	0h

Function

Defines the basic operating configuration of SYS_CTR, which operates using a fixed base frequency. However, the counter can increment at a lower alternate frequency than the base frequency, using a correspondingly larger increment. For example, the counter can increment by 46,875 and run at a frequency of 1/46875 of the base frequency, which is the normal operating frequency. The alternate frequency is a significantly lower operating frequency used to reduce power consumption. The frequency-modes table identifies the two available frequencies. These two frequencies are the base frequency (table entry 0) and the lower, alternate frequency (table entry 1). Writing 1 to CNTCR[FCR1] selects the alternate frequency, and writing 1 to CNTCR[FCR0] selects the base frequency. Writing 1 or writing 0 to both FCR0 and FCR1 has no effect and the frequency does not change.

31-0 CNTFID2	Counter Frequency ID 2 Indicates the end of the frequency-modes table.

10.8.1.9 Counter Control 2 (CNTCR2)

Offset

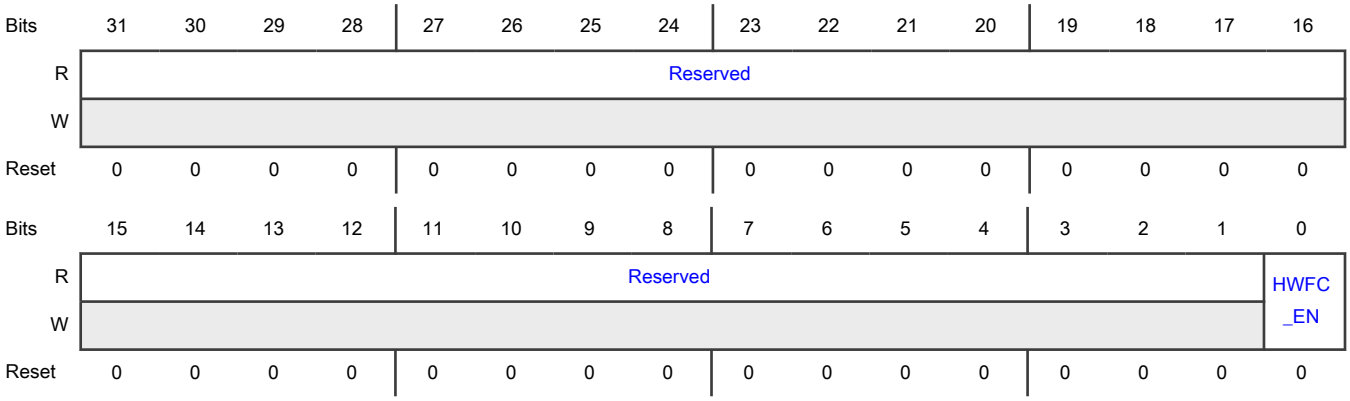
Register	Offset
CNTCR2	C0h

Function

Enables automatic configuration of SYS_CTR via hardware.

SYS_CTR operates using a fixed base frequency. However, the counter can increment at a lower alternate frequency than the base frequency, using a correspondingly larger increment. For example, the counter can increment by 46,875 and run at a frequency of 1/46875 of the base frequency, which is the normal operating frequency. The alternate frequency is a significantly lower operating frequency used to reduce power consumption. The frequency-modes table identifies the two available frequencies. These two frequencies are the base frequency (table entry 0), and the lower and alternate frequency (table entry 1). Writing 1 to CNTCR2[HWFC_EN] enables hardware to automatically switch to the lower, alternate frequency clock after the chip enters low-power mode. When exiting this mode, hardware automatically switches back to the base frequency. If CNTCR2[HWFC_EN] = 0, frequency changes are fully under software control via Counter Control (CNTCR).

Diagram



Fields

Field	Function
31-1 —	Reserved
0 HWFC_EN	Hardware Frequency Change Enable Enables automatic configuration of SYS_CTR via hardware. If this field is 1, it performs the same frequency change request that you can do using CNTCR[FCR0] and CNTCR[FCR1]. 0b - No effect 1b - Same as performed via software

NOTE

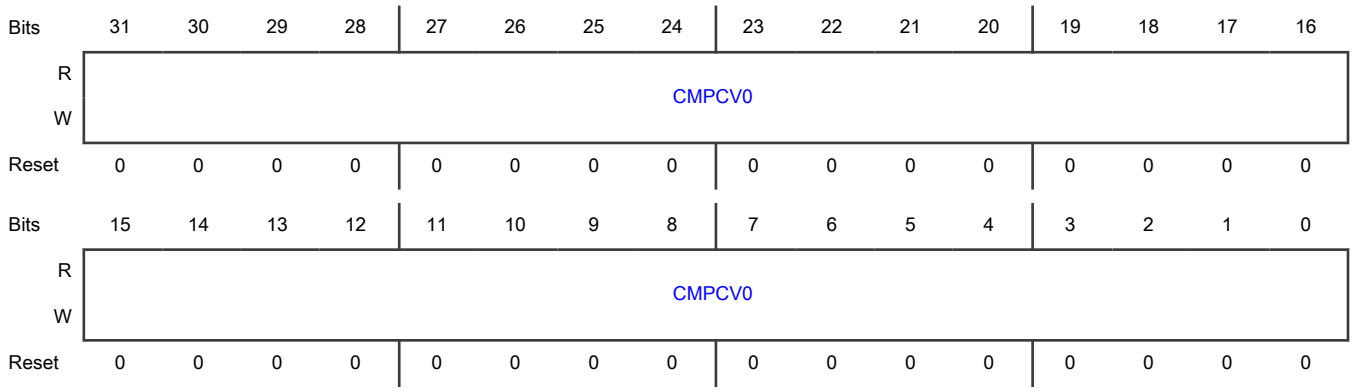
You must write to this set of registers when operating on the base frequency only. Writes to these registers when running on the alternate frequency may have unpredictable results.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 CMPCV1	Compare Count Value Bits [55:32] Specifies the upper 24 bits of the 56-bit compare value. Bits[63:56] are always zero.

10.8.3.4 Compare Control (CMPCR0 - CMPCR1)

Offset

Register	Offset
CMPCR0	2Ch
CMPCR1	12Ch

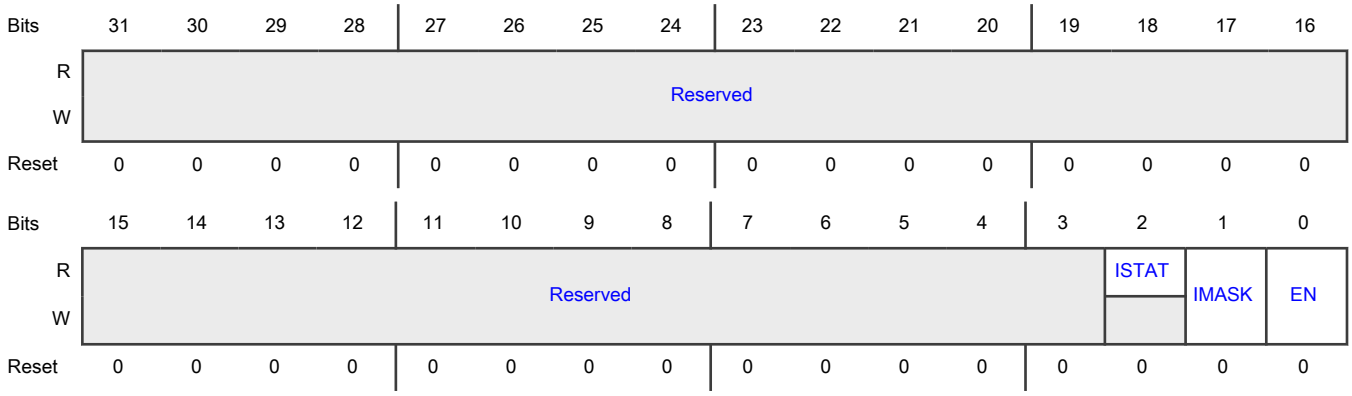
Function

Provides control and status of the compare function. When enabled, CMPCR0[ISTAT] indicates whether the counter value is greater than or equal to the value in CMPCV*n*. The ISTAT equation is:

Value of CMPCR0[ISTAT] = CNTCV*n* ≥ CMPCV*n*

CMPCR0[ISTAT] takes no account of the value of CMPCR0[IMASK]. If CMPCR0[ISTAT] = 1 and CMPCR0[IMASK] = 0, the interrupt request is asserted. Writing 0 to CMPCR0[EN] makes CMPCR0[ISTAT] = 0 and negates the interrupt output signal.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 ISTAT	Compare Interrupt Status Indicates whether the counter value is less than, greater than, or equal to the compare value. 0b - Either less than the compare value or compare is disabled 1b - Greater than or equal to the compare value and compare is enabled
1 IMASK	Interrupt Request Mask Specifies whether the interrupt output signal is masked. 0b - Not masked 1b - Masked
0 EN	Compare Enable Enables the compare function. 0b - Disable 1b - Enable

Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

11.2 Overview

TSTMR is a free-running, 56-bit incrementing clock cycle counter that requires two 32-bit reads to read the full timestamp value.

TSTMR:

- Resets after every system reset.
- Is accessible through the LOW and HIGH registers.
- Stops only when the clock to TSTMR is disabled.

11.2.1 Block diagram

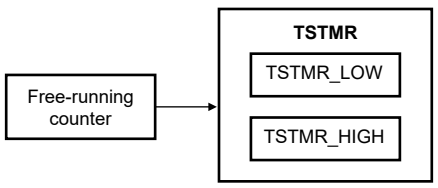

Figure 34. Block diagram

11.2.2 Features

TSTMR has the following features:

- Provides a free-running timer
- Counts the number of clock cycles since the last chip reset

11.3 Functional description

TSTMR starts running after system reset deassertion. You can read the counter at any time to determine software ticks. However, you must follow the read sequence as mentioned in the TSTMR register descriptions for correctly reading TSTMR values.

See the chip-specific TSTMR information for implementation details of this module's instances.

11.3.1 Dual mode

Dual Timer mode is used to implement a second virtual TSTMR for CPU2. The original TSTMR is assumed to be present in the CPU1 domain as a free running timer that resets only when the CPU1 domain power cycles. The CPU2 domain can power cycle independently of the CPU1 domain but it must do that while the CPU1 domain is power cycling. The second virtual TSTMR always runs in sync with the original TSTMR but starts from 0 when the CPU2 domain power cycles.

11.3.2 Clocking

TSTMR uses the 1 MHz chip clock.

11.3.3 Interrupts

TSTMR has no interrupts.

11.4 External signals

TSTMR has no external signals.

11.5 Initialization

You can initialize TSTMR after the chip is powered up. No additional steps or considerations are necessary.

11.6 TSTMR_A memory map and register definition

NOTE

You can read TSTMR registers with 32-bit accesses only.

11.6.1 Accessing registers

You must always perform the following procedure in full to receive consistent timer values:

- Use a 32-bit access to read Timestamp Timer Low (LOW) register.
- Use a 32-bit access to read Timestamp Timer High (HIGH) register.

This procedure is necessary because, after you read LOW, TSTMR freezes the value of HIGH until you read HIGH. If you neglect to read HIGH and attempt to read LOW again, the timestamp value remains unchanged.

11.6.2 TSTMR register descriptions

This section contains detailed register descriptions for the TSTMR registers.

11.6.2.1 TSTMR memory map

TSTMR1.TSTMRA base address: 442C_0000h

TSTMR2.TSTMRA base address: 4248_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Timestamp Timer Low (LOW)	32	R	0000_0000h
4h	Timestamp Timer High (HIGH)	32	R	0000_0000h

11.6.2.2 Timestamp Timer Low (LOW)

Offset

Register	Offset
LOW	0h

Function

Indicates the lower 32 bits of the full 56-bit timestamp value.

See Accessing registers for information on how to use this register.

Fields

Field	Function
31-0 VALUE	Timestamp Timer Low Indicates the lower 32 bits of the 56-bit timestamp value. You may not be able to detect the situation of VALUE = 0, because it increases before you can read it.

11.6.2.3 Timestamp Timer High (HIGH)

Offset

Register	Offset
HIGH	4h

Function

Indicates the higher 32 bits of the full 56-bit timestamp value.

See Accessing registers for information on how to use this register.

Diagram

23-0 VALUE	Timestamp Timer High Indicates the higher 24 bits of the 56-bit timestamp value. You may not be able to detect the situation of VALUE = 0, because it increases before you can read it.

Chapter 12
System Boot

12.1 Overview

The boot process begins at any Reset where the hardware reset logic forces the boot core (Cortex-M33 core) to begin execution starting from the on-chip boot ROM.

The boot ROM uses the state of the internal register bitfield SBMR2[BOOT_MODE] (which reflects the status of Boot Mode Pins), as well as the state of various fuse settings to determine the boot flow behavior of the device.

The boot ROM code also allows the downloading of programs to be run on the device. An example is a provisioning program that can make further use of the serial connection to provide a boot device with a new image. Typically, the provisioning program is downloaded to the internal RAM and allows to program the boot devices, such as the FlexSPI NOR flash. The boot ROM serial downloader uses LPSPI, LPUART, or a high-speed USB in a non-stream mode connection.

The External Memory Configuration Data (XMCD) allows the boot ROM code to configure the SDRAM connected to the SEMC controller, or the HyperRAM/APMemory PSRAM via the FlexSPI controller from an external program image residing on the boot device. The XMCD aims to simplify the external RAM enablement, and it is a replacement for the legacy Device Configuration Data (DCD).

A key feature of the boot ROM is the ability to perform a secure boot. The boot ROM is also called Advanced High-Assurance Boot (AHAB) which protects the system from executing unauthorized program images. Before the AHAB allows the user image to execute, the image must be signed. The signing process is done during the image build process by the private key holder and the signatures are then included as a part of the final program image. If configured to do so, the AHAB verifies the signatures using the public keys included in the program image. In addition to supporting the digital signature verification to authenticate the program images, encrypted boot is also supported. The encrypted boot can be used to prevent the cloning of the program image directly off the boot device. A secure boot with AHAB can be performed on all boot devices supported on the chip in addition to the serial downloader. The out-of-fab setting for the LIFE_CYCLE is the open configuration, in which the ROM/AHAB performs the image authentication, but all authentication errors are ignored and the image is still allowed to execute.

12.1.1 Features

The main features of the boot ROM include:

- Supports booting from Cortex-M33
- Supports booting from various boot devices
- Supports booting from recovery boot devices once failed booting from the primary boot device
- Supports serial downloader
- Supports external RAM expansion using eXternal Memory Configuration Data (XMCD)
- Supports encrypted boot via AES-CBC
- Supports digital signature and hash function based Advanced High-Assurance Boot (AHAB)
- Supports encrypted execute-in-place (XIP) booting on Serial NOR via FlexSPI interface powered by:
  - On-the-Fly AES Decryption (OTFAD)
  - Inline Encryption Engine (IEE)

  Supports loading NXP-supplied security firmware to expand the security features.

The boot ROM supports the following primary boot devices:

- Serial NOR Flash via FlexSPI
  - Supports booting from either FlexSPI instances (FlexSPI1 or FlexSPI2)
  - Supports booting from either pin groups of the FlexSPI instance

- Supports booting from either PORTA or PORTB.
- Supports Flash Auto-probing based on JESD216
- Supports Encrypted XIP booting via OTFAD or IEE

- Serial NAND Flash via FlexSPI
  - Supports booting from either FlexSPI instances (FlexSPI1 or FlexSPI2)
  - Supports booting from either pin groups of the FlexSPI instance
  - Supports booting from either PORTA or PORTB
- SLC RAWNAND Flash via SEMC
  - Supports FLASH build-in ECC or the SEMC BCH4/BCH8 ECC engine
- SD/eMMC via uSDHC
  - Supports booting from either uSDHC instance
  - Supports booting from SD, SDHC, SDXC card
  - Supports 1/4bit width for SD booting
  - Supports SDR12, SDR25, SDR50 and SDR104 for SD booting
  - Supports booting from eMMC4.5 and higher
  - Supports 4bit SDR, 8bit SDR, 4bit DDR, and 8bit DDR for eMMC booting
  - Supports booting from eMMC boot operation mode (Fast boot)

The boot ROM supports the following recovery boot device:

- SPI NOR/EEPROM via LPSPI
  - Supports booting from LPSPI1, 2, 4 or 5
  - Supports Dual and Quad mode for SPI NOR FLASH booting

The boot ROM supports the following serial downloader peripherals:

- USB-HID via USB1
- LPUART1
- LPSPI1

The boot ROM supports external RAM expansion:

- HyperRAM via FlexSPI
- APMemory via FlexSPI
- SDRAM via SEMC

The boot ROM supports the following digital signature features:

- Supports ECDSA: prime256, secp384, secp521
- Supports RSA PSS: 2048, 3072, 4096
- Supports hashes: SHA-256, SHA-384, SHA-512
- The maximum number of certificate supported: 4
- Supports revoking certificates

12.2 Chip-specific Boot Information

For booting consideration, the boot ROM needs to configure some modules. The settings are documented in this section.

12.2.1 Boot ROM Pinmux

This device has various peripherals supported by the boot ROM.

Table 47. Serial Downloader Peripherals PinMux

Peripheral	Instance	Port (IO function)	PAD	Mode	Note
LPUART	1	LPUART1_TX	GPIO_AON_08	ALT0	This peripherals can be used as serial downloader. Refer to Serial Boot (Serial Downloader) for more information. All serial downloader peripherals can be disabled by the DIS_SERIAL_DWNLD fuse. Each type of serial downloader peripheral can be disabled separately by setting DIS_USB_HID_DWNLD, DIS_SPI_WDNLD and DIS_UART_DWNLD.
		LPUART1_RX	GPIO_AON_09	ALT0	
LPSPI	1	LPSPI1_SCK	GPIO_AON_04	ALT0	
		LPSPI1_PCS0	GPIO_AON_05	ALT0	
		LPSPI1_SDO	GPIO_AON_06	ALT0	
		LPSPI1_SDI	GPIO_AON_07	ALT0	
USB	1	USB1_DN	USB1_DN	-	
		USB1_DP	USB1_DP	-	

Table 48. Boot ROM Peripheral PinMux

Peripheral	Instance	Port (IO function)	PAD	Mode	Note
LPSPI	1	LPSPI1_SCK	GPIO_AON_04	ALT0	Serial NOR/EEPROM connected to one of the LPSPI ports can be used as a recovery device. Refer to Serial NOR/EEPROM Recovery Boot via LPSPI for more information. Recovery device boot is disabled by default. The RECOVERY_BOOT_EN fuse must be blown in order to enable this option. The SPI instance 1 is selected by default, which can be overwritten by the LPSPI_PORT_SEL fuse. PCS2/DATA2 and PCS3/DATA3 are only used in Dual/Quad Mode, which can be selected by the LPSPI_SPEED fuse.
		LPSPI1_PCS0	GPIO_AON_05	ALT0	
		LPSPI1_SDO/DATA0	GPIO_AON_06	ALT0	
		LPSPI1_SDI/DATA1	GPIO_AON_07	ALT0	
		LPSPI1_PCS2/DATA2	GPIO_AON_09	ALT8	
		LPSPI1_PCS3/DATA3	GPIO_AON_03	ALT4	
	2	LPSPI2_SCK	GPIO_AON_22	ALT6	
		LPSPI2_PCS0	GPIO_AON_25	ALT6	
		LPSPI2_SDO/DATA0	GPIO_AON_23	ALT6	
		LPSPI2_SDI/DATA1	GPIO_AON_24	ALT6	
		LPSPI2_PCS2/DATA2	GPIO_AON_26	ALT1	
		LPSPI2_PCS3/DATA3	GPIO_AON_27	ALT1	
	4	LPSPI4_SCK	GPIO_SD_B2_08	ALT4	
		LPSPI4_PCS0	GPIO_SD_B2_09	ALT4	

Table continues on the next page...

Table 48. Boot ROM Peripheral PinMux (continued)

Peripheral	Instance	Port (IO function)	PAD	Mode	Note
		LPSPI4_SDO/DATA0	GPIO_SD_B2_10	ALT4	
		LPSPI4_SDI/DATA1	GPIO_SD_B2_11	ALT4	
		LPSPI4_PCS2/DATA2	GPIO_SD_B2_06	ALT4	
		LPSPI4_PCS3/DATA3	GPIO_SD_B2_05	ALT4	
	5	LPSPI5_SCK	GPIO_AD_28	ALT0	
		LPSPI5_PCS0	GPIO_AD_29	ALT0	
		LPSPI5_SDO/DATA0	GPIO_AD_30	ALT0	
		LPSPI5_SDI/DATA1	GPIO_AD_31	ALT0	
		LPSPI5_PCS2/DATA2	GPIO_AD_26	ALT2	
		LPSPI5_PCS3/DATA3	GPIO_AD_25	ALT2	
SEMC NAND/SDRAM	N/A	**SEMC_DATA00**	**GPIO_EMC_B1_00**	ALT0	Parallel NAND flash connected to the SEMC is a primary boot option. Refer to Parallel NAND Flash Boot via SEMC for more information. SDRAM connected to the SEMC is a memory expansion option. Refer to SDRAM support for more information. By default ROM reads from the 8-bit NAND device via the **bold** pins. The "I/O Port Size" fuse must be blown to enable 16-bit NAND device support. The PCS_Selection fuse must be blown to select other PCS configurations.
		SEMC_DATA01	**GPIO_EMC_B1_01**	ALT0	
		SEMC_DATA02	**GPIO_EMC_B1_02**	ALT0	
		SEMC_DATA03	**GPIO_EMC_B1_03**	ALT0	
		SEMC_DATA04	**GPIO_EMC_B1_04**	ALT0	
		SEMC_DATA05	**GPIO_EMC_B1_05**	ALT0	
		SEMC_DATA06	**GPIO_EMC_B1_06**	ALT0	
		SEMC_DATA07	**GPIO_EMC_B1_07**	ALT0	
		SEMC_DATA08	GPIO_EMC_B1_30	ALT0	
		SEMC_DATA09	GPIO_EMC_B1_31	ALT0	
		SEMC_DATA10	GPIO_EMC_B1_32	ALT0	
		SEMC_DATA11	GPIO_EMC_B1_33	ALT0	
		SEMC_DATA12	GPIO_EMC_B1_34	ALT0	
		SEMC_DATA13	GPIO_EMC_B1_35	ALT0	
		SEMC_DATA14	GPIO_EMC_B1_36	ALT0	

Table continues on the next page...

		USDHC2_DATA4	GPIO_SD_B2_08	ALT0	
		USDHC2_DATA5	GPIO_SD_B2_09	ALT0	
		USDHC2_DATA6	GPIO_SD_B2_10	ALT0	
		USDHC2_DATA7	GPIO_SD_B2_11	ALT0	
FlexSPI1 NOR/ NAND/RAM (Primary Pin Group)	1	FLEXSPI1_A_DQS (Primary DQS pin)	GPIO_B2_07	ALT7	If QSPI, HyperFlash, or Octal memory attached to FlexSPI is a primary boot option. Refer to Serial NOR Flash Boot via FlexSPI for more information. The ROM will read the 512-byte FlexSPI NOR configuration parameters described in FlexSPI Serial NOR Flash Boot Operation. If Serial NAND memory attached to FlexSPI is a primary boot option. Refer to Serial NAND Flash Boot via FlexSPI for more information. If HyperRAM or APMemory attached to FlexSPI is a memory expansion option. Refer to FlexSPI RAM Configuration Block for more information. This pin group is used for FlexSPI NOR/NAND boot if: • The FLEXSPI_INSTANCE fuse/ boot pin is 0. • The FLEXSPI_PIN_GROUP_SEL fuse bit is 0. The fuse FLEXSPI_DQS_PIN_SEL determines the DQS pin option. By default, ROM accesses the QSPI NOR/NAND via the **bold** pins. This default behavior can be overridden by setting the FLASH_CONNECTION_SEL fuse
		FLEXSPI1_A_DQS (Secondary DQS Pin)	GPIO_SD_B2_12_DUMMY	ALT0	
		FLEXSPI1_A_SS0_ B	**GPIO_B2_09**	ALT7	
		FLEXSPI1_A_SS1_B	GPIO_B2_01	ALT6	
		FLEXSPI1_A_SCLK	**GPIO_B2_08**	ALT7	
		FLEXSPI1_A_SCLK_B	**GPIO_B2_02**	ALT6	
		FLEXSPI1_A_DATA 0	**GPIO_B2_10**	ALT7	
		FLEXSPI1_A_DATA 1	**GPIO_B2_11**	ALT7	
		FLEXSPI1_A_DATA 2	GPIO_B2_12	ALT7	
		FLEXSPI1_A_DATA 3	GPIO_B2_13	ALT7	
		FLEXSPI1_A_DATA4	GPIO_B2_03	ALT7	
		FLEXSPI1_A_DATA5	GPIO_B2_04	ALT7	
		FLEXSPI1_A_DATA 6	GPIO_B2_05	ALT7	
		FLEXSPI1_A_DATA 7	GPIO_B2_06	ALT7	
		FLEXSPI1_B_DQS (Primary DQS pin)	GPIO_SD_B2_05	ALT1	
		FLEXSPI1_B_DQS (Secondary DQS Pin)	GPIO_SD_B2_12_DUMMY	ALT1	
		FLEXSPI1_B_SS0_B	GPIO_SD_B2_06	ALT1	

Table continues on the next page...

Table 48. Boot ROM Peripheral PinMux (continued)

Peripheral	Instance	Port (IO function)	PAD	Mode	Note
		FLEXSPI1_B_SS1_B	GPIO_SD_B2_04	ALT1	**NOTE** Primary pin group is not available on all packages. For example, BGA144 does not include the GPIO_B1/ GPIO_B2 pin group.
		FLEXSPI1_B_SCLK	GPIO_SD_B2_07	ALT1	
		FLEXSPI1_B_DATA 0	GPIO_SD_B2_08	ALT1	
		FLEXSPI1_B_DATA1	GPIO_SD_B2_09	ALT1	
		FLEXSPI1_B_DATA 2	GPIO_SD_B2_10	ALT1	
		FLEXSPI1_B_DATA 3	GPIO_SD_B2_11	ALT1	
		FLEXSPI1_B_DATA 4	GPIO_SD_B2_00	ALT1	
		FLEXSPI1_B_DATA 5	GPIO_SD_B2_01	ALT1	
		FLEXSPI1_B_DATA 6	GPIO_SD_B2_02	ALT1	
		FLEXSPI1_B_DATA 7	GPIO_SD_B2_03	ALT1	
FlexSPI1 NOR/ NAND/RAM (Secondary Pin Group)	1	FLEXSPI1_B_DQS (Primary DQS pin)	GPIO_B1_03	ALT7	If QSPI, Hyperflash, or Octal memory attached to FlexSPI is a primary boot option. Refer to Serial NOR Flash Boot via FlexSPI for more information. The ROM will read the 512-byte FlexSPI NOR configuration parameters described in FlexSPI Serial NOR Flash Boot Operation. If Serial NAND memory attached to FlexSPI is a primary boot option. Refer to Serial NAND Flash Boot via FlexSPI for more information. If HyperRAM or APMemory attached to FlexSPI is a memory expansion option. Refer to FlexSPI RAM Configuration Block for more information. This pin group is used for FlexSPI NOR/NAND boot if: • FLEXSPI_INSTANCE fuse/ boot pin is 0. • FLEXSPI_PIN_GROUP_SEL fuse bit is 1. Only PORTB is supported via the 2nd Pin group.
		FLEXSPI1_B_DQS (Secondary DQS Pin)	GPIO_SD_B2_12_DU MMY	ALT1	
		FLEXSPI1_B_SS0_ B	**GPIO_B1_04**	ALT7	
		FLEXSPI1_B_SS1_ B	GPIO_B1_02	ALT7

		FLEXSPI1_B_DATA 1	**GPIO_B1_12**	ALT7	
		FLEXSPI1_B_DATA 2	GPIO_B1_11	ALT7	
		FLEXSPI1_B_DATA 3	GPIO_B1_10	ALT7	
		FLEXSPI1_B_DATA4	GPIO_B1_09	ALT7	
		FLEXSPI1_B_DATA5	GPIO_B1_08	ALT7	
		FLEXSPI1_B_DATA 6	GPIO_B1_07	ALT7	
		FLEXSPI1_B_DATA 7	GPIO_B1_06	ALT7	

Table continues on the next page...

Table 48. Boot ROM Peripheral PinMux (continued)

Peripheral	Instance	Port (IO function)	PAD	Mode	Note
					The Maximum Flash frequency supported on this port is 100MHz. By default, ROM accesses the QSPI NOR/NAND via the **bold** pins. This default behavior can be overridden by setting the FLASH_CONNECTION_SEL fuse.
FlexSPI2 NOR/ NAND/RAM (Primary Pin Group)	2	FLEXSPI2_A_DQS (Primary DQS pin)	GPIO_AON_21	ALT8	If QSPI, Hyperflash, or Octal memory attached to FlexSPI is a primary boot option. Refer to Serial NOR Flash Boot via FlexSPI for more information. The ROM will read the 512-byte FlexSPI NOR configuration parameters described in FlexSPI Serial NOR Flash Boot Operation. If Serial NAND memory attached to FlexSPI is a primary boot option. Refer to Serial NAND Flash Boot via FlexSPI for more information. If HyperRAM or APMemory attached to FlexSPI is a memory expansion option. Refer to FlexSPI RAM Configuration Block for more information. This pin group is used for FlexSPI NOR/NAND boot if: • FLEXSPI_INSTANCE fuse/ boot pin is 1. • FLEXSPI_PIN_GROUP_SEL fuse bit is 0. By default, ROM accesses the QSPI NOR/NAND via the **bold** pins. This default behavior can be overridden by setting the FLASH_CONNECTION_SEL fuse.
		FLEXSPI2_A_DQS (Secondary DQS Pin)	GPIO_AON_28_DUMMY	ALT0	
		FLEXSPI2_A_SS0_ B	**GPIO_AON_22**	ALT0	
		FLEXSPI2_A_SS1_B	GPIO_AON_20	ALT1	
		FLEXSPI2_A_SCLK	**GPIO_AON_23**	ALT0	
		FLEXSPI2_A_DATA 0	**GPIO_AON_24**	ALT0	
		FLEXSPI2_A_DATA 1	**GPIO_AON_25**	ALT0	
		FLEXSPI2_A_DATA 2	GPIO_AON_26	ALT0	
		FLEXSPI2_A_DATA 3	GPIO_AON_27	ALT0	
		FLEXSPI2_B_DQS (Primary DQS pin)	GPIO_AON_20	ALT0	
		FLEXSPI2_B_DQS (Secondary DQS Pin)	GPIO_AON_28_DUMMY	ALT1	
		FLEXSPI2_B_SS0_B	GPIO_AON_21	ALT0	
		FLEXSPI2_B_SCLK	GPIO_AON_19	ALT0	
		FLEXSPI2_B_DATA 0	GPIO_AON_18	ALT0	
		FLEXSPI2_B_DATA 1	GPIO_AON_17	ALT0	
		FLEXSPI2_B_DATA 2	GPIO_AON_16	ALT0	
		FLEXSPI2_B_DATA 3	GPIO_AON_15	ALT0	

Table continues on the next page...

Table 48. Boot ROM Peripheral PinMux (continued)

Peripheral	Instance	Port (IO function)	PAD	Mode	Note
					NOTE The Maximum Flash frequency supported on this port (GPIO_AON) is 100MHz.
FlexSPI2 NOR/ NAND/RAM (Secondary Pin Group)	2	FLEXSPI2_A_DQS (Primary DQS pin)	GPIO_EMC_B1_40	ALT3	If QSPI memory attached to FlexSPI is a primary boot option. Refer to Serial NOR Flash Boot via FlexSPI for more information. The ROM will read the 512-byte FlexSPI NOR configuration parameters described in FlexSPI Serial NOR Flash Boot Operation. If Serial NAND memory attached to FlexSPI is a primary boot option. Refer to Serial NAND Flash Boot via FlexSPI for more information. If HyperRAM or APMemory attached to FlexSPI is a memory expansion option. Refer to FlexSPI RAM Configuration Block for more information. This pin group is used for FlexSPI NOR/NAND boot if: • FLEXSPI_INSTANCE fuse/ boot pin is 1. • FLEXSPI_PIN_GROUP_SEL fuse bit is 1. By default, ROM accesses the QSPI NOR/NAND via the **bold** pins. This default behavior can be overridden by setting the FLASH_CONNECTION_SEL fuse. **NOTE** If the GPIO_AON_28_DUMMY pin is used for DQS, the clock cannot exceed 100MHz.
		FLEXSPI2_A_DQS (Secondary DQS Pin)	GPIO_AON_28_DUMMY	ALT0	
		FLEXSPI2_A_SS0_ B	**GPIO_EMC_B1_39**	ALT3	
		FLEXSPI2_A_SS1_ B	GPIO_EMC_B1_26	ALT3	
		FLEXSPI2_A_SCLK	**GPIO_EMC_B1_41**	ALT3	
		FLEXSPI2_A_DATA 0	**GPIO_EMC_B1_35**	ALT3	
		FLEXSPI2_A_DATA 1	**GPIO_EMC_B1_36**	ALT3	
		FLEXSPI2_A_DATA 2	GPIO_EMC_B1_37	ALT3	
		FLEXSPI2_A_DATA 3	GPIO_EMC_B1_38	ALT3	

Table continues on the next page...

Table 48. Boot ROM Peripheral PinMux (continued)

Peripheral	Instance	Port (IO function)	PAD	Mode	Note
FLEXSPI2		FLEXSPI2_B_DQS (Primary DQS pin)	GPIO_EMC_B1_29	ALT3	
		FLEXSPI2_B_DQS (Secondary DQS pin)	GPIO_EMC_B1_32	ALT1	
		FLEXSPI2_B_SS0_B	GPIO_EMC_B1_28	ALT3	
		FLEXSPI2_B_SS1_B	GPIO_EMC_B1_27	ALT3	
		FLEXSPI2_B_SCLK	GPIO_EMC_B1_34	ALT3	
		FLEXSPI2_B_DATA 0	GPIO_EMC_B1_33	ALT3	
		FLEXSPI2_B_DATA 1	GPIO_EMC_B1_32	ALT3	
		FLEXSPI2__B_DATA 2	GPIO_EMC_B1_31	ALT3	
		FLEXSPI2__B_DATA 3	GPIO_EMC_B1_30	ALT3	
FlexSPI RESET	-	GPIO5_IO04 (Primary RESET Pin)	GPIO_SD_B1_00	ALT5	The FlexSPI RESET pin is used as the dedicated RESET pin to restore the Serial NOR/ NAND device connected to the FlexSPI interface. The FlexSPI RESET pin is enabled if the RESET_PIN_EN fuse bit is blown. The pin option is selected by RESET_PIN_SEL fuse bit.
		GPIO3_IO08 (Secondary RESET Pin)	GPIO_EMC_B1_40	ALT5	

NOTE

1. The boot ROM always tries to access Serial NOR/NAND flash using SS0 as the chip selection signal, as well as PORTA by default. It can access the Serial NOR/NAND device via CS0 and PORTB, if the xSPI_NOR_CONNECTION_SEL/xSPI_NAND_CONNECTION_SEL fuse is blown with a value of 1.
2. For Octal NOR/NAND, connected to FlexSPI2, the upper 4-bit pads must connect to the PORTB_DATA pads.
3. PORTB_SCLK serves as PORTA_SCLK_B for the 1.8V HyperFLASH/HyperRAM.
4. A_SS1/B_SS1 is not supported by default.
5. The FlexSPI RESET pin is not used by default. This feature can be enabled by the xSPI_NOR_RESET_TYPE/xSPI_NAND_RESET_TYPE and xSPI_RESET_PIN_SEL fuses.

12.2.2 Boot Fuse List

This following table is a comprehensive list of the configuration parameters that the ROM uses. For additional details, please refer to the related sections.

Table 49. Boot Fuses

Word Number	Fuse	Owner	Field	Definition	Shipped value
24	BOOT_CFG0	OEM	[15-0]	Boot flow configuration Refer to Boot Flow Fuse Configuration for more information.	0
			[23-16]	Recovery boot configuration Refer to Serial NOR FUSE Configuration for more information.	0
			[31-24]	MISC configuration0 Refer to MISC Fuse Configuration for more information.	0
25	BOOT_CFG1	OEM	[31-0]	FlexSPI NOR Flash boot configuration Refer to Serial NOR FUSE Configuration for more information.	0
26	BOOT_CFG2	OEM	[31-0]	FlexSPI common configuration ReferSerial NOR FUSE Configuration and Serial NAND FUSE Configuration for more information.	0
27	BOOT_CFG3	OEM	[31-0]	FlexSPI NAND Flash boot configuration Refer to Serial NAND FUSE Configuration for more information.	0
28	BOOT_CFG4	OEM	[31-0]	eMMC boot configuration Refer to eMMC/SD Device FUSE Configuration for more information.	0

12.2.3 Boot Block Activation

The boot ROM affects a number of different hardware blocks which are activated and play a vital role in the boot flow.

The ROM configures and uses the blocks listed in Table 50 during the boot process.

NOTE

The blocks actually used depend on the boot mode and the boot device selections.

Table 50. Boot Block List

Domain	Block(s)	Description
M7 Domain	Cortex-M7	Cortex-M7 Core and SCS
CCMSRCGPC Domain	SRC	System Reset Controller
AON Domain	Cortex-M33	Cortex-M33 Core and SCS
	WDOG1, WDOG2	Watch Dog
	IOMUXC	I/O Multiplexer Control
	LPUART1	Low Power UART
	MU	Message Unit
	LPSPI1, LPSPI2	Low Power SPI
	LPIT1, LPIT2	Periodic Interrupt Timer
	PMU	Power Management Unit
	XTALOSC	Crystal Oscillator
	CCM	Clock Control Module
	FlexSPI2 OTFAD	Flexible SPI Interface with On-the-Fly AES Decryption

Table continues on the next page...

Table 50. Boot Block List (continued)

Domain	Block(s)	Description
WAKEUP Domain	EDMA4	Enhanced DMA
	LPSPI4, LPSPI5	Low Power SPI
	GPIO4, GPIO5, GPIO6	General Purpose I/O
	WDOG3, WDOG4, WDOG5	Watch Dog
WAKEUP Domain	SEMC	Smart External Memory Controller
WAKEUP Domain	FlexSPI1 OTFAD	Flexible SPI Interface with On-the-Fly AES Decryption
MEGA Domain	uSDHC1, uSDHC2	Ultra-Secure Digital Host Controller
	USB1	USB

12.3 Boot Flow

This section describes the entire boot flow, and the related configurations to control the flows.

12.3.1 High-level Boot Sequence

Once the boot core starts from the on-chip boot ROM, the boot ROM performs the hardware initialization, loads the program image from the chosen boot device, performs the image validation using the AHAB library, and then jumps to an address derived from the program image. If an error occurs during the boot, the boot ROM jumps to the next boot alternative. A secure boot using the AHAB is possible in all the boot alternatives. After all boot alternatives have failed, the boot ROM jumps to the Serial Downloader.

Figure 35 shows the high-level boot ROM code flow.

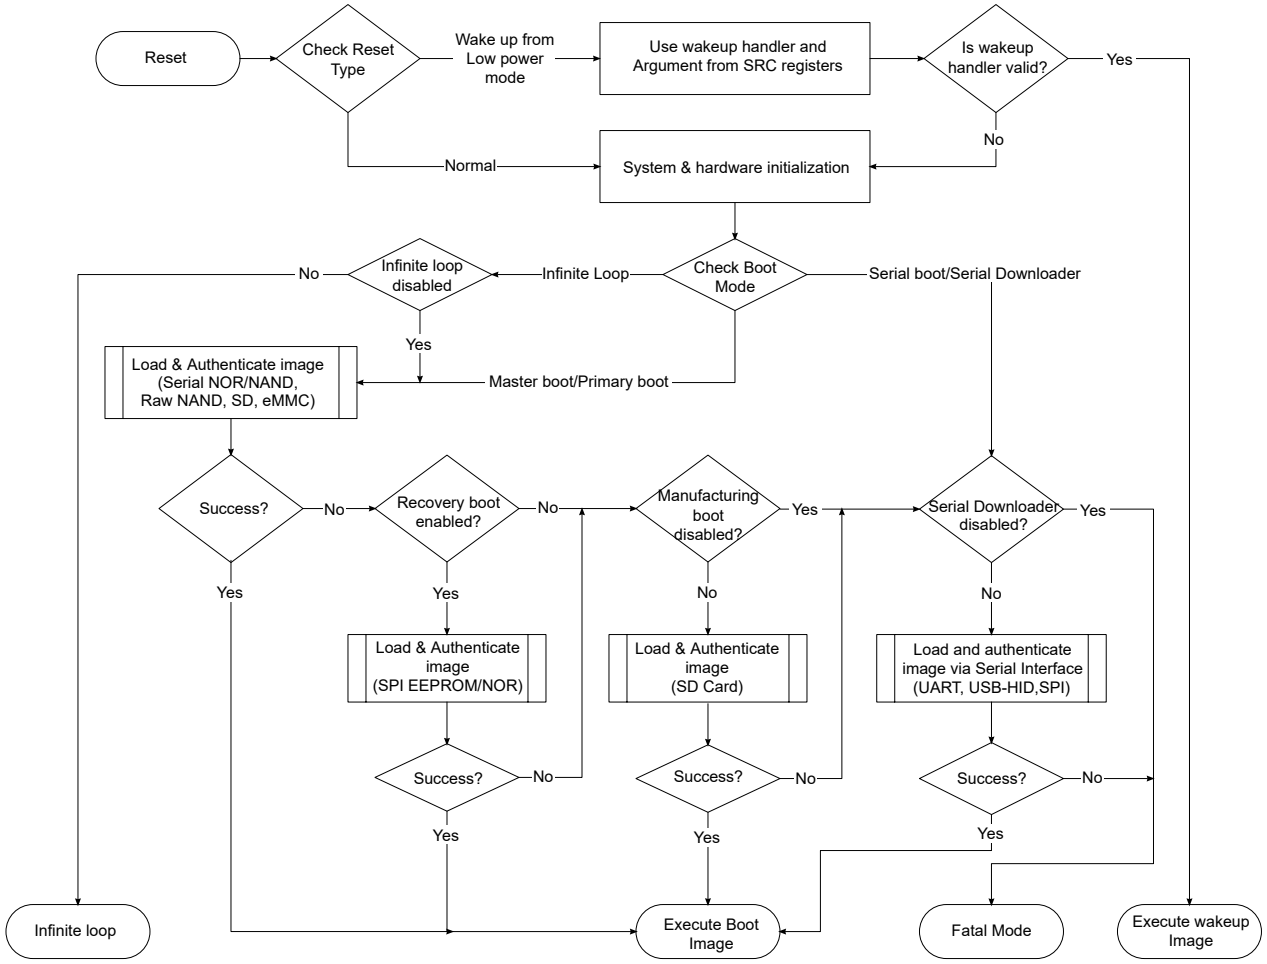

Figure 35. High-level Boot Flow

12.3.2 Boot Flow Fuse Configuration

The following table is a list of the configuration parameters that the ROM uses for boot flow control.

Table 51. Boot Flow Fuse Configuration

Fuse	Definitions	Settings	Shipped Value
BOOT_CFG0[2:0]	BOOT_MODE_FROM_FUSE	0 – FlexSPI NOR Flash 1 – FlexSPI NAND Flash 2 – eMMC 3 – SD 4 – SEMC SLC RAW NAND Flash Refer to Boot Mode Fuse Settings for more information	0

Table continues on the next page...

Table 51. Boot Flow Fuse Configuration (continued)

Fuse	Definitions	Settings	Shipped Value
BOOT_CFG0[3]	Reserved	Must be 0	0
BOOT_CFG0[4]	RECOVERY_BOOT_EN	0 – Recovery boot is disabled 1 – Recovery boot is enabled	0
BOOT_CFG0[5]	DIS_SDMMC_MFG_BOOT	0 – Manufacturing boot is enabled 1 – Manufacturing boot is disabled	0
BOOT_CFG0[6]	BT_FUSE_SEL	0 – Fuse configuration is invalid for ROM booting 1 – Fuse configuration is valid for ROM booting	0
BOOT_CFG0[7]	FORCE_BT_FROM_FUSE	0 – BOOT MODE is determined by BOOT MODE pins 1 – BOOT MODE is determined by BOOT_MODE_FROM_FUSE.	0
BOOT_CFG0[9-8]	Reserved	Must be 0	0
BOOT_CFG0[10]	DIS_UART_DWNLD	0 – UART serial downloader is enabled 1 – UART serial downloader is disabled	0
BOOT_CFG0[11]	DIS_SPI_DWNLD	0 – SPI serial downloader is enabled 1 – SPI serial downloader is disabled	0
BOOT_CFG0[12]	DIS_USB_HID_DWNLD	0 – USB-HID serial downloader is enabled 1 – USB-HID serial downloader is disabled	0
BOOT_CFG0[13]	DIS_INFINITE_LOOP	0 – Infinite loop is enabled 1 – Infinite loop is disabled	0
BOOT_CFG0[14]	DIS_BT_MODE_API	0 – BOOT MODE from ROM API call is allowed 1 – BOOT MODE from ROM API call is ignored Refer to Enter Bootloader API for more information.	0
BOOT_CFG0[15]	DIS_SERIAL_DWNLD	0 – All serial downloaders are enabled 1 – All serial downloaders are disabled.	0

12.3.3 Boot Modes

The boot ROM determines the boot mode via the combination of the following settings:

- ROM API calls
- Fuse settings: DIS_BT_MODE_API, FORCE_BT_FROM_FUSE, BT_FUSE_SEL, BOOT_MODE_FROM_FUSE, DIS_INFINTE_LOOP.
- BOOT_MODE Pins

Figure 36 depicts the boot mode determination logic.

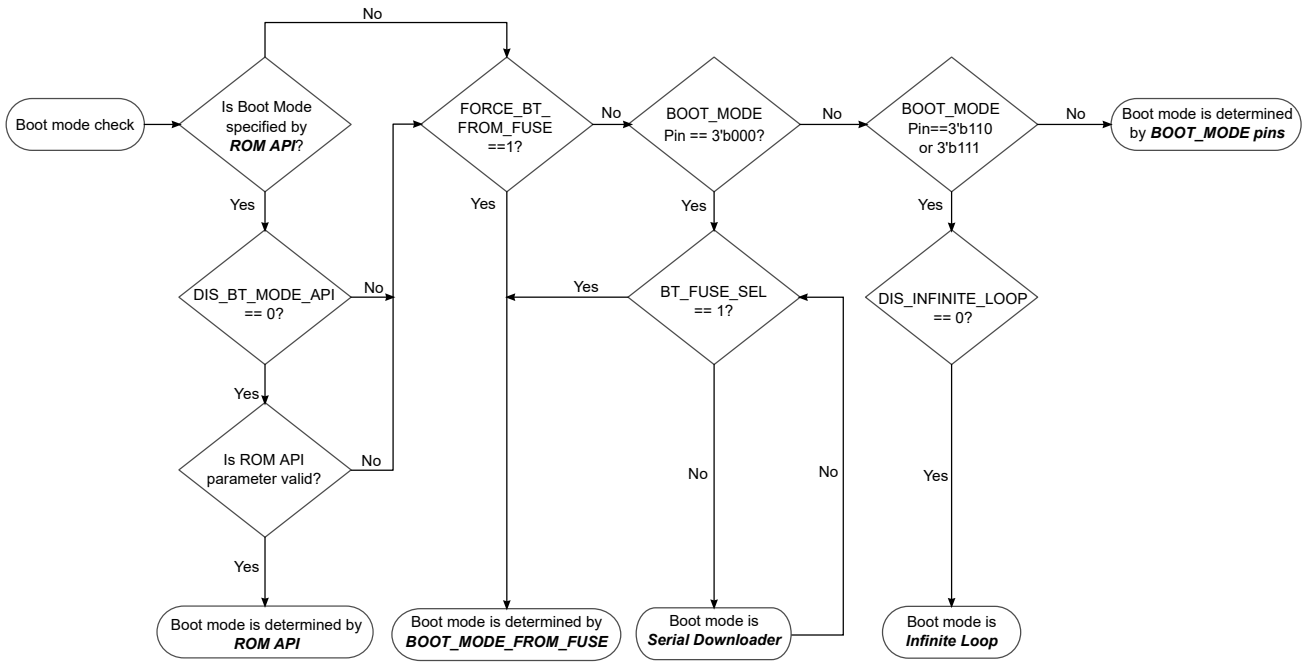

Figure 36. Boot Mode Determination

12.3.3.1 Boot Mode Pin Settings

The device has 3 boot mode pins. The boot mode is selected based on the binary value stored in the internal register field SBMR2[BOOT_MODE], which is initialized by sampling the BOOT_MODE[2:0] pin inputs on the rising edge of the POR_B. After these inputs are sampled, their subsequent state does not affect the contents of SBMR2[BOOT_MODE]. Table 52 shows the boot mode pin definitions.

Table 52. Boot Mode Pin Settings

BOOT_MODE[2:0]	Boot Type
000	Boot From Internal Fuses
001	Serial Downloader
010	eMMC 8bit via uSDHC2[1]
011	SD 4bit via uSDHC1[1]
100	Serial NOR Flash with JESD216 via FlexSPI1, Primary group, PortA[2]

Table continues on the next page...

Table 52. Boot Mode Pin Settings (continued)

BOOT_MODE[2:0]	Boot Type
101	Serial NAND Flash with 2K Page via FlexSPI1, Primary group, PortA[2]
110	Infinite Loop Modes
111	Test Mode[3]

1. Boot device, instance and bus width are fixed. The other options can be set by the values in the BOOT_CFG fuse words.
2. Boot device is fixed. The other options can be overwritten by the values in the BOOT_CFG fuse words, including instance, pin group, port, etc.
3. Test Mode is reserved for NXP usage only.

12.3.3.2 Boot Mode Fuse Settings

When booting from internal fuses, additional boot modes and options are supported by the boot ROM. The boot mode is selected via the BOOT_MODE_FROM_FUSE fuse.Table 53 shows the boot mode fuse definitions.

Table 53. Boot Mode Fuse Settings

BOOT_MODE_FROM_FUSE[2:0]	Boot Type
000	Serial NOR Flash via FlexSPI
001	Serial NAND Flash via FlexSPI
010	eMMC via uSDHC
011	SD via uSDHC
100	SLC RAW NAND via SEMC
101	Serial downloader
110	Invalid
111	Invalid

Additional boot device options can be set via the BOOT_CFG fuse words. Refer to the fuse configuration sections of each boot device for more information.

12.3.3.3 Boot From Internal Fuse

A value of 000b in the SBMR[BOOT_MODE] selects Boot From Internal Fuses.

In this mode, the boot ROM uses the BOOT_CFG fuse settings.

If set to Boot From Internal Fuses, the boot flow is controlled by the BT_FUSE_SEL fuse value. If BT_FUSE_SEL = 0, indicating that the boot device (for example, Flash, fuse) was not programmed yet, the boot flow jumps directly to the Serial Downloader. If BT_FUSE_SEL = 1, the normal boot flow is followed, where the ROM attempts to boot from the selected boot device.

Setting the BT_FUSE_SEL=0 forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded which can then provision the boot device with a program image and blow the BT_FUSE_SEL and the other boot configuration fuses. After the reset, the boot ROM code determines that the BT_FUSE_SEL is blown (BT_FUSE_SEL = 1) and the ROM code performs an internal boot according to the new fuse settings. This allows the user to set BOOT_MODE[2:0]=000b

on a production device and burn the fuses on the same device (by forcing the entry to the Serial Downloader), without changing the value of the BOOT_MODE[2:0] or the pullups/pulldowns on the BOOT_MODE pins.

The first time a board is used, the default fuses may be configured incorrectly for the hardware on the platform. In such case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads.

12.3.3.4 Serial Downloader

The Serial Downloader provides a means to download a Program Image to the on-chip RAM over USB, UART, and SPI connection. In this mode, typically a host PC can communicate to the ROM bootloader using the MCU-BOOT protocol. Serial downloader and the protocol are discussed in Serial Boot (Serial Downloader).

12.3.3.5 Infinite Loop

ROM will run into an infinite loop instead booting from the selected boot devices or running into serial downloader. This gives the user the benefit of debugging or developing their applications, during which booting is not required. The infinite loop mode can be disabled by setting the DIS_INFINITE_LOOP fuse.

12.3.4 Error Recovery Fast Boot

When the Cortex-M33 is warm reset without resetting the rest of the SoC, the Cortex-M33 Boot ROM jumps straight to the resume entry pointed by the INITSVTOR or INITNSVTOR register in BLK_CTRL_S_AONMIX (See the chip's Security Reference Manual for details), after validating the resume entry, as well as Stack Pointer and Program Counter pointed by the resume entry are valid.

This flow can be used to recover image execution quickly when an issue occurs and only the Cortex-M33 reset is needed. It can only be used after a standard boot flow, when image authentication has already been done.

To utilize recovery fast boot flow, the BLK_CTRL_S_AON INITSVTOR or INITNSVTOR register has to be filled in with a valid resume entry which should be an address in OCRAM or Cortex-M33 TCM, before the flow is executed. Similarly, Stack Pointer (SP) and Program Counter (PC) pointed by this resume entry should also be valid, either in OCRAM or Cortex-M33 TCM. Meanwhile, the SP should be in a readable and writable region and the PC should be in an executable region. This flow is executed right after a Cortex-M33 only reset.

12.4 Device Initialization

This section describes the details of the ROM and provides the initialization details. This includes details on:

- The ROM memory map
- The RAM memory map
- On-chip blocks that the ROM must use or change the POR register default values
- Clock initialization
- Exception handling and interrupt handling

12.4.1 Internal ROM/RAM Memory Map

The following figure shows the internal ROM and RAM memory map.

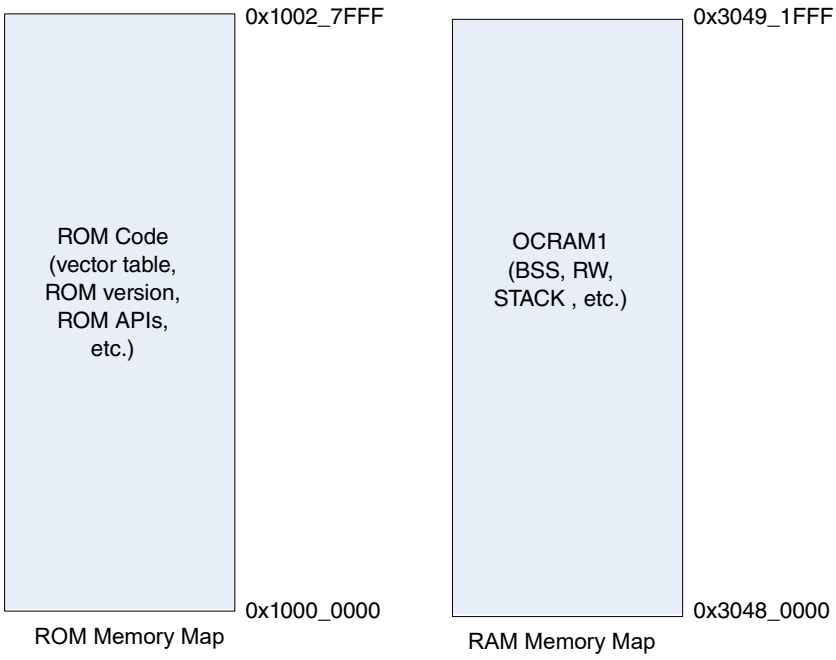

Figure 37. Internal ROM and RAM memory map

NOTE

The RAM space occupied by ROM cannot be used as part of the boot image. The entire OCRAM1 region can be used freely after the boot.

12.4.2 MISC Fuse Configuration

The following table is a list of the parameters that the ROM uses for misc configuration.

Table 54. MISC Fuse definitions

Fuse	Definitions	Settings	Shipped Value
BOOT_CFG0[27:24]	BOOT_FAIL_IND_PIN	Select the pin used as boot failure indicator pin 0x0 ~ 0xB – GPIO_AD_00 ~ GPIO_AD_12 0xC – GPIO_B1_00 0xD – GPIO_B1_01 0xE – GPIO_B2_00 0xF – GPIO_AD_33 Refer to Boot Failure Indicator for more information.	0
BOOT_CFG0[30:28]	Reserved	Must be 0	0

Table continues on the next page...

Table 54. MISC Fuse definitions (continued)

Fuse	Definitions	Settings	Shipped Value
BOOT_CFG0[31]	BOOT_FAIL_IND_EN	0 – Boot failure indicator pin is disabled 1 – Boot failure indicator pin is enabled	0
BOOT_CFG7[8]	WDOG_EN	0 – All watchdogs are disabled during boot 1 – WDOG1 is enabled during boot, the others are disabled. Refer to Boot Watchdog for more information.	0
BOOT_CFG7[11:9]	WDOG_TIMEOUT_SEL	WDOG1 timeout 0 – 128s 1 – 64s 2 – 32s 3 – 16s 4 – 8s 5 - 4s 6 - 2s 7 - 1s	0
BOOT_CFG7[15:12]	Reserved	Must be 0	0
BOOT_CFG7[16]	DIS_POR_PRELOAD_M33_TCM_ECC	0 – Cortex-M33 TCMs are preloaded with 0s by ROM 1 – Cortex-M33 TCMs are not preloaded with 0s by ROM Refer to TCM ECC Configuration for more information.	0
BOOT_CFG7[17]	POR_PRELOAD_M7_TCM_ECC_EN	0 – Cortex-M7 TCMs are not preloaded with 0s by ROM 1 – Cortex-M7 TCMs are preloaded with 0s by ROM (requires RELEASE_M7_RST_STAT to be set) Refer to TCM ECC Configuration for more information.	0
BOOT_CFG7[18]	RELEASE_M7_RST_STAT	Determine whether ROM will release Cortext-M7 Core reset and let it run. 0 – Cortex-M7 Reset is kept as hold 1 – Cortex-M7 Reset is released by ROM Refer to TCM ECC Configuration for more information.	0
BOOT_CFG7[19]	BOOT_FREQ	Select the boot core and bus frequency source. 0 – Derived from RCOSC200M 1 – Derived from PLL3	0

Table continues on the next page...

Table 54. MISC Fuse definitions (continued)

Fuse	Definitions	Settings	Shipped Value
		Refer to Clock Configuration for Boot ROM for more information.	
BOOT_CFG7[20]	XMC_CRC32_CHECK_EN	0 – XMCD CRC32 check is disabled 1 – XMCD CRC32 check is enabled Refer to External Memory Configuration Data (XMCD) for more information.	0
BOOT_CFG7[23:16]	Reserved	Must be 0	0
BOOT_CFG8[31:0]	XMC_CRC32_CHECK_SUM	XMCD CRC32 sum value Refer to External Memory Configuration Data (XMCD) for more information.	0
BOOT_CFG9[31:0]	Reserved	Must be 0	0
BOOT_CFG10[31:0]	Reserved	Must be 0	0
BOOT_CFG11[31:2]	Reserved	Must be 0	0

12.4.3 TCM ECC Configuration

The TCM ECC is enabled by default on this device. Any access to the TCM memories will cause an ECC error thrown out after a POR reset due to the TCM Memories are filled with invalid random bytes.

ROM offers a TCM preloading features to clear the TCM memories to all 0s after a POR reset. ROM will always perform a preloading for the entire Cortex-M33 Code TCM and System TCM. This operation can be canceled by setting DIS_POR_PRELOAD_M33_TCM_ECC fuse. ROM will perform a preloading for the entire Cortex-M7 ITCM and DTCM when POR_PRELOAD_M7_TCM_ECC_EN and RELEASE_M7_RST_STAT are set. Once RELEASE_M7_RST_STAT is set, ROM will release the Cortex-M7 core reset. Once the Cortex-M7 Core is released from reset, the default initial vector address (0x0) will be loaded into Cortex-M7 core, which means that the Cortex-M7 core can only start to run from address 0x0.

ROM also offers a user-configurable TCM preloading for the other types of reset. GPR9 low half-word is used for Cortex-M33 TCM preloading while high half-word is used for Cortex-M7 TCM preloading. Write 0x4646(ASICII code for “FF”, the abbreviation of “Forced Filling”) to the bitfield before issuing reset to activate the ROM execution. The writing is one-shot, ROM will clear the relative bitfield and then perform the preloading. User-configuration only takes effect when the relative ROM TCM preloading feature is enabled by setting DIS_POR_PRELOAD_M33_TCM_ECC and POR_PRELOAD_M7_TCM_ECC_EN correctly.

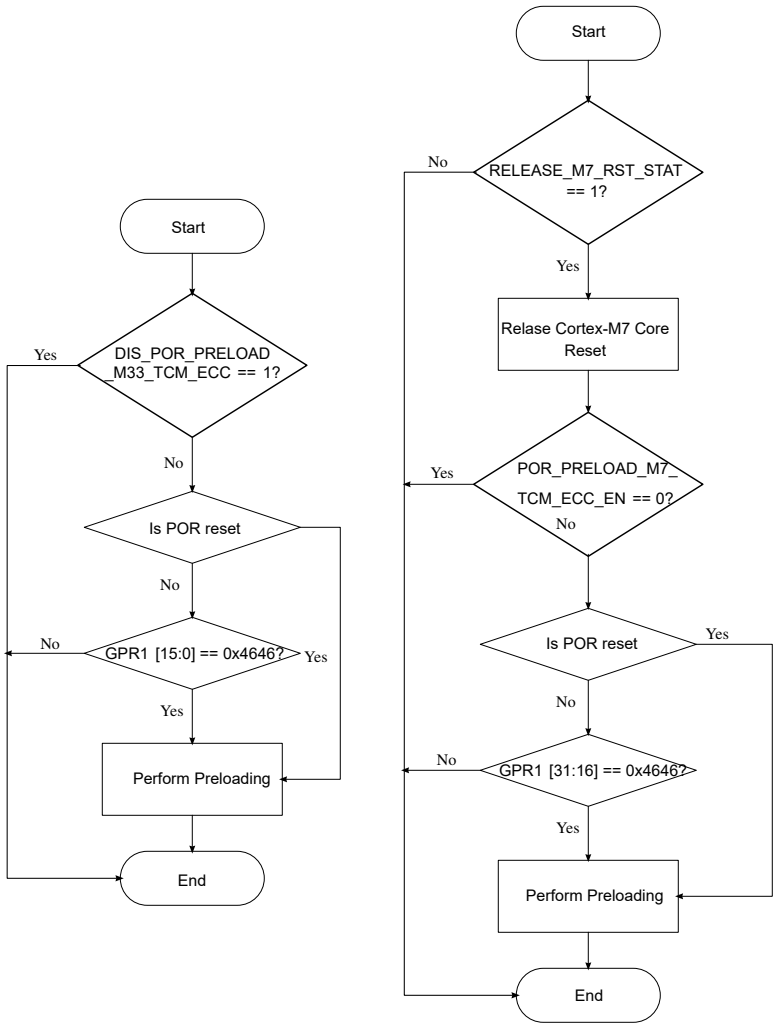

Figure 38. TCM ECC Configuration

NOTE

TCM preloading will increase the boot time significantly. If a user is concerned about the boot time, related fuses must be blown to optimize the boot time.

12.4.4 Clock Configuration for Boot ROM

The boot ROM configures the clocks of the boot core, bus, and other required controllers to a high frequency of clock roots during boot for high-performance consideration. When the user's application needs to re-configure the clock roots, PLLs or the PFDs, the SoC may crash if the clocks are not handled properly. To avoid such issues the following suggestions must be applied:

- Switch the root clock of the boot core, bus, and other affected controllers to a fixed clock root. before configuring the clocks.
- Configure the clock of each peripheral explicitly instead of relying on the default settings listed in the Reference Manual.

The following table provide the clock frequency configurations.

Table 55. Clock Configurations for Boot ROM

Clocks	BOOT_FREQ = 0		BOOT_FREQ=1	
	Clock Root	Frequency	Clock Root	Frequency
M33 Clock	RCOSC200M	200MHz	PLL3_CLK	240MHz
Edgelock Clock	RCOSC200M	133MHz	PLL2_PFD1_CLK	200MHz
Bus Aon Clock	RCOSC200M	100MHz	PLL2_CLK	132MHz
Bus Wakeup Clock	RCOSC200M	100MHz	PLL2_CLK	132MHz
Wakeup AXI Clock	RCOSC200M	133MHz	PLL3_CLK	160MHz
FlexSPI1 Clock	PLL3_PFD0_CLK	The value varies at different frequencies	The same values as for BOOT_FREQ = 0	
FlexSPI2 Clock	PLL3_PFD2_CLK	The value varies at different frequencies		
LPUART1 Clock	PLL3_DIV2_CLK	80MHz		
LPSPI1,2,3,4,5,6 Clock	PLL2_CLK	The value varies at different frequencies		
USDHC1 Clock	PLL2_PFD2_CLK	198MHz	The same values as for BOOT_FREQ = 0	
USDHC1 Clock	PLL2_PFD2_CLK	396MHz		
SEMC Clock	PLL2_PFD0_CLK	The value varies at different frequencies	The same values as for BOOT_FREQ = 0	
USB Clock	PLL3_CLK	480MHz		

12.4.5 ROM Settings and Considerations for User Applications

The registers in the modules listed below may be updated if they are in use for specific boot modes. ROM does not restore the registers in these modules after they are updated. The user application should not rely on the default values of the registers in these modules.

- FlexSPI1 - if the device boots from memory connected to FlexSPI1.
- FlexSPI2 - if the device boots from memory connected to FlexSPI2.
- uSDHC1 - if the device boots from memory connected to uSDHC1.
- uSDHC2 - if the device boots from memory connected to uSDHC2.
- SEMC - if the device boots from memory connected to SEMC.
- FlexSPI1, FlexSPI2, uSDHC1, uSDHC2, SEMC, LPSPI1, LPSPI2, LPSPI4, and LPSPI5 - if the device boots from memory connected to relative modules.
- USB1, USB-PHY1, LPUART1, and LPSPI1 - if serial downloader is used.
- ANADIG_OSC - The OSC related configurations are not restored.
- ANADIG_PMU - The ANADIG PMU related settings are not restored.

- ANADIG_PLL - The ANADIG_PLL related settings are not restored (e.g. PLL_480_CTRL, PLL_480_PFD, PLL_528_CTRL, PLL_528_PFD).
- CCM - The clock settings for the modules used during boot are not restored.
- IOMUXC - cannot fully be restored because some settings are still in use before leaving ROM.
- WDOG1-5 - disabled by ROM.
- SRC GPR - ROM occupies SRC GPR0-GPR4 and GPR9.

12.4.6 Error Handling

12.4.6.1 Exception Handling

All types of Faults cause SYSRESETREQ, including the following:

- HardFault, BusFault, MemMangeFault, UsageFault
- ROM boot flow mismatch (treated as a side-channel attack)
- Illegal ROM configuration (treated as a side-channel attack)

12.4.6.2 Boot Failure Indicator

ROM indicates the following failure(s) if the boot failure indicator feature is enabled by the BOOT_FAIL_IND_EN and BOOT_FAIL_IND_PIN fuse fields.

- The primary/recovery/manufacturing boot failed before entering serial downloader

12.4.6.3 Boot Watchdog

ROM provides the WDOG feature if the WDOG_EN fuse is blown. The WDOG_TIMEOUT_SEL fuse field provides the pre-defined timeout value.

WDOG1 is enabled and serviced by ROM during booting if the WDOG feature is enabled.

ROM will not disable the WDOG after booting, and application needs to keep servicing the WDOG or disable it.

12.4.7 Persistent Bits

Some modes of the boot ROM require the registers that keep their values after a warm reset. The SRC General-Purpose registers are used for this purpose. During ROM execution, neither registers can be changed, otherwise, the ROM behavior is unexpectable.

The following table provides the list of persistent bits and their descriptions.

Table 56. Persistent bits

Bit location	Bit name	Description
GPR0[31:0]	SRSR_BACKUP	32-bit value of SRC[SRSR] backed up at the beginning of error recovery fast boot flow for user application. See Error Recovery Fast Boot for more information.
GPR1[15:0]	FORCE_M33_TCM_LOADING	Force to preload zeros to M33 TCMs for user application, no matter it is a POR reset or a warm reset. See TCM ECC Configuration for more information.

Table continues on the next page...

Table 56. Persistent bits (continued)

Bit location	Bit name	Description
GPR1[31:16]	FORCE_M7_TCM_LOADING	Force to preload zeros to M7 TCMs for user application, no matter it is a POR reset or a warm reset. Refer to TCM ECC Configuration for more information.
GPR2[31:0]	FLASH_STATUS_CTX	Flash status context. This field logs the flash state during boot, so that the flash driver can retrieve the state of the flash and operate the flash devices properly.
GPR3[31:0]	ROM_API_CTX	ROM API context. See Enter Bootloader API for more information.
GPR9[15:0]	BOOT_STAGE	ROM current boot stage.
GPR9[26]	SECONDARY_BOOT	This bit identifies which image must be used — primary and secondary. Used only for eMMC/SD/FlexSPI NOR boot.
GPR9[27:26]	REDUNDANT_BOOT	This field identifies which image must be used - 0/1/2/3. Used for both SPI NAND and SLC raw NAND devices.

12.5 Boot Devices

The chip supports the following boot flash devices:

- Serial NOR Flash via FlexSPI Interface
- Serial NAND Flash via FlexSPI Interface
- NAND Flash with SEMC interface, located on CS0, 8-bit/16-bit bus width.
- SD/eMMC via uSDHC interface, supporting high capacity cards.
- Serial NOR/EEPROM via LPSPI

The selection of the external boot device type is controlled by the BOOT MODE. Refer to Boot Modes for more information.

12.5.1 Serial NOR Flash Boot via FlexSPI

12.5.1.1 Serial NOR FUSE Configuration

Table 57. Fuse definition for Serial NOR over FlexSPI

Fuse	Definition	Settings	Shipped Value
BOOT_CFG1[1:0]	XSPI_NOR_PROBE_TYPE	0 - JESD216 1 - MXIC Octal 2 - Micron Octal 3 - Adesto Octal	0
BOOT_CFG1[3:2]	XSPI_NOR_HOLD_TIME	0 - 500us 1 - 1ms 2 - 3ms	0

Table continues on the next page...

Table 57. Fuse definition for Serial NOR over FlexSPI (continued)

Fuse	Definition	Settings	Shipped Value
		3 - 10ms	
BOOT_CFG1[6:4]	XSPI_NOR_FREQ	0 - 100MHz 1 - 120MHz 2 - 133MHz 3 - 166MHz 4 - 200MHz 5 - 80MHz 6 - 60MHz 7 - 50MHz	0
BOOT_CFG1[7]	XSPI_NOR_CONNECTION_SEL	0 - PORTA CS0 1 - PORTB CS0	0
BOOT_CFG1[10:8]	XSPI_NOR_TYPE	0 - Boot with default 0x03 Read 1 - Reserved 2 - HyperFLASH 1V8 3 - HyperFLASH 3V0 4 - MXIC Octal Read 5 - Micron Octal DDR Read Others - Reserved	0
BOOT_CFG1[11]	RST_REQUIRED	0 - No system reset after NOR boot failure 1 - System reset after NOR boot failure	0
BOOT_CFG1[12]	XSPI_NOR_RESET_TYPE	0 - Reset sequence is specified in FLASH_STATE_CTX Register 1 - Reset FLASH by Reset Pin before access 2 - Reset FLASH by JEDEC Hardware Reset flow 3 - Typical Reset Sequence (0x66, 0x99)	0
BOOT_CFG1[16]	XSPI_NOR_ENCRYPT_XIP_EN	0 - Encrypted XIP is disabled 1 - Encrypted XIP is enabled	0
BOOT_CFG1[17]	XSPI_NOR_ENCRYPT_ENG	0 - OTFAD 1 - IEE	0
BOOT_CFG1[19:18]	XSPI_NOR_FCB_OFFSET	0 - 0x400 1 - 0x600 2 - 0xA00	0

Table continues on the next page...

Table 57. Fuse definition for Serial NOR over FlexSPI (continued)

Fuse	Definition	Settings	Shipped Value
		3 - 0xC00	
BOOT_CFG1[20]	DIS_XSPI_NOR_FCB	0 - Enable FLASH CFG Block 1 - Disable FLASH CFG Block	0
BOOT_CFG2[0]	XSPI_PAD_SLEW_OVERRIDE	0 - Fast 1 - Slow	0
BOOT_CFG2[1]	XSPI_PAD_DRIVE_OVERRIDE	0 - Normal Driver 1 - High Driver	0
BOOT_CFG2[2]	XSPI_PAD_PULL_OVERRIDE	0 - Float 1 - Internal Pulled	0
BOOT_CFG2[3]	XSPI_PAD_OVERRIDE_EN	0 - Use Default Pad Settings 1 - Use Pad Settings from BOOT_CFG2[2:0]	0
BOOT_CFG2[4]	XSPI_RESET_PIN_SEL	0 - Reset Pin Option 0 (GPIO_SD_B1_00) 1 - Reset Pin Option 1 (GPIO_EMC_B1_40)	0
BOOT_CFG2[5]	XSPI_LPB_DQS_PIN_SEL	0 - Dummy DQS Pin Used for Loopbacked DQS 1 - Standard DQS Pin Used for Loopbacked DQS	0
BOOT_CFG2[6]	XSPI_PIN_GROUP_SEL	0 - Primary Pin Group Selected 1 - Secondary Pin Group Selected	0
BOOT_CFG2[7]	XSPI_INSTANCE	0 - FlexSPI1 1 - FlexSPI2	0
BOOT_CFG2[12:8]	XSPI_DELAY_CELL_NUM	0 - Use the Delay cell value calculated by ROM Others - Use the Delay cell value in terms of 100ps	0
BOOT_CFG7[5:0]	XSPI_2ND_IMG_OFFSET	0 - No 2nd physical image presend n - 2nd physical image located at XSPI_2ND_IMG_SIZE_UNIT * n	0
BOOT_CFG7[21]	XMC_DISABLE	0 - Enabled 1 - Disabled	0
BOOT_CFG7[7:6]	XSPI_2ND_IMG_SIZE_UNIT	0 - 256KB, 1 - 1MB 2 - 4MB 3 - 16MB	0

NOTE

If the xSPI FLASH Auto Probe feature is enabled, the following is the logic of how this feature works with other fuse combinations:

- Flash Type - If Flash type is 0, the "xSPI FLASH Auto Probe Type" takes effect for the Flash type selection. If Flash Type is greater than 1, the "Flash Type" fuse is used for Flash type selection, ROM will issue specific command to probe the presence of Serial NOR FLASH.
- xSPI FLASH Frequency - This field is used for specifying the Flash working frequency.

12.5.1.2 FlexSPI Serial NOR Flash Boot Operation

The Boot ROM attempts to boot from Serial NOR flash if boot pins/BOOT_CFG0 fuse bits are configured correspondingly, then the ROM will initialize the FlexSPI interface. FlexSPI interface initialization is a two-step process.

1. The ROM expects the 512-byte FlexSPI NOR configuration parameters (refer to Serial NOR Flash Configuration Block (512 bytes)) to be present at offset 0x400 (ROM supports four FCBs, user can decide which one to use via Fuse XSPI_NOR_FCB_OFFSET if DIS_XSPI_NOR_FCB is not set) in Serial NOR flash attached to FLEXSPI_A_SS0_B. The ROM can probe the presence of Serial NOR Flash and generate these configuration parameters accordingly via the combination of Fuses in Table 57, or reads these configuration parameters using the read command specified with XSPI_NOR_TYPE with serial clock operating at 30 MHz.
2. ROM configures FlexSPI interface with the parameters provided in configuration block read from Serial NOR flash and starts the boot procedure. Refer to Table 65 for details regarding FlexSPI configuration parameters and to the FlexSPI NOR boot flow chart for the detailed boot flow of FlexSPI NOR.

Booting both XIP and non-XIP images is supported from the Serial NOR Flash. For XIP boot, the image has to be built for the FlexSPI address space. For non-XIP boot, the image can be built to execute from internal RAM.

NOTE

A non-XIP image's execute address space should NOT overlap with the reserved OCRAM region described in the section "Internal ROM/RAM memory map". It is also highly recommended to avoid using the address space near 0x0000_0000, typically up to 0x0000_0003.

12.5.1.3 FlexSPI NOR Boot Flow Chart

The FlexSPI NOR boot flow is provided below.

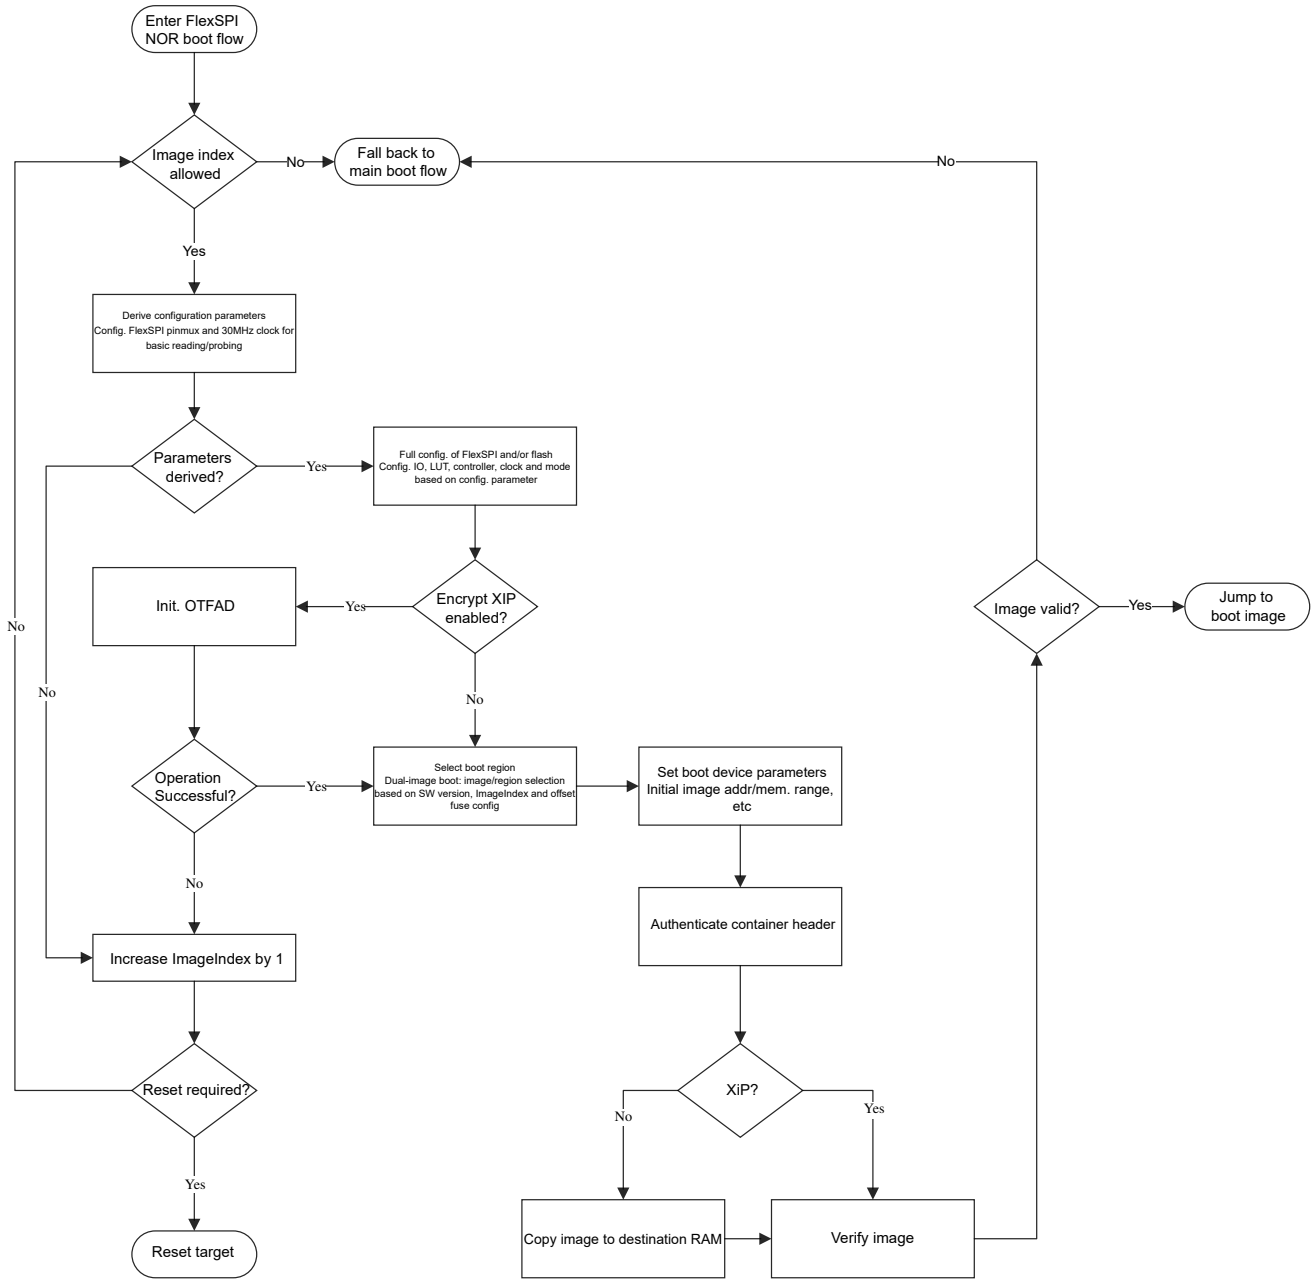

Figure 39. FlexSPI NOR boot flow

12.5.2 Serial NAND Flash Boot via FlexSPI

The boot ROM supports a number of Serial NAND Flash devices from different vendors. NAND devices' built-in ECC function is required.

NOTE

OEM image container can not cross NAND page.

12.5.2.1 Serial NAND FUSE Configuration

The boot ROM determines the configuration of external Serial NAND flash by parameters, either provided by fuses, or sampled on GPIO pins during boot. See the following table for parameters details.

Table 58. Fuse definition for Serial NAND over FlexSPI

Fuse	Definition	Settings	Shipped Value
BOOT_CFG2[4]	XSPI_RESET_PIN_SEL	0 - Reset Pin Option 0 (GPIO_SD_B1_00) 1 - Reset Pin Option 1 (GPIO_EMC_B1_40)	0
BOOT_CFG2[6]	XSPI_PIN_GROUP_SEL	0 - Primary Pin Group Selected 1 - Secondary Pin Group Selected	0
BOOT_CFG2[7]	XSPI_INSTANCE	0 - FlexSPI1 1 - FlexSPI2	0
BOOT_CFG3[0]	XSPI_NAND_SEARCH_CNT	0 - Search at most 1 block (for BCB) 1 - Search at most 2 blocks	0
BOOT_CFG3[1]	XSPI_NAND_COL_ADDR_WIDTH	0 - 12 bits (for 2KB-page devices) 1 - 13 bits (for 4KB-page devices)	0
BOOT_CFG3[3:2]	XSPI_NAND_CS_INTERVAL	CS de-asserted interval between two commands 0 - 100ns 1 - 200ns 2 - 400ns 3 - 50ns	0
BOOT_CFG3[5:4]	XSPI_NAND_SEARCH_STRIDE	BCB search step/stride, aligned with block size 0 - 64 pages 1 - 128 pages 2 - 256 pages 3 - 32 pages	0
BOOT_CFG3[7:6]	XSPI_NAND_HOLD_TIME	Hold time before interaction with NAND 0 - Wait until NAND is idle (by polling NAND's status register) 1 - 500us 2 - 1ms 3 - 3ms	0
BOOT_CFG3[11:10]	XSPI_NAND_RST_TYPE	0 - No reset before interaction with NAND 1 - Reset the NAND with 0xFF 2 - Reset the NAND with 0x66, 0x99 3 - Reset the NAND with dedicated Reset Pin	0

Table continues on the next page...

Table 58. Fuse definition for Serial NAND over FlexSPI (continued)

Fuse	Definition	Settings	Shipped Value
BOOT_CFG3[12]	XSPI_NAND_CONN_SEL	0 - Connected via PORTA CS0 1 - Connected via PORB CS0	0
BOOT_CFG3[18:16]	XSPI_NAND_FREQ	0 - 80MHz 6 - 60MHz 7 - 30MHz Otherwise - Reserved	

NOTE

All the fuse fields in BOOT_CFG2 are there for FCB derivation stage. After successful FCB derivation, FlexSPI is re-configured as per FCB.

12.5.2.2 FlexSPI NAND Flash Boot Flow and Boot Control Blocks (BCB)

There are two BCB data structures:

- FCB
- DBBT

As part of the NAND media initialization, the ROM driver uses safe NAND timings to search for a Firmware Configuration Block (FCB) that contains the optimum NAND timings, page address of Discovered Bad Block Table (DBBT) Search Area and start page address of primary and secondary firmware.

The built-in HW ECC in Serial NAND device is used during data read, the FCB data structure is protected using CRC checksum. Driver reads raw 2048 bytes of first sector and runs through CRC check that determines whether FCB data is valid or not.

If the FCB is found, the optimum NAND timings are loaded for further reads. If the ECC fails, or the fingerprints do not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next BCB until SearchCount pages have been read.

If search fails to find a valid FCB, the NAND driver responds with an error and the boot ROM falls back to the main boot flow (e.g., turn to recovery boot).

The FCB contains the page address of DBBT Search Area, and the page address for primary and secondary boot images. ROM searches DBBT Search Area for DBBT, resembling the search for FCB. After the FCB is derived, the DBBT is loaded, and the primary or secondary boot image is loaded using starting page address from FCB.

Figure 40 shows the state diagram of FCB search.

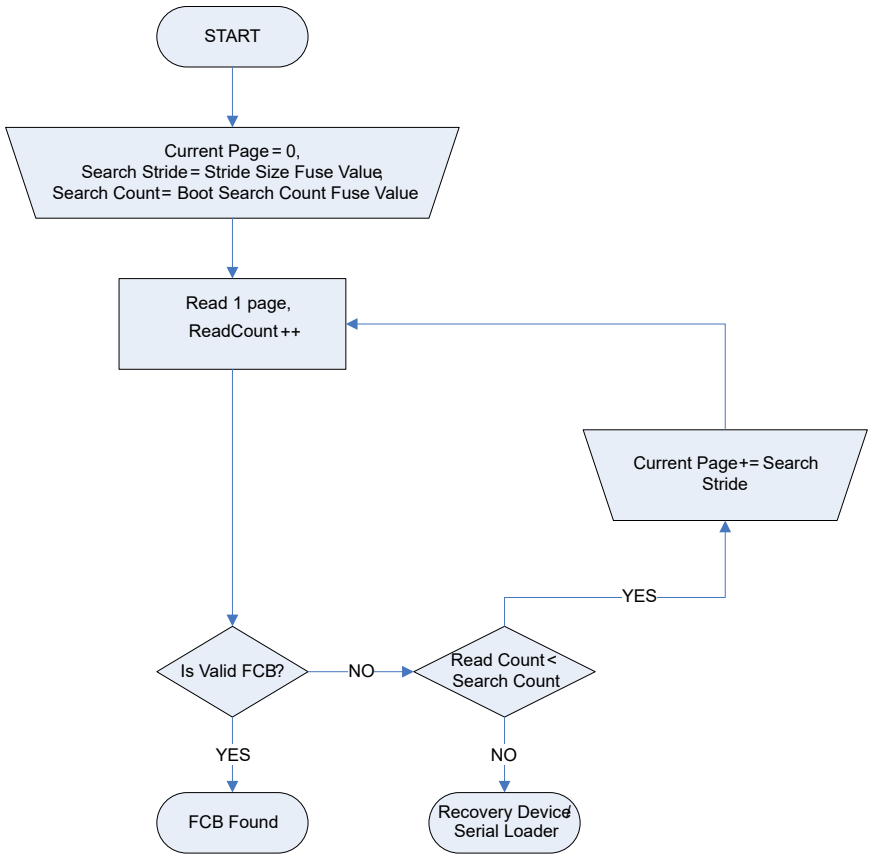

Figure 40. FCB Search Flow

After FCB is found, the boot ROM searches for the Discovered Bad Blocks Table (DBBT). If DBBTSearchStartPage is 0 in the FCB, then ROM assumes that there are no bad blocks in the NAND device boot area. See Figure 41 for the DBBT search flow.

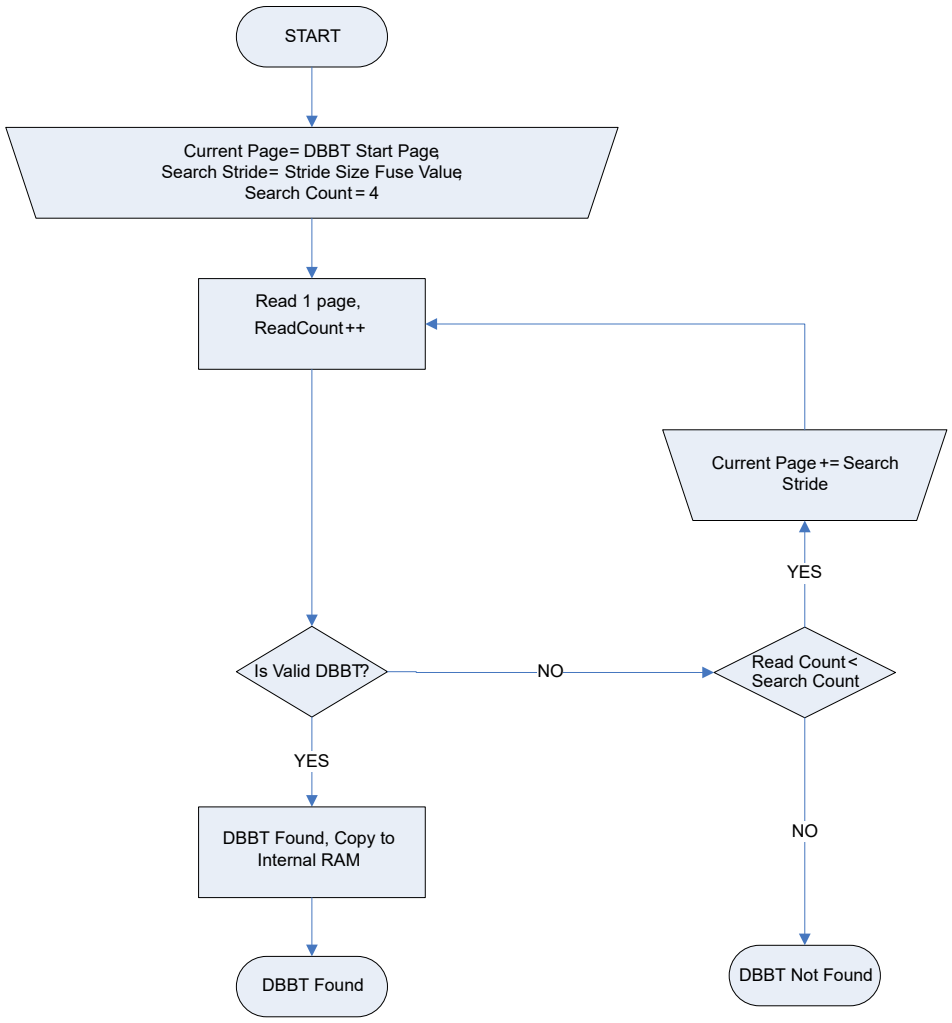

Figure 41. DBBT Search Flow

If during primary image read there is a page with a number of errors higher than ECC can correct, the boot ROM will turn on PERSIST_REDUNDANT_BOOT bit and try a secondary image.

If during secondary image read there is a page with number of errors higher than ECC can correct, the boot ROM goes back to main boot flow.

12.5.2.3 Firmware Configuration Block (FCB)

The Firmware Configuration Block (FCB) is at the first page in the first good block. The FCB should be present at each search stride of the search area.

The search area contains copies of the FCB at each stride distance, in case the first Serial NAND block becomes corrupted, the ROM will find its copy in the next Serial NAND block. The search area should span over at least two Serial NAND blocks. The location information for DBBT search area and images are all specified in the FCB. The following table shows the Flash Control Block Structure.

Table 59. Flash Control Block Structure

Name	Offset	Size Bytes	Description
crcChecksum	0x000	4	Checksum
fingerprint	0x004	4	0x4E46_4342 ASCII: “NFCB”
version	0x008	4	0x0000_0001
DBBTSearchStartPage	0x00C	4	Start Page address for bad block table search area
searchStride	0x010	2	Search stride for DBBT and FCB search. Not used by ROM Max value is 8.
searchCount	0x012	2	Copies of DBBT and FCB. Not used by ROM, max value is 8.
firmwareCopies	0x014	4	Firmware copies Valid range 1-4.
Reserved	0x018	40	Reserved for future use Must be set to 0.
firmwareInfoTable	0x40	64	This table consists of (up to 8 entries): **Field** / **Size** / **Description** StartPage / 4 / Start page of this firmware page Count / 4 / Pages in this firmware **NOTE** The StartPage must be the first page of a NAND block.
Reserved	0x080	128	Reserved Must be set to 0
spiNandConfigBlock	0x100	512	Serial NAND Flash configuration block over FlexSPI. Refer to Serial NAND Flash Configuration Block (512 bytes) for details.
Reserved	0x300	256	Must be set to 0

NOTE

1. The “crcChecksum” is calculated with an MPEG2 variant of CRC-32. See Table 60 for more details.
2. The “crcChecksum” calculation starts from fingerprint to the end of FCB, 1020 bytes in total.
3. The “spiNandConfigBlock” is FlexSPI NAND configuration block which consists of common FlexSPI memory configuration block and Serial NAND specified configuration parameters.

Table 60. CRC-32 variant algorithm

Property	Description
Width	32 bits
Polynomial	0x04C11DB7
Init Value	0xFFFFFFFF
Reflect in	False
Reflect Out	False
XOR Out	0x00000000

12.5.2.4 Discovered Bad Blocks Table (DBBT)

Table 61. DBBT Structure

Name	Offset	Size in Bytes	Description
crcChecksum	0x000	4	Checksum
Fingerprint	0x004	4	32-bit word with a value of 0x4442_4254, in ASCII “DBBT”
Version	0x008	4	32-bit version number, this version of DBBT is 0x00000001
-	0x00C	4	Reserved
badBlockNumber	0x010	4	Number of bad blocks
Reserved	0x014	12	Must be filled with 0x00s
Bad Block entries	0x020	1024 (256*4)	Each bad block entry is a 32- bit value specifying the number of a found bad block. The number of valid bad block entries is specified by the badBlockNumber field, where valid bad block entries are stored sequentially starting at the beginning of the bad block entries segment. Unused bad block entries (those beyond the badBlockNumber) should be filled with 0xFs.

NOTE

1. Maximum badBlockNumber is 256.
2. The "crcChecksum" is calculated with the same algorithm as the one in FCB, from Fingerprint to the end of DBBT, 1052 bytes in total.

12.5.2.5 Bad Block Handling in ROM

During the firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block.

If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

12.5.3 Serial NOR and NAND Flash Configuration based on FlexSPI Interface

The ROM SW supports Serial NOR Flash and Serial NAND Flash based on FlexSPI module, using a 448-bytes common FlexSPI configuration block and several specified parameters for Serial NOR Flash and Serial NAND Flash respectively. See the following sections for more details.

12.5.3.1 FlexSPI Configuration Block

FlexSPI Configuration block consists of parameters regarding specific Flash devices including read command sequence, quad mode enablement sequence (optional), etc.

Table 62. FlexSPI Configuration block

Name	Offset	Size(bytes)	Description
Tag	0x000	4	0x42464346, ascii: 'FCFB'
Version	0x004	4	[07:00] bugfix = 0 [15:08] minor [23:16] major = 1 [31:24] ascii ‘V’
-	0x008	4	Reserved
readSampleClkSrc	0x00C	1	0 – internal loopback 1 – loopback from DQS pad 3 – Flash provided DQS
csHoldTime	0x00D	1	Serial Flash CS Hold Time Recommend default value is 0x03
csSetupTime	0x00E	1	Serial Flash CS setup time Recommended default value is 0x03
columnAdressWidth	0x00F	1	3 – For HyperFlash 12/13 – For Serial NAND, see the NAND FLASH datasheet to find the correct value 0 – Other devices
deviceModeCfgEnable	0x010	1	Device Mode Configuration Enable feature 0 – Disabled 1 – Enabled
deviceModeType	0x011	1	0 - Generic 1 - Quad Enable

Table continues on the next page...

Table 62. FlexSPI Configuration block (continued)

Name	Offset	Size(bytes)	Description
			2 - SPI-to-xSPI mode 3 - xSPI-to-SPI mode 4 - SPI-to-NoCmd mode
waitTimeCfgCommands	0x012	2	Wait time for all configuration commands, unit 100us. Available for device that support v1.1.0 FlexSPI configuration block. If it is greater than 0, ROM will wait waitTimeCfgCommands * 100us for all device memory configuration commands instead of using read status to wait until these commands complete.
deviceModeSeq	0x014	4	Sequence parameter for device mode configuration Bit[7:0] - number of LUT sequences for Device mode configuration command Bit[15:8] - starting LUT index of Device mode configuration command Bit[31:16] - must be 0
deviceModeArg	0x018	4	Device Mode argument, effective only when deviceModeCfgEnable = 1
configCmdEnable	0x01C	1	Config Command Enable feature 0 – Disabled 1 – Enabled
-	0x01D	3	Reserved
configCmdSeqs	0x020	12	Sequences for Config Command, allow 3 separate configuration command sequences.
-	0x02C	4	Reserved
cfgCmdArgs	0x030	12	Arguments for each separate configuration command sequence.
-	0x03C	4	Reserved
controllerMiscOption	0x040	4	Bit0 – differential clock enable Bit1 – CK2 enable, must set to 0 in this silicon Bit2 – ParallelModeEnable Bit3 – wordAddressableEnable Bit4 – Safe Configuration Frequency enable set to 1 for the devices that support DDR Read instructions Bit5 – Pad Setting Override Enable

Table continues on the next page...

Table 62. FlexSPI Configuration block (continued)

Name	Offset	Size(bytes)	Description
			Bit6 – DDR Mode Enable, set to 1 for device supports DDR read command Bit 7 - Pad Setting Override Enable Bit 8 - Second Pin group Bit 9 - Second DQS pin group Bit 10 - Write Mask Enable Bit 11 - Write Opt1 Clear
deviceType	0x044	1	1 – Serial NOR 2 – Serial NAND 3 - Serial RAM (HyperRAM/APMemory)
sflashPadType	0x045	1	1 – Single pad 2 – Dual pads 4 – Quad pads 8 – Octal pads
serialClkFreq	0x046	1	Chip specific value, for this silicon 1 – 30 MHz 2 – 50 MHz 3 – 60 MHz 4 – 80 MHz 5 – 100 MHz 6 – 120 MHz 7 – 133 MHz 8 – 166 MHz Other value: 30 MHz
lutCustomSeqEnable	0x047	1	0 – Use pre-defined LUT sequence index and number 1 - Use LUT sequence parameters provided in this block
-	0x048	8	Reserved
sflashA1Size	0x050	4	For SPI NOR, need to fill with actual size For SPI NAND, need to fill with actual size * 2
sflashA2Size	0x054	4	The same as above
sflashB1Size	0x058	4	The same as above
sflashB2Size	0x05C	4	The same as above

Table continues on the next page...

Table 62. FlexSPI Configuration block (continued)

Name	Offset	Size(bytes)	Description
csPadSettingOverrideEn	0x060	1	Set to 0 if it is not supported
csPadSettingOverride	0x061	1	Overriding pad setting of CS
sclkPadSettingOverrideEn	0x064	1	Set to 0 if it is not supported
sclkPadSettingOverride	0x065	1	Overriding pad setting of SCLK
dataPadSettingOverrideEn	0x068	1	Set to 0 if it is not supported
dataPadSettingOverride	0x069	1	Overriding pad setting of data signals
dqsPadSettingOverrideEn	0x06C	1	Set to 0 if it is not supported
dqsPadSettingOverride	0x06D	1	Overriding pad setting of DQS
timeoutInMs	0x070	4	Maximum wait time during read busy status 0 – Disabled timeout checking feature Other value – Timeout if the wait time exceeds this value
commandInterval	0x074	4	Unit: ns Currently, it is used for SPI NAND only at high frequency
dataValidTime	0x078	4	Time from clock edge to data valid edge, unit ns. This field is used when the FlexSPI Root clock is less than 100 MHz and the read sample clock source is device provided DQS signal without CK2 support. [31:16] data valid time for DLLB in terms of 0.1 ns [15:0] data valid time for DLLA in terms of 0.1 ns
busyOffset	0x07C	2	busy bit offset, valid range :0-31
busyBitPolarity	0x07E	2	1. 0 – busy bit is 1 if device is busy 2. 1 – busy bit is 0 if device is busy
lookupTable	0x080	256	Lookup table
lutCustomSeq	0x180	48	Customized LUT sequence, see below table for details.
	0x1B0	16	Reserved for future use

Note:

1. To customize the LUT sequence for some specific device, users need to enable “lutCustomSeqEnable” and fill in corresponding “lutCustomSeq” field specified by command index below.
2. For Serial (SPI) NOR, the pre-defined LUT index is as follows:

Table 63. LUT sequence definition for Serial NOR

Command Index	Name	Index in lookup table	Description
0	Read	0	Read command Sequence
1	ReadStatus	1	Read Status command
2	WriteEnable	3	Write Enable command sequence
3	EraseSector	5	Erase Sector Command
4	PageProgram	9	Page Program Command
5	ChipErase	11	Full Chip Erase
6	Dummy	15	Dummy Command as needed
7-12	Reserved	2,4,6,7,8,10,12,13,14	All reserved indexes can be freely used for other purpose
13	NOR_CMD_LUT_SEQ_IDX_READ_SFDP	13	Read SFDP sequence in lookupTable id stored in config block
14	NOR_CMD_LUT_SEQ_IDX_RESTORE_NOCMD	14	Restore 0-4-4/0-8-8 mode sequence id in lookupTable stored in config block

3. For Serial (SPI) NAND, the pre-defined LUT index is as follows:

Table 64. LUT sequence definition for Serial NAND

Command Index	Name	Index in lookup table	Description
0	ReadFromCache	0	Read from cache
1	ReadStatus	1	Read Status
2	WriteEnable	3	Write Enable
3	BlockErase	5	Erase block
4	ProgramLoad	9	Program Load
5	ReadPage	11	Read page to cache
6	ReadEccStatus	13	Read ECC Status
7	ProgramExecute	14	Program Execute
8	ReadFromCacheOdd	4	Read from Cache while page in odd plane
9	ProgramLoadOdd	10	Program Load for pages within odd blocks
	Reserved	2,6,7,8,12,15	All reserved indexes can be freely used for other purposes

NOTE

1. All the pre-defined LUT indexes are only applicable to boot stage. User application can use the whole 16 LUT entries freely based on their requirement.
2. The FlexSPI NOR ROM APIs occupy LUT index 0-5. User application should **NOT** use these LUT indexes if the ROM API is called in their application frequently.

12.5.3.2 Serial NOR Flash Configuration Block (512 bytes)

Table 65. Serial NOR Flash configuration block

Name	Offset	Size (Bytes)	Description
memCfg	0	448	The common memory configuration block, see FlexSPI configuration block for more details
pageSize	0x1C0	4	Page size in terms of bytes, not used by ROM
sectorSize	0x1C4	4	Sector size in terms of bytes, not used by ROM
ipCmdSerialClkFreq	0x1C8	1	Chip specific value, not used by ROM 0 – No change, keep current serial clock unchanged 1 – 30 MHz 2 – 50 MHz 3 – 60 MHz 4 – 80 MHz 5 – 100 MHz 6 – 120 MHz – 133 MHz
isUniformBlockSize	0x1C9	1	Device has uniform block size 0 - No, block size != sector size 1 - Yes, block size = sector size
isDataOrderSwapped	0x1CA	1	The data order is swapped in OPI DDR mode 0 - Not swapped 1 - Swapped (this is applicable to Macronix MX25UM512/256/128 series only)

Table continues on the next page...

Table 65. Serial NOR Flash configuration block (continued)

Name	Offset	Size (Bytes)	Description
Reserved	0x1CB	5	Reserved
blockSize	0x1D0	4	blockSize
flashStateCtx	0x1D4	4	Flash State Context after being configured [7:0] Flash POR Mode: 0x00 - Extended SPI mode 0x42 - QPI DDR mode 0x82 - OPI DDR mode -- [15:8] Flash Current Mode: 0x00 - Extended SPI mode 0x42 - QPI DDR mode 0x82 - OPI DDR mode -- [23:16] Reserved -- [31:24] Flash Restoring Sequence: 0x6 - Send 0x66_0x99 (Micron Octal Flash) 0x7 - Send 0x6699_0x9966 (Macronix Octal Flash) 0x8 - Send 0x06 0xFF (Adesto Octal Flash)
Reserved	0x1D8	24	Reserved

12.5.3.3 Serial NAND Flash Configuration Block (512 bytes)

Table 66. Serial NAND Flash configuration block

Name	Offset	Size (Bytes)	Description
memCfg	0	448	The common memory configuration block, see FlexSPI configuration block for more details
pageDataSize	0x1C0	4	Page size in terms of bytes, usually, it is 2048 or 4096
pageTotalSize	0x1C4	4	It equals to 2 ^ width of column adddress

Table continues on the next page...

Table 66. Serial NAND Flash configuration block (continued)

Name	Offset	Size (Bytes)	Description
pagesPerBlock	0x1C8	4	Pages in one block
bypassReadStatus	0x1CC	1	0 – Read Status Register 1 – Bypass Read status register
bypassEccRead	0x1CD	1	0 – Perform ECC read 1 – Bypass ECC read
hasMultiPlanes	0x1CE	1	0 – Only 1 plane 1 – Has two planes
skippOddBlocks	0x1CF	1	0 – Read Odd blocks 1 – Skip Odd blocks
eccCheckCustomEnable	0x1D0	1	0 – Use the common ECC check command and ECC related masks 1 - Use ECC check related masks provided in this configuration block
ipCmdSerialClkFreq	0x1D1	1	Chip specific value, not used by ROM 0 – No change, keep current serial clock unchanged 1 – 30 MHz 2 – 50 MHz 3 – 60 MHz 4 – 75 MHz 5 – 80 MHz 6 – 100 MHz 7 – 133 MHz 8 – 166 MHz
readPageTimeUs	0x1D2	2	Wait time during page read, this field will take effect on if the bypassReadStatus is set to 1. **NOTE** Only applicable to ROM.

Table continues on the next page...

Table 66. Serial NAND Flash configuration block (continued)

Name	Offset	Size (Bytes)	Description
eccStatusMask	0x1D4	4	ECC Status Mask
eccFailureMask	0x1D8	4	ECC Check Failure mask
blocksPerDevice	0x1DC	4	Blocks in a Serial NAND
Reserved	0x1ED	32	Reserved for future use

Below is an example of Serial NAND configuration block for Winbond W25N01GVZEIG:

```
const flexspi_nand_config_t kSerialNandCfgBlk =
{
    .memConfig =
    {
        .tag = FLEXSPI_CFG_BLK_TAG,
        .version = FLEXSPI_CFG_BLK_VERSION,
        .readSampleClkSrc = kFlexSPIReadSampleClk_LoopbackInternally,
        .dataHoldTime = 3,
        .dataSetupTime = 3,
        .columnAddressWidth = 12,
        .deviceModeCfgEnable = 1,
        .deviceModeSeq = { 1, 2 },
        .deviceType = kFlexSpiDeviceType_SerialNAND,
        .sflashPadType = kSerialFlash_4Pads,
        .serialClkFreq = kFlexSpiSerialClk_50MHz,
        .lutCustomSeqEnable = 0,
        .sflashA1Size = 128 * 1024 * 1024U * 2, // Flash size = 2 * actual data size (exclude spare
space)
        .lookupTable =
        {
            // Read cache 4 I/0
            [4 * NOR_CMD_LUT_SEQ_IDX_READ] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD, 0xEB, CADDR_SDR,
FLEXSPI_4PAD, 0x10),
            [4 * NOR_CMD_LUT_SEQ_IDX_READ + 1] = FLEXSPI_LUT_SEQ(DUMMY_SDR, FLEXSPI_4PAD, 0x04,
READ_SDR, FLEXSPI_4PAD, 0x80),
            // Clear Status1 flag
            [4 * 2] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD, 0x1F, CMD_SDR, FLEXSPI_1PAD, 0xA0),
            [4 * 2 + 1] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD, 0x00, STOP, FLEXSPI_1PAD, 0x00),
            // Read Page
            [4 * NAND_CMD_LUT_SEQ_IDX_READPAGE] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD, 0x13,
RADDR_SDR, FLEXSPI_1PAD, 0x18),
            // Read Status
            [4 * NAND_CMD_LUT_SEQ_IDX_READSTATUS] = FLEXSPI_LUT_SEQ(CMD_SDR, FLEXSPI_1PAD, 0x0F,

CMD_SDR, FLEXSPI_1PAD, 0xC0),
            [4 * NAND_CMD_LUT_SEQ_IDX_READECCSTAT + 1] = FLEXSPI_LUT_SEQ(READ_SDR, FLEXSPI_1PAD,
0x01, STOP, FLEXSPI_1PAD, 0),
        },
    },
    .pageDataSize = 2048,
    .pageTotalSize = 4096,
    .pagesPerBlock = 64,
};
```

12.5.4 Parallel NAND Flash Boot via SEMC

The boot ROM supports a number of Parallel SLC NAND flash devices from different vendors. Both the Error Correction and Control (ECC) module in NAND device and software ECC algorithm (SECDED) in boot ROM can be used to detect the errors, based on the fuse settings.

12.5.4.1 Parallel NAND eFuse Configuration

The boot ROM determines the configuration of external Parallel NAND flash by parameters, either provided by eFuse, or sampled on GPIO pins, during boot. See below table for parameters details:

Table 67. Fuse definition for Parallel NAND over SEMC

Fuse	Definitions	Settings	Shipped Value
BOOT_CFG5[0]	SEARCH_COUNT	Boot Search count of FCB and DBBT 0 – 1 1 – 2	0
BOOT_CFG5[1]	PORT_WIDTH	I/O port size 0 – 8bit 1 – 16bit	
BOOT_CFG5[2]	ECC_SEL	ECC algorithm selection 0 - NAND Flash built-in ECC 1 – SEMC built-in ECC **NOTE** For “ECC selection” option, it can only be set as NAND Flash built-in ECC When the device has built-in ECC module and the ECC module is enabled by default.	

Table continues on the next page...

Table 67. Fuse definition for Parallel NAND over SEMC (continued)

Fuse	Definitions	Settings	Shipped Value
BOOT_CFG5[3]	ECC_MODE	SEMC BCH ECC mode 0 – BCH4 1 – BCH8	
BOOT_CFG5[4]	EDO_MODE	SEMC EDO mode 0 – EDO mode 1 – Non-EDO mode	
BOOT_CFG5[5]	ACCESS_CMD	SEMC access command 0 – IPG 1 – AXI	
BOOT_CFG5[6]	RDY_POLARITY	RDY pin active polarity 0 – High active 1 – Low active	
BOOT_CFG5[7]	RDY_CHECK_TYPE	RDY pin check type 0 – Via status register 1 – Via R/B# pin	
BOOT_CFG5[10:8]	TIMING_MODE	ONFI timing mode 000 - Mode0 -10MHz 001 - Mode1 -20MHz 010 - Mode2 -28MHz 011 - Mode3 -33MHz 100 - Mode4 -40MHz 101 - Mode5 -50MHz 11x - Fastest Mode	
BOOT_CFG5[11]	Reserved	Must be 0	
BOOT_CFG5[14:12]	PCS_SEL	PCS selection 000 - CS0 001 - CS1 010 - CS2 011 - CS3 100 – A8 Others – CSX0

Table 67. Fuse definition for Parallel NAND over SEMC (continued)

Fuse	Definitions	Settings	Shipped Value
		010 – 16 pages 011 – 32 pages 100 – 64 pages 101 – 256 pages 110 – 512 pages 111 – 1024 pages	
BOOT_CFG5[31]	ONFI_COMPLIANCE_SEL	NAND ONFI compliant 0 – ONFI 1.0 1 – Non-ONFI	

12.5.4.2 Parallel NAND Flash Boot Control Blocks (BCB)

There are two BCB data structures:

- Firmware Configuration Block (FCB)
- Discovered Bad Blocks Table (DBBT)

As part of the Parallel NAND media initialization, the ROM driver uses proper Parallel NAND parameters specified by FUSE to search for an FCB that contains the complete Parallel NAND parameters, page address of DBBT Search Area and Image info, including image copies, start page address and image size in terms of pages for each image.

FCB data structure is protected using Embedded ECC module in Parallel NAND devices or software ECC in ROM. The ROM driver reads 2048 bytes of first sector and checks the ECC check status to determine whether FCB data is valid or not.

If the FCB is found, the complete NAND parameters (Parallel NAND configuration block) are loaded for further reads, if the ECC fails, or the fingerprint does not match, or the CRC checksum does not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next FCB until Search Count pages have been read.

If search fails to find a valid FCB, the Parallel NAND driver responds with an error and the boot ROM enters into Recovery boot mode (Secondary boot, if it is enabled, or Serial download mode).

The FCB contains the page address of DBBT Search Area, and the info for images. DBBT is searched in DBBT Search area just like how FCB is searched. After the FCB is read, the DBBT is loaded, then the boot image is loaded using starting page address from FCB.

12.5.4.3 Firmware Configuration Block (FCB)

The FCB is at the first page in the first good block. The FCB should be present at each search stride of the search area.

The search area contains copies of the FCB at each stride distance, in case the first Serial NAND block becomes corrupted, the ROM will find its copy in the next Parallel NAND block. The search area should span over at least two Parallel NAND blocks. The location information for DBBT search area and images are all specified in the FCB. The following table shows the FCB Structure.

Table 68. FCB Structure

Name	offset	Size (Bytes)	Description
bcbHeader	0x000	12	See Table 69 for details

Table continues on the next page...

Table 68. FCB Structure (continued)

DBBTSerachAreaStartPage	0x00c	4	Start Page address for bad block table search area
searchStride	0x010	2	Search stride for DBBT and FCB search. Not used by ROM Max value is 8.
searchCount	0x012	2	Copies of DBBT and FCB. Not used by ROM, max value is 8.
firmwareCopies	0x014	4	Firmware copies Valid range 1-4.

-	0x080	128	Reserved
nandConfig	0x100	256	Parallel NAND configuration block over SEMC
-	0x200	512	Reserved

Table 69. Header Description

Field	Size	Description
crcChecksum	4	Checksum
fingerprint	4	0x4E46_4342 ASCII: “NFCB”
version	4	0x0000_0001

Table 70. Table Descriptions

Field	Size	Description
startPage	4	Start page of this firmware
pagesInFirmware	4	Pages in this firmware

NOTE

- The “crcChecksum” is calculated with an MPEG2 variant of CRC-32.
- The “crcChecksum” calculation starts from fingerprint to the end of FCB, 1020 bytes in total.
- The “nandConfig” is SEMC NAND configuration block which consists of common SEMC memory configuration block and Parallel NAND specified configuration parameters. See Parallel NAND eFuse Configuration for more details.

12.5.4.4 Discovered Bad Blocks Table (DBBT)

Table 71. DBBT Structure

Name	offset	Size (Bytes)	Description
bcbHeader	0x000	12	See Table 72 for details
-	0x00C	4	Reserved
badBlockNumber	0x010	4	Number of bad blocks
-	0x014	12	Reserved
badBlockTable	0x020	1024 (256*4)	Each bad block entry is a 32-bit value specifying the number of a found bad block. The number of valid bad block entries is specified by the badBlockNumber field, where valid bad block entries are stored sequentially starting at the beginning of the bad block entries segment. Unused bad block entries (those beyond the badBlockNumber) should be filled with 0xFs.

Table 72. Header Description

Field	Size	Description
crcChecksum	4	Checksum
fingerprint	4	0x4442_4254 ASCII: “DBBT”
version	4	0x0000_0001

NOTE

- Maximum bad block number is 256.
- The "crcChecksum" is calculated with the same algorithm as the one in FCB, from Fingerprint to the end of DBBT, 1052 bytes in total.

12.5.4.5 Bad Block Handling in ROM

During the firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block.

If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

12.5.5 Parallel NAND Configuration based on SEMC Interface

The ROM SW supports Parallel NAND based on SEMC module, using an 80-bytes common SEMC configuration block and several specified parameters for Parallel NAND. See the following sections for more details.

12.5.5.1 SEMC Configuration Block

SEMC Configuration block consists of all parameters related to specific Flash devices.

Table 73. SEMC control block structure

12.5.6 eMMC/SD Boot via uSDHC

The boot ROM supports booting from the eMMC and SD compliant devices via either uSDHC ports. The program image will be copied by boot ROM from devices to RAM where the code execution occurs.

The eMMC and SD devices shall match the following standards:

- eMMC which matches JESD84(Embedded Multi-Media Card Electrical Standard) Version 4.2/4.3/4.4/4.41/4.5/5.0
- SDSC, SDHC and SDXC card, which match SD Specifications Version 3.0.

eMMC fast boot mode and SD UHSI mode are supported on all uSDHC ports. eMMC fast boot mode requires JESD84 Version 4.3 or higher. SD UHSI mode is not applied to SDSC card, and can be applied to SDHC and SDXC card.

eMMC multiple partition is supported by fast boot and normal boot, which requires JESD84 Version 4.4 or higher.

12.5.6.1 eMMC/SD Device FUSE Configuration

The ROM determines the configuration of eMMC and SD by the parameters provided by fuses.

Table 76 shows the details of the configurations for eMMC boot.

Table 76. uSDHC Fuse Descriptions for eMMC

Fuse	Definition	Settings	Shipped value
BOOT_CFG4[0]	USDHC_PORT	0– uSDHC1 is used for eMMC boot 1 – uSDHC2 is used for eMMC boot	0
BOOT_CFG4[1]	SION_DISABLE	0 – SION is enabled for uSDHC.CMD line 1 – SION is disabled for uSDHC.CMD line	0
BOOT_CFG4[2]	USDHC1_RST_POLARITY	0 – uSDHC1.RST is active low 1 – uSDHC1.RST is active high	0
BOOT_CFG4[3]	USDHC2_RST_POLARITY	0 – uSDHC2.RST is active low 1 – uSDHC2.RST is active high	0
BOOT_CFG4[5:4]	PWR_CYCLE	uSDHC2.RST active time 0 – 20ms 1 – 10ms 2 – 5ms 3 – 2.5ms	0
BOOT_CFG4[6]	PWR_CYCLE_EN	0 – No power cycle is performed 1 – Power cycle is issued via uSDHCx.RST	0
BOOT_CFG4[7]	PWR_STABLE_CYCLE	Stable time after uSDHC2.RST is turned from active to inactive 0 – 5ms 1 – 2.5ms	0
BOOT_CFG4[8]	MMC_SPEED	eMMC bus speed mode	0

Table continues on the next page...

Table 76. uSDHC Fuse Descriptions for eMMC (continued)

Fuse	Definition	Settings	Shipped value
		0 – Backwards Compatibility with legacy MMC card, Max to 26MHz 1 – High Speed, 52MHz	
BOOT_CFG4[9]	NO_PREIDLE_STATE	0 – Issue GO_PRE_IDLE_STATE command(CMD0 with argument of 0xF0F0F0F0) before starting fastboot 1 – Do not issue GO_PRE_DILE_STATE command	0
BOOT_CFG4[10]	USDHC1_VSEL	Configure the uSDHC1.VSELECT pin output 0 – uSDHC1.VSELECT = 0, 3.3V is supplied to eMMC VCCQ 1 – uSDHC1.VSELECT = 1, 1.8V is supplied to eMMC VCCQ	0
BOOT_CFG4[11]	USDHC2_VSEL	Configure the uSDHC2.VSELECT pin output 0 – uSDHC2.VSELECT = 0, 3.3V is supplied to eMMC VCCQ 1 – uSDHC2.VSELECT = 1, 1.8V is supplied to eMMC VCCQ	0

Table 77. uSDHC Fuse Descriptions for SD (continued)

Fuse	Definition	Settings	Shipped value
		11b – 8	
BOOT_CFG6[30:24]	DLL_DELAY_CALIB_START	The start value for DLL delay calibration during tuning procedure	0
BOOT_CFG6[31]	DLL_DELAY_OVERRIDE	Control if the values in DLL_DELAY_CALIB_STEP and DLL_DELAY_CALIB_START will overwrite the default ones (DLL_DELAY_CALIB_STEP=2, DLL_DELAY_CALIB_START=10) in ROM	0

12.5.6.2 eMMC Boot

The boot ROM supports booting from eMMC normal mode and boot mode.

12.5.6.2.1 eMMC Normal Boot

At the beginning of the initialization, the eMMC frequency is set to 300KHz. ROM puts the eMMC card into the device identification mode by performing a power cycle and sending CMD0 with the argument of 0xF0F0F0F0. Power cycle is controlled by the fuse bits PWR_CYCLE, PWR_CYCLE_EN and PWR_STABLE_CYCLE.

When the eMMC card enters the device identification mode, the boot ROM validates the operation voltage range and the access mode, identifies the device information, and finally assign a Relative Device Address(RCA) to the eMMC card.

The eMMC card enters the data transfer mode once a RCA is assigned to it. The boot ROM switches to the max frequency supported by normal mode(26MHz) to perform the later initializations.

After the initialization phase is complete, the boot ROM switches to the eMMC card clock to the final frequency selected by MMC_SPEED.

For the eMMC card that supports partition management(eMMC version 4.4 or higher), the boot ROM supports booting the images from the selected partitions. The boot ROM reads the BOOT_PARTITION_ENABLE field in EXT_CSD[179] to get the boot partition to be set. If there is no boot partition mentioned in the BOOT_PARTITION_ENABLE field or the user partition was mentioned, the ROM boots from the user partition.

12.5.6.2.2 eMMC Fast Boot

For the eMMC card that supports the boot mode (eMMC version 4.4 or higher), the boot ROM supports fast boot to skip the eMMC card initialization progress to reduce the boot time.

ROM puts the eMMC card into the boot mode by holding the CMD line for 74 clock cycles and more after performing a power cycle and sending CMD0 with the argument of 0xF0F0F0F0. Then the eMMC card starts to send the first boot data to the master on the DATA lines according to the non-volatile configurations in EXT_CSD.

The partition that is used for data transferring is selected by the BOOT_PARTITION_ENABLE field in EXT_CSD[179].

The data size that can be transferred in the boot mode is defined by the BOOT_SIZE_MULT field in EXT_CSD[226].

The speed and bus width are determined by the BOOT_MODE and BOOT_BUS_WIDTH field in EXT_CSD[177].

The boot acknowledge can be enabled by the BOOT_ACK field in EXT_CSD[179].If the boot acknowledge is enabled, the eMMC device has to send the acknowledge pattern [3b010] via the DATA lines within 50ms after the CMD line goes LOW. And the ROM waits 50ms to read the acknowledge patter to identify if the eMMC device enters the boot mode. If boot acknowledge is disabled, the ROM waits 1 second for data. If the BOOT ACK or data was received, the eMMC device is booted in the "boot mode", otherwise the ROM treats it as a boot failure.

The fast boot mode can be selected by the MMC_FAST_BOOT_EN fuse. The boot acknowledge is selected by the MMC_FAST_BOOT_ACK_EN fuse. The fuses, MMC_FAST_BOOT_ACK_EN, MMC_SPEED and MMC_BUS_WIDTH must match the relative configurations in BOOT_ACK, BOOT_MODE and BOOT_BUS_WIDTH. The BOOT_PARTITION_ENABLE must be specified to enable partition used in boot mode.

Despite the setting of BOOT_SIZE_MULT, the maximum image size supported in the eMMC fast boot mode is 32 MB. This is due to a limited number of uSDHC ADMA Buffer Descriptors allocated by the ROM.

12.5.6.3 SD Boot

After the normal boot mode initialization begins, the frequency is set to 300 kHz. During the identification phase, the boot ROM validates the operation voltage range, performs the voltage switch sequence if UHSI mode is selected.

The capacity of the card is also checked. The boot code supports the high-capacity and low-capacity SDSC/SDHC/SDXC cards after the voltage validation card initialization is done.

For the UHSI cards, the clock speed fuses can be set to SDR50 or SDR104 on USDHC1, USDHC2 ports. This enables the voltage switch process to set the signaling voltage to 1.8 V during the voltage validation. The bus width is fixed at a 4-bit width and a sampling point tuning process is needed to calibrate the number of the delay cells.

Comparing SDR12 and SDR25 mode, the boot time of SD UHSI mode might be increased when booting a small image, due the voltage switch process and tuning process might cost more time than the reduce of a higher speed. The calibration start value (DLL_DELAY_CALIB_START) and the step value DLL_DELAY_CALIB_STEP can be set to optimize the sample point tuning process. But it is suggested to use SD UHSI mode for large images(over 10MB) booting.

If the PWR_CYCLE_EN fuse is set, the ROM sets the uSDHC.RST low, waits for several milliseconds which determined by PWR_CYCLE fuse, and then sets the uSDHC.RST high and wait for several milliseconds which determined by PWR_STABLE_CYCLE fuse. If the uSDHC.RST is connected to the SD power supply enable logic on board, it enables the power cycle of the SD card. This may be crucial in case the SD logic is in the 1.8 V states and must be reset to the 3.3 V states.

12.5.6.4 eMMC/SD Boot Flow

The eMMC/SD boot flow is detailed in the following figures.

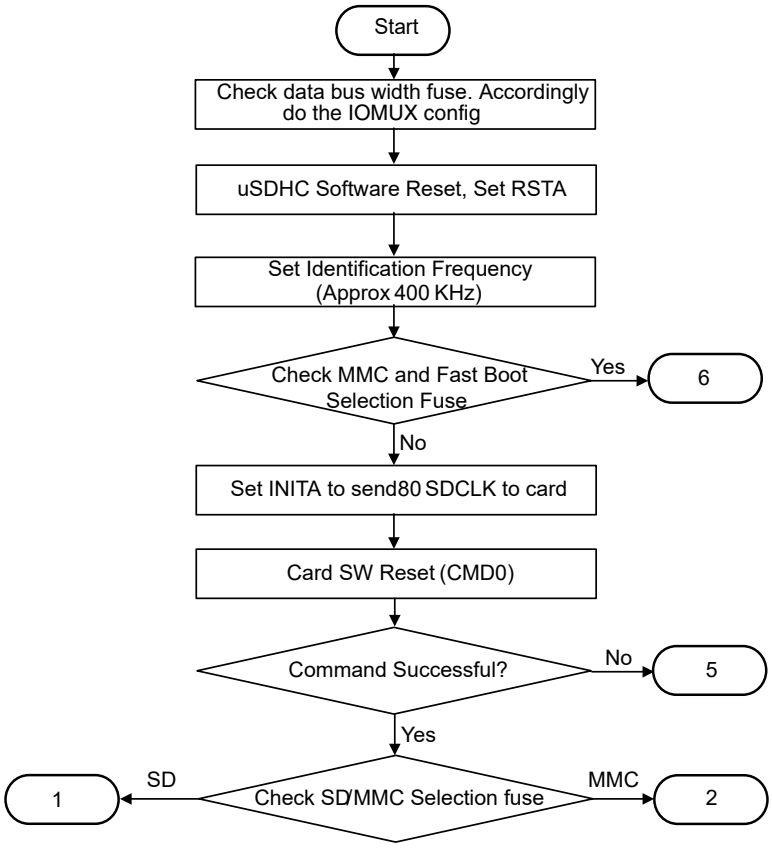

Figure 42. Expansion device boot flow (1 of 6)

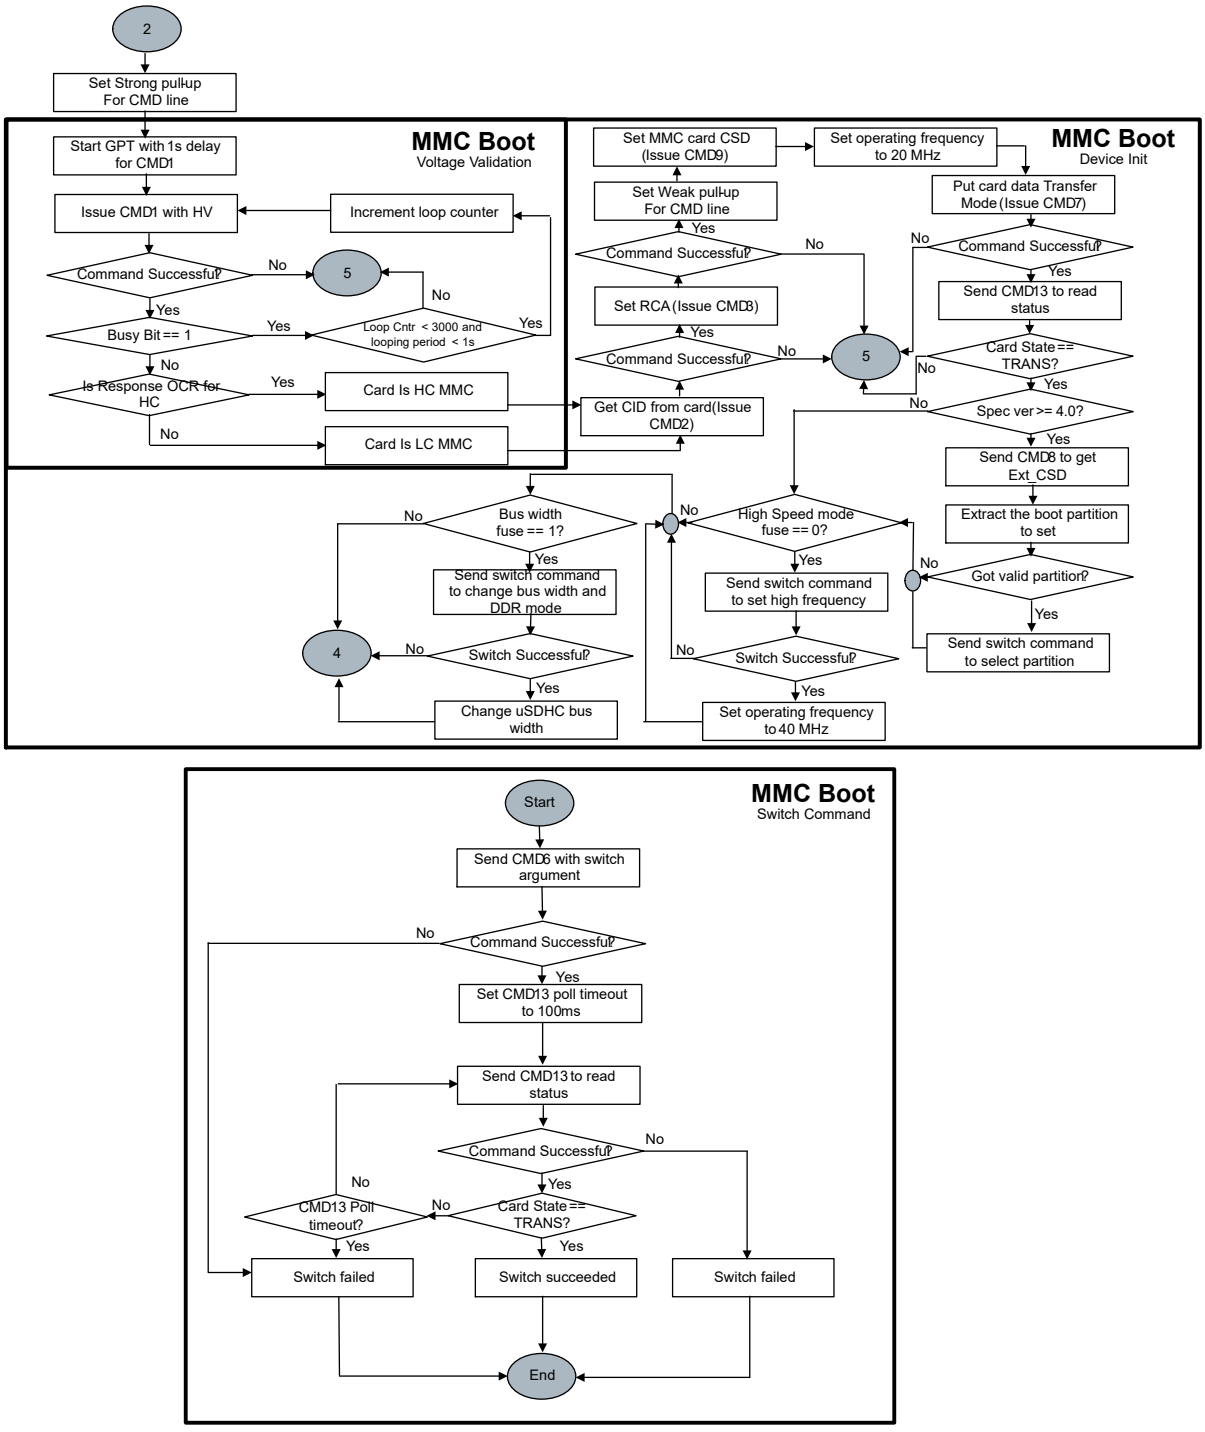

Figure 43. Expansion device (MMC) boot flow (2 of 6)

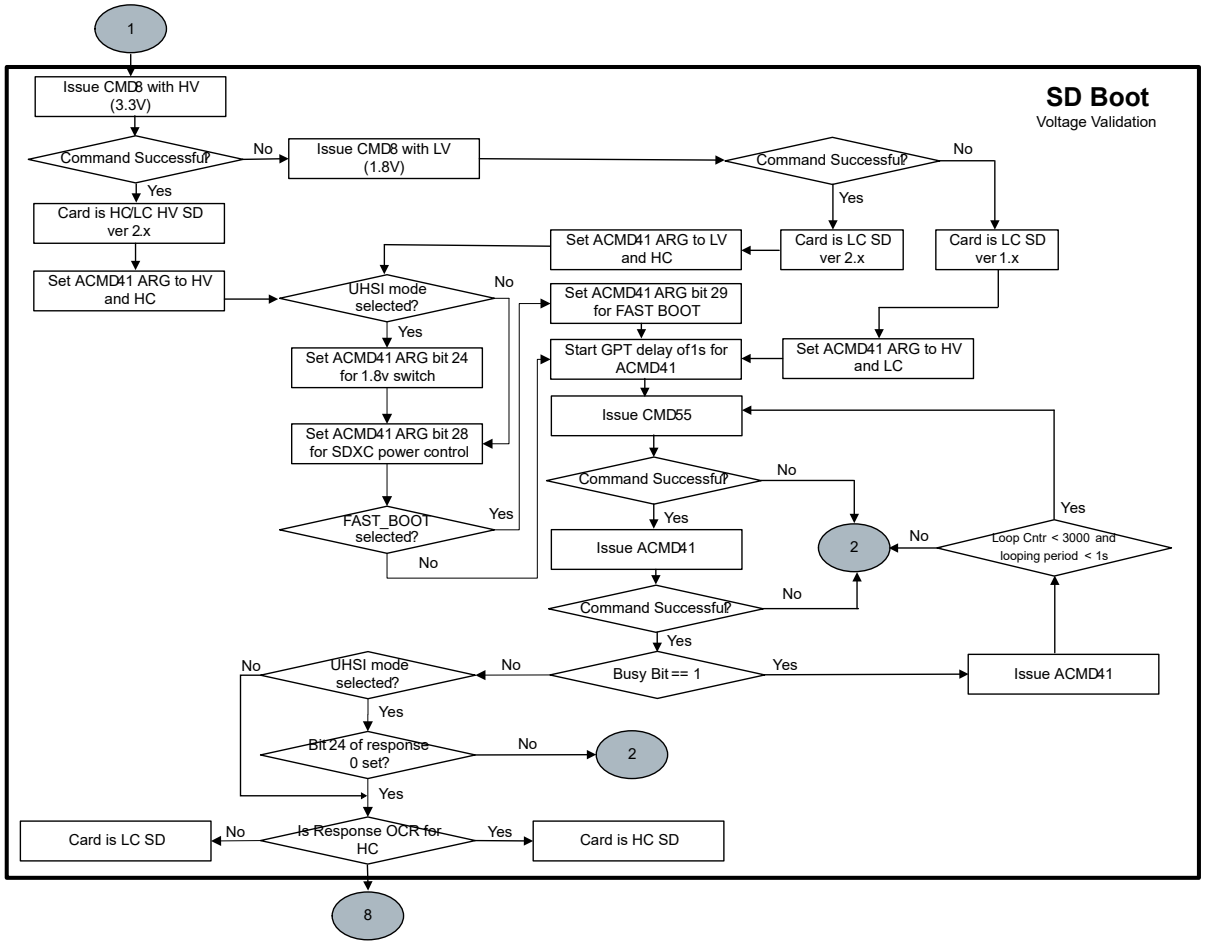

Figure 44. Expansion device (SD/eSD/SDXC) boot flow (3 of 6) part 1

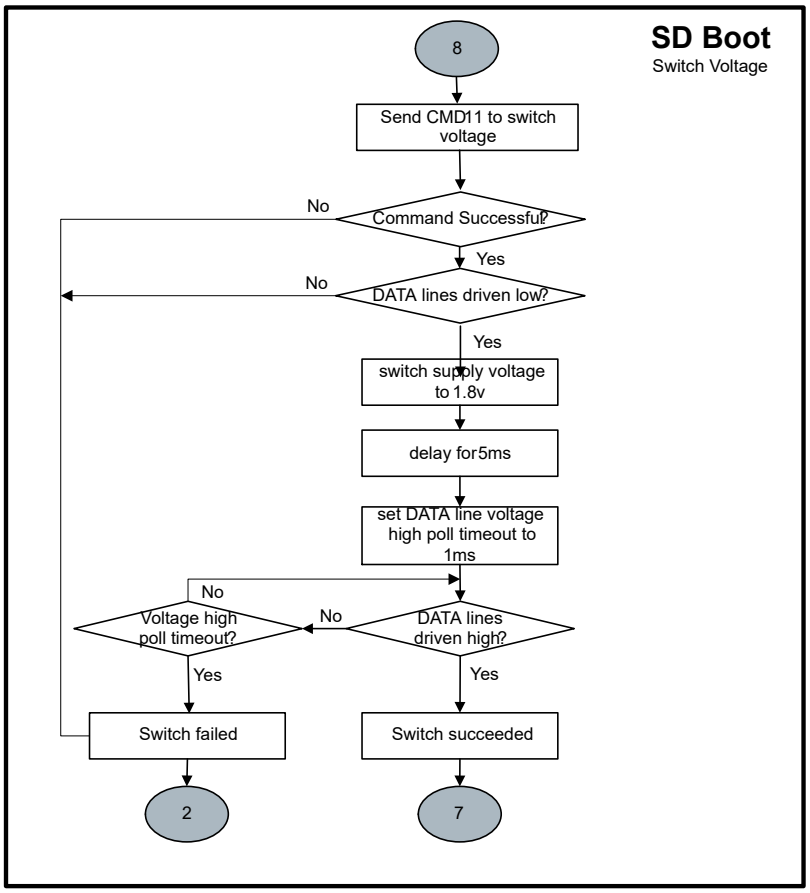

Figure 45. Expansion device (SD/eSD/SDXC) boot flow (3 of 6) part 2

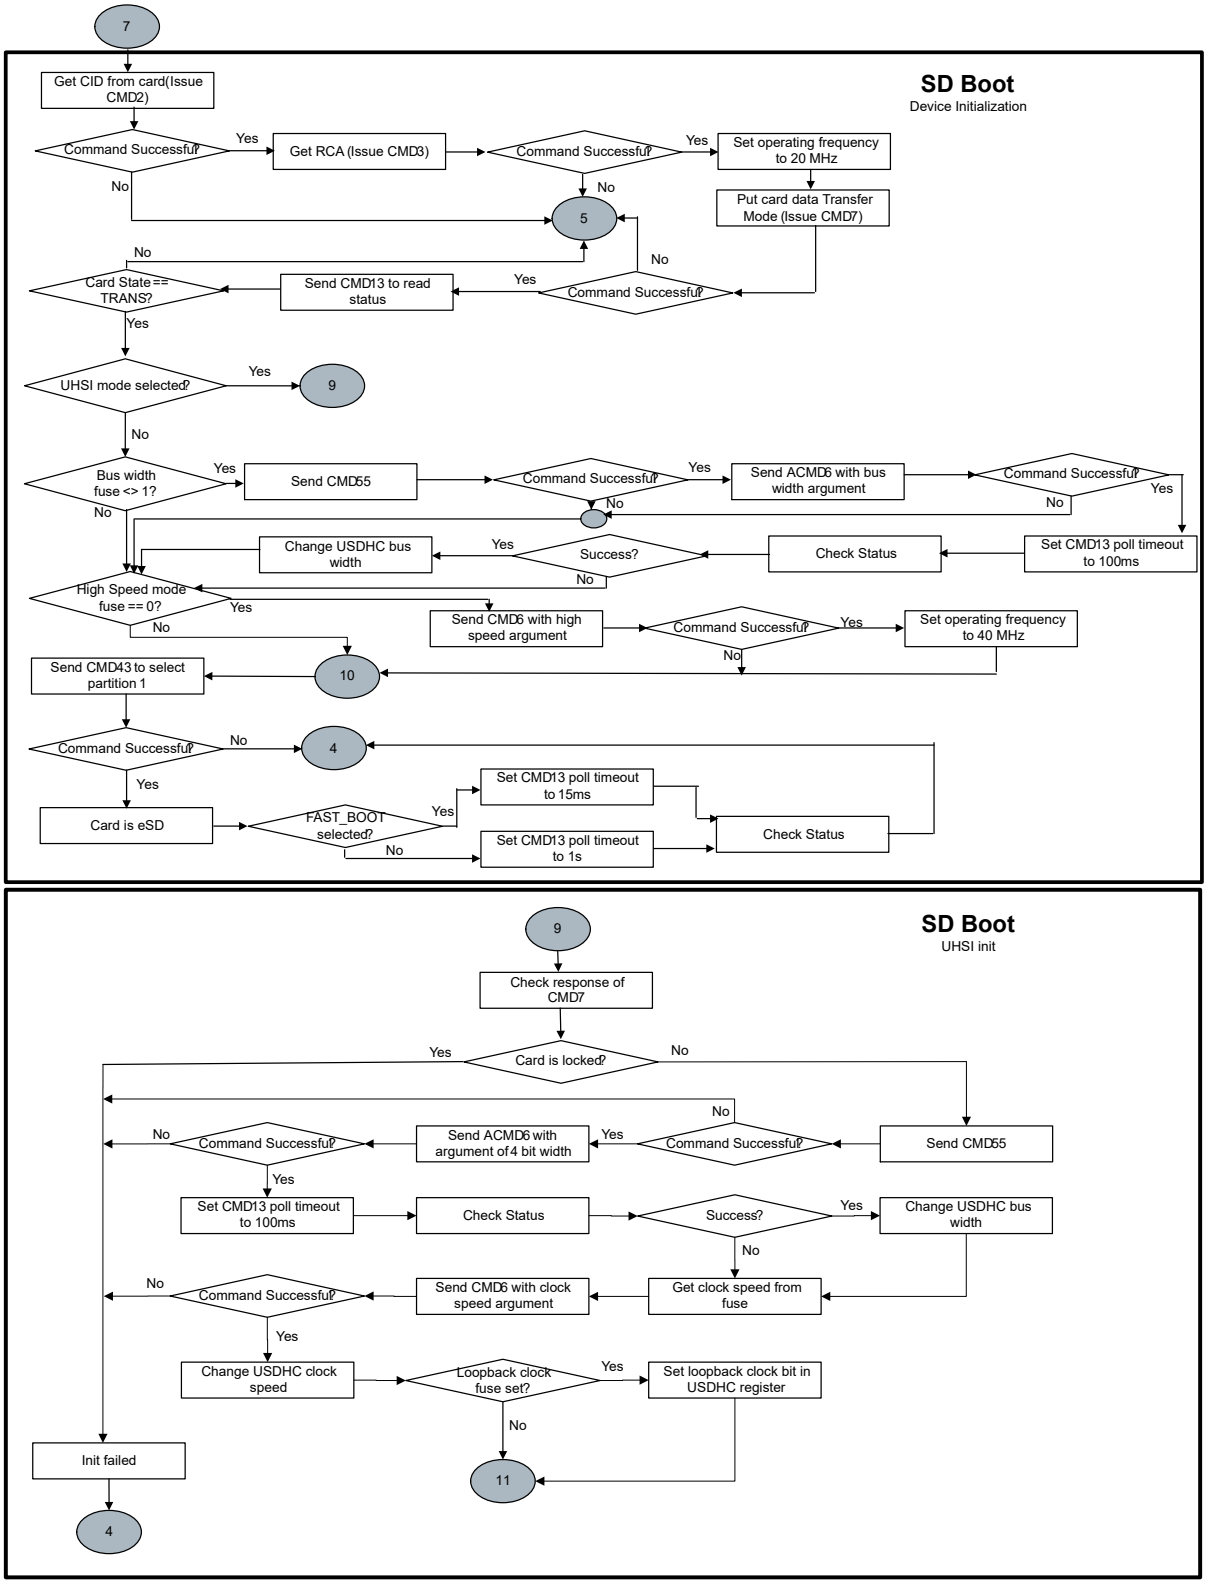

Figure 46. Expansion device (MMCSD/eSD/SDXC) boot flow (4 of 6)

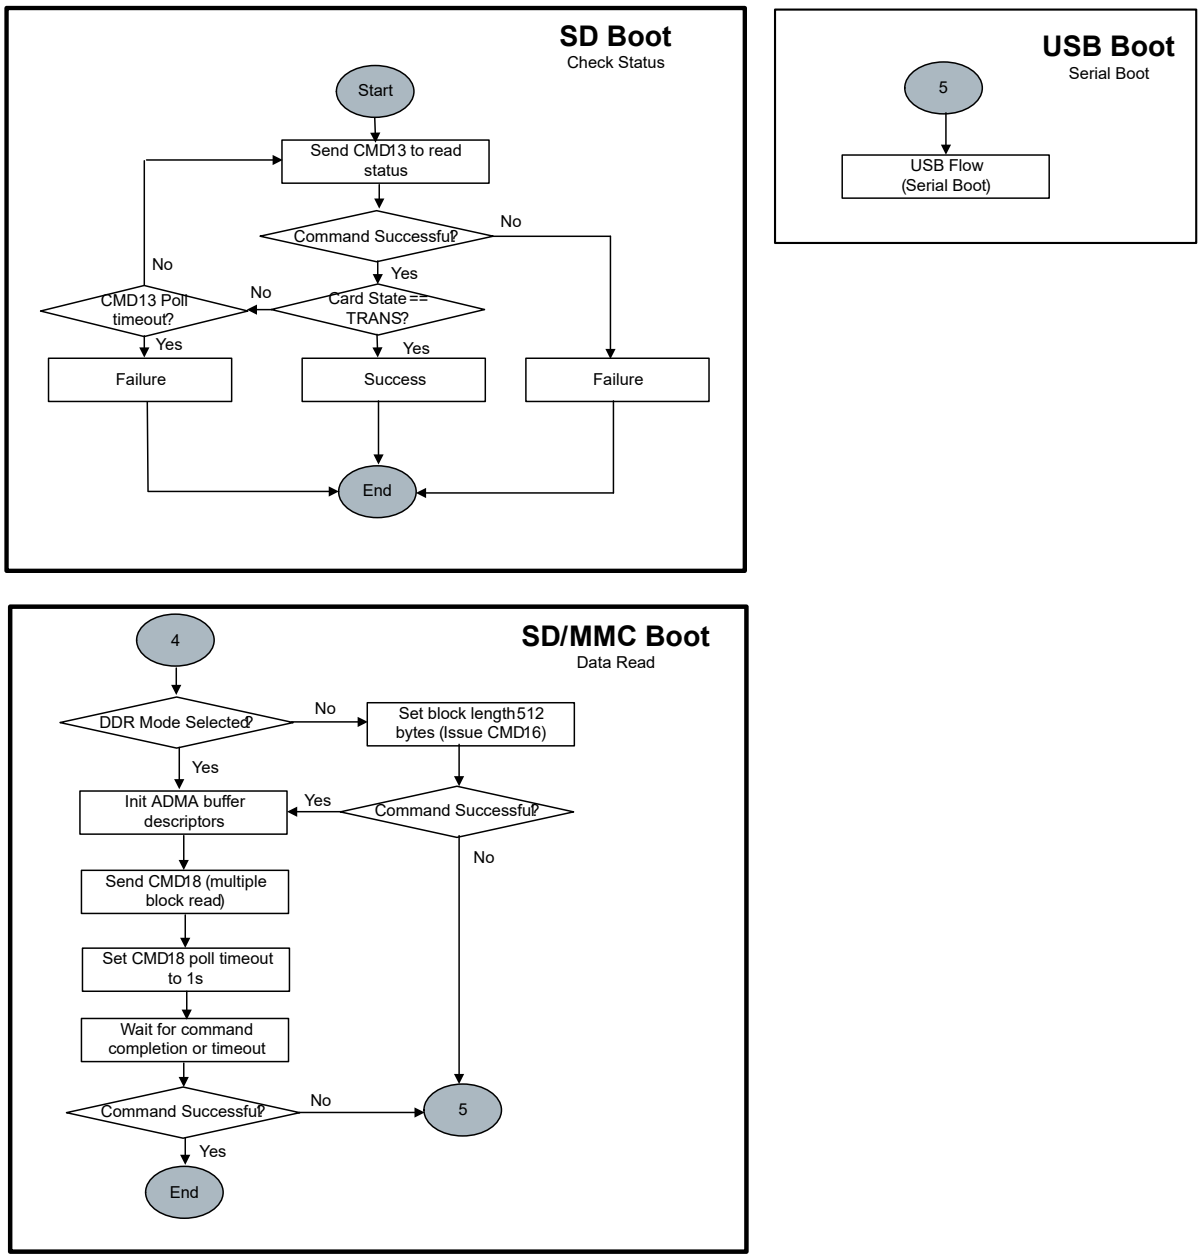

Figure 47. Expansion device (SD/eSD) boot flow (5 of 6)

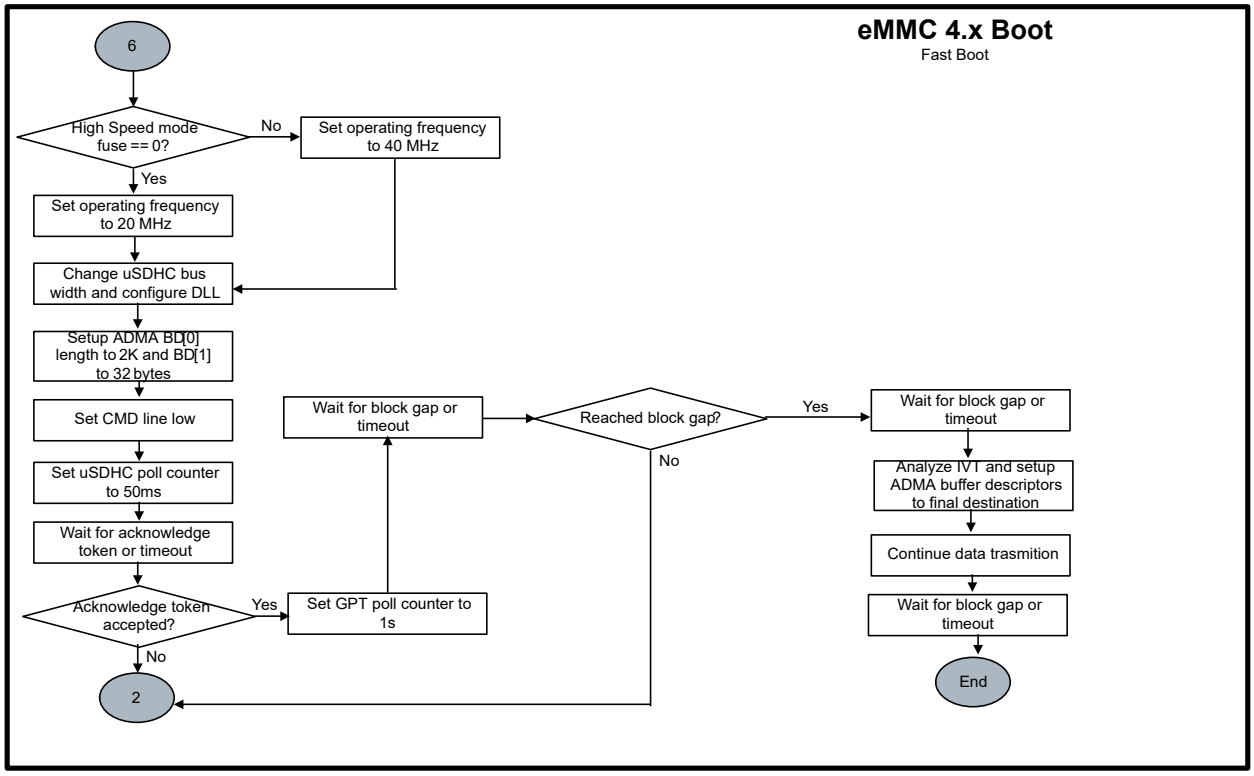

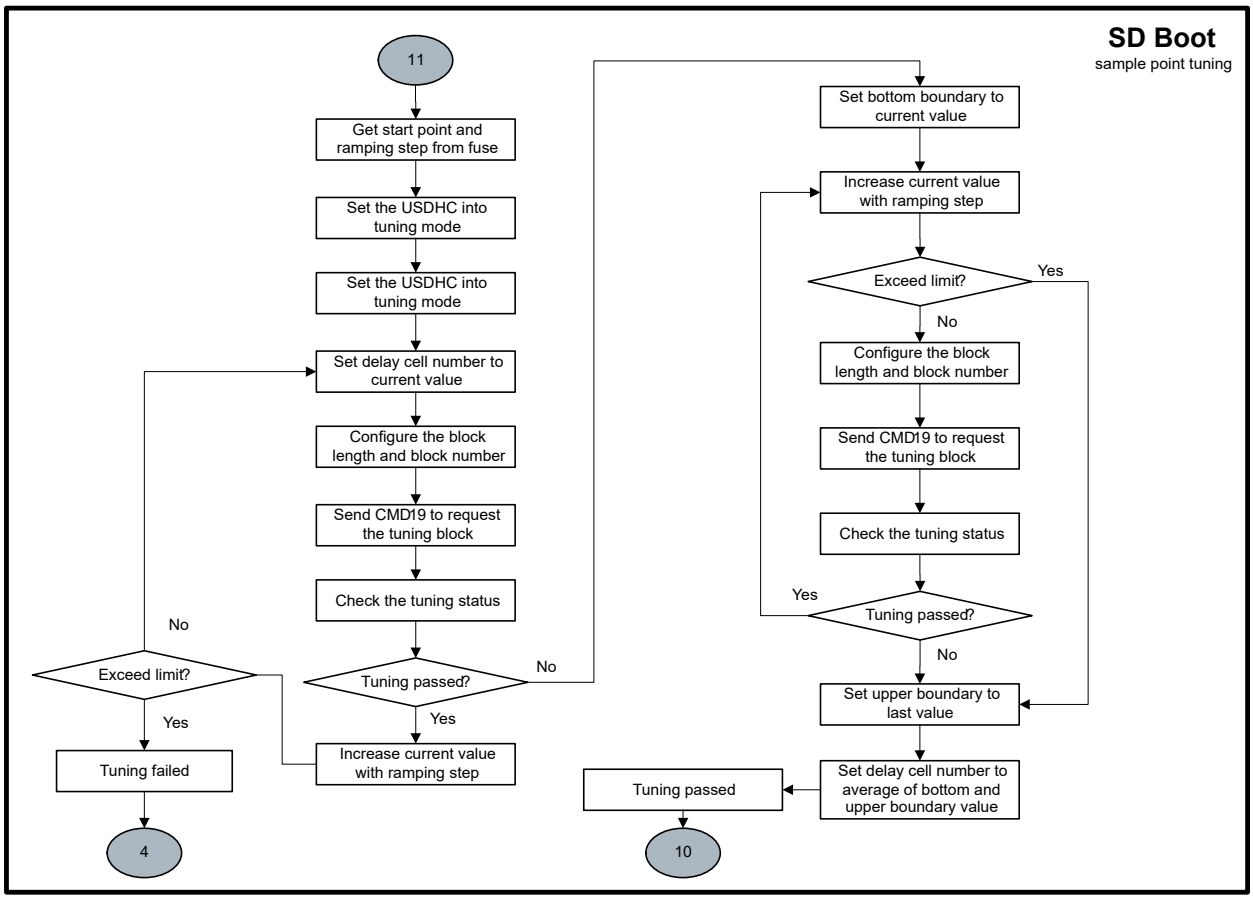

Figure 48. Expansion device boot flow (6 of 6)

12.5.6.5 Redundant Boot Support for eMMC/SD

The ROM supports the redundant boot for an eMMC/SD device. The primary or secondary image is selected, depending on the PERSIST_SECONDARY_BOOT setting. See Table 56.

If the PERSIST_SECONDARY_BOOT is 0, the boot ROM uses address 0x0 for the primary image.

If the PERSIST_SECONDARY_BOOT is 1, the boot ROM reads the secondary image table from address 0x200 on the boot media and uses the address specified in the table.

Table 78. Secondary image table format

Reserved (chipNum)
Reserved (driveType)
tag
firstSectorNumber
Reserved (sectorCount)

Where:

- The tag is used as an indication of the valid secondary image table. It must be 0x00112233.
- The firstSectorNumber is the first 512-byte sector number of the secondary image.

For the secondary image support, the primary image must reserve the space for the secondary image table. See the following figure for the typical structures layout on an expansion device.

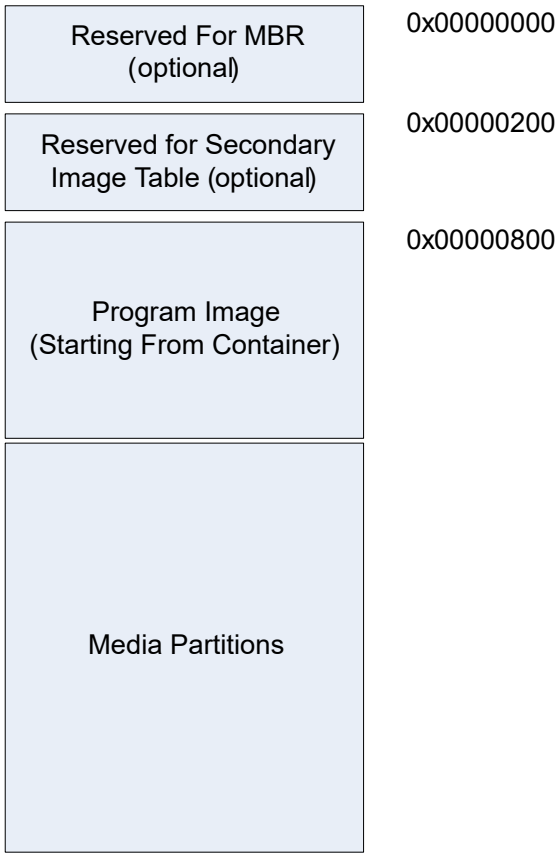

Figure 49. eMMC/SD structures layout

For the Closed mode, if there are failures during primary image authentication, the boot ROM turns on the PERSIST_SECONDARY_BOOT bit (see Table 56) and performs the software reset. After the software reset, the secondary image is used.

12.5.7 Serial NOR/EEPROM Recovery Boot via LPSPI

The chip supports recovery devices, such as serial EEPROM and NOR flash, using the LPSPI. If the primary boot device fails, the boot ROM tries to boot from the recovery device using one of the LPSPI ports.

NOTE

Only 16-bit image offset is supported. If multi-images are used and the image offset is over 16 bits, then combine multi-images into one CM33 image and handle the other images by CM33 application.

12.5.7.1 Serial NOR/EEPROM FUSE Configuration

The boot ROM code determines the type of device using the following parameters, provided by the fuse settings during boot.

Table 79. Serial NOR/EEPROM boot FUSE descriptions

Fuse	Definition	Settings	Shipped Value
BOOT_CFG0[4]	RECOVERY_BOOT_EN	0 - Recovery boot is forbidden 1 - Recovery boot is allowed	0

Table continues on the next page...

Table 79. Serial NOR/EEPROM boot FUSE descriptions (continued)

Fuse	Definition	Settings	Shipped Value
BOOT_CFG0[17:16]	LPSPI_PORT_SEL	0 - LPSPI1 1 - LPSPI2 2 - LPSPI4 3 - LPSPI5	0
BOOT_CFG0[19:18]	LPSPI_SPEED	0 - 30MHz 1 - 10MHz 2 - 30MHz Dual Read (1-2-2, 0xBB) 3 - 30MHz Quad Read (1-4-4, 0xEB)	0
BOOT_CFG0[22:20]	LPSPI_DUMMY_BYTES	0 - Default (4 cycles for dual/6 cycles for quad) *n* (non-zero) - 4*n* cycles for dual/2*n* cycles for quad	0
BOOT_CFG0[23]	LPSPI_INTERNAL_PULL	0 - No internal pull-up 1 - Internal pull-up enabled	0

The LPSPI*n* block can be used as a boot device using the LPSPI interface for the serial ROM boot. The SPI interface is configured to operate at the speed specified by the LPSPI_SPEED fuse field.

The boot ROM tries to copy the boot image container header from serial NOR/EEPROM's offset 0x400, to the MCU's internal RAM. If it is a valid container, ROM then tries to boot with it. External Memory Configuration_Data (XMCD) is supported for recovery boot. For more information on XMCD, refer to the External Memory Configuration Data (XMCD) section.

12.5.8 SD/MMC Manufacturing Boot via uSDHC

When the master/primary boot and recovery boot (if enabled) fail, the boot goes to the SD/MMC manufacture mode before the serial download mode. In the manufacture mode, uSDHC1, 1-bit bus width and SDR12 is used despite of the fuse settings in the BOOT_CFG.

uSDHC.CD pin is configured to detect if SD/MMC is inserted or not. Low means the card is inserted, otherwise, manufacturing boot will be treated as failure, and ROM goes to serial downloader mode.

12.6 Program Image

This section describes the boot image format that is used by ROM. The format names container-based image format.

The top level view of the boot image layout is shown in the figure below.

Table 80. Top-level view of the boot image

Memory Configuration Block	
Container 1	Container Header
	Image Array Entry
	Signature Block
	Padding to 1KB (0x400) Alignment

Table continues on the next page...

Table 80. Top-level view of the boot image (continued)

Container 2(Optional)	Container Header
	Image Array Entry
	Signature Block
	Padding to 1KB (0x400) Alignment
Padding to 8KB(0x2000) Alignment	
NXP Images(Optional)	NXP Firmware
User/OEM Images	Application Data (Optional)
	CM7 Image (Optional)
	CM33 Image

12.6.1 Memory Configuration Block

The memory configuration block is a data region from the beginning of the boot device memory, to the start of the container-based image. The data region contains words used by ROM to initialize the boot devices. It includes BCB, Serial NOR FLASH configuration Block, and XMCD.

The memory configuration block has different size and layout for different boot devices. The different layouts and sizes are provided in the following figures.

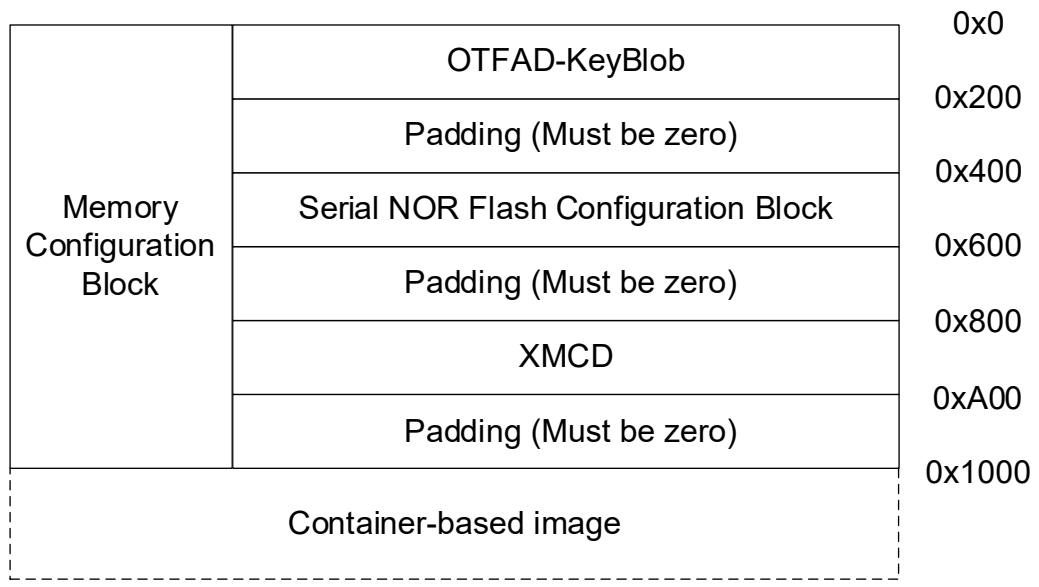

Figure 50. Layout for Serial NOR FLASH boot

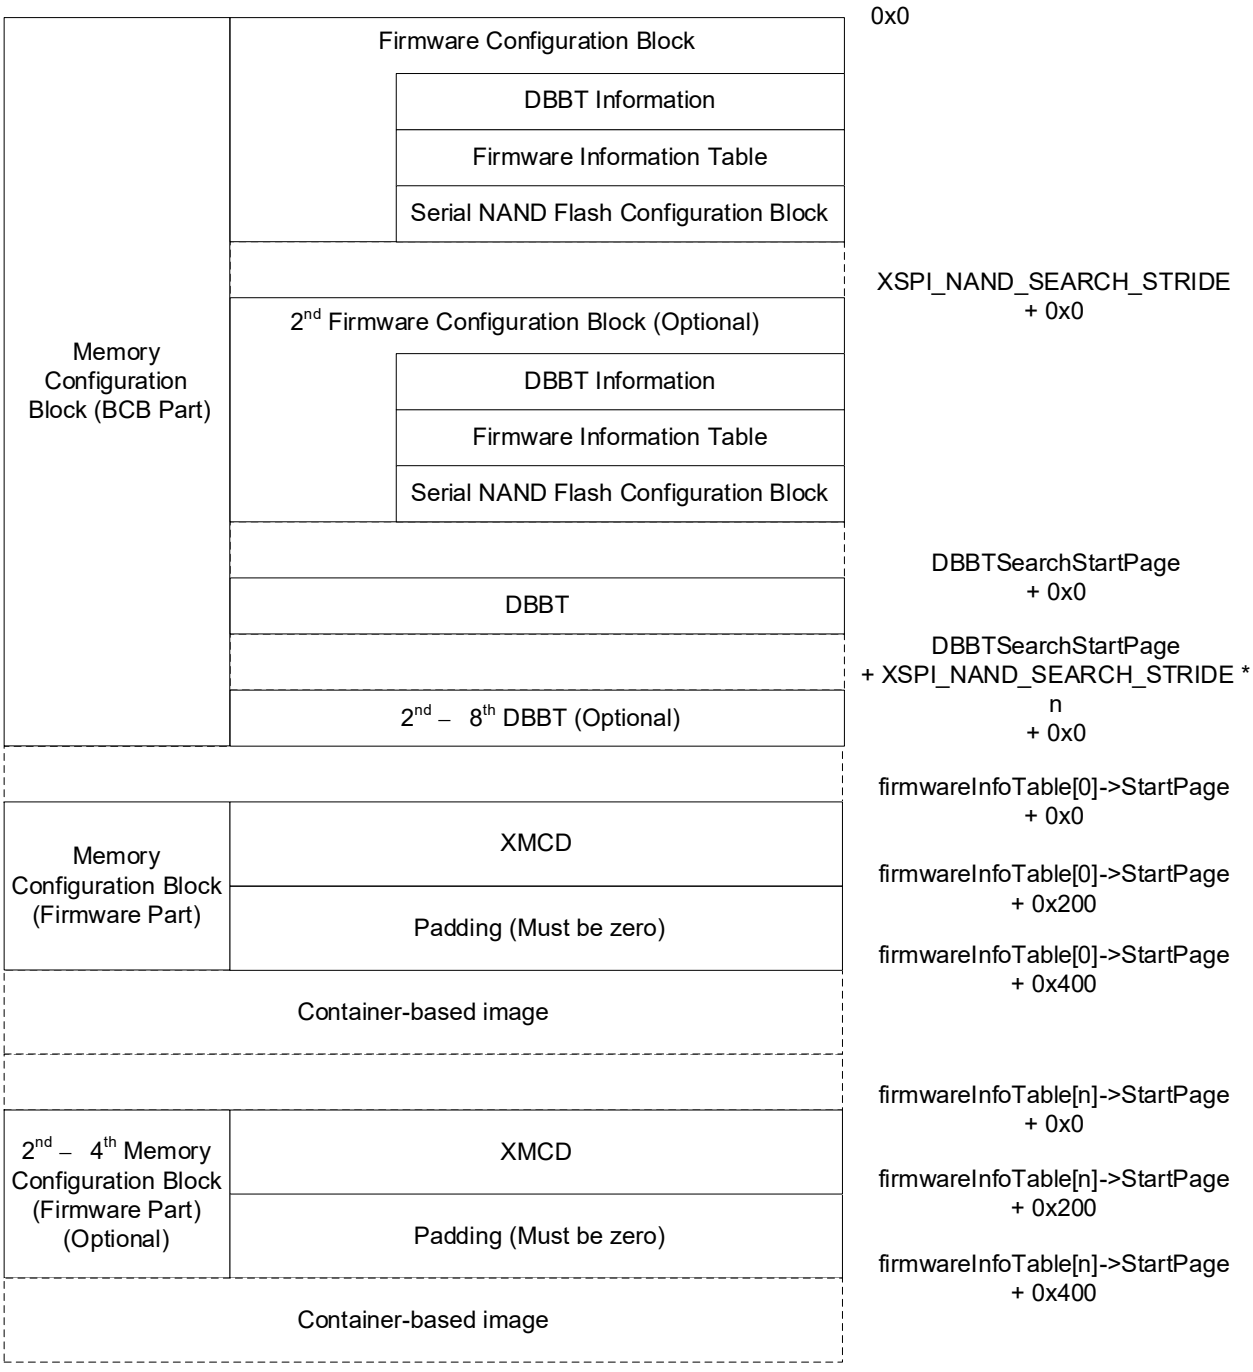

Figure 51. Layout for Serial/Parallel NAND Flash

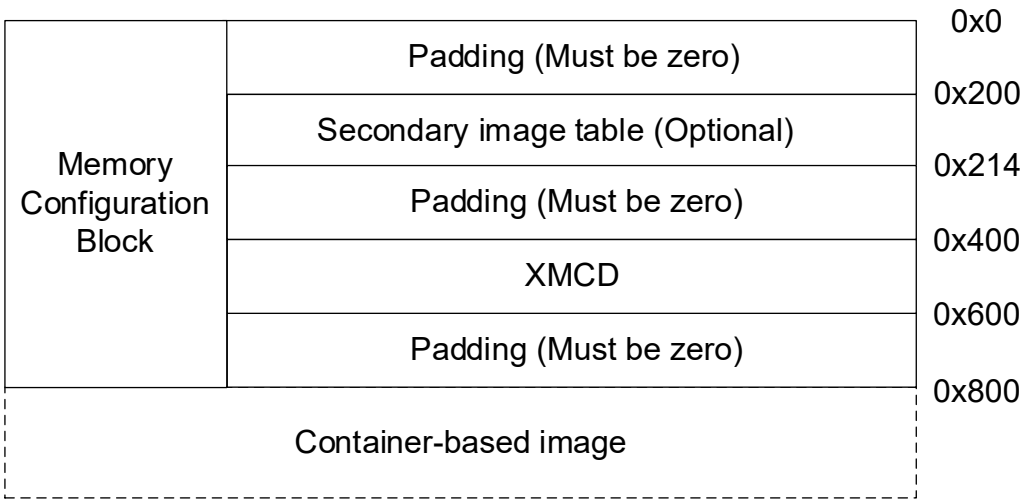

Figure 52. Layout for SD/eMMC boot

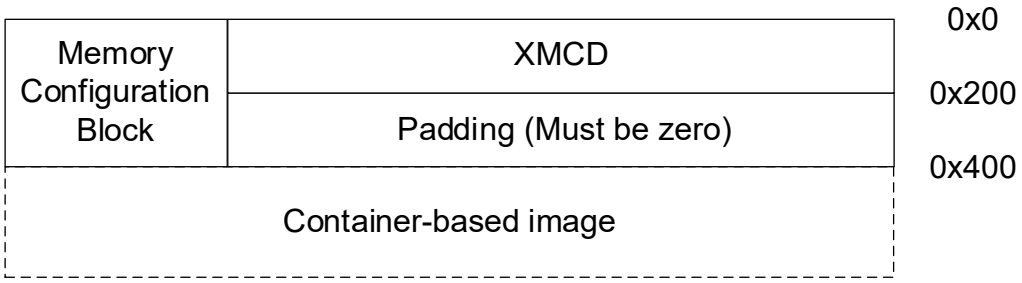

Figure 53. Layout for Serial NOR Flash/E2PROM (Recovery) boot and serial downloader boot

12.6.2 Container Format

The image container format consists of the following parts.

- Container header
- Image array entry
- Signature block
- User program images and data

The high-level view of the container format is shown in the following figure.

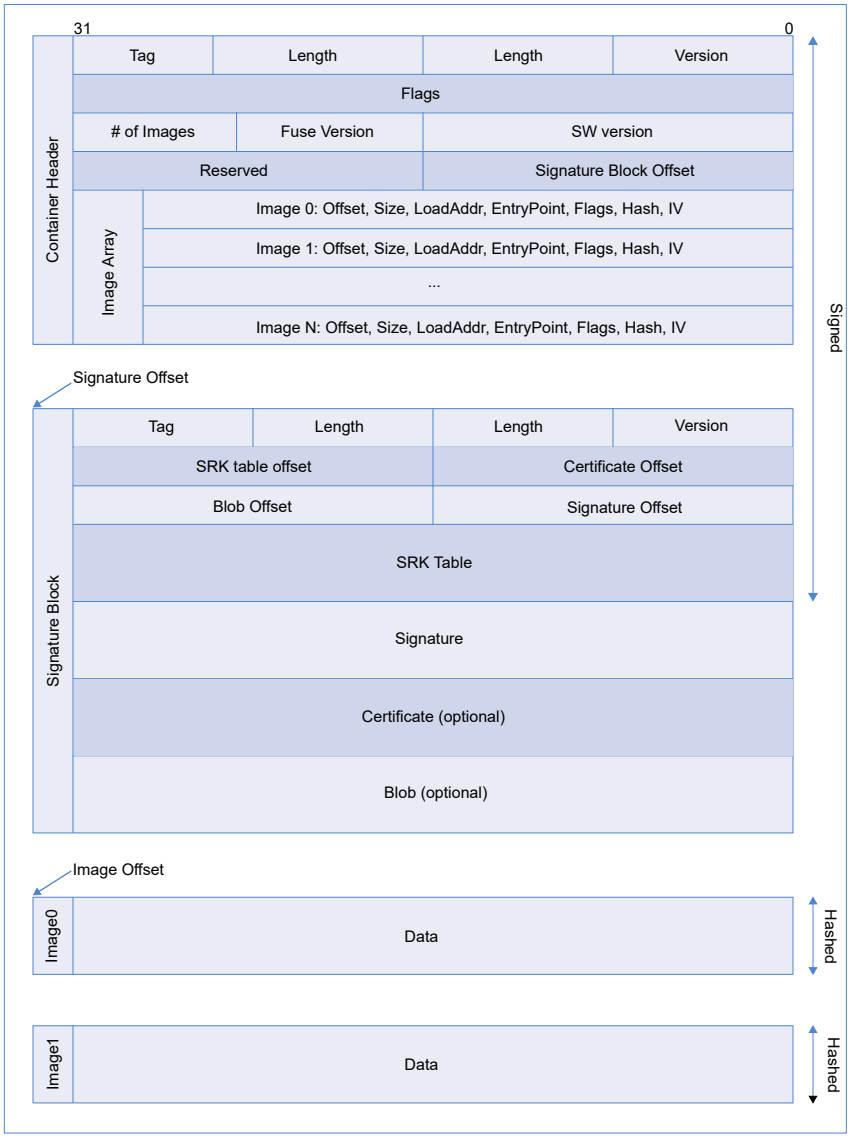

Figure 54. High-level view of the container format

NOTE

Certificate and Blob are not currently supported and will be supported by a future version of the Edgelock FW.

NOTE

If there are multiple images in the container, ELE verifies the hash for each image. If there is a failure on hash check, the device falls into infinite reset loop. Limitation: If multiple images are used, the hash for each image must be correct.

The container is located at a fixed address which is determined by the selected boot device.

Table 81. Image container start offset

Boot device	Container start offset
Serial NOR Flash via FlexSPI	4 KB = 0x1000 byte
Serial NAND Flash via FlexSPI	1 KB = 0x400 byte after FCB/DBBT blocks
Parallel NAND Flash via SEMC	1 KB = 0x400 byte after FCB/DBBT blocks
eMMC/SD via uSDHC(including manufacturing boot)	2 KB = 0x800 byte
SPI NOR Flash/EEPROM via LPSPI	1 KB = 0x400 byte
Serial downloader	1 KB = 0x400 byte

The maximum number of the containers is restricted to 2, one NXP container for NXP firmware, one OEM container for user/OEM images. If NXP firmware is required, the NXP container must be located at the first container position, while the OEM container must be located after the NXP container. If NXP firmware is not used, first container can be the OEM container, and the second container shall be padded with zeros.

The maximum number of the images in the NXP container is restricted to 1. The OEM container can have 8 images at the maximum. The Cortex-M33 core (booting core) images must be located after the other ones.

Following are the general notes for the container format.

- All multi-byte fields are stored in little-endian format
- The first word of each structure matches the format as used in HAB and other legacy (i.MX 6/7) used data structures
- All padding bytes are filled with zeros
- Only container header, image array entry and most of signature block are signed. Image data is not used to calculate the signature, but is only used indirectly via hash values
- Header can be signed by SRK or by image key that was signed by SRK. If an image key is used, it must be the same algorithm and key size as the SRK. In both cases, the referenced SRK must not have been revoked.
- If SRK is used to sign header, there is only one signature verification per container. If an image key is used, then there are 2 verifications.
- If an SRK revoke bit is set, Edgelock will set the fuse for that, only after successful authentication of the header that contains the SRK revocation command. A revoked SRK cannot be used to authenticate an image.
- Images may be encrypted individually, but all use the same decryption key, which is stored in the decryption blob.
- Encrypted images are encrypted before assembling the container. In other words, the hash is the hash of the encrypted image.
- The IV field is always present in the image array descriptor, whether the image is encrypted or not, and it is the SHA256 hash over the plaintext. While only the lower 128 bits will be used as IV in the encryption process, the IV field size is always 256 bits since it will serve for integrity checking the decrypted image as well.
- The image array immediately follows the signature block. Each image must start on a 64-bit boundary.
- The signature is done only over the part of the header containing data blocks information (including the corresponding hashes), not over the entire file.
- All data in the container header, including most of the signature block (everything except the signature itself, optional certificate and optional blob) is signed.

12.6.2.1 Container Header

The container header contains essential information about the entire container image which is used by the ROM. Table 82 shows the container header format.

Table 82. Container header format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Flags			
0x08	# of Images	Fuse Version	SW Version	
0x0c	Reserved		Signature Block Offset	

The container header format fields are defined below.

- **TAG**: Must be 0x87
- **Length**: Size of the container in bytes, from header, up through and including signature block.
- **Version**: Must be 0x00
- **Flags**: Table 83 provides the description of each bit field in the Flags.

Table 83. Flags bitfield description

Bit Field	Description
0-1	SRK Set 0x0 – Container not authenticated 0x1 – NXP SRK 0x2 – OEM SRK 0x3 – Reserved
2-3	Reserved (must be 0)
4-5	SRK Selection 0x0 – SRK1 is used 0x1 – SRK2 is used 0x2 – SRK3 is used 0x3 – SDR4 is used
6-7	Reserved (must be 0)
8-11	SRK Revoke Mask bitmask used to indicate which SRKs to revoke – zero bits set means no SRKs are to be revoked, bit0 – SRK1 is to be revoked, bit1 – SRK2 is to be revoked,

Table continues on the next page...

Table 83. Flags bitfield description (continued)

Bit Field	Description
	bit2 – SRK3 is to be revoked, bit3 – SRK4 is to be revoked,
12-15	Reserved (must be 0)
16-31	Reserved (must be 0)

- **# of images**: Number of images in the image array
- **Fuse Version**: This value must be equal to or greater than the version stored in the fuses to allow loading this container
- **SW Version**: Used to select between multiple images with same Fuse version field.
- **Signature Block Offset**: Offset in bytes from beginning of header to signature block (keys, signature, blob)

12.6.2.2 Image Array Entry

The boot ROM loads images in the order that the images appear in the array.

Table 84 shows the Image Array Entry format

Table 84. Image Array Entry format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Image Offset			
0x04	Image Size			
0x08	Load Address (64 bits)			
0x0c				
0x10	Entry point (64 bits)			
0x14				
0x18	Flags			
0x1c	Image meta data			
0x20	Hash (512 bits)			
…				
0x60	IV (256 bits)			

The image array entry format fields are defined below.

- **Image Offset**: Offset in bytes from start of current container header to beginning of the image

NOTE

The image offset should be page-size aligned if the NAND boot was used. The image offset should be within 16bit and 256 byte aligned if the recovery boot was used.

- **Image Size**: Size of the image in bytes
- **Load Address**: Address where the image is copied to in memory (absolute address in system memory map) by the ROM
- **Entry Point**: Entry point of the image (absolute address). Only valid for executable image types.
- **Flags**: Table 85 provides the description of each bit field in the Flags.

Table 85. Flags bitfield description

Bit Field	Description
0-3	Type of image 0x3 Executable 0x4 Data 0x7 Provisioning image 0x9 Provisioning data All other values reserved (These values extend HAB IVT V1)
4-7	Core ID 0x1 Cortex-M33 0x2 Cortext-M7 All other values reserved
8-10	Hash type (all images in the container have the same HASH size) 0x0 – SHA256 0x1 – SHA384 0x2 – SHA512
11	Encrypted Indicate if this image is encrypted or not
12-31	Reserved

- **Image meta data**: For NXP FW private usage.
- **Hash**: SHA hash of image. Fixed size at 512 bits. Left aligned and padded with zero for hash sizes below 512 bits.
- **IV**: Used only for encrypted images (zero otherwise): SHA256 of the plain text image. Fixed size at 256 bits. The lower 128-bit part of the SHA256 value will be retained as IV in the encryption/decryption process.

12.6.2.3 Signature Block

Table 86. Signature block format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	SRK Table Offset		Certificate Offset	
0x08	Blob Offset		Signature Offset	
0x0A	Reserved (for 64bit alignment purposes) 32 bit			
0x10	SRK Table			
…	Signature			
…	Certificate			
…	Blob			

The signature block format fields are defined below.

- **TAG**: 0x90
- **Version**: 0x00
- **SRK Table Offset**: Offset in bytes from beginning of signature block to SRK table. If 0x0000, then SRK table is not present. This should be the case only if the container is not authenticated, and the SRK key set field in the Container header should be 0.
- **Certificate Offset**: Offset in bytes from beginning of signature block to signing key certificate. If 0x0000, then only a SRK is used in signature verification
- **Signature Offset**: Offset in bytes from beginning of signature block to signature
- **Blob Offset**: Offset in bytes from beginning of signature block to DEK Blob. If 0x0000, then no images are encrypted

NOTE

1. SRK Table, Signature, Certificate and Blob must be in the order shown
2. Certificate and Blob are optional
3. SRK Table, Certificate, Blob, and Signature must start on 64 bit boundaries. Any padding needed to make this happen must be zeros.
4. The container signature is calculated of all data from beginning of container header to the last byte before the signature starts. In other words, most of the signature block itself is included in the signature calculations.

12.6.2.3.1 SRK Table

The SRK table determines the signature type and length, and consists of 1 to 4 SRK records which contains the public keys. The format of the SRK table is inherited from HAB v4.x

Table 87. SRK table format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Version	Length of SRK Table		Tag
0x04	SRK Record 1			
-	SRK Record 2			
-	SRK Record 3			
-	SRK Record 4			

The SRK table fields are defined below.

- **TAG**: 0xD7
- **Length**: The size of the SRK table in bytes
- **Version**: 0x42

12.6.2.3.1.1 SRK Record

Table 88. SRK record format

Offset	Bits 31-24	Bits 23-16		Bits 15-8	Bits 7-0
0x00	Signing Algorithm	Length of SRK			Tag
0x04	SRK Flags	Reserved	Key Size/Curve		Hash Algorithm
0x08	RSA: Exponent Length (bytes)	RSA: Modulus Length (bytes)			
	ECDSA: Y Length (bytes)	ECDSA: X Length (bytes)			
0x0C	RSA: Modulus (Big endian)				
	ECDSA: X (Big endian)				
-	RSA: Exponent (Big endian)				
	ECDSA: Y (Big endian)				

The SRK record fields are defined below.

- **TAG**: 0xE1
- **Length**: The size of the SRK record
- **Signing Algorithm**:
  - RSA-PSS: 0x22
  - ECDSA: 0x27
- **Hash Algorithm**:
  - SHA-256: 0x00
  - SHA-384: 0x01
  - SHA-512: 0x02

- **Key Size/Curve**:
  - PRIME256V1: 0x1
  - SEC384R1: 0x2
  - SEC521R1: 0x3
  - RSA2048: 0x5
  - RSA3072: 0x6
  - RSA4096: 0x7
- **SRK Flags**:
  - None: 0x00
  - CA Flag: 0x80

NOTE

The keys in the SRK table must match the signing key in algorithm and key length

12.6.2.3.2 Signature

Table 89. Signature format

Offset	>Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Reserved			
0x08	Signature Data			

The signature format fields are defined below.

- **TAG**: 0xD8
- **Version**: 0x00
- **Signature Data**:Signature.
  - RSA-PSS encoding
  - ECDSA: The r and s components are padded with leading zeros to make them each 8 bit aligned, then concatenated – r|s

12.7 External Memory Configuration Data (XMCD)

For comprehensive or feature-rich applications, the on-chip RAM may not be enough for the application use. Usually, such an application requires a large capacity of RAM and needs to run on the external RAM for high execution performance. However, enabling the external RAM on the SoC is relatively complicated, and the settings are SoC specific. The Boot ROM on the SoC simplifies the external RAM configuration by introducing the XMCD.

The XMCD data structure resides out of the program image, and the offset varies depending on the boot device. The XMCD offset for each device type is provided in the following table.

Table 90. XMCD Offset

Boot device	XMCD Offset
Serial NOR Flash via FlexSPI	0x800

Table continues on the next page...

Table 90. XMCD Offset (continued)

Boot device	XMCD Offset
Serial NAND Flash via FlexSPI	0x0 after FCB/DBBT blocks
Parallel NAND Flash via SEMC	0x0 after FCB/DBBT blocks
eMMC/SD via uSDHC(including manufacturing boot)	0x400
Serial NOR Flash/EEPROM via LPSPI	0x0
Serial downloader	0x0

XMCD consists of a XMCD header and a memory specific configuration block. On this SoC, the following types of external RAM devices are supported. Each type of RAM device has a specific configuration block.

- HyperRAM/APMemory via FlexSPI – FlexSPI RAM configuration block
- SDRAM via SEMC – SEMC SDRAM Configuration block

12.7.1 XMCD Header

The header definition is as follows.

Table 91. XMCD Header Definition

[31:28] Tag	[27:24] Version	[23:20] Memory Interface	[19:16] Instance	[15:12] Configuration Block Type	[11:0] Configuration block size
Valid value = 0xC	Fixed value of '0'	0 - FlexSPI 1 - SEMC	SoC defined instances	0 - Simplified Configuration Option Block 1 - Full Configuration Block	Configuration block size (including the XMCD Header itself).

12.7.2 XMCD CRC

There is an optional integrity check of the XMCD by programming the CRC checksum to the fuse. The ROM can perform the integrity check before adopting the XMCD block settings. It calculates the CRC check based on the value of the "Configuration block size" field. ROM determines whether to enable the XMCD integrity check by checking the XMC_CRC32_CHECK_EN fuse field and the XMC_CRC32_CHECK_SUM fuse. Details of the CRC algorithm used for the integrity check are provided in the following table.

Table 92. CRC Algorithm Details

Description	Value
Width	32
Polynomial	0x04C11BD7
Init Value	0xFFFFFFFF
Reflect In	FALSE
Reflect Out	FALSE
XOR Out	0x00000000

The following procedure shows the steps in the CRC calculation:

1. CRC initialization
   - Set the initial CRC as 0xFFFFFFFF, which clears the CRC byte count to 0.
2. CRC calculation
   - Start the calculation from the first byte of the XMCD header. Total calculation bytes are "Configuration block size" bytes.
3. CRC finalization
   - Check if the CRC byte count is 4-bytes aligned. If it is not 4-bytes aligned, then pad it with the necessary zeroes to finalize the CRC. Otherwise, return to the current computed CRC.

12.7.3 FlexSPI RAM Configuration Block

The XMCD offers a simplified FlexSPI RAM configuration option block which can meet the typical usage of the HyperRAM or APMemory devices.

However, the user application may need to enable the advanced features of the external RAM which cannot be configured by the simplified configuration option. In this case, the XMCD also offers the complete 512-bytes FlexSPI RAM configuration block which supports flexible configuration.

12.7.3.1 Simplified FlexSPI RAM Configuration Option Structure

The simplified FlexSPI RAM configuration option structure is shown in the following tables.

Table 93. Simplified FlexSPI RAM Configuration Option 0

[31:28] Tag	[27:24] Option Size	[23:20] device type	[19:16] Reserved	[15:12] Misc.	[11:8] Maximum Frequency	[7:0] Size in MB
Fixed to 0x0C	0 - Option words = 1 1 - Option words = 2 Others - Reserved	0 - HyperRAM 1 - APMemory	Reserved	For HyperRAM 0 - Differential clock driven 1 - Single-ended clock driven	0 - Invalid 1 - 30MHz 2 - 50MHz 3 - 60MHz 4 - 80MHz 5 - 100MHz 6 - 120MHz 7 - 133MHz 8 - 166MHz 9 - 200MHz Others - Reserved	0 - Auto detection Others - Size in MB

Table 94. Simplified FlexSPI RAM Configuration Option 1

[31:28] RAM_CONNECTION	[27:24] Reserved	[23:20] DQS_PINMUX_GROUP	[19:16] PINMUX ROUP	[15:8] Reserved	[7:4] write dummy cycles	[3:0] read dummy cycles
0 - PORTA 1 - PORTB	Reserved	0 - Default Group 1 - Secondary group	0 - Primary group 1 - Secondary group	Reserved	0 - Auto detection Others - Specified dummy cycles	0 - Auto detection Others - Specified dummy cycles

12.7.3.2 Full FlexSPI RAM Configuration Block Structure

The following table lists the data structure of the full 512-bytes FlexSPI RAM Configuration Block.

Table 95. Full HyperRAM/APMemory Configuration Block Structure

Name	Offset	Size(Bytes)	Description
Tag	0x000	4	0x42464346, ascii: "FCFB"
Version	0x004	4	[07:00] bugfix [15:08] minor [23:16] major = 1 [31:24] ascii 'V'
Reserved	0x008	4	Reserved
readSampleClkSrc	0x00c	1	0 – Internal loopback 1 – loopback from DQS pad 2 - Reserved 3 – Flash provided DQS
csHoldTime	0x00d	1	Serial Flash CS Hold Time Recommend default value is 0x03
csSetupTime	0x00e	1	Serial Flash CS setup time Recommended default value is 0x03
columnAdressWidth	0x00f	1	3 – For HyperFlash/HyperRAM 12/13 – For Serial NAND. See datasheet to find correct value. 0 – Other devices
deviceModeCfgEnable	0x010	1	Device Mode Configuration Enable feature 0 – Disabled 1 – Enabled
deviceModeType	0x11	1	Device Mode Type

Table continues on the next page...

Table 95. Full HyperRAM/APMemory Configuration Block Structure (continued)

Name	Offset	Size(Bytes)	Description
			0 – Generic 1 – Quad Enable 2 – SPI-to-xSPI Mode 3 – xSPI-to-SPI mode
waitTimeCfgCommands	0x12	2	Time in terms of 100us This field is defined for the mode switch from SPI to xSPI mode or vice versa.
deviceModeSeq	0x014	4	Sequence parameter for device mode configuration [7:0] - Number of sequences [15:8] - Sequence Index [31:16] - Reserved, fixed to 0
deviceModeArg	0x018	4	Device Mode argument, effective only when deviceModeCfgEnable = 1
configCmdEnable	0x01c	1	Config Command Enable feature 0 – Disabled 1 – Enabled
configModeType	0x01d	3	This field has the same definitions as "deviceModeType" byte 0 - configModeType for configCmdSeq[0] byte 1 - configModeType for configCmdSeq[1] byte 2 - configModeType for configCmdSeq[2]
configCmdSeqs	0x020	12	Sequences for Config Command allows 3 separate configuration command sequences. For each configCmdSeq, the definition of the word is: [7:0] - Number of sequences [15:8] - Sequence Index [31:16] - Reserved, fixed to 0
Reserved	0x02c	4	Reserved
cfgCmdArgs	0x030	12	Arguments for each separate configuration command sequence.
Reserved	0x03c	4	Reserved
controllerMiscOption	0x040	4	Bit0 – differential clock enable Bit1 – CK2 enable Bit2 – ParallelModeEnable

sflashB2Size	0x05c	4	For SPI NOR, need to fill with actual size For SPI NAND, need to fill with actual size * 2
csPadSettingOverride	0x060	4	Set to 0 if it is not supported
sclkPadSettingOverride	0x064	4	Set to 0 if it is not supported

Table continues on the next page...

Table 95. Full HyperRAM/APMemory Configuration Block Structure (continued)

Name	Offset	Size(Bytes)	Description
dataPadSettingOverrid e	0x068	4	Set to 0 if it is not supported
dqsPadSettingOverride	0x06c	4	Set to 0 if it is not supported
timeoutInMs	0x070	4	Maximum wait time during read/write
commandInterval	0x074	4	Unit: ns. Currently, it is for SPI NAND at the high working frequency. For the serial NAND and serial RAM device, this field is 0.
dataValidTime	0x078	4	Time from clock edge to data valid edge. Unit: ns. This field takes effect when the FlexSPI Root clock is less than 100MHz, and the read sample clock source is a device provided DQS signal without CK2 support. [31:16] - data valid time for DLLB in terms of 0.1ns [15:0] - data valid time for DLLA in terms of 0.1ns
busyOffset	0x07c	2	Busy bit offset. Valid range :0-31.
busyBitPolarity	0x07e	2	0 – 1 represents busy 1 – 0 represents busy
lookupTable	0x080	16*4*4	Lookup table
lutCustomSeq	0x180	4*12	Customized LUT sequence. See the note at the end of the table for details.
Reserved	0x1b0	5*16	Reserved for future use

NOTE

- LUT for read must be placed at LUT entry 0.
- LUT for write must be placed at LUT entry 9.

12.7.3.3 Example of XMCD for HyperRAM Support

The following table shows an example of XMCD for HyperRAM support.

Table 96. Example XMCD block for HyperRAM

Offset	Field	Description
0	0xC000_0008	Tag = 0x0C Version = 0 Memory Interface: FLEXSPI Instance: 1 - First Instance Configuration block type: Simplified

Table continues on the next page...

Table 96. Example XMCD block for HyperRAM (continued)

Offset	Field	Description
		Configuration block size: 8 (4-byte header + 4-byte option block)
1	0xC000_0700	Tag = 0x0C Option_Size = 0 DeviceType: HyperRAM Reserved: 0 Misc: HyperRAM 1V8 Max Freq: 7 Memory Size: Auto-detection

NOTE

- The XMCD feature can be disabled by Fuse XMC_DISABLE.
- Dual-Die-Package (DDP) HyperRAM is not supported.

12.7.4 SEMC SDRAM Configuration Block

The XMCD also supports the SDRAM configuration via the SEMC SDRAM Configuration Block, which offers both the simplified configuration option and the fully customizable configuration block.

12.7.4.1 SEMC SDRAM Configuration Block Structure

The SEMC SDRAM configuration block structure is shown in the following table.

Table 97. SDRAM Configuration Block structure

Offset	Width (bytes)	Field	Description
0	1	magic_number	Must be 0xA1
1	1	version	Set to 1 for this implementation
2	1	config_option	0x00 - Simplified configuration • Select SDRAM CS0 as default and can only config clk_MHz, sdram0_size_kB and port_size • All unconfigured fields must be 0-filled 0xFF - Full configuration • Must config all fields.
3	1	clk_MHz	Set the working frequency in the unit of MHz
4	4	sdram0_size_kB	Set the memory size of SDRAM CS0 in the unit of kilobytes Range: 4~4*1024*1024

Table continues on the next page...

Table 97. SDRAM Configuration Block structure (continued)

Offset	Width (bytes)	Field	Description
8	1	port_size	Port size of SDRAM 0 - 8bit 1 - 16bit 2 - 32bit Others - Invalid value
9	1	pin_config_pull	Pull config of the SDRAM GPIO pin 0 – forbidden 1 – pull up 2 – pulldown 3 – no pull Others - Invalid value
10	1	pin_config_drive_strength	Driver config of SDRAM GPIO pin 0 – high driver 1 – normal driver Others - Invalid value
11	1	mux_rdy	SDRAM CSn device selection 1 - SDRAM CS1 2 - SDRAM CS2 3 - SDRAM CS3 Others – Invalid for SDRAM, select other external devices **NOTE** To select CS1/CS2/CS3, you can only use one of the five items: mux_rdy ,mux_csx0, mux_csx1,mux_csx2 ,mux_csx3). If using one item, other items cannot be used, set them to 0.
12[3:0]	1	mux_csx0	SDRAM CSn device selection 1 - SDRAM CS1 2 - SDRAM CS2 3 - SDRAM CS3 Others – Invalid for SDRAM, select other external devices

Offset	Width (bytes)	Field	Description
40	4	sdram0_base	Base address of SDRAM CS0 Range: 0x80000000~0xDFFFFFFF **NOTE** SDRAM CS0~CS3 addresses cannot overlap and when CSn is not used, set the address to 0.
44	4	sdram1_base	Base address of SDRAM CS1 Range: 0x80000000~0xDFFFFFFF
48	4	sdram2_base	Base address of SDRAM CS2 Range: 0x80000000~0xDFFFFFFF
52	4	sdram3_base	Base address of SDRAM CS3 Range: 0x80000000~0xDFFFFFFF
56	4	sdram1_size_kB	Set the memory size of SDRAM CS1 in unit of kbytes Range: 4~4*1024*1024
60	4	sdram2_size_kB	Set the memory size of SDRAM CS2 in unit of kbytes Range: 4~4*1024*1024
64	4	sdram3_size_kB	Set the memory size of SDRAM CS3 in unit of kbytes Range: 4~4*1024*1024

12.7.4.2 Example for SDRAM Support (32-bit)

The following table shows an example for the SDRAM support (32-bit) on this device.

Table 98. Example SDRAM Configuration Block

Offset	Field	Description
0	0xC010_000D	Tag = 0xC Version = 0 Memory Interface: SEMC Instance: 0 - ignored Configuration block type: 0 - Ignored (Handled inside the SDRAM configuration structure) Configuration block size: 13 (4-byte header + 9-byte option block)
1	0xA600_01A1	Magic_number = 0xA1

Table continues on the next page...

Table 98. Example SDRAM Configuration Block (continued)

Offset	Field	Description
		Version = 1 Config_option: Simplified SDRAM clock: 166MHz
2	0x0001_0000	SDRAM CS0 size: 64MBytes
3	0x02	Port_size: 32-bit

12.8 Serial Boot (Serial Downloader)

The Serial boot provides a means to download a boot image to the chip and execute the image over the following serial peripherals:

- LPUART
- USB-HID
- LPSPI

The default enabled peripherals for active peripheral detection is determined by the combination of fuses and Boot Mode pins.

The boot ROM can detect the active peripherals and shut down all inactive peripherals before any communications between the host and the device.

The high-level serial boot flow is provided below. Details of communication protocols, sequences, and flows can be found in the following sections.

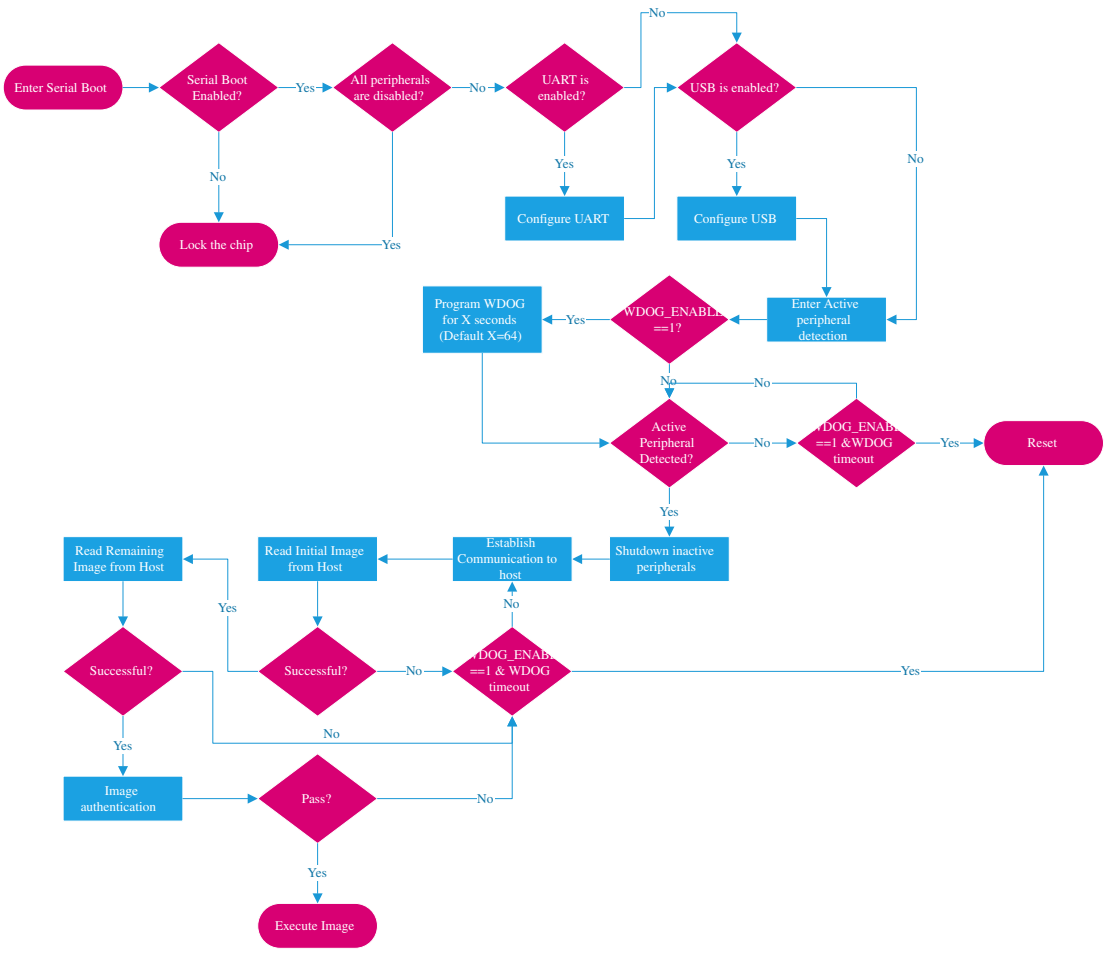

Figure 55. Serial Boot Flow

The communication protocol for serial boot mode is compatible with the widely-used MCUBOOT protocol in the NXP MCU products. Using simplified protocol, only two types of phase are supported:

1. **Command-only phase**. “get-property” command is supported, but the supported properties are limited to:
   - Bootloader version
   - Target version
   - Maximum payload size in the packet
   - Last Status

   For all other properties queried by the host, the boot ROM responds with unknown property error code.
2. **Data-only phase**. Boot ROM treats the data from the host as data streaming; no command phase is needed in this phase.

12.8.1 MCU-BOOT Protocol

The section demonstrates the general protocol for the packet transfers between the host and the boot ROM. The description includes the transfer of packets for different transactions, such as command with no data phase and data only phase. The next section describes various packet types used in a transaction.

- Each command sent from the host is replied to with a response command.

- Each data sent from the host is replied with an ACK at the packet level.
- In all protocols (described in the following subsections), the Ack sent in response to a Command or Data packet can arrive at any time before, during, or after the Command/Data packet has processed.

Command-only phase

The protocol for command-only phase content:

- Command packet (from the host)
- Response command packet (to host)

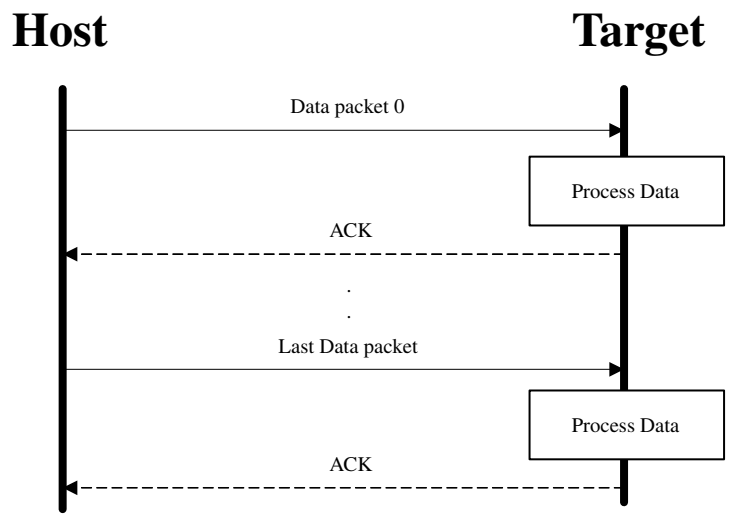

Figure 56. Protocol for a command-only phase

Data-only phase

The protocol for data-only phase content:

- A data packet (from the host)

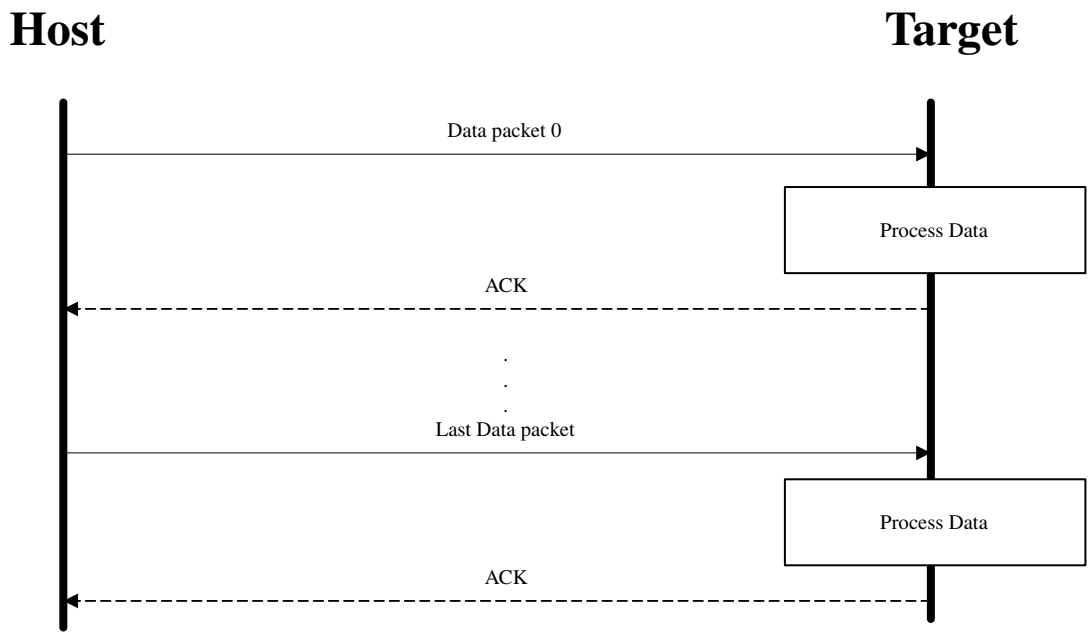

Figure 57. Protocol for a data-only phase

There are 2 types of packet protocol defined for the peripherals with or without built-in flow control.

- **Serial packet protocol**. It is defined for UART. A packet level flow control mechanism and error-detection mechanism is designed in this protocol.
- **HID packet protocol**. It is defined for USB-HID, the USB built-in flow control and error-detection is used behind this protocol.

In each protocol, several packet types are defined to let the boot ROM:

- Establish the communication to a host
- Recognize different phases (command-only/ data-only)

12.8.1.1 Packet Types for Serial Packet Protocol

There are 5 types of packets supported by the Serial Packet Protocol:

- Ping packet
- Ping Response packet
- Framing packet
- Command packet
- Data packet

12.8.1.1.1 Ping Packet

The ping packet is the first packet sent from a host to target, in order to establish a connection on a UART peripheral for auto-baudrate detection. For other peripherals, it is optional.

Table 99. Ping packet format

Byte #	Value	Name
0	0x5A	Start Byte
1	0xA6	Packet Type: Ping packet

12.8.1.1.2 Ping Response Packet

In response to a Ping packet, the target sends a Ping Response packet.

Table 100. Ping response packet format

Byte #	Value	Parameter
0	0x5A	Start Byte
1	0xA7	Packet Type: Ping Response packet
2		Protocol version: bug fix
3		Protocol version: minor
4		Protocol version: major
5		Protocol name: 'P' (0x50)
6		Reserved: set to 0
7		Reserved: set to 0
8		crc16_low
9		crc16_high

NOTE

1. Please refer to CRC Algorithm for details regarding the CRC algorithm.
2. Byte 0 - 7 are including in the CRC calculation.

Example ping packet:

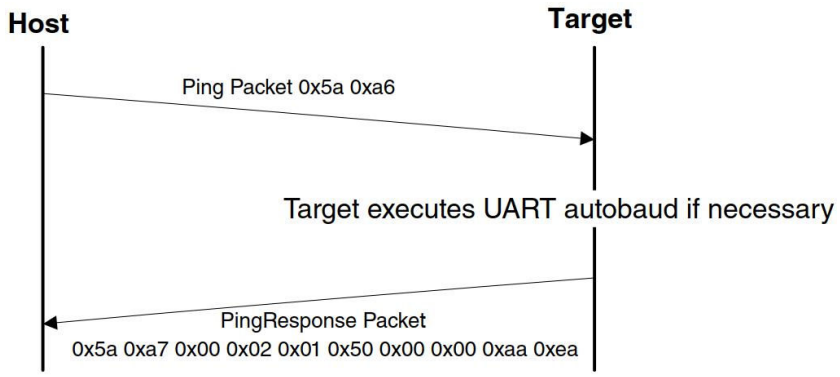

Figure 58. Ping Command Protocol

12.8.1.1.3 Framing Packet

The framing packet is for flow control and error detection, for the communications links that do not have such features built-in. The framing packet structure sits between the link layer and the command layer. It wraps command and data packets as well.

NOTE

Command packet is optional in ROM

Every framing packet containing data sent in one direction results in a synchronizing response framing packet in the opposite direction.

The framing packet described in the section is for serial peripherals, including UART

The framing packet format for serial packet is provided below:

Table 101. Framing packet format

Byte #	Data type	Value	Field	Notes
0	Framing header	0x5a	Start Byte	Must be 0x5A
1		0xA5/0xA4	Packet Type	0xA5 for Data packet 0xA4 for command packet
2		2	Payload Size	16-bit little-endian, max size is 512 bytes
4		2	CRC-16 checksum	CRC checksum covers the whole packet including start byte, packet type, payload size, and payload data, but does not contain the CRC checksum bytes
6…n	Payload	payload data	The payload of the data	Max size is 512

A particular framing packet that contains only a start byte and a packet type is employed for synchronization between the host and target. The format details are provided below:

Table 102. Special Framing Packet Format

Byte #	Value	Parameter
0	0x5A	Start Byte
1	0xAn	Packet Type: 0xA1 - Ack: The previous packet was received successfully; the sending of more data is allowed 0xA2 - NAK: The previous packet was corrupted, and needs to be re-sent. 0xA3 - Abort: Data transfer is aborted.

12.8.1.1.4 CRC Algorithm

This section provides details about the CRC-16 algorithm.

The CRC is computed over each byte in the framing packet header, excluding the crc16 field itself, plus all the payload bytes. The CRC algorithm is the XMODEM variant of CRC-16.

The Characteristics of the XMODEM variants are:

Table 103. Characteristics of the XMODEM variant

Name	Value
width	16
polynomial	0x1021
init value	0x0000
reflect in	false
reflect out	false

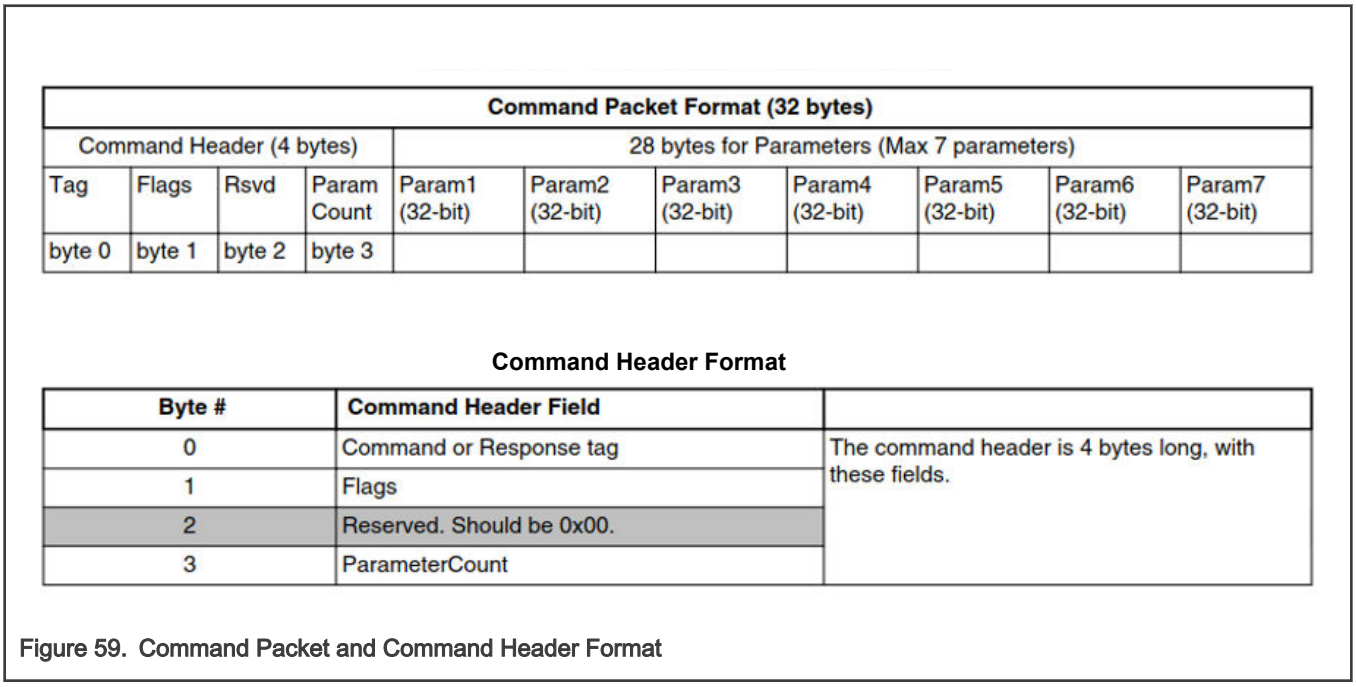
Table continues on the next page...

Table 103. Characteristics of the XMODEM variant (continued)

Name	Value
xor out	0x0000
check result	0x31C3

12.8.1.1.5 Command Packet

The command packet carries a 32-bit command header and a list of 32-bit parameters.



Command Packet Format (32 bytes)										
Command Header (4 bytes)				28 bytes for Parameters (Max 7 parameters)						
Tag	Flags	Rsvd	Param Count	Param1 (32-bit)	Param2 (32-bit)	Param3 (32-bit)	Param4 (32-bit)	Param5 (32-bit)	Param6 (32-bit)	Param7 (32-bit)
byte 0	byte 1	byte 2	byte 3							

Command Header Format

Byte #	Command Header Field	
0	Command or Response tag	The command header is 4 bytes long, with these fields.
1	Flags	
2	Reserved. Should be 0x00.	
3	ParameterCount	

Figure 59. Command Packet and Command Header Format

The header is followed by 32-bit parameters up to the value of the ParameterCount field specified in the header. Because a command packet is 32 bytes long, only 7 parameters can fit into the command packet.

Command packets are also used by the target to send responses back to the host. Command packets and data packets are embedded into framing packets for all the transfers.

The supported command and response list is provided in the following tables:

Table 104. Supported command list

Command	Name
0x07	GetProperty

Table 105. Supported response list

Response	Name
0xA0	Generic Response
0xA7	GetProperty Response - used for sending a response to GetProperty command only

12.8.1.1.6 Data Packet

The data packet carries just the data that the host sends to target. The data packet is also wrapped within a framing packet to ensure the correct packet data is received.

The contents of a data packet are simply the data itself. There are no other fields so that the most data per packet can be transferred. Framing packets are responsible for ensuring that the correct packet data is received.

The host must send the data packet with the maximum payload size until the last packet, the packet with smaller payload size is treated as the last packet during the transfer.

12.8.1.1.7 Response Packet

The responses are carried using the same command packet format wrapped with framing packet data. Types of responses supported in the boot ROM include:

- GenericResponse
- GetPropertyResponse

GenericResponse: After the boot ROM has processed a command, the boot ROM sends a generic response with status and command tag information to the host. The generic response is the last packet in the command protocol sequence. The generic response packet contains the framing packet data and the command packet data (with generic response tag = 0xA0) and a list of parameters. The parameter count field in the header is always set to 2, for status code and command tag parameters.

The GenericResponse parameters are provided below:

Table 106. GenericResponse parameters

Byte #	Parameter	Description
0 - 3	Status code	The status codes are errors encountered during the execution of a command by the target. If a command succeeds, then a success code is returned.
4 - 7	Command tag	The command tag parameter identifies the response to the command sent by the host.

NOTE

GenericResponse in ROM is only used as a response for all unsupported commands, in which:

- Status = 10000 (Unknown command)
- Command tag = command tag in the Command header.

GetPropertyResponse: The target sends the GetPropertyResponse packet in response to the host query that uses the GetProperty command. The GetPropertyResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a GetPropertyResponse tag value (0xA7).

The parameter count field in the header is set to greater than 1, to always include the status code and one or many property values.

The GetPropertyResponse parameters are provided below:

Table 107. GetPropertyResponse parameters

Byte #	Value	Parameter
0 - 3		Status code
4 - 7		Property code
. . .		. . .
		Can be up to maximum 6 property values. Limited to the size of the 32-bit command packet and property type.

The possible status are:

- 0 - kStatus_Success
- 10300 - Unknown Property

12.8.1.2 Packet Types for USB-HID Protocol

There are 3 types of packets supported in USB-HID protocol:

- Framing packet
- Command packet
- Data packet

12.8.1.2.1 HID Reports

There are 4 HID reports defined and used by the boot ROM USB HID protocol. The report ID determines the direction and type of packet sent in the report. Otherwise, the contents of all reports are the same.

The HID reports for the USB-HID protocol are provided below:

Table 108. HID reports for the USB-HID protocol

Report ID	Packet Type	Direction
1	Command	OUT (Host -> Device)
2	Data	OUT (Host -> Device)
3	Command	IN (Device -> Host)

12.8.1.2.2 Framing Packet

The framing packet has a 4-byte framing header, in which the report ID and the packet length is used for the packet type definition and the real payload size.

Table 109. USB-HID Framing Packet

Byte #	Data Type	Value	Note
0	Framing Header	Report ID	
1		Padding byte	Must be 0
2		Packet Length LSB	Max size is limited to 1016 bytes
3		Packet Length MSB	
4	Payload	Packet [0]	
5		Packet [1]	
		…	
N+4-1		Packet [N-1]	

12.8.1.2.3 Command Packet

The Report ID needs to be '1' for Command, and it must be '3' for Response. The payload definition is the same with Serial Packet Protocol.

12.8.1.2.4 Data Packet

The Report ID must be '2' in data packet. The payload definition is the same with Serial Protocol.

12.8.2 Serial Boot via UART and LPSPI

12.8.2.1 UART Configuration Details

Provided below are the details of UART configuration in boot ROM:

- **8-N-1** (8-bit data, No parity bit, 1 stop bit)
- Auto-baud detection is supported during Serial Boot.
- The host tool needs to send out the data packet with maximum payload size (512 bytes) set in framing packet by packet, except for the last packet. ROM will end the transfer if the payload size is less than the maximum payload size.
- The first packet on UART must be Ping to perform auto-baud detection.

12.8.2.2 LPSPI Configuration Details

Provided below are the details of LPUART configuration in boot ROM:

- 4-wire interface: CS, SCK, MOSI(SIN) and MISO(SOUT)
- After the host tool sent out a request, ROM may need some time to process the request before sending out actual response. If SPI host is expecting a response packet, the host tool should poll for start byte(0x5A). A valid start byte, instead of an empty byte(0x00), indicates ROM has done processing and response packet is ready.
- Recommended polling interval is ≥120μs.
- The host tool needs to send out the data packet with maximum payload size (512 bytes) set in framing packet by packet, except for the last packet. ROM will end the transfer if the payload size is less than the maximum payload size.

12.8.2.3 Example Communication Sequences

1. **Ping** (for auto-baud detection)
   Host: Ping packet [5a **a6**]
   Device: Ping response < 5a **a7** 00 02 01 50 00 00 aa ea>
2. **Command packet** (Get-Property 1)
   Host: Command [5a **a4** 0c 00 4b 33 07 00 00 02 01 00 00 00 00 00 00 00]
   - 5a - Start Byte
   - **a4** - Packet Type: Command packet
   - 0c 00 - Payload size(0x000c)
   - 4b 33 - CRC checksum(0x334b)
   - 07 00 00 02 01 00 00 00 00 00 00 00 - Payload (Get-property 1)

   Device: Ack < 5a **a1**>
   - 5a - Start Byte
   - **a1 -** ACK

   Device: GetPropertyResponse < 5a **a4** 0c 00 64 18 a7 00 00 02 00 00 00 00 00 01 02 4b>
   - 5a - Start Byte
   - **a4** - Packet Type: Command packet
   - 0c 00 - Payload size (0x000c)
   - 64 18 - CRC Checksum (0x1864)
   - a7 00 00 02 00 00 00 00 00 01 02 4b - Payload (GetPropertyResponse, status = 0, property = 0x4b020100)

   Host: Ack [5a **a1**]
   - 5a - Start Byte
   - **a1 -** ACK
3. **Load Image**
   1. First Data packet:
      Host: Data packet [5a **a5** 00 02 55 03 d1 00 20 41 …]
      - 5a - Start Byte
      - **a5** - Packet Type: Data packet
      - 00 02 - Payload size(0x0200)
      - 55 03 - CRC Checksum(0x0355)
      - d1 00 20 41 … - Payload (Data stream)

      Device: Ack < 5a **a1**>
      - 5a - Start Byte
      - **a1 -** ACK

   2. Report the remaining data transfer following the same flow as the first data packet.
   3. Last Data packet:
      Host: Data packet [5a **a5** 84 00 37 39 07 46 38 …]
      - 5a - Start Byte
      - **a5** - Packet Type: Data packet
      - 84 00 - Payload size(0x0084)
      - 37 39 - CRC Checksum(0x3937)
      - 07 46 38 … - Payload (Data stream)

      Device: Ack < 5a **a1**>

Figure 60. Example Communication sequences

12.8.3 Serial Boot via USB-HID

12.8.3.1 USB configuration Details

The USB OTG function device driver supports a high speed (HS for UTMI) non-stream mode with a maximal packet size of 512 B and a low-level USB OTG function.

The VID/PID and strings for the USB device driver are listed in the following table.

Table 110. VID/PID and strings for USB device driver

Descriptor	Value
VID	0x1FC9 (NXP vendor ID)
PID[1]	0x014C
String Descriptor1 (manufacturer)	NXP SEMICONDUCTORS
String Descriptor2 (product)	#LC Blank RT Family **NOTE** #LC is the 2 characters of the abbreviation for lifecycles: OEM OPEN: OO OEM SECURE: OS OEM CLOSED: OC OEM FIELD RETURN: FO OEM LOCKED: OL
String Descriptor3	MCU HID GENERIC DEVICE

1. Allocation based on the BPN (Before Part Number)

12.8.3.2 Endpoints

The HID peripheral uses 3 endpoints:

- Control (0)
- Interrupt IN (1)
- Interrupt OUT (2)

The interrupt OUT endpoint is optional for HID class devices, but the boot ROM uses it as a pipe, where the firmware can NAK send requests from the USB host.

12.8.3.3 Example Communication Sequences

1. **Command packet** (Get-Property 1)
   Host: Command [**01** 00 0c 00 07 00 00 02 01 00 00 00 00 00 00 00]
   - **01** - Command report, Direction: OUT, Host to device
   - 00 - Padding byte
   - 0c 00 - Payload size(0x000c)
   - 07 00 00 02 01 00 00 00 00 00 00 00 - payload

   Device: Ack (USB Hardware Ack)
   Device: GetPropertyResponse < **03** 00 0c 00 a7 00 00 02 00 00 00 00 00 01 03 4b 00 00 00 00 00 … 00>
   - **03 -** Command report, Direction: IN, Device to host
   - 00 - Padding byte
   - 0c 00 - Payload size(0x000c)
   - a7 00 00 02 00 00 00 00 00 01 02 4b - Payload (GetPropertyResponse, status=0, property=0x4b030100)
   - 00 00 00 00 00 … 00 - Padding bytes

   Host: Ack (USB Hardware Ack)
2. **Load Image**
   1. First Data packet:
      Host: Data packet [**02** 00 f4 03 d1 00 20 41 01 a4 00 00 00 00 00 00 00 …]
      02 - Data report, Direction: OUT, Host to device
      00 - Padding byte
      f4 03 - Payload size(0x03f4)
      d1 00 20 41 01 a4 00 00 00 00 00 00 00 … - Payload
      Device: Ack (USB Hardware Ack)
   2. Report the remaining data transfer following the same flow as the first data packet.
   3. Last Data packet:
      Host: Data packet [**02** 00 d4 00 20 c5 28 d9 00 f0 0b f8 00 …]
      02 - Data report, Direction: OUT, Host to device
      00 - Padding byte
      d4 00 - Payload size(0x00d4)
      20 c5 28 d9 00 f0 0b f8 00 … - Payload
      Device: Ack (USB Hardware Ack)

Figure 61. Example Communication sequences

12.9 ROM APIs

12.9.1 Introduction

The ROM bootloader provides a set of ROM APIs to simplify the In-Application Programming (IAP).

The ROM bootloader supports the following APIs:

- runBootloader API
- FlexSPI NOR FLASH Driver API

The ROM API root pointer for Cortex-M33 core is located at address 0x1000_001C. There is no ROM API root pointer for Cortex-M7 due to the vector table is only for Cortex_M33 core. The ROM API root for Cortex-M7 is located at 0x0011_F000. Please see the following figure for details of the ROM API layout.

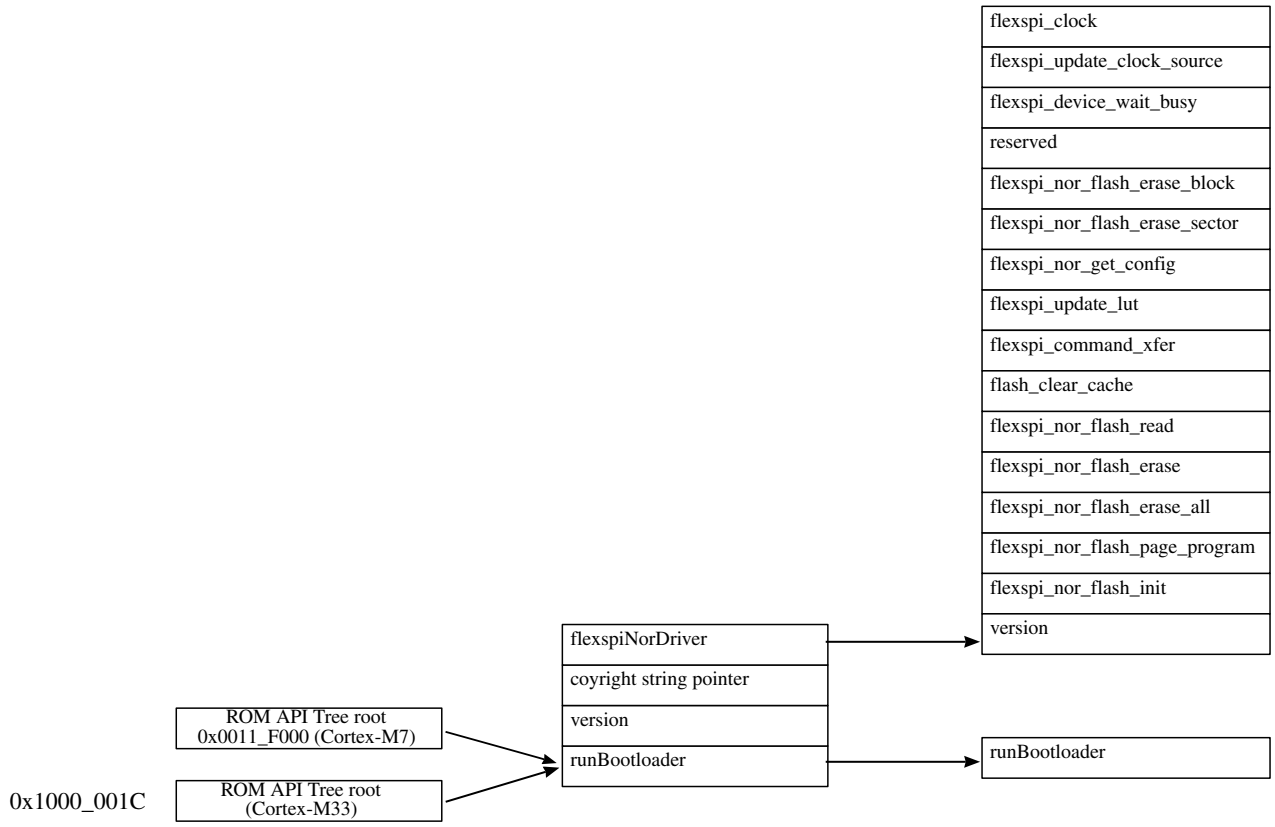


Figure 62. ROM API Structure

The ROM API structure definitions are as below.

- Bootloader API Entry Structure

```
                    typedef struct BootloaderTree
                    {
                        void (*runBootloader)(void *arg);                   //Function to start
the bootloader executing.
                        standard_version_t version;                         //Bootloader
version number.
                        const char *copyright;                              //Copyright string.
                        const flexspi_nor_flash_driver_t *flexspiNorDriver; //FlexSPI NOR FLASH
Driver API.
                    } bootloader_tree_t;
```

- FlexSPI NOR Driver API structure

```
                typedef struct
                {
                    uint32_t version;
                    status_t (*init)(uint32_t instance, flexspi_nor_config_t *config);

                    status_t (*page_program)(uint32_t instance, flexspi_nor_config_t *config,
uint32_t dstAddr, const uint32_t *src);
```

```
                    status_t (*erase_all)(uint32_t instance, flexspi_nor_config_t *config);
                    status_t (*erase)(uint32_t instance, flexspi_nor_config_t *config, uint32_t
start, uint32_t length);

                    status_t (*read)(uint32_t instance, flexspi_nor_config_t *config, uint32_t
*dst, uint32_t start, uint32_t bytes);
                    void (*clear_cache)(unit32_t instance);
                    status_t (*xfer)(uint32_t instance, flexspi_xfer_t *xfer);

                    status_t (*update_lut)(uint32_t instance, uint32_t seqIndex, const uint32_t
*lutBase, uint32_t numberOfSeq);
                    status_t (*get_config)(uint32_t instance, flexspi_nor_config_t *config,
serial_nor_config_option_t *option);
                    status_t (*erase_sector)(uint32_t instance, flexspi_nor_config_t *config,
uint32_t address);
                    status_t (*erase_block)(uint32_t instance, flexspi_nor_config_t *config,
uint32_t address);
                    uint32_t reserved;
                    status_t (*wait_busy)(uint32_t instance, flexspi_nor_config_t *config, bool
isParallelMode, uint32_t address);
                    status_t (*set_clock_source)(uint32_t instance, uint32_t clockSrc);
                    void (*config_clock)(uint32_t instance, uint32_t freqOption,
uint32_t sampleClkMode);

                } flexspi_nor_flash_driver_t;
```

12.9.2 FlexSPI NOR APIs

The ROM bootloader provides a set of Serial NOR FLASH APIs to simplify the external FLASH enablement on the chip. The version of the FlexSPI NOR API in the chip's ROM bootloader is 1.8.3.

12.9.2.1 Flexspi_nor_get_config

This API is used for getting the flash_config context.

Prototype

status_t flexspi_nor_get_config(uint32_t instance, flexspi_nor_config_t *config, serial_nor_config_option_t *option)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
option	Serial NOR flash configuration option

The flexspi_nor_config_t is defined as following:

```
          typedef struct _flexspi_nor_config
          {
              flexspi_mem_config_t memConfig; // Common memory configuration info via FlexSPI
              uint32_t pageSize;              // Page size of Serial NOR
              uint32_t sectorSize;            // Sector size of Serial NOR
              uint8_t ipcmdSerialClkFreq;     // Clock frequency for IP command
              uint8_t isUniformBlockSize;     // Sector/Block size is the same
```

```
                uint8_t isDataOrderSwapped;     // Data order (D0, D1, D2, D3) is swapped (D1,D0, D3,
D2)
                uint8_t reserved0[1];           // Reserved for future use
                uint8_t serialNorType;          // Serial NOR Flash type: 0/1/2/3
                uint8_t needExitNoCmdMode;      // Need to exit NoCmd mode before other IP command
                uint8_t halfClkForNonReadCmd;   // Half the Serial Clock for non-read command: true/
false
                uint8_t needRestoreNoCmdMode;   // Need to Restore NoCmd mode after IP commmand
execution
                uint32_t blockSize;             // Block size
                uint32_t flashStateCtx;         // Flash State Context
                uint32_t reserve2[10];          // Reserved for future use
            } flexspi_nor_config_t;
```

The flexspi_mem_config_t is defined as following:

```

            typedef struct _FlexSPIConfig
            {
                uint32_t tag;               // [0x000-0x003] Tag, fixed value 0x42464346UL
                uint32_t version;           // [0x004-0x007] Version,[31:24] -'V', [23:16] - Major,
[15:8] - Minor, [7:0] - bugfix
                uint32_t reserved0;         // [0x008-0x00b] Reserved for future use
                uint8_t readSampleClkSrc;   // [0x00c-0x00c] Read Sample Clock Source, valid value:
0/1/3
                uint8_t csHoldTime;         // [0x00d-0x00d] CS hold time, default value: 3
                uint8_t csSetupTime;        // [0x00e-0x00e] CS setup time, default value: 3
                uint8_t columnAddressWidth; // [0x00f-0x00f] Column Address with, for HyperBus
protocol, it is fixed to 3, For
                //! Serial NAND, need to refer to datasheet
                uint8_t deviceModeCfgEnable; // [0x010-0x010] Device Mode Configure enable flag, 1 -
Enable, 0 - Disable
                uint8_t deviceModeType; // [0x011-0x011] Specify the configuration command type:Quad
Enable, DPI/QPI/OPI switch,
                //! Generic configuration, etc.
                uint16_t waitTimeCfgCommands; // [0x012-0x013] Wait time for all configuration
commands, unit: 100us, Used for
                //! DPI/QPI/OPI switch or reset command
                flexspi_lut_seq_t deviceModeSeq; // [0x014-0x017] Device mode sequence info, [7:0] -
LUT sequence id, [15:8] - LUt
                //! sequence number, [31:16] Reserved
                uint32_t deviceModeArg;    // [0x018-0x01b] Argument/Parameter for device
configuration
                uint8_t configCmdEnable;   // [0x01c-0x01c] Configure command Enable Flag, 1 -
Enable, 0 - Disable
                uint8_t configModeType[3]; // [0x01d-0x01f] Configure Mode Type, similar as
deviceModeTpe
                flexspi_lut_seq_t
                configCmdSeqs[3]; // [0x020-0x02b] Sequence info for Device Configuration command,
similar as deviceModeSeq
                uint32_t reserved1;   // [0x02c-0x02f] Reserved for future use
                uint32_t configCmdArgs[3];     // [0x030-0x03b] Arguments/Parameters for device
Configuration commands
                uint32_t reserved2;            // [0x03c-0x03f] Reserved for future use
                uint32_t controllerMiscOption; // [0x040-0x043] Controller Misc Options, see Misc
feature bit definitions for more
                //! details
                uint8_t deviceType;    // [0x044-0x044] Device Type:  See Flash Type Definition for
more details
```

```
                uint8_t sflashPadType; // [0x045-0x045] Serial Flash Pad Type: 1 - Single, 2 - Dual,
4 - Quad, 8 - Octal
                uint8_t serialClkFreq; // [0x046-0x046] Serial Flash Frequencey, device specific
definitions, See System Boot
                //! Chapter for more details
                uint8_t lutCustomSeqEnable; // [0x047-0x047] LUT customization Enable, it is required
if the program/erase cannot
                //! be done using 1 LUT sequence, currently, only applicable to HyperFLASH
                uint32_t reserved3[2]; // [0x048-0x04f] Reserved for future use
                uint32_t sflashA1Size; // [0x050-0x053] Size of Flash connected to A1
                uint32_t sflashA2Size; // [0x054-0x057] Size of Flash connected to A2
                uint32_t sflashB1Size; // [0x058-0x05b] Size of Flash connected to B1
                uint32_t sflashB2Size; // [0x05c-0x05f] Size of Flash connected to B2
                uint16_t reserved4;    // [0x060-0x063] CS pad setting override value
                uint8_t csPadSettingOverrideEn;
                uint8_t csPadSettingOverride;
                uint16_t reserved5; // [0x064-0x067] SCK pad setting override value
                uint8_t sclkPadSettingOverrideEn;
                uint8_t sclkPadSettingOverride;
                uint16_t reserved6; // [0x068-0x06b] data pad setting override value
                uint8_t dataPadSettingOverrideEn;
                uint8_t dataPadSettingOverride;
                uint16_t reserved7; // [0x06c-0x06f] DQS pad setting override value
                uint8_t dqsPadSettingOverrideEn;
                uint8_t dqsPadSettingOverride;
                uint32_t timeoutInMs;                // [0x070-0x073] Timeout threshold for read
status command
                uint32_t commandInterval;            // [0x074-0x077] CS deselect interval between
two commands
                flexspi_dll_time_t dataValidTime[2]; // [0x078-0x07b] CLK edge to data valid time for
PORT A and PORT B
                uint16_t busyOffset;                 // [0x07c-0x07d] Busy offset, valid value: 0-31
                uint16_t busyBitPolarity; // [0x07e-0x07f] Busy flag polarity, 0 - busy flag is 1
when flash device is busy, 1 -
                //! busy flag is 0 when flash device is busy
                uint32_t lookupTable[64];           // [0x080-0x17f] Lookup table holds Flash command
sequences
                flexspi_lut_seq_t lutCustomSeq[12]; // [0x180-0x1af] Customizable LUT Sequences
                uint32_t reserved8[4];              // [0x1b0-0x1bf] Reserved for future use
            } flexspi_mem_config_t;
```

The serial_nor_config_option_t is defined as following:

```

            typedef struct _serial_nor_config_option
            {
            union
            {
            struct
            {
            uint32_t max_freq : 4;                  // Maximum supported Frequency
            uint32_t misc_mode : 4;                 // miscellaneous mode
            uint32_t quad_mode_setting : 4;     // Quad mode setting
            uint32_t cmd_pads : 4;                  // Command pads
            uint32_t query_pads : 4;                // SFDP read pads
            uint32_t device_type : 4;               // Device type
            uint32_t option_size : 4;               // Option size, in terms of uint32_t, size =
(option_size + 1) * 4
            uint32_t tag : 4;                           // Tag, must be 0x0E
```

```
            } B;
            uint32_t U;
            } option0;

            union
            {
            struct
            {
            uint32_t dummy_cycles : 8;             // Dummy cycles before read
            uint32_t status_override : 8;          // Override status register value during device
mode configuration
            uint32_t pinmux_group : 4;            // The pinmux group selection
            uint32_t dqs_pinmux_group : 4;     // The DQS Pinmux Group Selection
            uint32_t pad_setting : 3;              // The Drive Strength of FlexSPI Pads
            uint32_t pad_setting_en : 1;        // The Drive Strength enable of FlexSPI Pads
            uint32_t flash_connection : 4;         // Flash connection option: 0 - Single Flash
connected to port A, -
            //! 1- Parallel mode, 2 - Single Flash connected to Port B
            } B;
            uint32_t U;
            } option1;

            } serial_nor_config_option_t;
```

Table 111. serial_nor_config_option_t definition

Offset	Field	Description
0	Option0	See Table 112 for more details.
4	Option1	Optional, valid only if the Option Size field in Option0 is non-zero. See Table 113 for more details.

Table 112. Option0 definition

Field	Bits	Description
tag	31:28	The tag of the config option, fixed to 0x0C
option_size	27:24	Size in bytes = (Option Size + 1) × 4 It is 0 if only option0 is required
device_type	23:20	Device Detection Type 0 - Read SFDP for SDRcommands 1 - Read SFDP for DDR Read commands 2 - HyperFLASH 1V8 3 - HyperFLASH 3V 4 - Macronix Octal DDR 6 - Micron Octal DDR 8 - Adesto EcoXiP DDR
query_pad	19:16	Data pads during Query command (read SFDP or read MID)

Table continues on the next page...

Table 112. Option0 definition (continued)

Field	Bits	Description
		0 - 1 2 - 4 3 – 8
cmd_pad	15:12	Data pads during Flash access command 0 - 1 2 - 4 3 – 8
quad_mode_sett ing	11:8	Quad Mode Enable Setting 0 - Not configured 1 - Set bit 6 in Status Register1 2 - Set bit 1 in Status Register2 3 - Set bit 7 in Status Register2 4 - Set bit 1 in Status Register 2 vis 0x31command **NOTE** This field is valid only if a device is compliant with JESD216 only (9 longword SDFP table).
misc_mode	7:4	Set to 0.
max_freq	3:0	Max Flash Operation speed 0 - Do not change FlexSPI clock setting **NOTE** The field has a restriction that the FlexSPI clock source must be PLL480_PFD0. Keep it as 0 and manually configure the FLEXSPI clock if another clock source is selected in user application.

Table 113. Option1 definition

Field	Bits	Description
flash_connection	31:28	Flash connection selection 0 - Single FLASH connected to Port A 1 - Parallel mode 2 - Single FLASH connected to Port B
reserved	27:20	Reserved

Table continues on the next page...

Table 113. Option1 definition (continued)

Field	Bits	Description
pin_group	19:16	PinMux group 0 - Primary pin group 1 - Secondary pingroup
reserved	15:8	Reserved
dummy_cycles	7:0	Dummy cycles for the read command 0 - Use detected dummy cycle Others - dummy cycles provided in flash datasheet

NOTE

- These APIs only support FLASH devices connected to SS0.
- The APIs always use 30MHz clock for the programming option. Users will need to change the "ipcmdSerialClkFreq" field in flexspi_nor_config_t field after flexspi_nor_get_config option, if a higher programming speed is expected.
- User application needs to set "max_freq" to 0 and manually configure the FLEXSPI clock before calling the flexspi_nor_get_config API, if the expected FLEXSPI clock source is not the default clock source configured by the ROM bootloader.
- The pad drive strength is configured to full-driver mode (see IOMUXC chapter for more details). Users can change the "dataPadOverride" and "sclkPadOverride" setting in flexspi_nor_config_t structure after calling flexspi_nor_get_config, if necessary.

12.9.2.2 flexspi_nor_flash_init

This API is used for initializing the flash controller and the flash_config context.

Prototype

status_t flexspi_nor_flash_init(uint32_t instance, flexspi_nor_config_t *config)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
config	Pointer to flash_config_t data structure in memory to store driver runtime state.

12.9.2.3 flexspi_nor_flash_page_program

This API is used for programming data to Serial NOR via FlexSPI.

Prototype

status_t flexspi_nor_flash_page_program(uint32_t instance, flexspi_nor_config_t *config, uint32_t dstAddr, const uint32_t *src)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
dstAddr	The destination address
src	The source address

12.9.2.4 flexspi_nor_flash_erase_all

This API is used for erasing all the Serial NOR devices connected on FlexSPI.

Prototype

status_t flexspi_nor_flash_erase_all(uint32_t instance, flexspi_nor_config_t *config)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
config	Pointer to flash_config_t data structure in memory to store driver runtime state.

12.9.2.5 flexspi_nor_flash_erase

This API is used to erase Flash region specified by address and length.

Prototype

status_t flexspi_nor_flash_erase(uint32_t instance, flexspi_nor_config_t *config, uint32_t start, uint32_t length)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
start	The start address to be erased.
length	The length of bytes to be erased.

The start address will be aligned down to the sector size. Erase size is sector aligned.

12.9.2.6 flexspi_nor_flash_read

This API is used for reading the FLASH via FLEXSPI using IP read command.

Prototype

status_t flexspi_nor_flash_read(uint32_t instance, flexspi_nor_config_t *config, uint32_t *dst, uint32_t start, uint32_t bytes)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
dst	The rx buffer to be read to.
start	The start address to be read from.
bytes	Number of bytes to be read.

12.9.2.7 flexspi_update_lut

This API is used to update the specified LUT entries.

Prototype

status_t flexspi_update_lut(uint32_t instance, uint32_t seqIndex, const uint32_t *lutBase, uint32_t numberOfSeq)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
seqIndex	The sequence index.
lutBase	Pointer to lookup table base.
numberOfSeq	Number of sequence.

12.9.2.8 flexspi_command_xfer

This API is used to perform FlexSPI command.

Prototype

status_t flexspi_command_xfer(uint32_t instance, flexspi_xfer_t *xfer)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
xfer	Pointer to flexspi_xfer_t

flexspi_xfer_t definition is as below:

```
typedef struct _FlexSpiXfer
{
    flexspi_operation_t operation;        // FlexSPI operation
    uint32_t baseAddress;                     // FlexSPI operation base address
    uint32_t seqId;                       // Sequence Id
    uint32_t seqNum;                       // Sequence Number
    bool isParallelModeEnable;         // Is a parallel transfer
    uint32_t *txBuffer;                    // Tx buffer
    uint32_t txSize;                       // Tx size in bytes
    uint32_t *rxBuffer;                    // Rx buffer
```

```
    uint32_t rxSize;                    // Rx size in bytes
} flexspi_xfer_t;
```

flexspi_operation_t definition is as below:

```
typedef enum _FlexSPIOperationType
{
kFlexSpiOperation_Command,
kFlexSpiOperation_Config,
kFlexSpiOperation_Write,
kFlexSpiOperation_Read,
kFlexSpiOperation_End = kFlexSpiOperation_Read,
} flexspi_operation_t;
```

12.9.2.9 flexspi_clear_cache

This API is used to clear the AHB buffer in FlexSPI.

Prototype

void flexspi_clear_cache(uint32_t instance)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance

12.9.2.10 flexspi_update_clock_source

This API is used to configure the FLEXSPI NOR clock to specified frequency.

Prototype

status_t flexspi_update_clock_source(uint32_t instance, uint32_t source)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
source	Clock sourcet. See the following table for details.

The source values are as defined below:

Value of source	FlexSPI1	FlexSPI2
0	Clk sourced from RC24M	
1	Clk sourced from RC400M	
2	Clk sourced from PFD0 of PLL480	Clk sourced from PFD2 of PLL480
3	Clk sourced from PFD0 of PLL528	Clk sourced from PFD1 of PLL528

12.9.2.11 flexspi_clock_config

This API is used to Configure the FLEXSPI clock to specified frequency.

Prototype

void flexspi_clock_config(uint32_t instance, uint32_t freq, uint32_t sampleClkMode)

The parameters are defined below:

Parameter	Description
instance	FlexSPI instance
freq	Enum of flexSpi serial clock.
sampleClkMode	Enum of clock mode.

flexSpi serial clock is defined as following.

```
enum
{
kFlexSpiSerialClk_30MHz = 1,
kFlexSpiSerialClk_50MHz = 2,
kFlexSpiSerialClk_60MHz = 3,
kFlexSpiSerialClk_80MHz = 4,
kFlexSpiSerialClk_100MHz = 5,
kFlexSpiSerialClk_120MHz = 6,
kFlexSpiSerialClk_133MHz = 7,
kFlexSpiSerialClk_166MHz = 8,

};
```

Clock mode is defined as following.

```
enum
{
kFlexSpiClk_SDR, // Clock configure for SDR mode
kFlexSpiClk_DDR, // Clock configurat for DDR mode
};
```

12.9.2.12 Status Codes for the FlexSPI NOR API

The following table lists all the error and status codes for the FlexSPI NOR API.

Table 114. Status and error codes for the FlexSPI NOR API

Status	Code	Description
kStatus_Success	0	Operation succeeded without error
kStatus_Fail	1	The operation failed with a generic error

Table continues on the next page...

Table 114. Status and error codes for the FlexSPI NOR API (continued)

Status	Code	Description
kStatus_InvalidArgument	4	The requested argument is invalid
kStatus_Timeout	5	A timeout occurred
kStatus_FLEXSPI_SequenceExecutionTimeout	7000	The command timed out
kStatus_FLEXSPI_InvalidSequence	7001	Invalid LUT sequence
kStatus_FLEXSPI_DeviceTimeout	7002	The busy time exceeded the specified timeout value
kStatus_FLEXSPINOR_ProgramFail	20100	Program Command failed
kStatus_FLEXSPINOR_EraseSectorFail	20101	Erase sector command failed
kStatus_FLEXSPINOR_EraseAllFail	20102	Erase All command failed
kStatus_FLEXSPINOR_WaitTimeout	20103	The wait time exceeded the specified timeout value
kStatus_FlexSPINOR_NotSupported	20104	The operation is not supported
kStatus_FlexSPINOR_WriteAlignmentEr ror	20105	Write address is unaligned to page size
kStatus_FlexSPINOR_CommandFailure	20106	Command failed
kStatus_FlexSPINOR_SFDP_NotFound	20107	SFDP table was not found, used for flexspi_nor_flash_get_config API
kStatus_FLEXSPINOR_Flash_NotFound	20109	Cannot detect a FLASH device
kStatus_FLEXSPINOR_DTRRead_Dum myProbeFailed	20110	The dummy cycle for DDR/DTR read cannot be probed.

12.9.2.12.1 Typical Options for the Serial NOR Devices in the Market

The following list provides typical options for the serial NOR flash devices in the market.

- QuadSPI NOR - Quad SDR Read: option0 = 0xc0000007 (133MHz)
- QuadSPI NOR - Quad DDR Read: option0 = 0xc0100003 (60MHz)
- HyperFLASH 1V8: option0 = 0xc0233008 (166MHz)
- HyperFLASH 3V0: option0 = 0xc0333005 (100MHz)
- MXIC OPI DDR (OPI DDR enabled by default): option=0xc0433007(133MHz)
- Micron Octal DDR: option0=0xc0600005 (100MHz)
- Micron OPI DDR: option0=0xc0603007 (133MHz), SPI->OPI DDR
- Micron OPI DDR (DDR read enabled by default): option0 = 0xc0633007 (133MHz)
- Adesto OPI DDR: option0=0xc0803007(133MHz)

12.9.2.12.2 FLASH API Example

The following is a typical use case of the FlexSPI NOR API.

```
            #ifdef CPU_IS_ARM_CORTEX_M7
            #define G_BOOTLOADER_TREE_ADDR         (0x0011f000u)
            #else
            #define G_BOOTLOADER_TREE_ADDR         ((uint32_t) (*(uint32_t *)(0x1000001cu)))
            #endif
            #define g_bootloaderTree              ((bootloader_tree_t *)G_BOOTLOADER_TREE_ADDR)

            flexspi_nor_config_t config;
            serial_nor_config_option_t option;
            status_t status;
            uint32_t address = 0x40000; // 256KB
            uint32_t sector_size = 0x1000; // 4KB
            uint32_t page_buffer[256/ sizeof(uint32_t)];
            uint32_t instance = 1;
            option.option0.U = 0xC0000007; // QuadSPI NOR, Frequency: 133MHz
            status = g_bootloaderTree->flexspiNorDriver->get_config(instance, &config, &option);
            if (status != kStatus_Success)
            {
            return status;
            }
            status = g_bootloaderTree->flexspiNorDriver->init(instance, &config);
            if (status != kStatus_Success)
            {
            return status;
            }
            status = g_bootloaderTree->flexspiNorDriver->erase(instance, &config, address ,
sector_size); // Erase 1 sector
            if (status != kStatus_Success)
            {
            return status;
            }

            // Fill data into the page_buffer;
            for (uint32_t i=0; i<sizeof(page_buffer)/sizeof(page_buffer[0]); i++)
                {
                page_buffer[i] = (i << 24) | (i << 16) | (i << 8) | i;
                }
                // Program data to destination
                status = g_bootloaderTree->flexspiNorDriver->page_program(instance, &config, address,
page_buffer); //Program 1 page
                if (status != kStatus_Success)
                {
                return status;
                }

                // Do cache maintenance here if the D-Cache is enabled
                // Use memory mapped access to verify whether data are programmed into Flash
correctly uint32_t mem_address = 0x3800_0000 + address;

                if (0 == memcmp((void*)mem_address, page_buffer, sizeof(page_buffer))
                {
                // Success
                }
                else
                {
```

```
                // Report error
                }
```

12.9.3 Enter Bootloader API

The ROM bootloader provides an API for the user application to safely boot from a newly updated application after In-Application Programming (IAP) or re-enter serial downloader mode for an image update.

Prototype

void run_bootloader(void *arg)

The parameters are defined below.

Parameter	Description
arg	See following table.

The arg definition is provided below.

Table 115. ARG definition

Field	Offset	Description
Tag	[31:24]	Fixed value: 0xEB (Enter Boot)
boot mode	[23:20]	0– Default boot mode based on bootloader. 1 – Force serial downloader
Serial downloader media	[19:16]	0 - Auto detection 1 - USB 2 - UART
Reserved	[15:04]	Reserved
Boot image selection	[03: 00]	0 - Image0 1 - Image1 2 - Image2 3 - Image3 **NOTE** It takes effect only if the boot mode is 0. For FlexSPI NOR boot, the maximum Image index is 1. The address and length of the backup image is specified in the fuse. Image 0 is always the latest image. Image 1 always implies the backup image. If the dual image boot feature is not implemented, the backup image means the 2nd image, otherwise, the backup image means the "old" image. For the NAND FLASH devices, the maximum image index is 3. The Image address is specified in FCB.

12.9.3.1 Enter Bootloader Example

Typical use cases:

1. Enter Serial downloader mode and select USB as the communication peripheral:

```
uint32_t arg = 0xeb110000;
runBootloader (&arg);
```

2. Select Image1 as the boot image after reliable update in user application:

```
uint32_t arg = 0xeb000001;
runBootloader (&arg);
```

12.10 Cortex-M7 kick-off procedure

The kick-off sequence for Cortex-M7 is as follows:

1. On POR, by default, Cortex-M7 is held in reset state and Cortex-M7 CPUWAIT is high (See M7_CFG[WAIT] in the chapter "Block Control Secure AONMIX").
2. Configure VTOR (See M7_CFG[INITVTOR] in the chapter "Block Control Secure AONMIX").
3. If you want to use non-default Cortex-M7 TCM size, configure M7_CFG[TCM_SIZE] (see chapter "Block Control Secure AONMIX"). This will be overridden by fuse CM7_TCM_CFG.
4. Release Cortex-M7 reset (See SCR[BT_RELEASE_M7] in the chapter "System Reset Controller (SRC)").
5. M33 enables DMA4 to initialize Cortex-M7 TCM to all zero by 64-bit write operation.

   NOTE

   If POR_PRELOAD_CM7_TCM_ECC fuse bit is programmed, skip the steps 4 and 5. But the VTOR is fixed to 0 and step 2 has no effect.

6. Load image of Cortex-M7 to target memory.
7. Authenticate the image using ELE OEM Container Authenticate followed by Verify Image and Release Container commands.

   NOTE

   If Cortex-M7 image is put as an individual image in container, ROM can authenticate image and get ELE to release it, may skip this step.

8. Check TRDC configuration, and ensure execution access allowable in target memory.
9. Send "Enable APC request" command to ELE to release Cortex-M7.
10. Clear Cortex-M7 CPUWAIT (See M7_CFG[WAIT] in the chapter "Block Control Secure AONMIX") to kick-off Cortex-M7.

    NOTE

    When the two applications of Cortex-M33 and Cortex-M7 run in the same device (for example, Flash, SDRAM), Cortex-M33 application needs to release TRDC for Cortex-M7 application before its kick-off.

Chapter 13
External Signals and Pin Multiplexing

13.1 Overview

The chip contains a limited number of pins, most of which have multiple signal options. These signal-to-pin and pin-to-signal options are selected by the input-output multiplexer called IOMUX. The IOMUX is also used to configure other pin characteristics, such as voltage level, drive strength. The hysteresis for pin input is supported in default, and can not be configured.

The muxing options table lists the external signals grouped by the module instance, the muxing options for each signal, and the registers used to route the signal to the chosen pad.

The IOMUX allows to share one pin/pad for several modules. This sharing is achieved by multiplexing pin/pad's input and output signals. Each pin/pad has more than one function, called alternate functions, and as result, each pin/pad can have many alternate logical pin names. The function selected depends on the pin setting in the appropriate IOMUX registers; each pin/pad has a set of dedicated registers.

13.1.1 Muxing Options

Table 116. Muxing Options

Instance	Port(logical pin names)	Pad	Mode (alternate functions)
ACMP1	ACMP1_OUT	GPIO_AD_17	ALT1
	ACMP1_IN1	GPIO_AD_00	No muxing
	ACMP1_IN2	GPIO_AD_01	No muxing

14.2 Overview

The Always-On Domain, Non-secure (AON NS) Block Control (BLK_CTRL_NS_AON) consists of a group of registers to provide miscellaneous control and status for peripherals within the AON domain. These registers provide chip-level control outside the peripherals.

14.2.1 Block diagram

A block diagram of the AON NS BLK CTRL implementation is shown below.

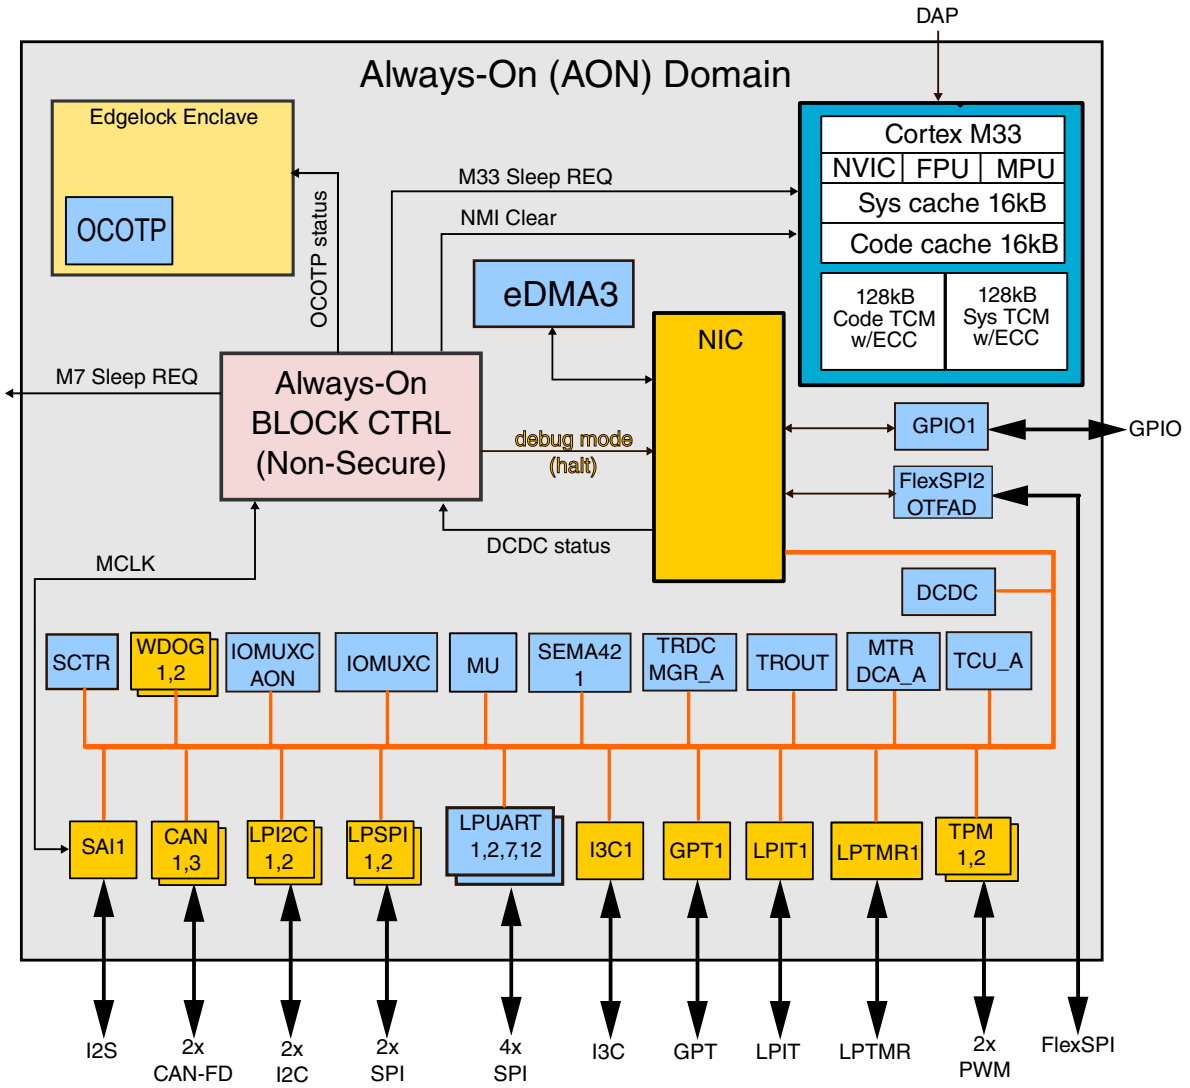

Figure 63. AON NS BLK CTRL Block Diagram

14.2.2 Features

Block Control Non-Secure AON Domain has the following features:

- Sleeping or deep sleeping selection for low power mode entry
- Debug halt mask bits for peripherals in AON Domain
- AON Domain SSI master block low power bits
- SAI1 MCLK direction control
- DCDC status bit and exception bits read and clear
- OCOTP miscellaneous status bits
- CM33 NMI interrupt clear bit
- I3C1 asynchronous interrupt clear bit
- I3C1 IO on chip strong pull enable bit

- GPIO_AON bank voltage range control

14.3 Clocks

The table found here describes the clock sources for BLK_CTRL_NS_AON. Please see the Clock Control chapter for clock setting, configuration, and gating information.

Table 119. Clocks

Clock Name	Description
bus_aon_clk	AON bus clock for register access.

14.4 Reset

The AON NS BLK_CTRL resets with the AON Domain.

14.5 Initialization

There are no initialization steps required for BLK_CTRL_NS_AON.

14.6 Memory Map and register definition

This section includes the BLK_CTRL_NS_AON memory map and detailed register descriptions.

14.6.1 Block Control Non-Secure AON Domain register descriptions

14.6.1.1 AON Domain Non_Secure Block Control memory map

BLK_CTRL_NS_AONMIX base address: 4421_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	GPC CORE SLEEP Request Select (GPC_CFG)	32	RW	0000_0000h
8h	IPG Debug mask (IPG_DEBUG)	32	RW	0000_0000h

28h	Fuse access disable register (FUSE_ACC_DIS)	32	R	0000_0000h
2Ch	M33 NMI interrupt clear register (M33_NMI_CLR)	32	RW	0000_0000h
30h	I3C1 async wakeup control register (I3C1_ASYNC_WAKEUP_CTRL)	32	RW	0000_0000h
34h	Miscellaneous control register of IO (MISC_IO_CTRL)	32	RW	0000_0000h

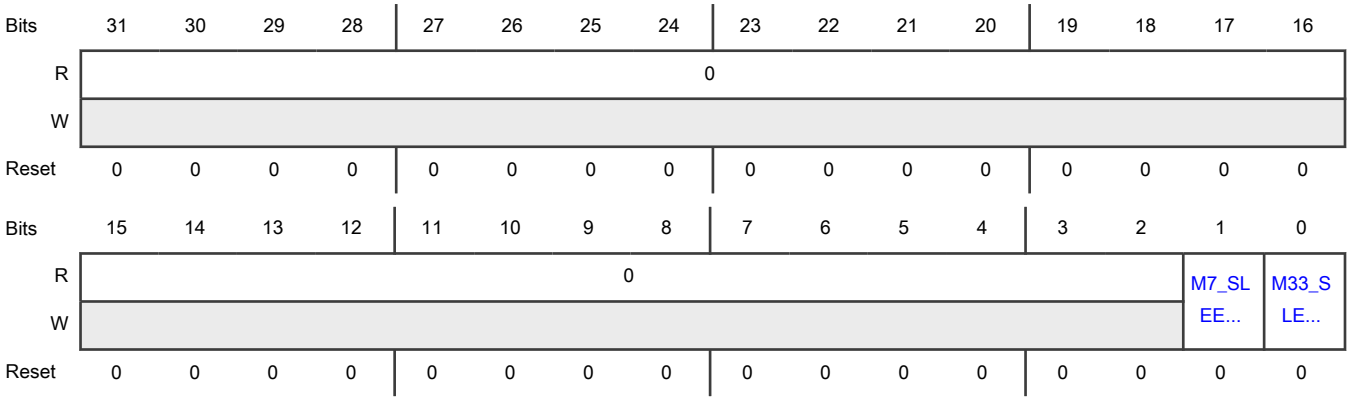
14.6.1.2 GPC CORE SLEEP Request Select (GPC_CFG)

Offset

Register	Offset
GPC_CFG	0h

Function
This register selects source for M33 and M7 core sleep request.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 M7_SLEEP_SEL	M7 SLEEP Request Select 0b - Select SLEEPING as request source 1b - Select SLEEPDEEP as request source
0 M33_SLEEP_SEL	M33 SLEEP Request Select 0b - Select SLEEPING as request source 1b - Select SLEEPDEEP as request source

14.6.1.3 IPG Debug mask (IPG_DEBUG)

Offset

Register	Offset
IPG_DEBUG	8h

Function

This register includes mask bits for HALTED from CM33/CM7 to peripheral ipg_debug

0: mask to 0

1: unmask

6 M33_LPSPI2	Mask bit for LPSPI2 debug halted mode with M33 core 0b - LPSPI2 does not enter debug halted mode with CM33 1b - LPSPI2 enters debug halted mode when CM33 is debug halted
5 M33_LPSPI1	Mask bit for LPSPI1 debug halted mode with M33 core 0b - LPSPI1 does not enter debug halted mode with CM33 1b - LPSPI1 enters debug halted mode when CM33 is debug halted

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 M33_LPIT1	Mask bit for LPIT1 debug halted mode with M33 core 0b - LPIT1 does not enter debug halted mode with CM33 1b - LPIT1 enters debug halted mode when CM33 is debug halted
3 M33_LPI2C2	Mask bit for LPI2C2 debug halted mode with M33 core 0b - LPI2C2 does not enter debug halted mode with CM33 1b - LPI2C2 enters debug halted mode when CM33 is debug halted
2 M33_LPI2C1	Mask bit for LPI2C1 debug halted mode with M33 core 0b - LPI2C1 does not enter debug halted mode with CM33 1b - LPI2C1 enters debug halted mode when CM33 is debug halted
1 M33_EDMA3	Mask bit for EDMA3 debug halted mode with M33 core 0b - EDMA3 does not enter debug halted mode with CM33 1b - EDMA3 enters debug halted mode when CM33 is debug halted
0 M33_CAN1	Mask bit for CAN1 debug halted mode with M33 core 0b - CAN1 does not enter debug halted mode with CM33 1b - CAN1 enters debug halted mode when CM33 is debug halted

14.6.1.4 (SSI)

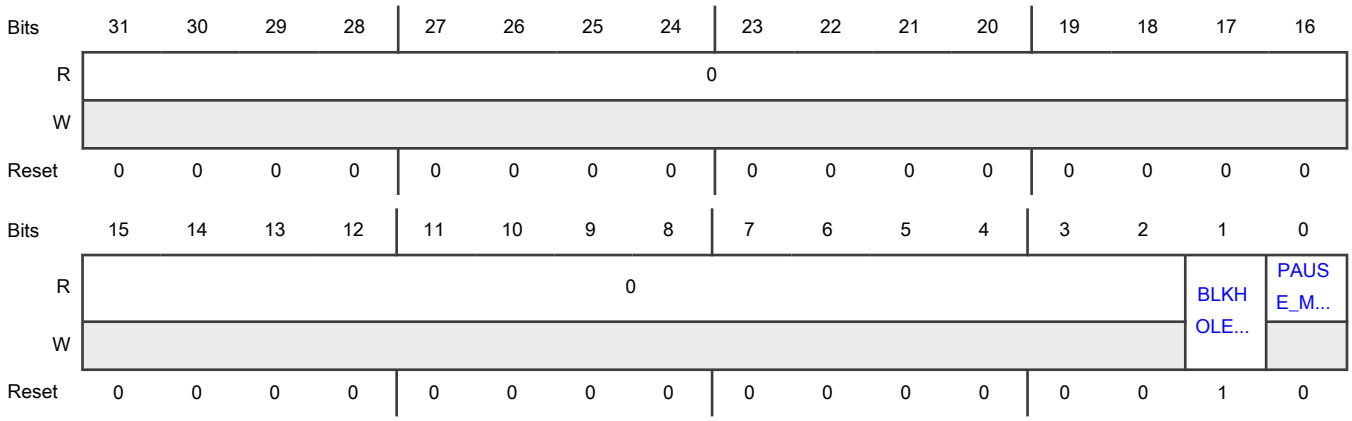
Offset

Register	Offset
SSI	1Ch

Function

SSI Master: AXI Async Bridge from AXIM to NIC400. Low power mode control.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 BLKHOLE_MODE_B	AON Domain SSI master blackhole mode 0: AON Domain SSI master will enter into blackhole mode 1: AON Domain SSI master will exit from blackhole mode 0b - AON Domain SSI master will enter into blackhole mode 1b - AON Domain SSI master will exit from blackhole mode
0 PAUSE_MODE	AON Domain SSI master pause mode 0: AON Domain SSI master is not in pause mode 1: AON Domain SSI master is in pause mode 0b - AON Domain SSI master is not in pause mode 1b - AON Domain SSI master is in pause mode

14.6.1.5 SAI1 MCLK control register (SAI1_MCLK_CTRL)

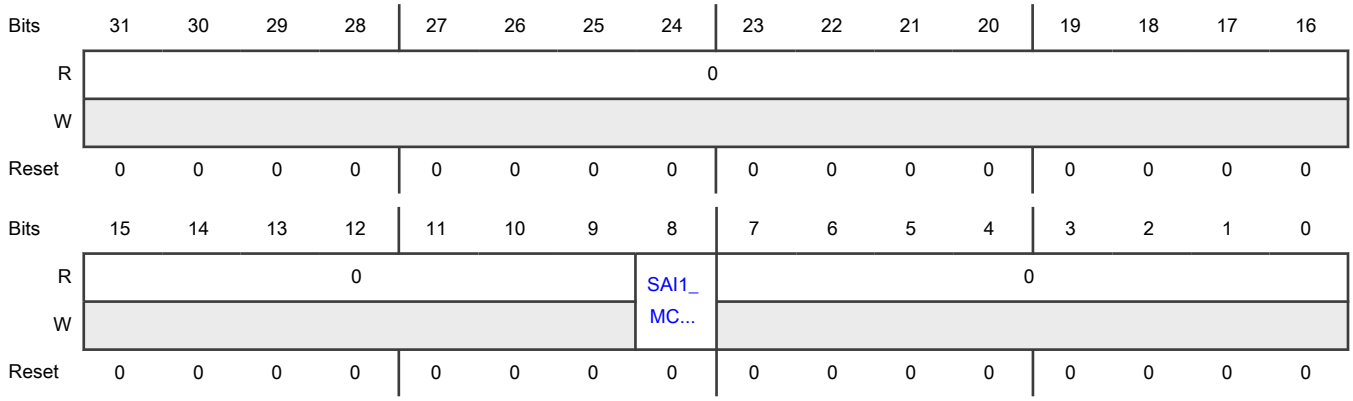
Offset

Register	Offset
SAI1_MCLK_CTRL	20h

Function

This register provides control of SAI1 MCLK direction

Diagram



Fields

Field	Function
31-9 —	Reserved
8 SAI1_MCLK_DIR	SAI1_MCLK IO direction control. IOMUX need select SAI1 MCLK function 0b - SAI1_MCLK is input signal 1b - SAI1_MCLK is output signal
7-0 —	Reserved

14.6.1.6 DCDC status register (DCDC_STATUS)

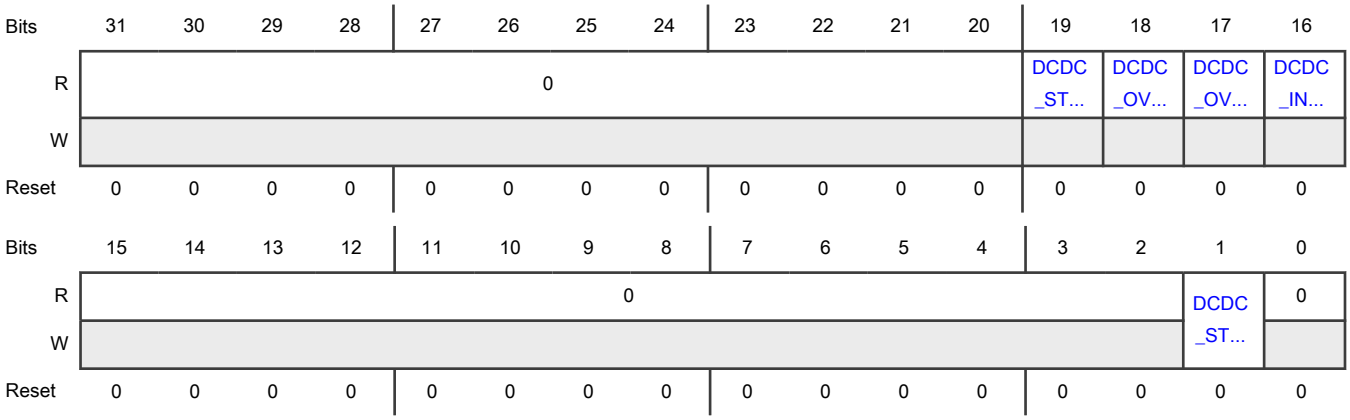
Offset

Register	Offset
DCDC_STATUS	24h

Function

This register records DCDC status. Failure statuses are stored in battery domain and can be read out via this register in next POR

Diagram



Fields

Field	Function
31-20 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
19 DCDC_STS_DC_OK	DCDC status OK Status register to indicate DCDC status. 0b - DCDC is settling 1b - DCDC already settled
18 DCDC_OVER_VOL	DCDC output over voltage alert 0b - No Overvoltage on DCDC VDDLP0 or VDDLP8 output 1b - Overvoltage on DCDC VDDLP0 or VDDLP8 output
17 DCDC_OVER_CUR	DCDC output over current alert 0b - No Overcurrent on DCDC output 1b - Overcurrent on DCDC output
16 DCDC_IN_LOW_VOL	DCDC_IN low voltage detect 0b - Voltage on DCDC_IN is higher than 2.6V 1b - Voltage on DCDC_IN is lower than 2.6V
15-2 —	Reserved
1 DCDC_STATUS_CAPT_CLR	DCDC captured status clear Write logic 1 to clear the 3 bits of DCDC captured status: DCDC_OVER_VOL, DCDC_OVER_CUR, and DCDC_IN_LOW_VOL. 0b - No change 1b - Clear the 3 bits of DCDC captured status: DCDC_OVER_VOL, DCDC_OVER_CUR, and DCDC_IN_LOW_VOL
0 —	Reserved

14.6.1.7 Fuse access disable register (FUSE_ACC_DIS)

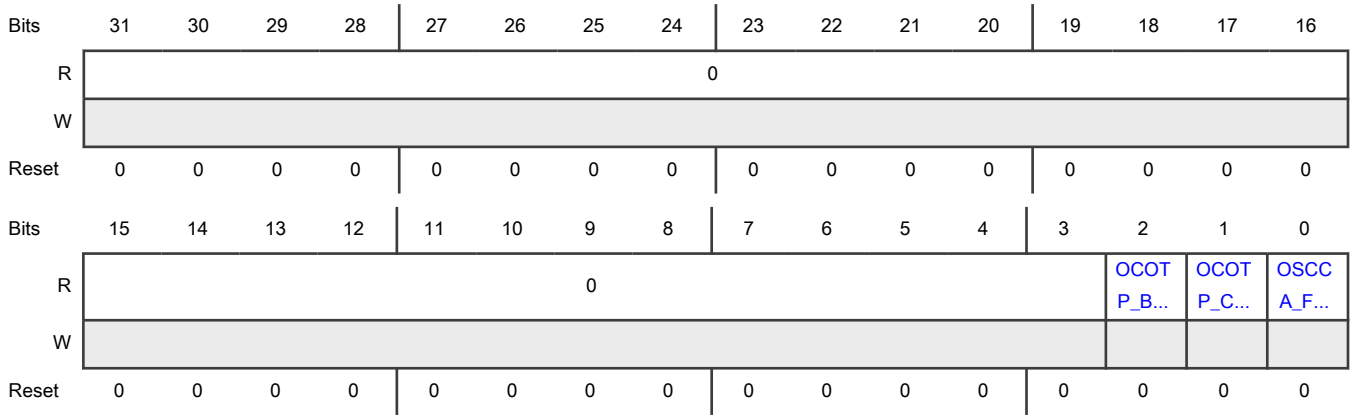
Offset

Register	Offset
FUSE_ACC_DIS	28h

Function

This register provides status bit to detect that SoC read access is not permitted of the OCOTP's shadow SRAM

Diagram



Fields

Field	Function
31-3 —	Reserved
2 OCOTP_BUSY	OCOTP busy flag This bit indicates whether OCOTP is busy. When it's busy fuse value is not readable. 0b - OCOTP is not busy 1b - OCOTP is busy
1 OCOTP_CALIBRATED	Fuse calibrate flag This bit indicates whether OCOTP calibration is done. 0b - OCOTP is not calibrated 1b - OCOTP is calibrated
0 OSCCA_FUSE_READ_DIS	Fuse read disable flag This bit indicates whether SoC is allowed to read OCOTP's shadow RAM. 0b - Read is allowed 1b - Read is not allowed

14.6.1.8 M33 NMI interrupt clear register (M33_NMI_CLR)

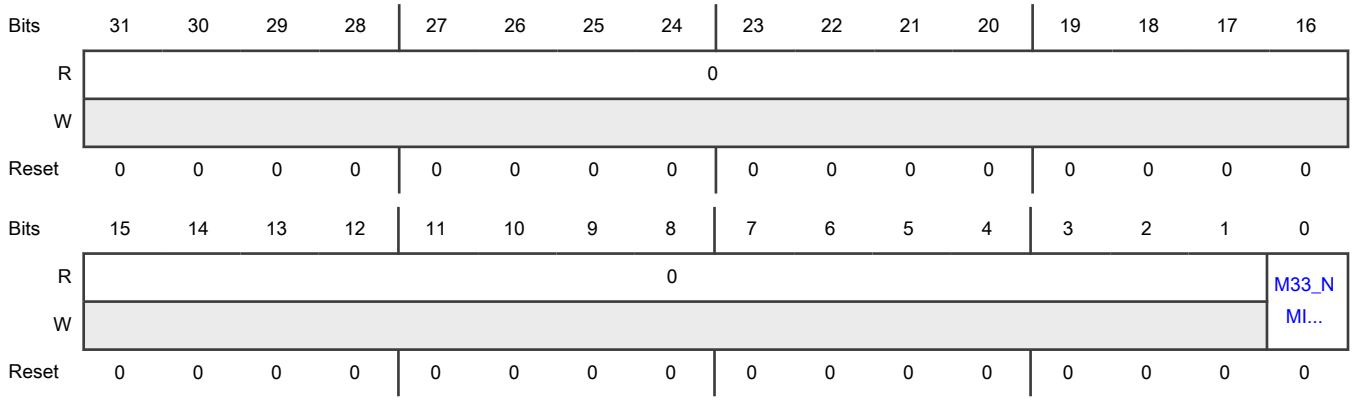
Offset

Register	Offset
M33_NMI_CLR	2Ch

Function

This register contains the M33_NMI_CLEAR bit used to clear the interrupt from the NMI input.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 M33_NMI_CLEAR	Clear CM33 NMI holding register The NMI input from IO will be held internally until this bit is set to 1. Note that this bit needs software to clear. Set it to 1 to clear the interrupt and following with writing it to 0 to complete the operation.

14.6.1.9 I3C1 async wakeup control register (I3C1_ASYNC_WAKEUP_CTRL)

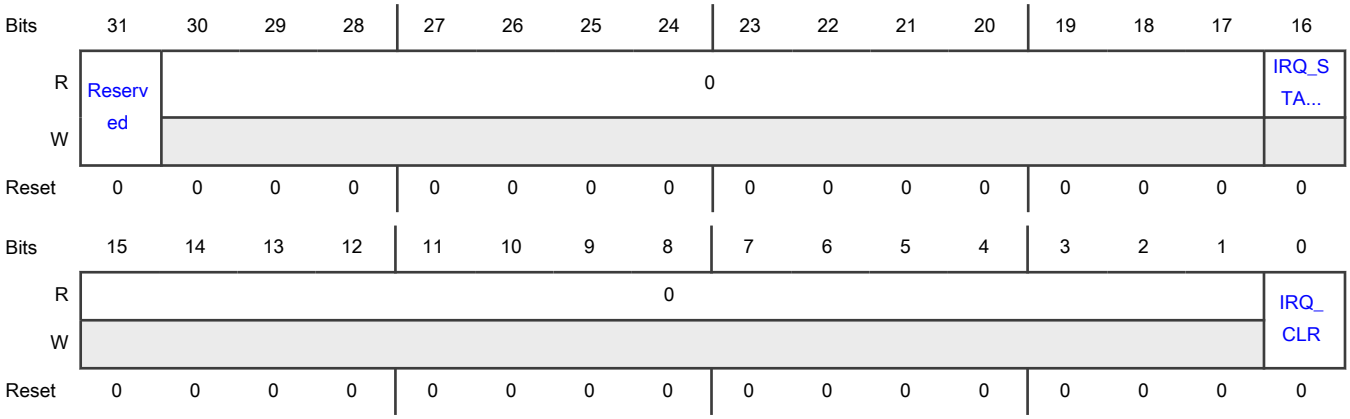
Offset

Register	Offset
I3C1_ASYNC_WAKEUP_CTRL	30h

Function

This register contains status and control for I3C1 async wakeup interrupt.

Diagram



Fields

Field	Function
31 —	Reserved
30-17 —	Reserved
16 IRQ_STATUS	Async wakeup interrupt status This bit indicates the status of I3C1 async wakeup interrupt for slave mode. The interrupt is enabled by bit 9 of I3C1 interrupt enable register of the I3C chapter. I3C master mode doesn't support async wakeup. 0b - Interrupt not asserted 1b - Interrupt asserted
15-1 —	Reserved
0 IRQ_CLR	Async wakeup interrupt clear This bit is to clear I3C1 async wakeup interrupt. The interrupt will be held until this bit is set to 1. Note that this bit needs software to clear. Set it to 1 to clear the interrupt and following with writing it to 0 to complete the operation.

14.6.1.10 Miscellaneous control register of IO (MISC_IO_CTRL)

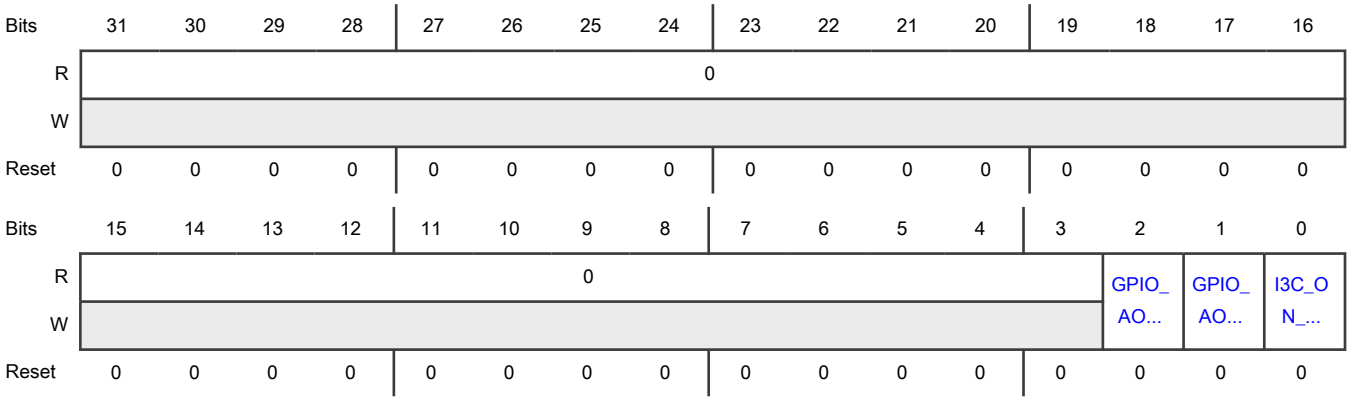
Offset

Register	Offset
MISC_IO_CTRL	34h

Function

This register provides controls to IO supply voltage detector and IO voltage range of particular IO banks.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 GPIO_AON_LOW_RANGE	GPIO_AON IO bank supply voltage range selection

GPIO_AON_HIGH_RANGE	GPIO_AON_LOW_RANGE	Mode

Chapter 15
Block Control - Always-on Domain, Secure (BLK_CTRL_S_AON)

15.1 Overview

Block control consists of a group of registers that provide control or status bits for other peripherals on the chip. These registers are to provide chip level control outside the peripherals. Block control covers peripherals of the corresponding mix. BLK_CTRL_NS_AONMIX and BLK_CTRL_S_AONMIX are in AONMIX.

Block Control Secure AONMIX has configuration controls that can potentially have security implications. Block Control Secure AONMIX memory slot is protected by TRDC configuration. The registers can only be accessed by TrustZone Secure World.

15.2 Features

Block Control Secure AONMIX has the following features:

- AXBS_AON priority and arbitration controls
- CM33 and CM7 NVIC interrupt masking
- EdgeLock interrupt and reset masking
- CM33 INITVTOR
- CM7 INITVTOR
- EdgeLock low power handshake enable
- IOMUXC domain control

15.3 Functional description

This block is a register container and doesn't have any function itself. The regisers it contained cover:

- AXBS_AON priority and arbitration controls
- CM33 and CM7 NVIC interrupt masking
- EdgeLock interrupt and reset masking
- CM33 INITVTOR
- CM7 INITVTOR
- EdgeLock low power handshake enable
- IOMUXC domain control

15.3.1 Clocks

Block Control Secure AONMIX uses BUS_AON_CLK for register read and write.

15.3.2 Reset

Block Control Secure AONMIX resets together with the AONMIX.

15.4 Memory Map and register definition

This section includes the Block Control Secure AONMIX module memory map and detailed descriptions of registers.

15.4.1 Block Control Secure AONMIX register descriptions

15.4.1.1 AONMIX Block Control for Secure World memory map

BLK_CTRL_S_AONMIX base address: 444F_0000h

15.4.1.19 EdgeLock IRQ request mask (EDGELOCK_IRQ_MASK)

Offset

Register	Offset
EDGELOCK_IRQ_MASK	5Ch

Function

This register provides mask bits for the interrupt requests from EdgeLock to ARM core. When the mask bit is set 1 the corresponding interrupt will not be sent to ARM core.

Diagram

15.4.1.29 IOMUXC domain configure (IOMUXC_DOMAIN_CFG)

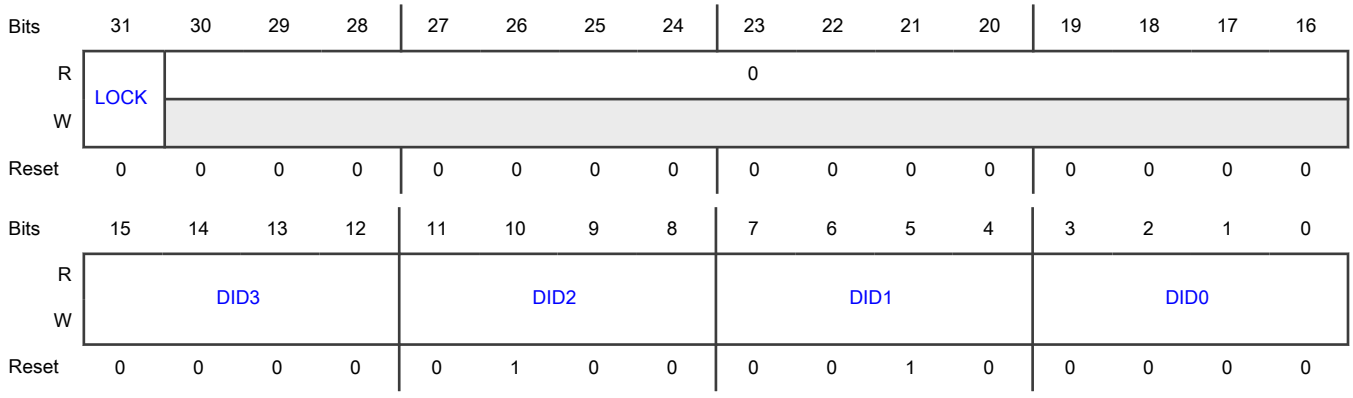
Offset

Register	Offset
IOMUXC_DOMAIN_CFG	148h

Function

This register provides the domain ID allowed to write IOMUXC registers. Only the write access from processor/bus master whose domain ID matches any of the ID in this register will be passed to IOMUXC, otherwise the write will be ignored. Read access to IOMUXC is always allowed regardless its domain ID. It provides write protection with smaller granularity in addition to the 64KB AIPS slot based protection of TRDC. Default domain ID of the masters can be found in TRDC chip specific information section.

Diagram



Fields

Field	Function
31 LOCK	Lock bit Once set to 1 this register cannot be changed any more.
30-16	Reserved

Table continues on the next page...

16.2 Overview

The WAKEUP Domain Block Control (BLK_CTRL_WAKEUP) module consists of a group of registers to provide miscellaneous control and status for peripherals within the WAKEUP Domain. These registers provide chip-level control outside the peripherals.

16.2.1 Block diagram

A block diagram of the Wakeup BLK_CTRL implementation is shown below.

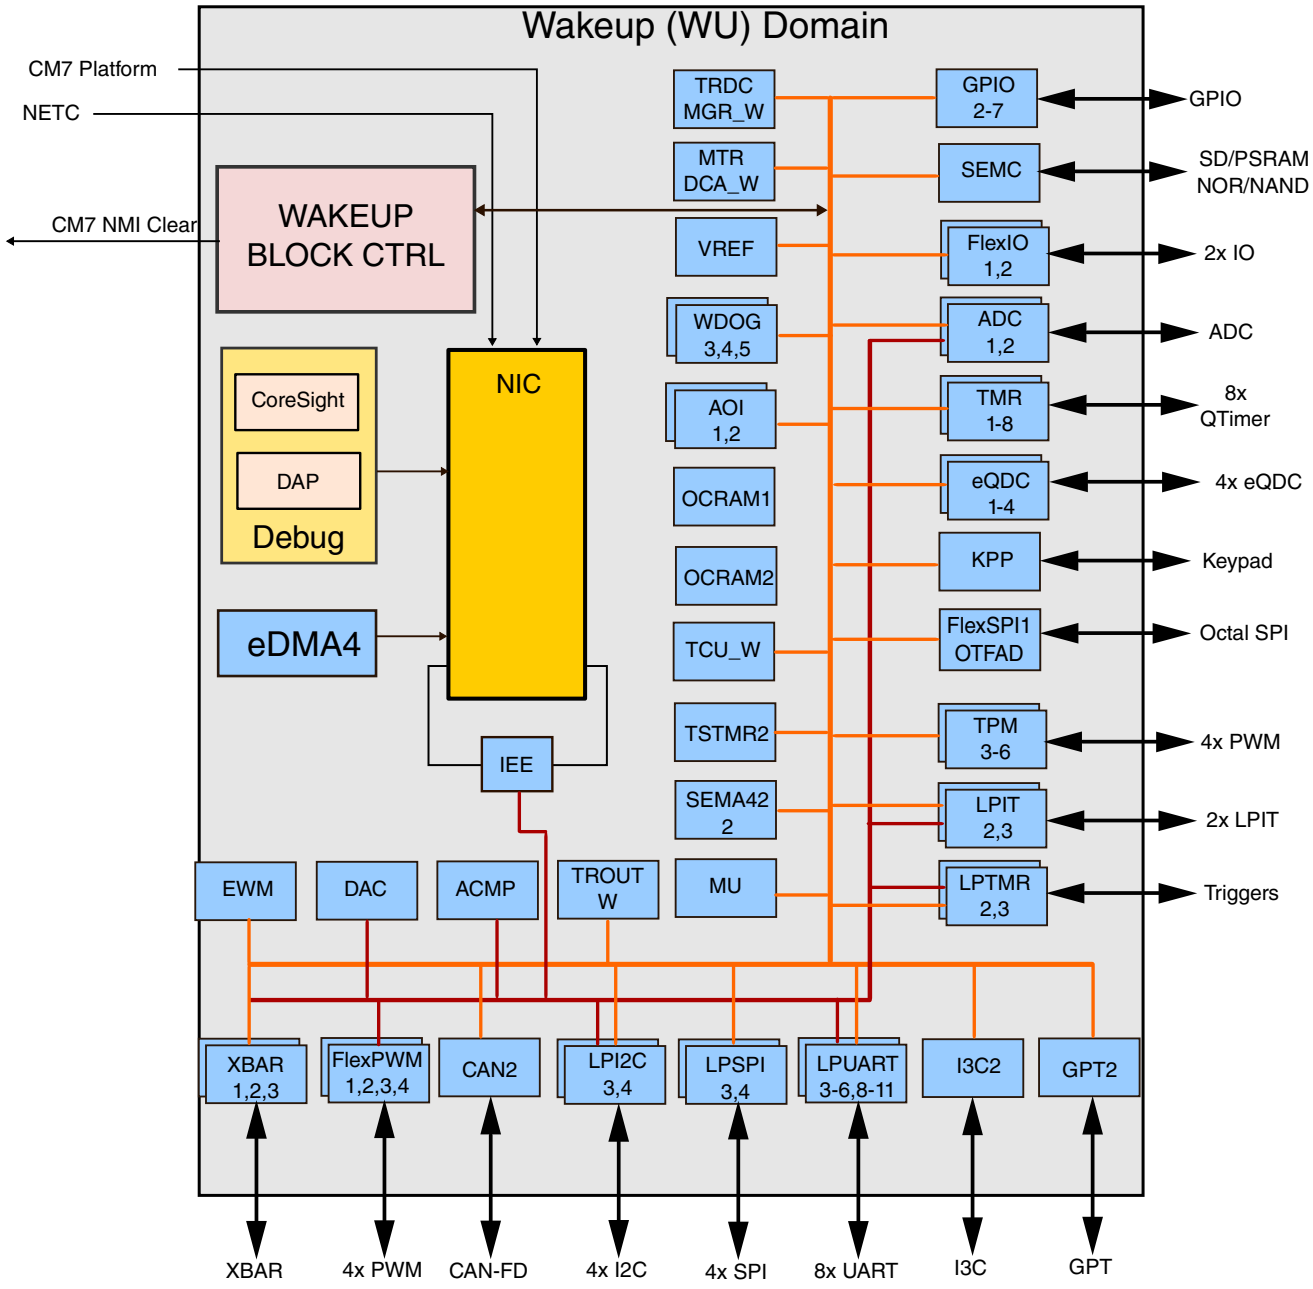

Figure 64. Wakeup BLK_CTRL Block Diagram

16.2.2 Features

The WAKEUP BLK_CTRL has the following features:

- Debug halt mask bits for peripherals in WAKEUP Domain
- WAKEUP SSI master block low power bits
- SAI2/3/4 MCLK direction control and MCLK source selection
- CM7 NMI interrupt clear bit
- USBPHY asynchronous interrupt clear bit

- I3C2 asynchronous interrupt clear bit
- I3C2 IO on-chip strong pull enable bit
- GPIO_AD bank voltage range control
- GPIO compensation cell registers
- Safety clock monitor registers
- XBAR and AOI write protection register
- XBAR pulse configuration registers
- XBAR IO direction control
- CM7 tight coupled SRAM controller registers
- EtherCAT SoC-level configuration register
- NETC SoC-level configuration registers
- USB and uSDHC on-chip AXI bus attribute configuration
- TMR (Quad Timer) and LPIT input trigger selection
- Exclusive access response configuration
- ADC stop mode configuration

16.3 Clocks

The table found here describes the clock sources for Wakeup BLK_CTRL. Please see the Clock Control chapter for clock setting, configuration, and gating information.

Table 121. Clocks

Clock Name	Description
bus_wakeup_clk	Wakeup bus clock for register access.

16.4 Reset

The Wakeup BLK_CTRL resets with the Wakeup Domain.

16.5 Initialization

There are no initialization steps required for Wakeup BLK_CTRL.

16.6 Memory Map and register definition

This section includes the BLK_CTRL_WAKEUP module memory map and detailed descriptions of all registers.

16.6.1 Block Control WAKEUP Domain register descriptions

16.6.1.5 SSI master low power mode control (SSI)

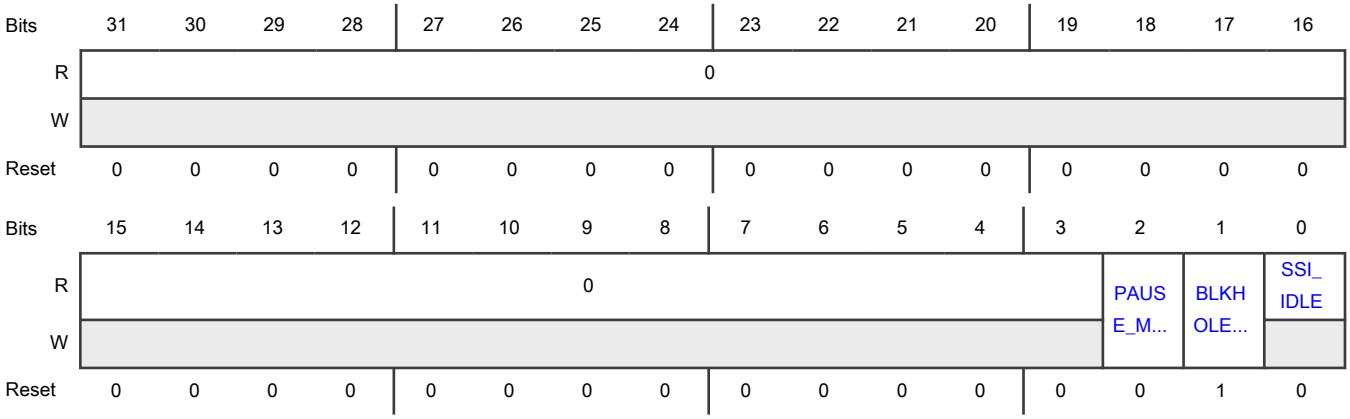
Offset

Register	Offset
SSI	14h

Function

This register enables WAKEUP Domain to M7 SSI Master to enter and exit pause mode.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 PAUSE_MODE	WAKEUP Domain to M7 SSI master pause mode When entering pause mode, new transactions are stopped by de-asserting ready. Any previously started transactions proceed as normal. 0b - WAKEUP Domain to M7 SSI master will enter pause mode 1b - WAKEUP Domain to M7 SSI master will exit pause mode
1	WAKEUP Domain to M7 SSI master blackhole mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
BLKHOLE_MODE_B	In blackhole mode any new transaction will be accepted and will generate slave errors. It is a requirement that the SSI first be moved to Pause mode to let the system drain and after SSI_IDLE is asserted then move to black hole mode. 0b - WAKEUP Domain to M7 SSI master will exit blackhole mode 1b - WAKEUP Domain to M7 SSI master will enter blackhole mode
0 SSI_IDLE	WAKEUP Domain to M7 SSI master idle 0b - WAKEUP Domain to M7 SSI master is not idle 1b - WAKEUP Domain to M7 SSI master is idle

16.6.1.6 EtherCAT miscellaneous configuration (ECAT_MISC_CFG)

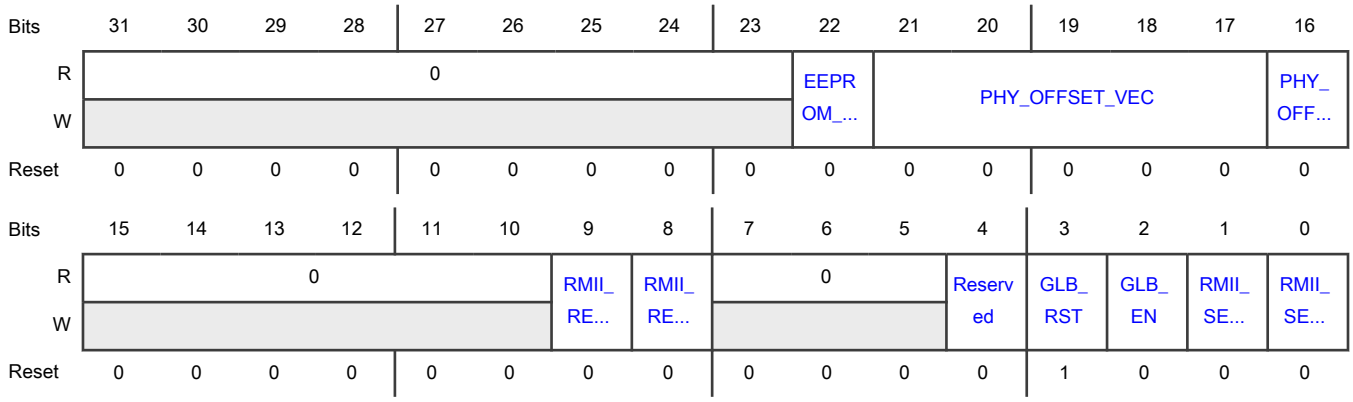
Offset

Register	Offset
ECAT_MISC_CFG	18h

Function

This register provides miscellaneous configuration of EtherCAT.

Diagram



Fields

Field	Function
31-23 —	Reserved
22	EtherCAT EEPROM SIZE OPTION

Table continues on the next page...

Table continued from the previous page...

Field	Function
EEPROM_SIZE_OPTION	This field configures EtherCAT EPROM size, 0: little EPROM Size, 8 bit I2C memory address range 1: larger EEPROM size 16 bit I2C memory address range.
21-17 PHY_OFFSET_VEC	EtherCAT PHY_OFFSET_VEC This field configures EtherCAT PHY_OFFSET_VEC[4:0] input value.
16 PHY_OFFSET	EtherCAT PHY_OFFSET This bit configures EtherCAT PHY_OFFSET input value.
15-10 —	Reserved
9 RMII_REF_CLK_DIR1	RMII Port1 REF_CLK direction control This bitfield controls the direction of RMII REF_CLK on IO for EtherCAT port 1. RMII REF_CLK is the 50MHz RMII clock. It can be input from PT1_TX_CLK IO when this bit is 0. It can be driven by ECAT_CLK_ROOT/2 when this bit is 1. This bit should be set together with the corresponding IOMUXC SW_MUX_CTL_PAD_xx SION bit so that ECAT_CLK_ROOT can provide 50MHz RMII clock to both EtherCAT and board. 0b - RMII REF_CLK is input 1b - RMII REF_CLK is output driven by ECAT_CLK_ROOT/2
8 RMII_REF_CLK_DIR0	RMII Port0 REF_CLK direction control This bitfield controls the direction of RMII REF_CLK on IO for EtherCAT port 0. RMII REF_CLK is the 50MHz RMII clock. It can be input from PT0_TX_CLK IO when this bit is 0. It can be driven by ECAT_CLK_ROOT/2 when this bit is 1. This bit should be set together with the corresponding IOMUXC SW_MUX_CTL_PAD_xx SION bit so that ECAT_CLK_ROOT can provide 50MHz RMII clock to both EtherCAT and board. 0b - RMII REF_CLK is input 1b - RMII REF_CLK is output driven by ECAT_CLK_ROOT/2
7-5 —	Reserved
4 —	Reserved
3 GLB_RST	Global reset of EtherCAT Clearing this bit gets EtherCAT out of reset. 0b - EtherCAT is out of reset 1b - EtherCAT is held in reset
2	Global enable of EtherCAT

Table continues on the next page...

Table continued from the previous page...

Field	Function
GLB_EN	Set this bit to enable EtherCAT. 0b - EtherCAT is off 1b - EtherCAT is on
1 RMII_SEL1	RMII mode selection for EtherCAT port 1 0b - EtherCAT port1 is in MII mode 1b - EtherCAT port1 is in RMII mode
0 RMII_SEL0	RMII mode selection for EtherCAT port 0 0b - EtherCAT port0 is in MII mode 1b - EtherCAT port0 is in RMII mode

16.6.1.7 DEXSC error response configuration (DEXSC_ERR)

Offset

Register	Offset
DEXSC_ERR	1Ch

Function

This register contains exclusive error response configuration bits.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

R	0														LOCK_EX...	EXC_ERR...
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 LOCK_EXC_ERR_RESP_EN	Lock bit of EXC_ERR_RESP_EN Once is it set to 1, EXC_ERR_RESP_EN is locked
0 EXC_ERR_RESP_EN	Exclusive error response enable This bit sets the bus response value when CM7 or CM33 exclusive access to CM7 TCM, OCRAM1 or OCRAM2 fails. OKAY response: Normal access okay indicates if a normal access has been successful. Can also indicate an exclusive access failure. SLVError response: Slave error is used when the access has reached the slave successfully, but the slave wishes to return an error condition to the originating master. 0b - OKAY response 1b - SLVError response

16.6.1.8 USBPHY miscellaneous control (USBPHY_MISC_CTRL)

Offset

Register	Offset
USBPHY_MISC_CTRL	20h

Function

This register contains miscellaneous configuration bits for USBPHY1 and USBPHY2.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0							USBPHY2...	0							USBPHY1...

R	0							USBPHY2...	0							USBPHY1...
W																
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Fields

Field	Function
31-25 —	Reserved
24 USBPHY2_WAKEUP_IRQ_CLEAR	Clear USBPHY2 wakeup interrupt holding register The wakeup interrupt from USBPHY2 will be held internally until this bit is set to 1. Not that this bit need software to clear. Set it to 1 to clear the interrupt and following with writing it to 0 to complete the operation.
23-17 —	Reserved
16 USBPHY1_WAKEUP_IRQ_CLEAR	Clear USBPHY1 wakeup interrupt holding register The wakeup interrupt from USBPHY1 will be held internally until this bit is set to 1. Not that this bit need software to clear. Set it to 1 to clear the interrupt and following with writing it to 0 to complete the operation.
15-9 —	Reserved
8 USBPHY2_IPG_CLK_ACTIVE	USBPHY2 register access clock enable Clearing this bit to 0 will stop USBPHY2 register access clock to save power.
7-1 —	Reserved
0 USBPHY1_IPG_CLK_ACTIVE	USBPHY1 register access clock enable Clearing this bit to 0 will stop USBPHY1 register access clock to save power.

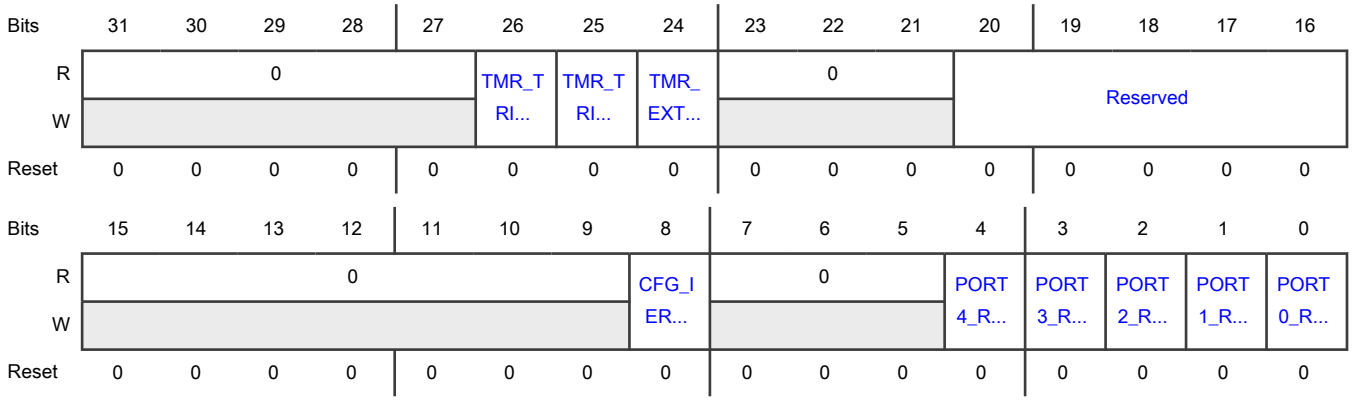
16.6.1.9 NETC Port miscellaneous configuration (NETC_PORT_MISC_CFG)

Offset

Register	Offset
NETC_PORT_MISC_CFG	24h

Function
This register contains miscellaneous configuration bits for NETC Port0-Port4.

Diagram



Fields

Field	Function
31-27 —	Reserved
26 TMR_TRIG2_SEL	1588 timer trigger2 input selection 0b - Input from IOMUX 1b - Input from XBAR
25 TMR_TRIG1_SEL	1588 timer trigger1 input selection 0b - Input from IOMUX 1b - Input from XBAR
24 TMR_EXT_CLK_SEL	1588 timer external clock selection When NETC is configured to select external clock input as 1588 timer reference clock, this bit can further configure the external clock input to be from CCM clock root or from chip pin. IOMUX need select the timer 1588 clock function to use the chip pin. 0b - CCM tmr_1588_clk_root is selected 1b - External pin is selected
23-21 —	Reserved
20-16 —	Reserved
15-9 —	Reserved
8	Default value for IERB NETCRR[LOCK] bit. Determines write accessibility of IERB registers after power-on-reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
CFG_IERB_LOCK	0b - Unlocked after power-on-reset. Normal read/write access to all IERB registers 1b - Locked after power-on-reset. Write access inhibited to all IERB registers, except NETCRR
7-5 —	Reserved
4 PORT4_RMII_REF_CLK_DIR	Port4 RMII Reference clock direction control 0b - Port4 RMII Reference clock is input 1b - Port4 RMII Reference clock is output
3 PORT3_RMII_REF_CLK_DIR	Port3 RMII Reference clock direction control 0b - Port3 RMII Reference clock is input 1b - Port3 RMII Reference clock is output
2 PORT2_RMII_REF_CLK_DIR	Port2 RMII Reference clock direction control 0b - Port2 RMII Reference clock is input 1b - Port2 RMII Reference clock is output
1 PORT1_RMII_REF_CLK_DIR	Port1 RMII Reference clock direction control 0b - Port1 RMII Reference clock is input 1b - Port1 RMII Reference clock is output
0 PORT0_RMII_REF_CLK_DIR	Port0 RMII Reference clock direction control When NETC Port0 is configured to RMII mode, this bitfield controls the direction of the 50MHz RMII clock. It should be set together with the corresponding IOMUXC SW_MUX_CTL_PAD_xx SION bit so that CCM can provide 50MHz RMII clock to both NETC Port0 and board. 0: Port0 RMII Reference clock is input 1: Port0 RMII Reference clock is output

16.6.1.10 M7 NMI interrupt clear register (M7_NMI_CLR)

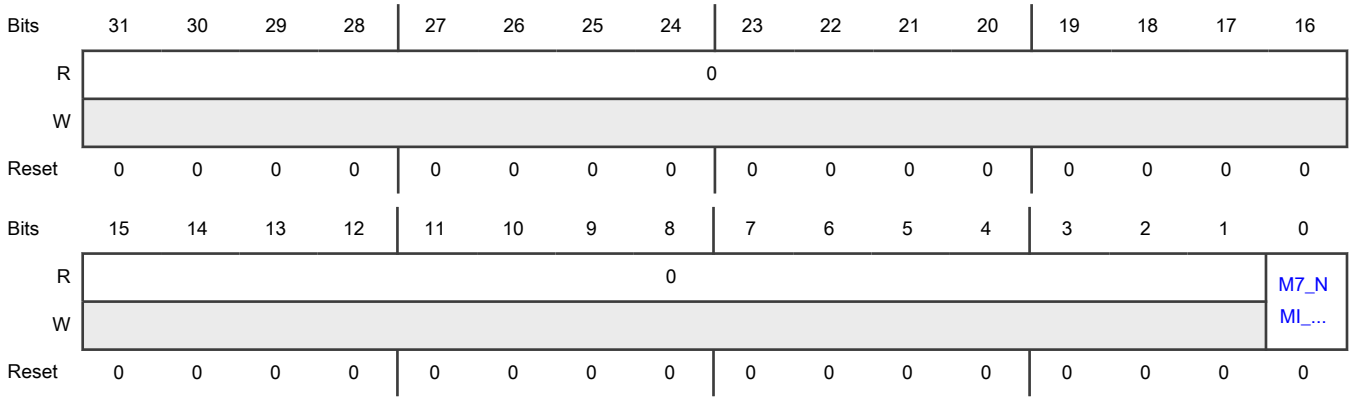
Offset

Register	Offset
M7_NMI_CLR	28h

Function

This register contains the M7_NMI_CLEAR bit used to clear the interrupt from the NMI input.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 M7_NMI_CLEAR	Clear CM7 NMI holding register The NMI input from IO will be held internally until this bit is set to 1. **NOTE** This bit need software to clear. Set it to 1 to clear the interrupt and following with writing it to 0 to complete the operation.

16.6.1.11 Qtimer miscellaneous control register 1 (QTIMER_CTRL1)

Offset

Register	Offset
QTIMER_CTRL1	30h

Function

This register provides input trigger select of QTIMER1-4

Diagram

16.6.1.19 AXI bus attribute configuration register (AXI_ATTR_CFG)

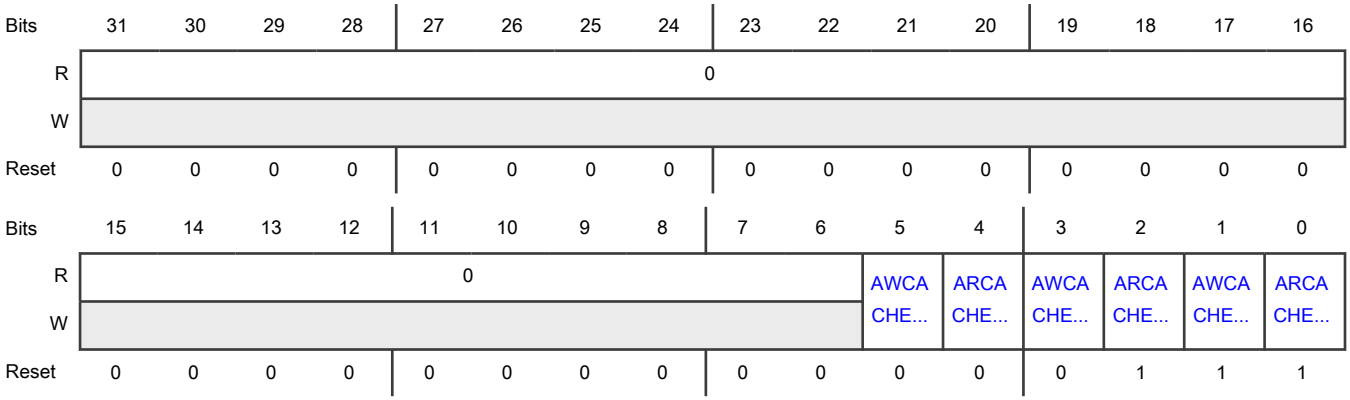
Offset

Register	Offset
AXI_ATTR_CFG	50h

Function

Write this register to configure AXI bus attribute for masters including USB and uSDHC.

Diagram



Fields

Field	Function
31-6 —	Reserved
5 AWCACHE_USB	USB block cacheable attribute value of AXI write transactions If the current transaction is cacheable, the bus infrastructure (NIC) will reorganize the transaction to optimize bus performance. The NIC will combine two 32-bit USB transactions into one 64-bit transaction. 0b - Cacheable attribute is off for write transactions 1b - Cacheable attribute is on for write transactions
4 ARCACHE_USB	USB block cacheable attribute value of AXI read transactions If the current transaction is cacheable, the bus infrastructure (NIC) will reorganize the transaction to optimize bus performance. The NIC will combine two 32-bit USB transactions into one 64-bit transaction. 0b - Cacheable attribute is off for read transactions 1b - Cacheable attribute is on for read transactions
3 AWCACHE_USDHC2	uSDHC2 block cacheable attribute value of AXI write transactions

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If the current transaction is cacheable, the bus infrastructure (NIC) will reorganize the transaction to optimize bus performance. The NIC will combine two 32-bit uSDHC transactions into one 64-bit transaction. 0b - Cacheable attribute is off for write transactions 1b - Cacheable attribute is on for write transactions
2 ARCACHE_USDHC2	uSDHC2 block cacheable attribute value of AXI read transactions If the current transaction is cacheable, the bus infrastructure (NIC) will reorganize the transaction to optimize bus performance. The NIC will combine two 32-bit uSDHC transactions into one 64-bit transaction. 0b - Cacheable attribute is off for read transactions 1b - Cacheable attribute is on for read transactions
1 AWCACHE_USDHC1	uSDHC1 block cacheable attribute value of AXI write transactions If the current transaction is cacheable, the bus infrastructure (NIC) will reorganize the transaction to optimize bus performance. The NIC will combine two 32-bit uSDHC transactions into one 64-bit transaction. 0b - Cacheable attribute is off for write transactions 1b - Cacheable attribute is on for write transactions
0 ARCACHE_USDHC1	uSDHC1 block cacheable attribute value of AXI read transactions If the current transaction is cacheable, the bus infrastructure (NIC) will reorganize the transaction to optimize bus performance. The NIC will combine two 32-bit uSDHC transactions into one 64-bit transaction. 0b - Cacheable attribute is off for read transactions 1b - Cacheable attribute is on for read transactions

16.6.1.20 SRAM Control Register 0 (SRAMCR0)

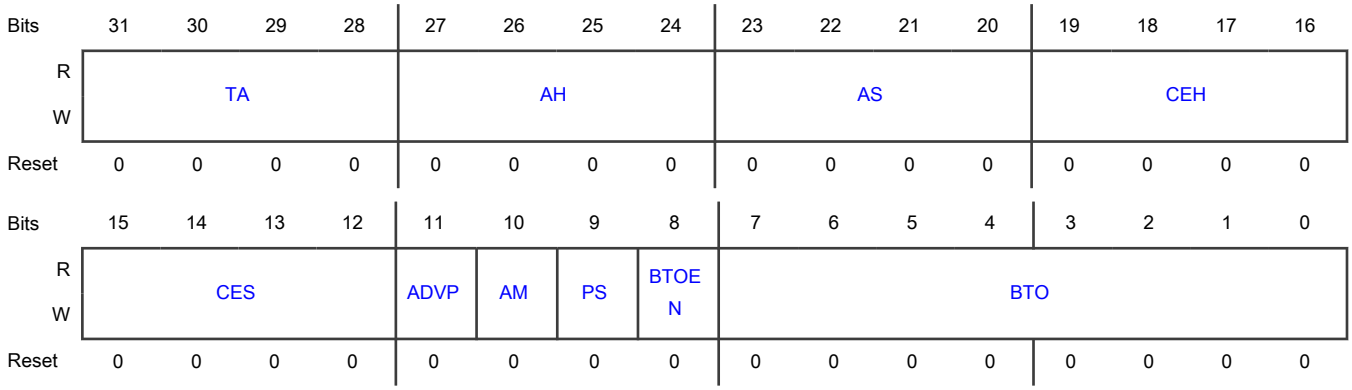
Offset

Register	Offset
SRAMCR0	54h

Function

This register configures SRAM device

Diagram



Fields

Field	Function
31-28 TA	Turnaround time Turnaround time is TA+1 time granularity. The time granularity is configured by SRAMCR1[PRE] field. Both the SRAMC and Device do not drive Data Lines to avoid bus confliction.
27-24 AH	Address hold time Address hold time is AH+1 time granularity. The time granularity is configured by SRAMCR1[PRE] field. The address hold time follows address setup time only.
23-20 AS	Address setup time Address setup time is AS time granularity. The time granularity is configured by SRAMCR1[PRE] field. Address setup time has 1 clock cycle when AS is 0 in ADMUX mode.
19-16 CEH	CE hold time CE Hold time is CEH time granularity. The time granularity is configured by SRAMCR1[PRE] field.
15-12 CES	CE setup time CE setup time is CES time granularity. The time granularity is configured by SRAMCR1[PRE] field.
11 ADVP	ADV# polarity 0b - ADV# is active low. 1b - ADV# is active high.
10 AM	Address Mode It defines the address mode. 0b - Address/Data MUX mode (ADMUX) 1b - Address/Data non-MUX mode (Non-ADMUX)
9 PS	Port Size The port size must be aligned with SRAM data width.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - 8bit 1b - 16bit
8 BTOEN	AHB Bus Timeout Enable AHB bus timeout enable. 0b - AHB bus timeout counter is not enabled. 1b - AHB bus timeout counter is enabled.
7-0 BTO	AHB Bus Timeout Wait Cycle If AHB Command is not granted by arbitrator, it will timeout after BTO * 1024 AHB Clock cycles. When an AHB command grant timeout occurs, there will be an AHB bus error response.

16.6.1.21 SRAM Control Register 1 (SRAMCR1)

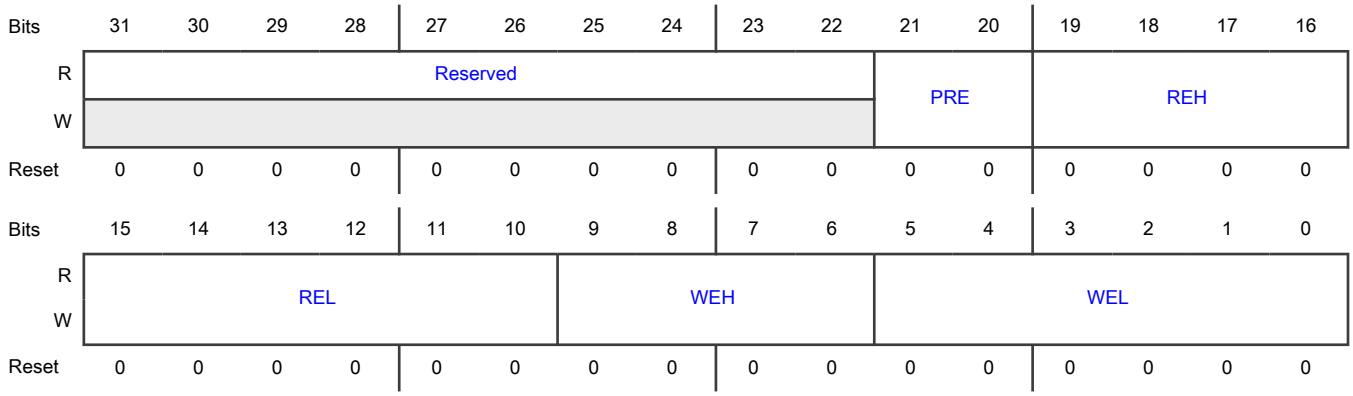
Offset

Register	Offset
SRAMCR1	58h

Function

This register configures SRAM device

Diagram



Fields

Field	Function
31-22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-20 PRE	Prescaler timer Prescaler timer controls the time granularity for CES, CEH, AS, AH, TA, WEL, WEH, REL and REH. 00b - Time granularity is 1 clock cycle. 01b - Time granularity is 2 clock cycles. 10b - Time granularity is 3 clock cycles. 11b - Time granularity is 4 clock cycles.
19-16 REH	RE high time RE high time is REH+1 time granularity. The time granularity is configured by SRAMCR1[PRE] field.
15-10 REL	RE low time RE low time is REL+1 time granularity. The time granularity is configured by SRAMCR1[PRE] field.
9-6 WEH	WE high time WE high time is WEH+1 time granularity. The time granularity is configured by SRAMCR1[PRE] field.
5-0 WEL	WE low time WE low time is WEL+1 time granularity. The time granularity is configured by SRAMCR1[PRE] field.

16.6.1.22 Slave stop mode configure register (SLAVE_STOP_MODE_CFG)

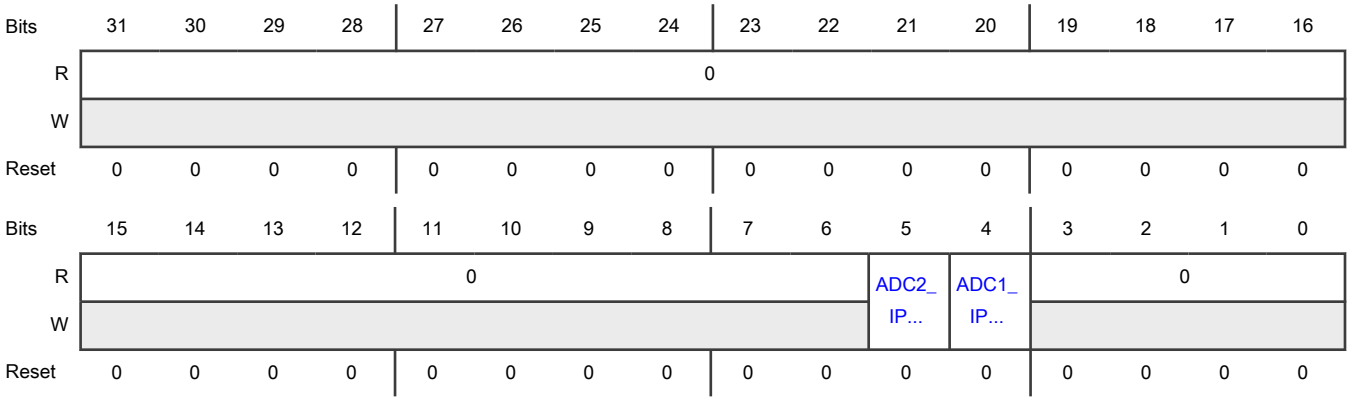
Offset

Register	Offset
SLAVE_STOP_MODE_CFG	60h

Function

Write this register to configure slave behavior under stop mode

Diagram



Fields

Field	Function
31-6 —	Reserved
5 ADC2_IPG_STOP_MODE	ADC2 stop mode selection. 0b - This module is functional in Stop Mode 1b - This module is not functional in Stop Mode
4 ADC1_IPG_STOP_MODE	ADC1 stop mode selection. 0b - This module is functional in Stop Mode 1b - This module is not functional in Stop Mode
3-0 —	Reserved

16.6.1.23 I3C2 async wakeup control register (I3C2_ASYNC_WAKEUP_CTRL)

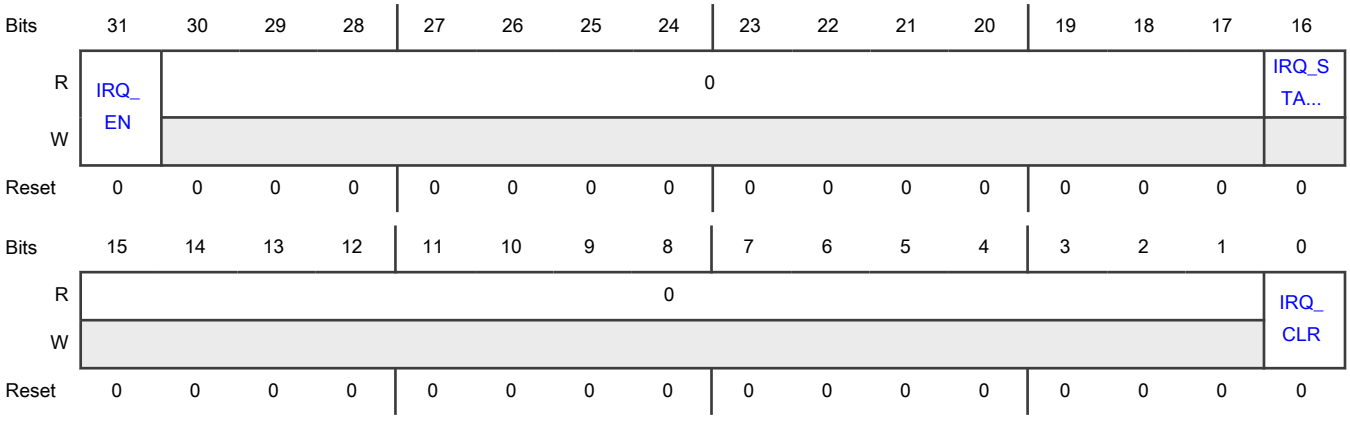
Offset

Register	Offset
I3C2_ASYNC_WAKEUP_CTRL	74h

Function

This register contains status and control for I3C2 async wakeup interrupt

Diagram



Fields

Field	Function
31 IRQ_EN	Master mode async wakeup interrupt enable This bit is to enable I3C2 master mode async wakeup interrupt. If enabled the interrupt happens when I3C2 is in master mode, FCLK is stopped and SCA is driven low by slave. 0b - Interrupt disabled 1b - Interrupt enabled
30-17 —	Reserved
16 IRQ_STATUS	Async wakeup interrupt status This bit indicates the status of I3C2 async wakeup interrupt. For master the interrupt is enabled by SCA_IRQ_EN bit of this register. For slave mode the interrupt is enabled by bit 9 of I3C2 interrupt enable register of the I3C chapter. 0b - Interrupt not asserted 1b - Interrupt asserted
15-1 —	Reserved
0 IRQ_CLR	Async wakeup interrupt clear This bit is to clear I3C2 async wakeup interrupt. The interrupt will be held until this bit is set to 1. Note that this bit need software to clear. Set it to 1 to clear the interrupt and following with writing it to 0 to complete the operation.

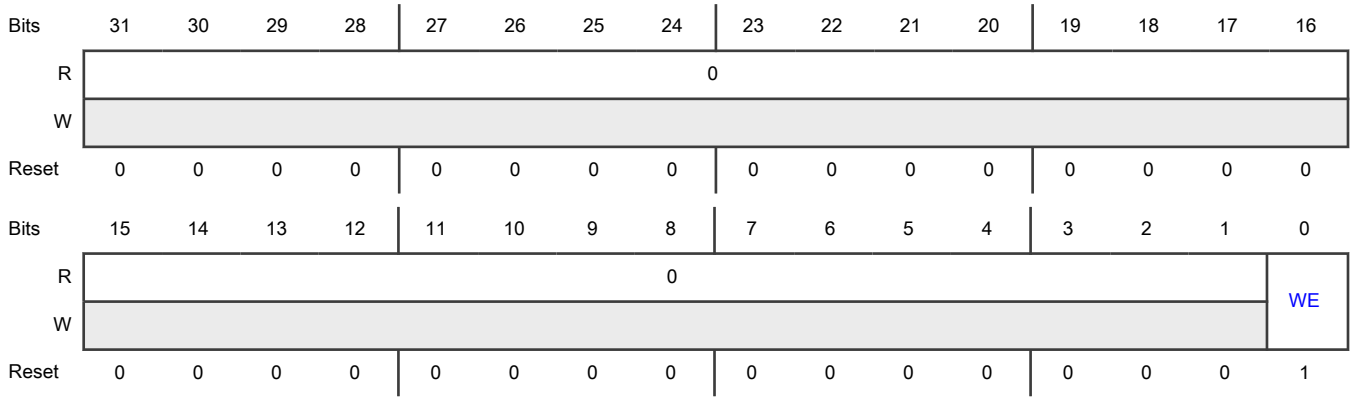
16.6.1.24 XBAR and AOI write protect register (XBAR_AOI_WE)

Offset

Register	Offset
XBAR_AOI_WE	78h

Function
Register write enable bit of XBAR and AOI

Diagram



Fields

Field	Function
31-1 —	Reserved
0 WE	Write Enable to XBAR and AOI When this bit is cleared the register write to AOI1, AOI2, AOI3, AOI1, XBAR1, XBAR2 and XBAR3 will be ignored so that their configuration won't be changed unexpectedly. 0b - Write is disabled 1b - Write is enabled

16.6.1.25 XBAR trigger synchronizer control register1 (XBAR_TRIG_SYNC_CTRL1)

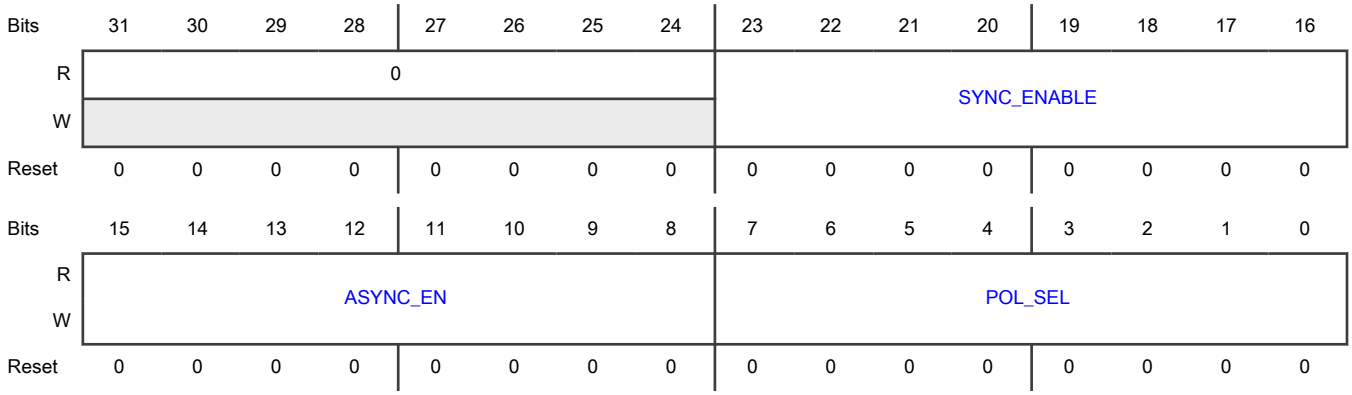
Offset

Register	Offset
XBAR_TRIG_SYNC_CTRL1	7Ch

Function

This register contains XBAR trigger synchronizer configuration bits.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 SYNC_ENABLE	Trigger out synchronizer enable The XBAR trigger synchronizer include eight channels and each channel can synchronize one trigger in to trigger out. The fields include eight bits to enable the corresponding channel. The channel should be disabled with this field before change other fields of XBAR_TRIG_SYNC_CTRL1/2 register. 0000_0000b - Channel is disabled 0000_0001b - Channel is enabled
15-8 ASYNC_EN	Asynchronous trigger in enable Set the corresponding bit of this field to 1 when the channel's trigger in is asynchronous to XBAR clock so that the trigger in can be captured correctly. 0000_0000b - Trigger in is synchronous 0000_0001b - Trigger in is asynchronous
7-0 POL_SEL	Trigger out polarity select This field controls the polarity of the trigger out for the corresponding channel. 0000_0000b - Same as trigger in 0000_0001b - Invert trigger in

16.6.1.26 XBAR trigger synchronizer control register2 (XBAR_TRIG_SYNC_CTRL2)

Offset

Register	Offset
XBAR_TRIG_SYNC_CTRL2	80h

Function

The XBAR trigger synchronizer include eight channels and each channel can synchronize one trigger in to trigger out. This register contains the pulse width control for each channel's trigger out.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

16.6.1.37 Safety clock monitor control and status register (SAFETY_CLK_MON_CS)

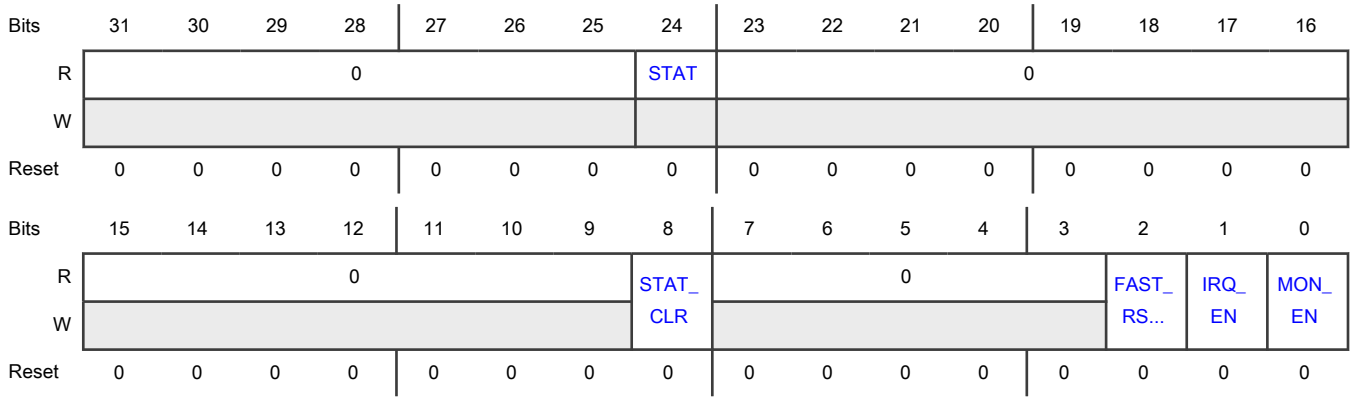
Offset

Register	Offset
SAFETY_CLK_MON_CS	130h

Function

This register provides control and status bits for the safety clock monitor

Diagram



Fields

Field	Function
31-25 —	Reserved
24 STAT	XBAR_OUT220 clock failure status 0b - No failure detected by the monitor 1b - Clock failure has been detected by the monitor
23-9 —	Reserved
8 STAT_CLR	Status clear 0b - No effect to clock failure status bit 1b - Clear clock failure status bit
7-3 —	Reserved
2 FAST_RST_EN	Reset out enable 0b - Clock failure will not assert EWM_OUT 1b - Clock failure will assert EWM_OUT_b immediately regardless EWM state
1 IRQ_EN	Interrupt enable 0b - Clock failure will not assert interrupt 1b - Clock failure will assert interrupt
0 MON_EN	Monitor enable bit 0b - The monitor is off 1b - The monitor is on

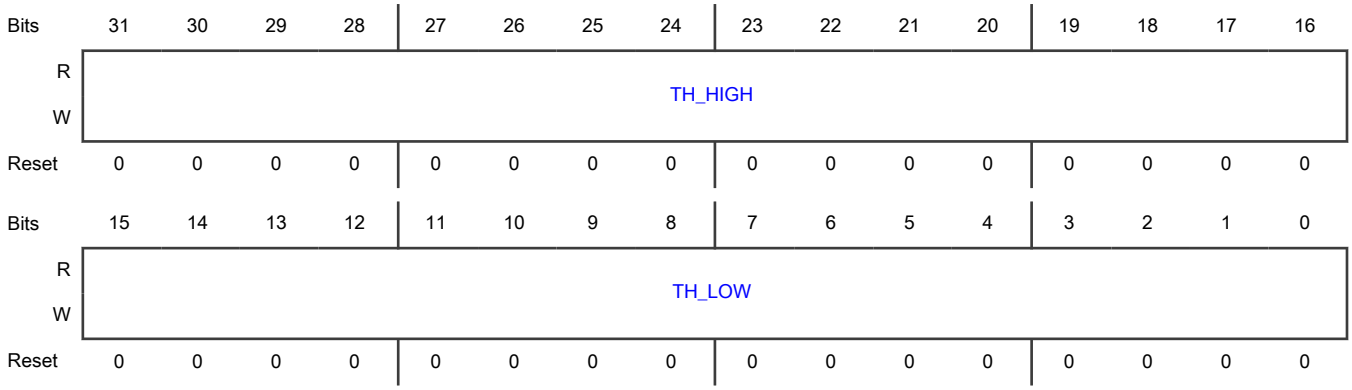
16.6.1.38 Safety clock monitor threshold register (SAFETY_CLK_MON_TH)

Offset

Register	Offset
SAFETY_CLK_MON_TH	134h

Function
This register configures the threshold value for the safety clock monitor

Diagram



Fields

Field	Function
31-16 TH_HIGH	Threshold high value When the cycle number of the monitored clock within one 32KHz clock is above this value, clock failure will be generated
15-0 TH_LOW	Threshold low value When the cycle number of the monitored clock within one 32KHz clock is below this value, clock failure will be generated

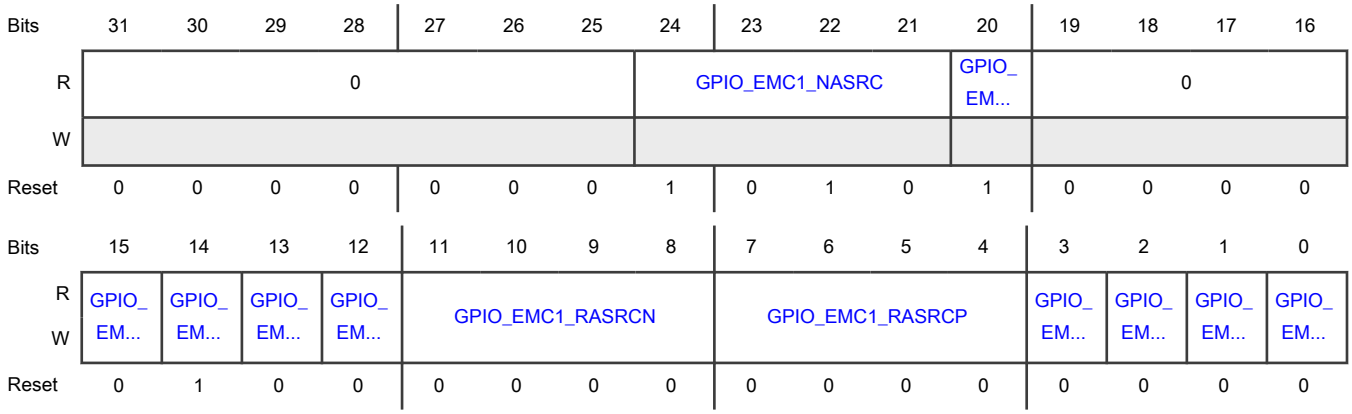
16.6.1.39 GPIO_EMC_B1 bank IO control (EMC_B1_IO_CTRL)

Offset

Register	Offset
EMC_B1_IO_CTRL	140h

Function
This register provides control to IO compensation block of GPIO_EMC_B1 IO bank

Diagram



Fields

Field	Function
31-25 —	Reserved
24-21 GPIO_EMC1_NASRC	GPIO_EMC_B1 IO bank compensation codes 4-bit NMOS compensation codes or 4-bit PMOS compensation codes selected by GPIO_EMC1_SELECT_NASRC. The meaning of codes: PVT ASRCP 3:0 and ASRCN 3:0. Slow 00001111, Typical 10100101, Fast 11110000.
20 GPIO_EMC1_COMPOK	GPIO_EMC_B1 IO bank compensation OK flag It can be high only in the Normal mode and when a new measured code is available.
19-16 —	Reserved
15 GPIO_EMC1_FASTFRZ	Compensation code fast-freeze When COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is low, low, low, high, compensation cell Fast Freeze mode is enabled. On the rising edge of FASTFRZ, it fast-freezes the compensation code at its running value. The compensation cell delivers a refreshed compensation code, at a comparatively lesser delay after signal falling edge than the delay of FREEZE signal.
14 GPIO_EMC1_SUPLYDET_LATCH	GPIO_EMC_B1 IO bank power supply mode latch enable Supply detector cell is used to detect the IO supply range and set IO to 3V3 supply mode or 1V8 supply mode according to the detection. Setting this bit will latch the current detect result.
13 GPIO_EMC1_REFGEN_SLEEP	GPIO_EMC_B1 IO bank reference voltage generator cell sleep enable Reference voltage generator cell provides reference voltages to the IO bank. When this bit is high, it puts the reference voltage generator cell in sleep mode to reduce the static power consumption.
12	GPIO_EMC1_NASRC selection

Table continues on the next page...

Table continued from the previous page...

Field	Function
GPIO_EMC1_SELECT_NASRC	0: Show the 4-bit PMOS compensation codes in GPIO_EMC1_NASRC field 1: Show the 4-bit NMOS compensation codes in GPIO_EMC1_NASRC field
11-8 GPIO_EMC1_RASRCN	GPIO_EMC_B1 IO bank's 4-bit NMOS compensation codes from core These codes are used in compensation Read mode when COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is high, high, low, low.
7-4 GPIO_EMC1_RASRCP	GPIO_EMC_B1 IO bank's 4-bit PMOS compensation codes from core These codes are used in compensation Read mode when COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is high, high, low, low.
3 GPIO_EMC1_FASTFRZ_EN	Compensation code fast freeze enable When COMPEN, COMPTQ, FREEZE, FASTFRZ_EN is low, low, low, high, compensation cell Fast Freeze mode is enabled. Fast Freeze mode is activated on FASTFRZ rising edge. The compensation cell delivers a refreshed compensation code, at a comparatively lesser delay after signal falling edge than the delay of Freeze mode.
2 GPIO_EMC1_COMPEN	COMPEN and COMPTQ control the operating modes of the compensation cell Normal Mode: In this mode, the macro cell constantly tracks the Process Voltage temperature (PVT) condition of the chip and generates an 8-bit digital code. This 8-bit code is referred to as f(PVT) and it represents current PVT state. In Normal mode, the internal reference current generators are active and power consumption is higher than that in all the other modes. Freeze mode: This mode is used where the current consumption is to be kept low. In this mode, all the internal blocks are switched off to reduce the static power consumption. Internal latches keep the code, which is calculated before the cell enters the Freeze mode. Fast Freeze mode: This mode is used to freeze the digital compensation codes, when the data is transferred from the compensated IOs on a chip to an external device during Burst mode. This ensures signal integrity and eliminates the jitter caused due to modification in IO driver strength. In this mode, the current consumption is comparable to consumption in the Normal mode. Read Mode: In this mode, it is possible to force the digital codes from the chip core logic. The bandgap, measurement block, and comparator blocks are switched off to reduce static power consumption to minimum value. Fixed Code mode: The digital code is forced to a fixed value, obtained at typical PVT conditions and represents typical bit patterns. The bandgap, measurement, and other blocks are switched off to reduce static power consumption to minimum value.

17.2 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or keeper), and for each pad, there are up to 12 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

17.2.1 Block diagram

The figure below illustrates the IOMUX/IOMUXC connectivity in the system.

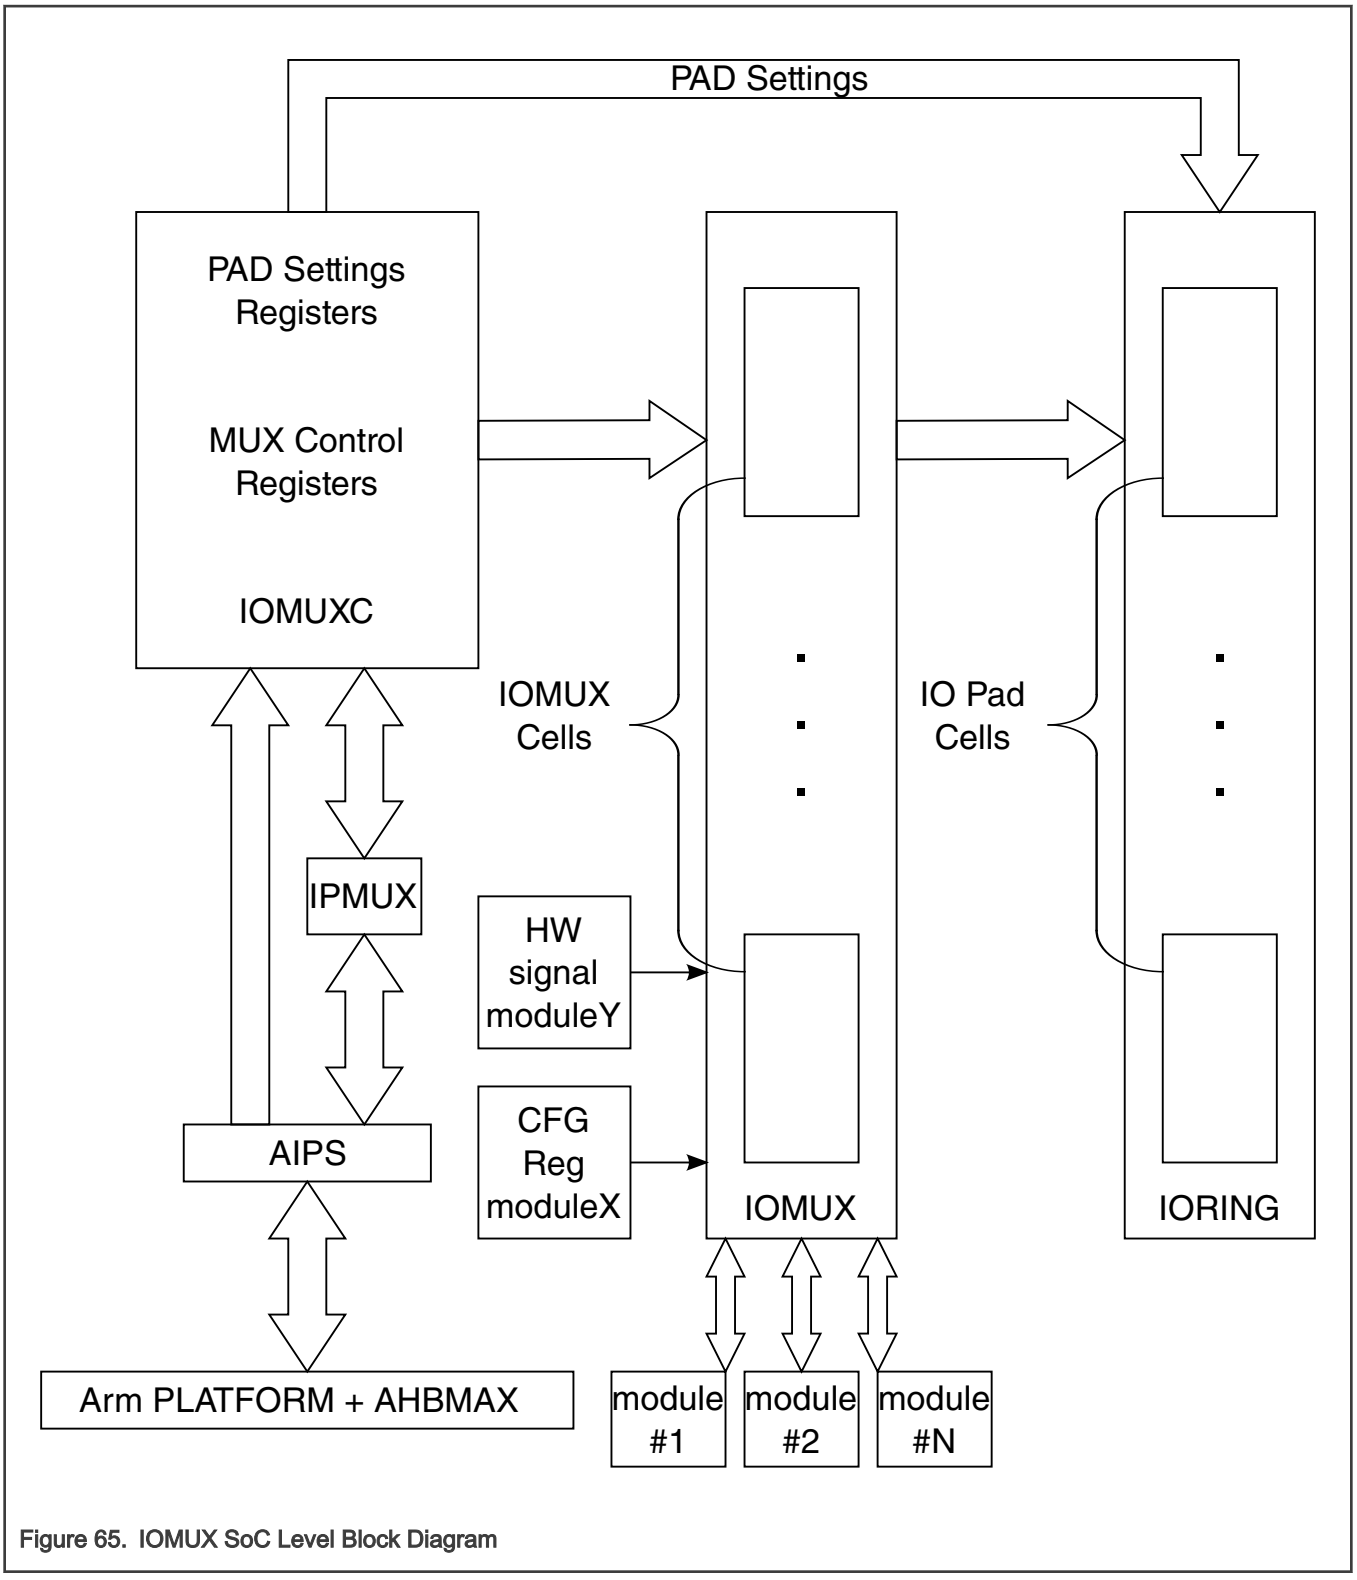

Figure 65. IOMUX SoC Level Block Diagram

17.2.2 Features

The IOMUXC features include:

- 32-bit software mux control registers (SW_MUX_CTL_PAD_<PAD NAME>) to configure 1 of 12 alternate (ALT) MUX_MODE fields of each pad and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (SW_PAD_CTL_PAD_<PAD_NAME>) to configure specific pad settings of each pad.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

17.3 Functional description

This section provides a complete functional description of the block.

The IOMUX consists of a number of basic iomux cell units. If only one functional mode is required for a specific pad, it would have been no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

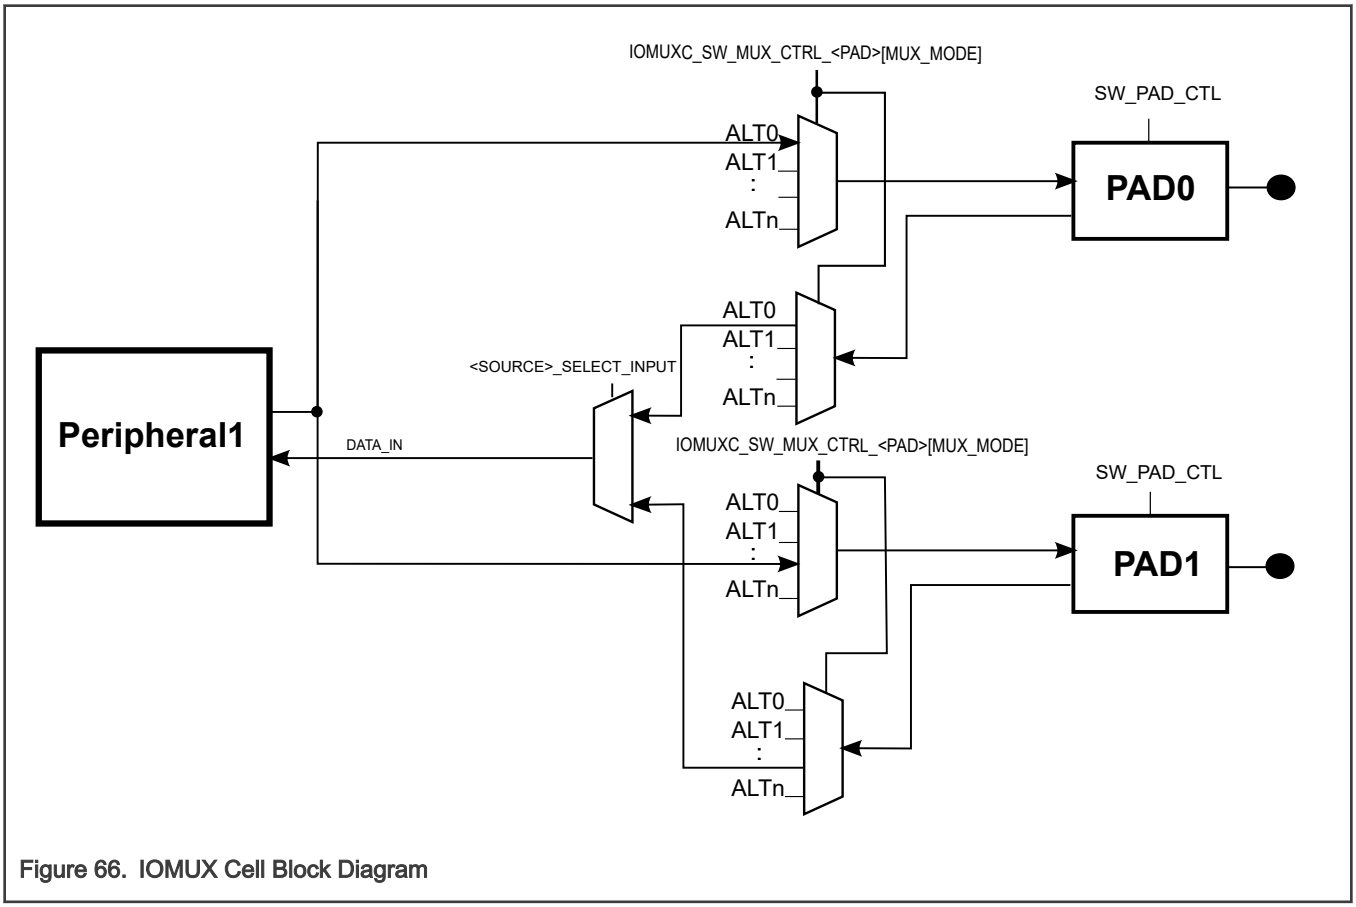

Figure 66. IOMUX Cell Block Diagram

17.3.1 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.

17.3.2 Disable Input Buffer Enable (IBE_OFF)

When pad function is not configured as an output, the Input Buffer Enable (IBE) is asserted and the input buffer enabled. IBE_OFF can force Input Buffer Enable (IBE) to be de-asserted. IBE_OFF can override SION. Once IBE_OFF is 1, SION does not work, SION works only when IBE_OFF is 0.

For ADC/CMP application, IBE_OFF must be set to avoid analog single degrade.

17.3.3 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programmable via the SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programmable via the SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

The daisy chain is illustrated in the figure below.

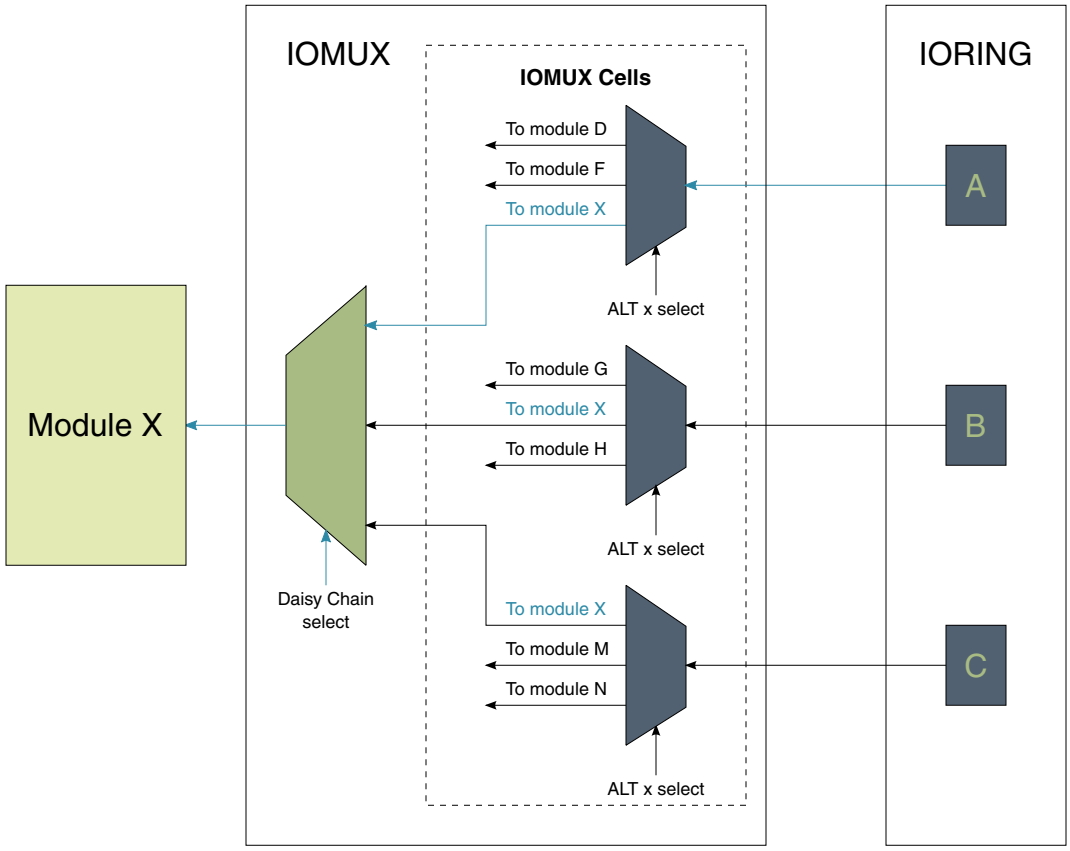

Figure 67. Daisy chain illustration

17.3.4 Clocks

The table found here describes the clock sources for IOMUXC. Please see Clock Controller Module (CCM) chapter for clock setting, configuration and gating information.

Table 123. IOMUXC Clocks

Clock Name	Description
ipg_clk_s	Peripheral access clock

17.4 Memory Map and register definition

This section includes the IOMUXC module memory map and detailed descriptions of all registers.

18.2 Overview

The GPIO module communicates to the processor core via a zero wait-state interface for maximum pin performance.

18.2.1 Block diagram

The following figure shows the block diagram for the GPIO module.

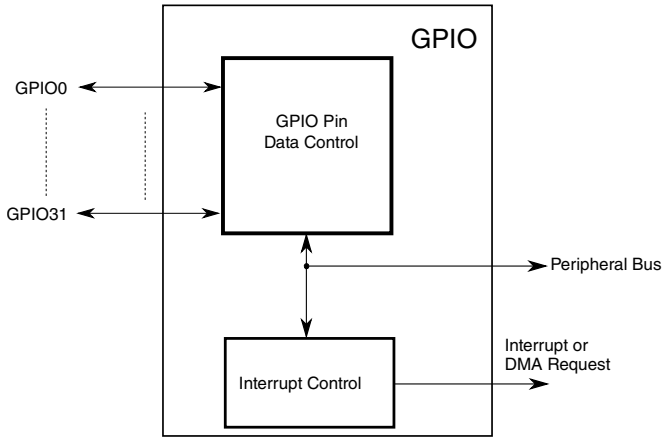

Figure 68. GPIO block diagram

18.2.2 Features

The GPIO module includes the following features:

- Port Data Input (PDIR) register displays the logic value on each pin when the pin is configured for any digital function provided the corresponding Port Control and Interrupt module for that pin are enabled.
- Port Data Output (PDOR) register with corresponding set/clear/toggle registers controls output data of each pin when the pin is configured for the GPIO function.
- Port Data Direction (PDDR) register controls the direction of each pin when the pin is configured for the GPIO function.
- Port Input Disable (PIDR) register controls the disable of the input for each general-purpose pin.
- Pin interrupts
  - Interrupt flag and enable registers for each pin are functional in all digital pin muxing modes.
  - Support for interrupt or DMA request configured per pin.
  - Support for edge sensitive (rising or falling, or both) or level sensitive (low, high) configured per pin.
  - Asynchronous wake-up in Low-Power modes.
  - GPIO module generates a total of 2 interrupts and 2 DMA requests.
  - Each pin can be used to generate a single interrupt or DMA request.
- Protection registers
  - Each pin is configured for Secure or Non-Secure and Privilege/Non-Privilege access.
  - Each interrupt and DMA request domain is configured for Secure or Non-Secure and Privilege/Non-Privilege access.

18.3 Functional description

18.3.1 Low-Power modes

The GPIO module can be configured to exit the Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

18.3.2 Debug mode

The GPIO module remains functional in debug mode.

18.3.3 General-purpose input

The logic state of each pin is available via the Port Data Input registers (PDIR) if,

- the corresponding bit in the Port Input Disable Register (PIDR) is clear, and
- the pin is configured for a digital function.

18.3.4 General-purpose output

The logic state of each pin is controlled via the Port Data Output Registers(PDOR) and Port Data Direction Registers(PDDR), provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input/output.

If	Then
A pin is configured for the GPIO function and the corresponding PDDR bit is clear.	The pin is configured as an input.

Table continues on the next page...

Table continued from the previous page...

A pin is configured for the GPIO function and the corresponding PDDR bit is set.	The pin is configured as an output and the logic state of the pin is equal to the corresponding PDOR.

For efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers allows one or more outputs within one port to be set, cleared, or toggled from a single register write, eliminating the need for a read-modify-write operation to prevent changing pins accidentally.

18.3.5 Clocking

The GPIO module receives a single clock, which is used for register access and synchronize external pin inputs. There are no special considerations.

18.3.6 Reset

The GPIO module receives a single reset, which resets the peripheral. There are no special considerations.

18.3.7 External interrupts

The external interrupt capability of the GPIO module is available in all digital pin muxing modes.

GPIO module generates a total of 2 interrupts and 2 DMA requests. Each pin can be individually configured for interrupt or DMA request.

- Each output implements a separate interrupt status flag register for that domain
- Each output generates a single interrupt
- Each output generates a single DMA request

Each pin can be individually configured for any of the following external interrupt modes:

Table 125. Available pin configuration for external interrupt

Signal conditions	Software polling using flags	Interrupts	DMA requests
Rising-edge	Yes	Yes	Yes
Falling-edge	Yes	Yes	Yes
Rising- and falling-edge	Yes	Yes	Yes
High-level	—	Yes	—
Low-level	—	Yes	—

The interrupt status flag is set when the configured edge or level is detected on the pin. Unless the GPIO module is in a Low-Power mode, the input is first synchronized to the system clock to detect the configured level or edge transition.

The GPIO module generates a pin interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that output. The interrupt negates after the interrupt status flags for all enabled interrupts are cleared by writing a logic 1 to the ISF flag in either the ISFR or ICRn registers.

The GPIO module generates a DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that output. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

In Low-Power mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit the Low-Power mode.

18.3.8 Global interrupt control

The two global interrupt control registers (GICLR and GICHR) allow a single register write to update the upper 16-bit of the Interrupt Control Register for up to 16 pins, all with the same value.

The global interrupt control registers allow software to quickly configure multiple pins within the same port with the same interrupt configuration.

The global interrupt control registers are write-only registers and always read as 0.

18.3.9 DMA

The GPIO module generates 2 requests. Each pin can be configured to generate one of those DMA requests on either or both pin edge detection. See External interrupts section for further details.

18.3.10 Access protection

The GPIO module implements access protection registers (PCNS and PCNP) for each pin as follows:

Access	Description
Secure	Pins configured for Secure access can only be written or read by software in Secure state.
Non-Secure	Pins configured for Non-Secure access can only be written or read by software in Non-Secure state.
Privilege	Pins configured for Privilege access can only be written by software in Privilege state.
Non-Privilege	Pins configured for Non-Privilege access can be written by software in both Privilege and Non-Privilege states.

The GPIO module implements access protection registers (ICNS and ICNP) for each interrupt and DMA request as follows:

Access	Description
Secure	Outputs configured for Secure access can only be configured by software in Secure state.
Non-Secure	Outputs configured for Non-Secure access can only be configured by software in Non-Secure state.
Privilege	Outputs configured for Privilege access can only be configured by software in Privilege state.
Non-Privilege	Outputs configured for Non-Privilege access can be configured by software in both Privilege and Non-Privilege states.

The access protection registers (PCNS, PCNP, ICNS and ICNP) can only be written by software in secure-privilege state and can be optionally locked until the next reset.

Configuring a pin interrupt/DMA request requires the following access permissions:

- Access permission to configure that pin.
- Access permission to configure to the desired interrupt/DMA request or writing IRQC=0.
- Access permission to configure with the existing interrupt/DMA request or currently IRQC=0.
- The interrupt configuration is not locked.

18.4 External signals

Table 126. GPIO external signals

Signal	Description		Direction
GPIO31 - GPIO0	General-purpose input/output		I/O
	State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.	
	Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.	

NOTE

Not all pins within each GPIO are implemented on each device. See the chapter on signal multiplexing for the number of GPIO pins within each port available in the device.

18.5 Initialization

To initialize the GPIO module:

1. Initialize GPIO pins for output function
    a. Configure the output logic value for each pin by using PDOR register.
    b. Configure the direction for each pin by using PDDR register.
2. Initialize interrupt function
    - Write to ICRn for the corresponding pins and desired configuration.
    - If the pin is previously used for a different function, first write 0x0100_0000 to ICRn register to disable the previous function and clear the flag.

18.6 Application information

The GPIO module has the following applications:

- Read the state of a single pin
    - Perform a byte read of PnDR register.
- Update the state of a single pin
    - Perform a byte write to PnDR register.
- Read the state of multiple pins
    - Read PDIR register.
- Update the state of multiple pins
    - Write to PDOR register bits.
    - Write to PSOR register to set PDOR register bits.
    - Write to PCOR register to clear PDOR register bits.
    - Write to PTOR register to toggle PDOR register bits.

18.7 Memory map and register definition

The GPIO registers support 8-bit, 16-bit, or 32-bit accesses. Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

NOTE

For simplicity, each GPIO port's register appears with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. See the Signal Multiplexing for exact control bits for each port.

Fields

Field	Function
31-0 PDOn	Port Data Output This field configures the logic level on the pin if it is configured for general-purpose output. **NOTE** Reading the fields for unbonded pins returns an undefined value. 0b - Logic level 0 is driven on pin, if the pin is configured for general-purpose output. 1b - Logic level 1 is driven on pin, if the pin is configured for general-purpose output.

18.7.1.10 Port Set Output Register (PSOR)

Offset

Register	Offset
PSOR	44h

Function

Configures whether to set the corresponding fields of the PDOR.

Diagram

Field	Function
31-0 PTTOn	Port Toggle Output Writing to this field updates the content of the corresponding field in the PDOR as follows: 0b - Corresponding field of PDOR[PDOn] does not change. 1b - Corresponding field of PDOR[PDOn] is set to the inverse of its current logic state.

18.7.1.13 Port Data Input Register (PDIR)

Offset

Register	Offset
PDIR	50h

Function

Captures the logic levels of each general-purpose input pin.

NOTE

Do not modify the pin configuration registers associated with the pins that are not available in your selected package. These unbonded pins are default set to Disable state for lowest power consumption.

Diagram

Fields

Field	Function
31-0 PIDn	Port Input Disable This field is used to disable a pin for general-purpose input 0b - Pin is configured for general-purpose input provided, the pin is configured for any digital function. 1b - Pin is disabled for general-purpose input.

18.7.1.16 Pin Data Register a (P0DR - P31DR)

Offset

For a = 0 to 31:

Register	Offset
PaDR	60h + (a × 1h)

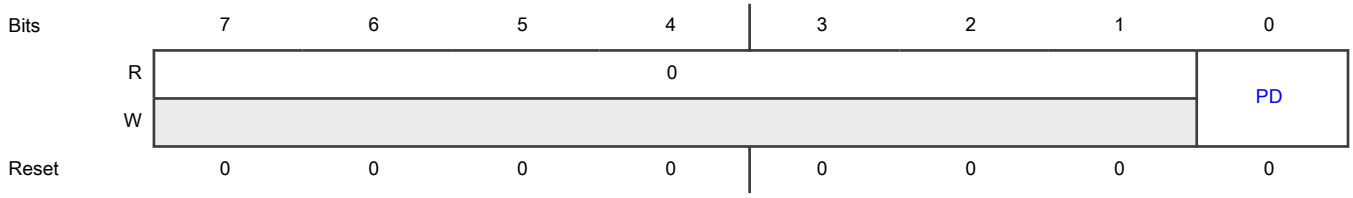
Function

Configures the data feature of a pin. Pin that is unimplemented or not configured for a digital function reads as zero.

NOTE

Do not modify PaDR registers associated with the pins that are not available in your selected package. These unbonded pins are default set to Disable state for lowest power consumption.

Diagram



Fields

Field	Function
7-1 —	Reserved
0 PD	Pin Data (input and output) Writing to this bit field of PaDR register will update corresponding bit a in the PDOR register, reading this bit field of PaDR register will return value in the corresponding bit a of the PDIR register. 0b - Pin logic level is logic zero or not configured for use by digital function. 1b - Pin logic level is logic one.

18.7.1.17 Interrupt Control Register a (ICR0 - ICR31)

Offset

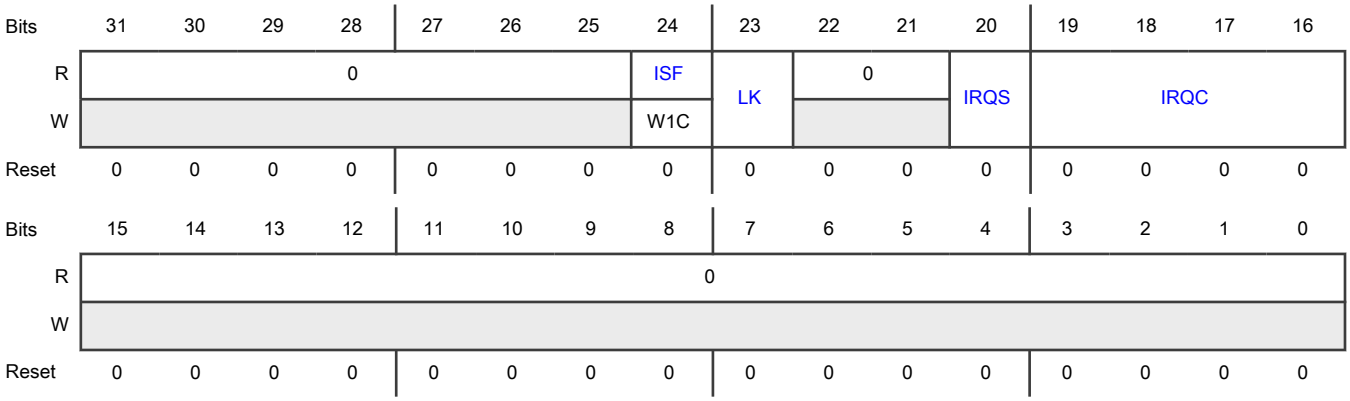
For a = 0 to 31:

Register	Offset
ICRa	80h + (a × 4h)

Function

Configures interrupt features on each pin.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 ISF	Interrupt Status Flag This field indicates whether the configured interrupt is detected. The pin interrupt configuration is valid in all digital pin muxing modes. The bit fields in the ISFR register have the same function. The interrupt status flag can be cleared with either register bit. 0b - Configured interrupt is not detected. 1b - Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.
23 LK	Lock Register This field is used to lock ICR[23:0], and the locked field cannot be updated until the next system reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Interrupt configuration by ICR[23:0] is not locked and can be updated. 1b - Interrupt configuration by ICR[23:0] is locked and cannot be updated until next system reset.
22-21 —	Reserved
20 IRQS	Interrupt Select This field configures the interrupt/DMA request. **NOTE** See GPIO chip-specific info to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0b - Interrupt/DMA request 0. 1b - Interrupt/DMA request 1.
19-16 IRQC	Interrupt Configuration The pin interrupt configuration is valid in all digital pin muxing modes. When changing the interrupt configuration, it is recommended to first disable the interrupt status flag and then write the new configuration. The corresponding pin is configured to generate interrupt, or DMA request as follows: **NOTE** See GPIO chip-specific info to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0000b - Interrupt Status Flag (ISF) is disabled. 0001b - ISF flag and DMA request on rising edge. 0010b - ISF flag and DMA request on falling edge. 0011b - ISF flag and DMA request on either edge. 0100b - Reserved. 0101b - ISF flag sets on rising edge. 0110b - ISF flag sets on falling edge. 0111b - ISF flag sets on either edge. 1000b - ISF flag and Interrupt when logic 0. 1001b - ISF flag and Interrupt on rising-edge. 1010b - ISF flag and Interrupt on falling-edge. 1011b - ISF flag and Interrupt on either edge. 1100b - ISF flag and Interrupt when logic 1. 1101b - Reserved 1110b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1111b - Reserved.
15-0 —	Reserved

18.7.1.18 Global Interrupt Control Low Register (GICLR)

Offset

Register	Offset
GICLR	100h

Function

Only 32-bit writes are supported to this register, any 16-bit or 8-bit writes are ignored.

Diagram

Fields

Field	Function
31-16 GIWD	Global Interrupt Write Data Write value that is written to upper 16 bits of the Interrupt Control Registers that are selected by GIWE.
15-0 GIWEn	Global Interrupt Write Enable This field selects whether the upper 16-bit field of the Interrupt Control Register ICR(n) will be updated with the value in GIWD. 0b - Upper 16-bit of corresponding Interrupt Control Register is not updated with the value in GIWD. 1b - Upper 16-bit of corresponding Interrupt Control Register is updated with the value in GIWD.

18.7.1.20 Interrupt Status Flag Register (ISFR0 - ISFR1)

Offset

Register	Offset
ISFR0	120h
ISFR1	124h

Function

The Interrupt Status Flag Register (ISFR) indicates whether the related configured interrupt is detected on each pin. The pin interrupt configuration is valid in all digital pin muxing modes. The Interrupt Status Flag for each pin is also visible in the corresponding Interrupt Control Register, and each flag can be cleared in either location.

There is a separate Interrupt Status Flag Register for each interrupt or DMA request domain. Each status flag is only visible in the register that corresponds to that flag's domain as configured in IRCa[IRQS].

Fields

Field	Function
31-0 ISFn	Interrupt Status Flag Each bit in the field indicates the detection of the configured interrupt on each pin of the same number. 0b - Configured interrupt is not detected on the pin of the same number. 1b - Configured interrupt is detected on the pin of the same number. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.

Chapter 19
Clock and Power Overview

19.1 Overview

This chip targets many applications with power requirements that include low power consumption, long battery life, always-on capability, instant-on capability, and doesn't require active cooling. To meet these requirements, the chip design focuses on reducing current consumption, while simultaneously enabling the maximum level of peak performance, and also a balanced level of sustained performance. The chip architecture uses a wide range of power-management techniques, used in combination, for system design flexibility.

This chapter describes these architecture details as a high-level clock and power management overview of the chip. This overview chapter covers:

- Structural components of the power and clock management systems
- Clock generation and distribution system
- Power generation and distribution system
- Power mode definition
- Power and clock and management techniques supported.

NOTE

All numerical values in this chapter are either typical values or used as an example. See the data sheet for accurate values.

19.2 Components of Clock and Power Management

The centralized clock generation, power generation and distribution are implemented by the following blocks:

Table 127. Clock and Power Components

IP Module	Description
Crystal OSC (XTALOSC)	The XTALOSC includes a 24 MHz and 32 kHz oscillators. The 24MHz crystal oscillator is the primary clock source for all the PLLs, and clock generation for the CPU and high-speed interfaces. The 32KHz crystal oscillator is the primary clock source for the RTC as well as the low-speed clock source for CCM/SRC/GPC. See the Crystal Oscillator (XTALOSC) section of the ANADIG chapter for details.
PLLs and PFDs	The PLLs and their associated PFDs generate the clocks with various frequencies required to feed the CCM clock generator that supplies the different functional blocks. See the PLL and PFD section for information on the PLL and PFD architecture and functional description. The PLL registers are in the ANADIG chapter.
Clock Control Module (CCM)	The CCM module provides control for clock generation, division, distribution, synchronization, and coarse-level gating. See Clock Controller Module (CCM) for information on the CCM architecture, functional description and programming model.
Low Power Clock Gating (LPCG)	The LPCG distributes the clocks to all blocks in the SoC and handles automated clock gating and block level software-controllable clock gating. See

Table continues on the next page...

Table 127. Clock and Power Components (continued)

IP Module	Description
	Clock Controller Module (CCM) for information on the LPCG architecture and functional description.
General Power Controller (GPC)	This module controls the power state of the SoC. The GPC handles the power gating under low power modes and also manages the power up / power down sequences. See the General Power Controller (GPC) chapter for information on the GPC architecture, functional description and programming model.
Power Management Unit (PMU)	This module generates the internal power supplies distributed to the entire SoC. See the Power Management Unit (PMU) section of the ANADIG chapter for information on the PMU architecture, functional description, and programming model.
System Reset Controller (SRC)	This module generates the reset signals to all the modules in the SoC and controls power gating of power domains and memory low power mode. The SRC will appropriately assert reset signals for power transitions, entry, and exit. See the System Reset Controller (SRC) chapter for information on the SRC architecture, functional description and programming model.
DCDC Converter (DCDC)	This module generates the power supply for chip's core logic. See DCDC converter (DCDC) chapter for information on functional description, and programming model.
Trusted Resource Domain Controller (TRDC)	This module provides domain based resource control architecture for the memory/peripheral resource sharing and isolation between the Arm Cortex M33 core, Arm Cortex-M7 core and other bus masters. See the Trusted Resource Domain Controller (TRDC) chapter for more information.

Together, the modules listed above provide enhanced power-management features with the centralized control for the clock, reset, and power-management signals on the SoC.

19.3 Power Management

The power management design on the chip satisfies many use cases that depend on a key balance of performance and low-power consumption. In order to meet these criteria, the system power management needs to be dynamic and flexible. This is accomplished on a multi-core system by utilizing a power scheme that considers each CPU domain, and arbitrates the appropriate power mode configuration to satisfy the needs of both CPUs, and the system as a whole. The following are additional features supported by the power management architecture:

- Programmable power mode transition rules
- Independent operation mode for individual CPU cores
- Intelligent clock and power management for multi-core architecture
- Unified power management interface (UPI) for all on-chip resources, including clock, power, reset, and peripherals

A high-level view of the power management controllers and connections is shown below:

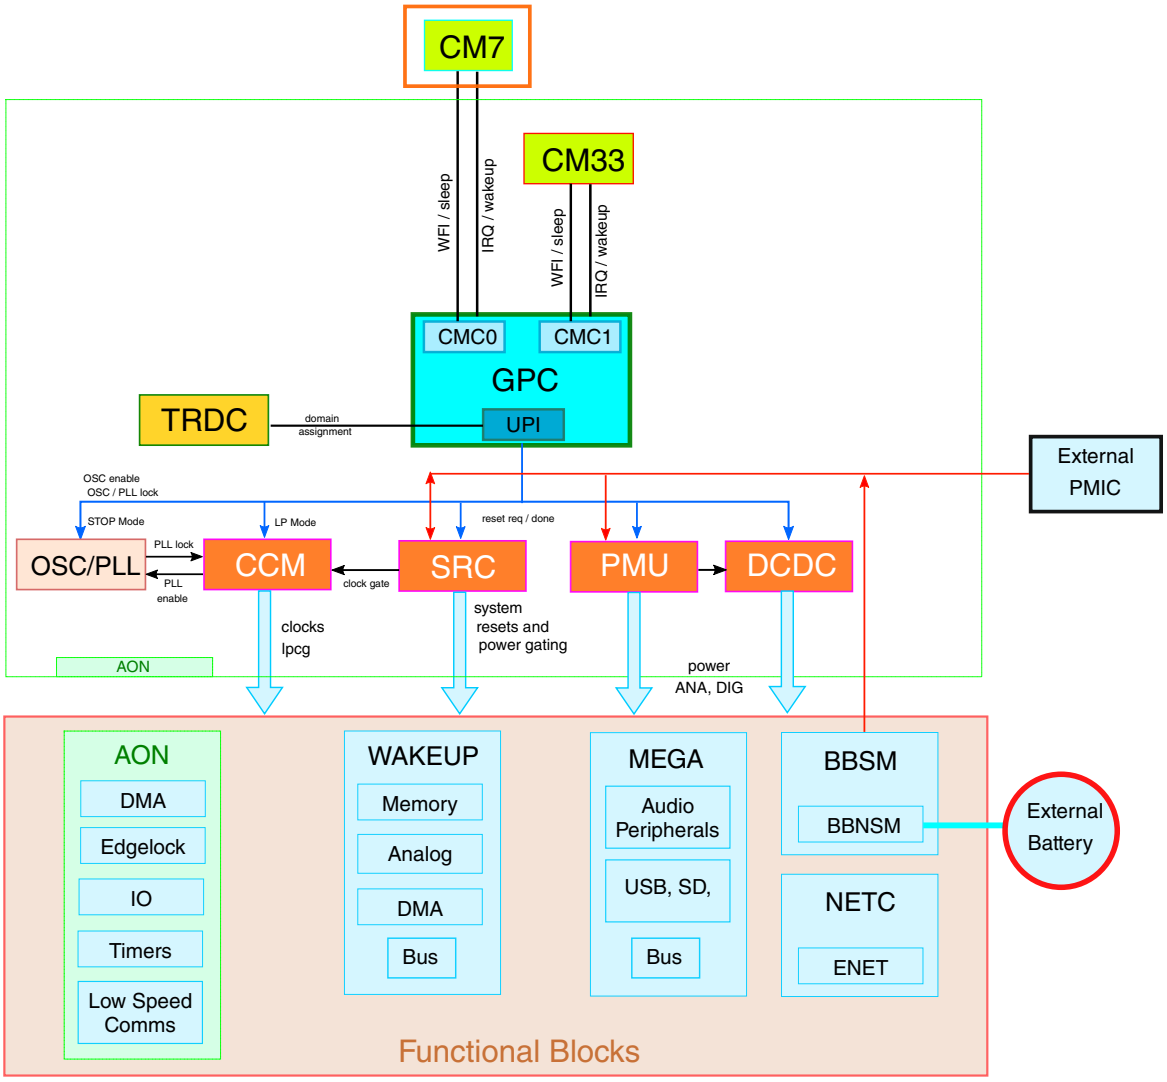

Figure 69. Power Management Block Diagram

19.3.1 Resources and Chip Domains

The chip is divided into resources and domains. Resources are controlled by resource controllers. Domains are grouped by central bus controllers and crossbars. Some domains reside within larger domains, which may have power dependencies. For illustrative representation of the power domains and bus configurations, see the Power Management Block Diagram. The Resource types and Chip Domains are listed in the tables below:

Table 128. Resources

Resource	Description
CPU Platforms	The processor and associated on-platform peripherals that support the complex. The CPU Platforms supported on this chip are the CM7 and the CM33 platforms.

Table continues on the next page...

Table 128. Resources (continued)

Resource	Description
System Controllers	The System Controllers are the associated peripherals that control or define the power management resources for the chip. These modules include GPC, PMU, CCM, SRC, and TRDC.
Functional blocks	The functional blocks are comprised of all the other peripherals, other than System Controllers. These modules include external memory controllers, timers, high-speed and low-speed peripherals, audio peripherals, connectivity, and others.

Table 129. Chip Domains

Domain	Description
CM7	The Cortex-M7 core and platform.
AON	The AON Domain contains the Cortex-M33 core and platform, which includes Tightly Coupled Memory (TCM). It also contains modules: SCTR, WDOG1-2, IOMUX_AON, IOMUXC, MU, MTR DCA_A, TSTMR1, GPIO1, SAI1, CAN1,3, LPI2C1-2, LPSPI1-2, LPUART1,2,7,12, I3C1, GPT1, LPIT1, TPM1-2, DCDC
WAKEUP	The WAKEUP Domain contains the memory controllers and analog on the chip. The specific modules in WAKEUP include: EWM, WDOG3-5, eDMA4, 2x DMAMUX (WAKEUP), ACMP, LPADC1-2, DAC, XBAR1-3, KPP, GPIO2-7, LPUART3,6,8-11, MTR DCA_W, FLEXCAN2 (CANFD), QDC1-8, LPIT2-3, AOI1-2, GPT2, TMR2-3, FlexPWM1-4, LPI2C3-4, I3C2, LPSPI3-4, FlexIO1-2, FlexSPI1, SEMC, IEE
NETC	Contains the NETC subsystem and 5x NETC Ethernet controllers.
MEGA	Contains the connectivity peripherals and audio peripherals. The specific modules include: EtherCAT, uSDHC1-2, 2xUSB, FlexSPI Slave, DMIC, SINC1-3, ASRC, SAI2-4, SPDIF
ANADIG	The ANA Domain contains: XTAL OSC and Control, PLL and Control, Temp Sensor and Control.
CCMSRCGPC	The CCMSRCGPC Domain contains: GPC, SRC, and CCM.
BBSM	The BBSM Domain contains BBNSM, which connects to a coin cell or non-interruptible power source. This domain contains control logic for security, startup, and RTC.

19.3.2 Power Management Unit (PMU)

The PMU has the following components integrated for power management:

- DCDC
  - Generates the core power supply
  - Supports dynamic voltage scaling
- LDOs
  - Internal logic power supply
- Power Switches for sophisticated power mode management

The typical power architecture of the chip is shown below. The use case illustrated shows the whole system working with a single 3.3V power supply and a coin cell. This is the power system configuration of traditional MCU. Depending on the application, other power supply schemes may be used, including bypassing the DCDC converter and using an external voltage regulator or PMIC.

NOTE

The on-chip DCDC converter is suitable for consumer and industrial applications up to the rated temperature specified in their respective market data sheets. Check the data sheet or consult with your NXP representative for appropriate power supply requirements.

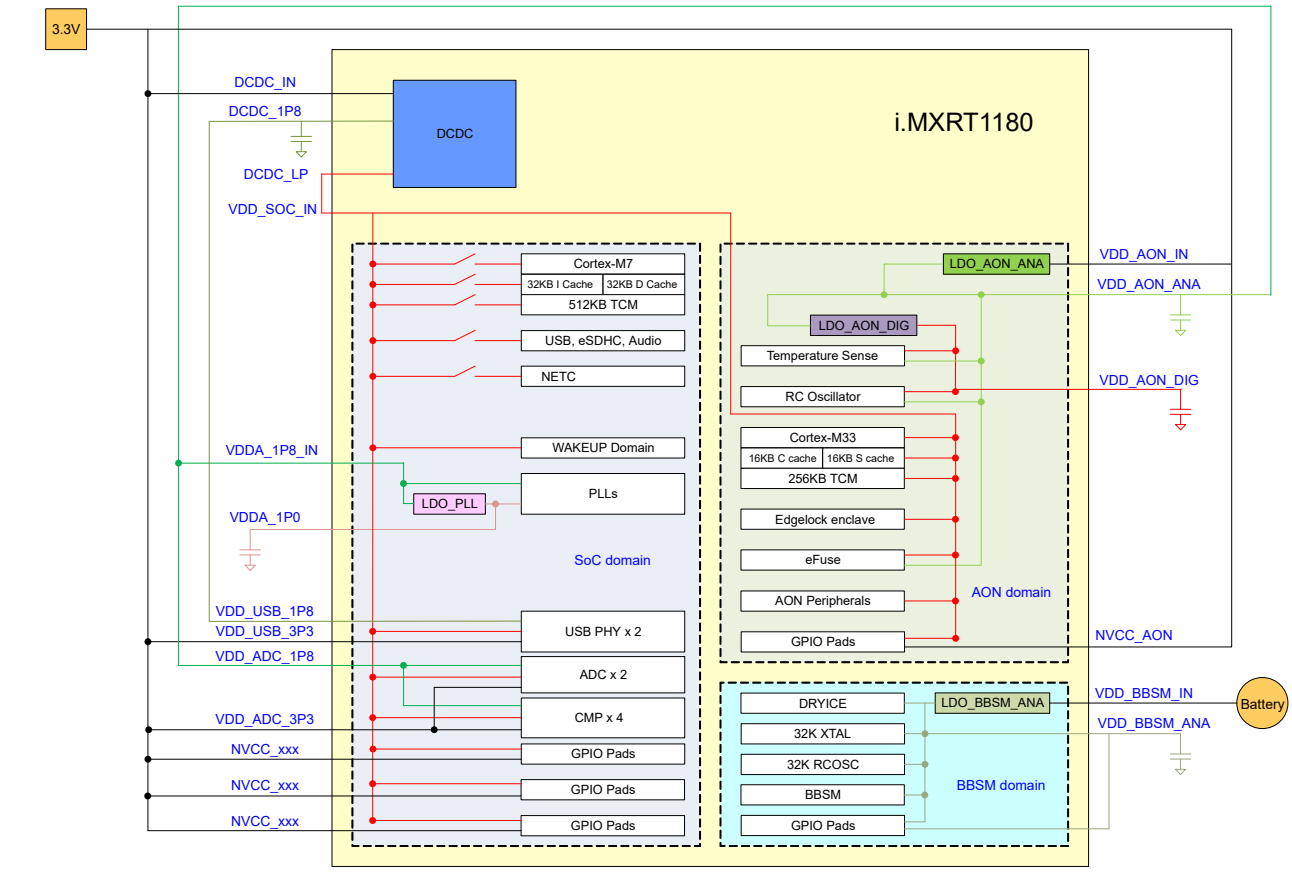

Figure 70. Power Architecture

19.3.3 Body Biasing (BB)

Forward Body Biasing (FBB) is implemented in the CM7 platform in order to achieve higher performance. See PMU for more information.

19.3.4 Power Modes

The chip resources abide by CPU or system-level power modes, depending on their resource assignment. Resources are assigned to one of four categories, which are defined below.

Table 130. Resources Categories

Category	Description
Private	A resource that is fully owned and controlled by one CPU platform. These resources can be controlled by hardware and software.

Table continues on the next page...

Table 130. Resources Categories (continued)

Category	Description
Shared	A resource that is shared by more than one CPU platform. These resources are limited by the other CPU power state. Software must take into regard shared resources, since they are limited by other CPU power states.
Public	A resource that is managed at the system level, which is not owned and controlled by any of the CPU platforms. These resources can only be controlled by hardware.
Unassigned	A resource that is not assigned as private, shared, or public. This is the default state of a resource after reset.

Resources can be assigned to different CPU domains by the TRDC. If one CPU wants to put the chip into a power mode, it must arbitrate with the other CPU to ensure the appropriate power state is chosen for shared resources. Depending on the resource type, varying power control mechanisms are followed.

Table 131. Power modes

Power Modes	CONDITION														Entry	Exit

19.3.4.1 CPU Mode

The CPU platforms both support the same power states that are defined as CPU modes. The CPU Modes are detailed below.

Table 132. CPU Mode

CPU Mode	Description
RUN	The CPU is active and running.
WAIT	The CPU is in the WFI state. The CPU core and L1 cache are clock gated, TCM and peripheral can still be alive. The chip can wakeup from this mode from IRQ with a very short latency.
STOP	The CPU is in the WFI state. The CPU core, L1 cache, TCM, and its private peripherals are all clock gated. The chip requires a longer time to wakeup from this mode.
SUSPEND	The CM7 core and L1 cache are power gated. The TCM is in retention mode. SUSPEND mode consumes the least amount of power, while keeping parts of the system alive. But the chip requires a much longer time to wakeup from this mode. The CM33 and CM33 cache is not power gated.

For the 3 types of resources mentioned above, the CPU platform is naturally a private resource, the system resources and functional blocks can be configured as private, public or shared. For example:

- A UART module can be a private resource
- The clock root dedicated for a UART can also be a private resource
- The DCDC which provides power to the entire chip is a public resource
- The AXI bus which provides connection for both CPU platforms is a shared resource

For private resources, they can be controlled by SW, or controlled by HW (based on CPU state). For example:

- A clock for UART can be gated OFF when CPU is in STOP mode
- Audio PLL reserved for one CPU core can be configured by the CPU at any time

For public resources, they need to be controlled by HW through GPC. For example:

- DCDC voltage goes to 0.8V when chip goes to SYSTEM SLEEP mode

- LDO goes to STANDBY mode when chip goes to SYSTEM SLEEP mode

For shared resources, they can be controlled by SW, or controlled by HW (based on CPU state). For example:

- A clock for shared AXI bus can be gated OFF when both CPUs disable this clock
- A clock for shared AXI bus can also be gated OFF when both CPUs are in STOP mode

NOTE

AXI bus clock can NOT be gated off by application.

For unassigned resources, they are expected to be assigned or disabled by SW during chip initialization phase.

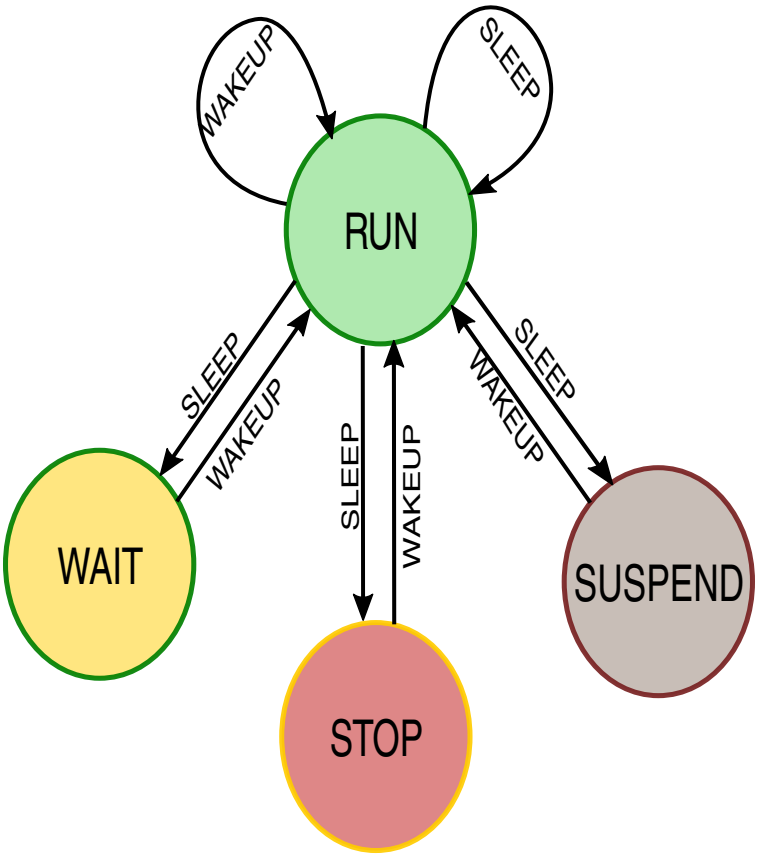

Figure 71. CPU Modes

19.3.4.1.1 Memory Power Connection

A few of the power connections that exist in this chip are shown below:

- M7 Cache and TCM memory:
  - M7 core and the memory interface to the SoC are on the same power domain, which are on/off together. For example, "M7 can be OFF while the memories are ON" means the memory array is powered on, while M7 and the memory interface to the SoC are powered off
  - Supported modes:
    - M7 on, cache and TCM on
    - M7 off, cache and TCM on
    - M7 off, cache off, TCM off

- No access to TCM memory when M7 core is power gated

- M33 Cache & TCM memory:
  - M33 Cache and TCM is in AON Domain, supplied from VDD_SOC_IN, no power gate.
- OCRAM memories:
  - OCRAM is in WAKEUP Domain, supplied from VDD_SOC_IN, no power gate
- RAM in AON Domain:
  - All RAM in AON Domain are supplied by VDD_SOC_IN, no power gate.
- RAM in WAKEUP Domain:
  - All RAM in WAKEUP Domain are supplied by VDD_SOC_IN, no power gate.
- RAM in MEGA Domain:
  - RAM in the MEGA Domain share same power supply as logic cells in the MEGA Domain, when MEGA Domain is power off, RAM in the MEGA Domain are powered off.

19.3.4.2 System Sleep Mode

System sleep mode is a low-power mode that has distinguishing settings outside of CPU mode. When system is in SLEEP mode:

- Analog modules like LDO/BG can be put into their own STANDBY mode
- DCDC can be decreased into lower voltage to reduce leakage
- DCDC module clock can be turned off

System sleep mode is related to the state of all CPU platforms. The system sleep controller in GPC maintains the system sleep sequence. Only when all CPU platforms send system sleep requests, the system enter into system sleep mode. Any interrupt can abort system sleep sequence so that system can be quickly woken up.

19.3.5 Power Sequence

Power Up:

- VDD_BBSM_IN supply must be turned on before all other power supplies, or be connected (shorted) with VDD_AON_IN and DCDC_IN supply
- If a coin cell is used to power VDD_BBSM_IN, then ensure that it is connected before all other supplies are switched on
- When internal DCDC is enabled, external delay circuit is required to delay the “DCDC_PSWITCH” signal 1ms after DCDC_IN is stable
- POR_B should be held low during the entire power up sequence

Power Down:

- VDD_BBSM_IN supply must be turned off after all other power supplies, or be connected (shorted) with VDD_AON_IN and DCDC_IN supply
- If a coin cell is used to power VDD_BBSM_IN, then ensure that it is removed after all other supplies are switched off

19.4 Low-Power Control Architecture

There are 3 types of controllers used in the system for power management:

- **General Power Controller (GPC)** - GPC is the centralized power controller, which controls the power mode of the entire processor. GPC takes the WFI signal from CPU platforms and wakeup events from peripherals, determine the power mode based on power management policy, and controls the power mode transition. GPC does not control the state of the resource directly. During power mode transition, it communicates with the resource controllers through the UPI (Unified Power management Interface) to accomplish the power mode transition.

- **Trusted Resource Domain Controller (TRDC)** - TRDC is used for system resource protection and sharing in multi-core system. The resources of the entire chip can be assigned to different CPU core domains so that resources that belong to one CPU core are not affected by the other core. In power management system, the TRDC delivers the domain assignment information to GPC and other components to support multi-core-aware clock and power management. It does not control the resources directly.
- **System Resource Controllers (SRC)** - System resource controllers are not a single block. It is a set of controllers that manages the system resources such as clock, power and reset. It gets the power mode transition information from UPI interface and get the resource ownership information from TRDC, then change the state of the system resource based on pre-defined policy.

The following blocks are the typical system resource controllers:

- CCM (Clock Controller Module) - Generates the clocks for the entire chip
- SRC (System Reset Controller) - Generates resets for the entire chip
- PMU (Power Management Unit) - Controls the on-chip LDO/DCDC modules
- Other resource controllers

NOTE

Power gating to control ON/OFF of various power domains, as well as memory low-power control for sleep/retention of memories, are performed by the SRC.

19.5 Clock Generation

The clock system is designed to provide a scalable, powerful, and easy-to-use clock solution.

19.5.1 Clock System Diagram

The overall clock system for the chip is shown in the diagram below.

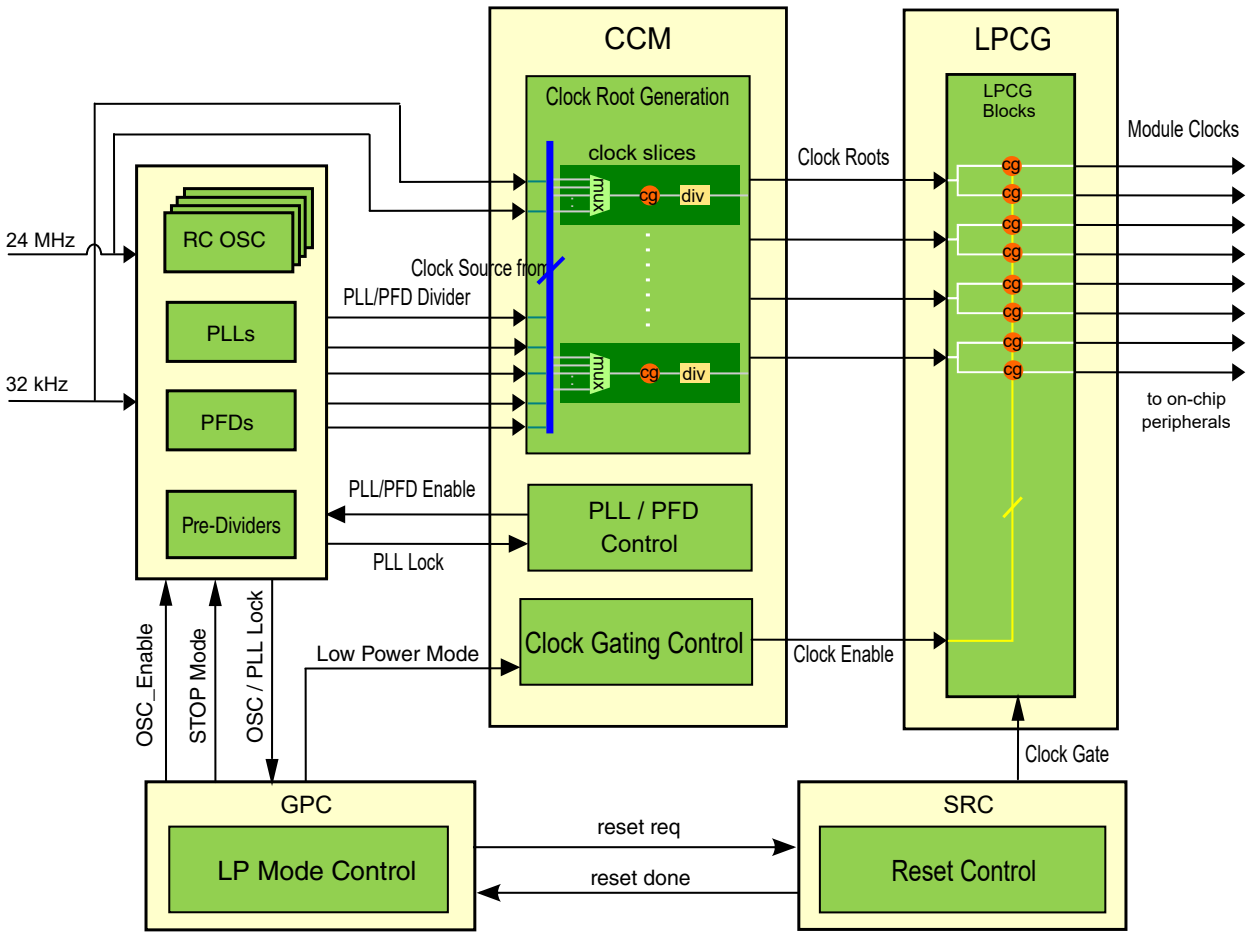

Figure 72. Clock System

The OSCs, PLLs, PFDs and Pre-Dividers generate the clock sources with fixed or variable frequency. The clock sources feed the clock root generation logic inside CCM, which generates numerous clock roots required for core, bus, and peripheral blocks. These clock roots are branched to each module through the LPCG logic, which contains the clock gating cells for each clock. Control signals for the LPCGs are in CCM (clock enable signal). Some of the clocks need to be gated off during reset, because of this, the SRC module will also send clock gate signals to the LPCG.

In low power mode, GPC will drive the low power mode state signal to CCM, then CCM will enable clock gating based on the configuration. At the same time, CCM may also deassert enable signals for PLLs and PFDs, so these modules can power off during low power modes. When the chip enters STOP mode, CCM may deassert the OSC enable signal to shut off the OSC, it may also assert the STOP mode signal to set OSC to low power mode.

The detailed functional description for each block will be described in the following sections.

19.5.2 Oscillator

This chip has two crystal oscillators and three RC oscillators:

Table 133. Oscillators

Oscillator	Description
24 MHz Crystal Oscillator (OSC_24M)	The primary clock source for all PLLs to generate the clocks for CPU, bus, and high-speed interfaces
32 kHz Crystal Oscillator (OSC_32K)	The primary clock source for RTC as well as low-power clock source for CCM, SRC, and GPC. The typical frequency is 32.768KHz.
24 MHz RC Oscillator (OSC_RC_24M)	Generates the 24 MHz clock source for the chip during startup, before the 24MHz crystal oscillator is ready. The OSC_RC_24M can also be used as an alternative 24 MHz clock source in low power mode, when the crystal oscillator is turned off, or in a system that doesn't have a crystal oscillator.
32 kHz RC Oscillator (OSC_RC_32K)	The 32 kHz clock source for the chip during startup when 32 kHz crystal is not ready. It can also be used as alternative 32 kHz clock source when the external 32 kHz crystal oscillator is not stable, or in system which does not have any crystal oscillator. The switch from external 32 kHz to internal 32 kHz RC is controlled by hardware, and it happens automatically when the system detects a loss of the 32 kHz crystal clock.
400 MHz RC Oscillator (OSC_RC_400M)	The clock source during chip boot up, before PLLs are enabled, or in low-power mode when the PLLs are turned off.

See Crystal Oscillator (XTALOSC) chapter for functional description details and the programming model on these blocks.

19.5.3 PLL and PFD

The PLLs are used in the chip to generate the high speed clocks required by the modules in SoC. A few PLLs are equipped with Phase Fractional Dividers (PFDs) in order to generate additional frequencies. The following PLLs are used in this chip:

Table 134. PLLs

PLL	Description	Spread Spectrum	Configurable
ARM_PLL	The ARM_PLL is used to generate the clock for the Arm Cortex-M7 platform. It is a programmable integer-frequency multiplier PLL, capable of an output frequency over 2 GHz.	-	Yes
SYS_PLL1	The SYS_PLL1 is used primarily by the ENET module. It has a dedicated frequency of 1GHz.	Yes	1 GHz
SYS_PLL2	The SYS_PLL2 main output clock has a dedicated frequency of 528MHz, but has several configurable PFDs.	Yes	528 MHz
SYS_PLL3	The SYS_PLL3 main output clock has a dedicated frequency of 480MHz, but has several configurable PFDs.	-	480 MHz
AUDIO_PLL	The AUDIO_PLL used to generate reference clocks, mainly for serial audio interfaces, and external audio codecs. This fractional multiplier PLL provides a low-jitter and high precision audio clock with standardized audio frequencies. The PLL's oscillator frequency range is from 650MHz to 1300MHz, and the frequency resolution is better than 1Hz.	Yes	Yes

NOTE

See the datasheet for all supported maximum PLL frequencies

Each PLL can use one of the following clock sources as its reference clock:

- Primary Option: 24 MHz clock from 24 MHz oscillator (XTAL)
- Secondary Option: 24 MHz clock from 24 MHz RCOSC

The main output clocks for the SYS_PLL2 and SYS_PLL3 (PLLx_CLK) are not configurable, but their PFDs are. Each PFD works independently by interpolating the VCO of the PLL to which it is connected. It effectively takes the PLL VCO frequency and produces 18/N x Fvco at its output where N ranges from 13 to 35. PFD is a completely digital design with no analog components or feedback loops. The frequency switch time is much faster than a PLL because keeping the base PLL locked and changing the integer N only changes the logical combination of the interpolated outputs of the VCO. Note that the PFD not only enables faster frequency changes than a PLL, but also allows the configuration to be safely changed "on-the-fly" without going through the output clock disabling/enabling process.

The basic logical connections for the PLLs, PFDs and Dividers is shown in the diagram below:

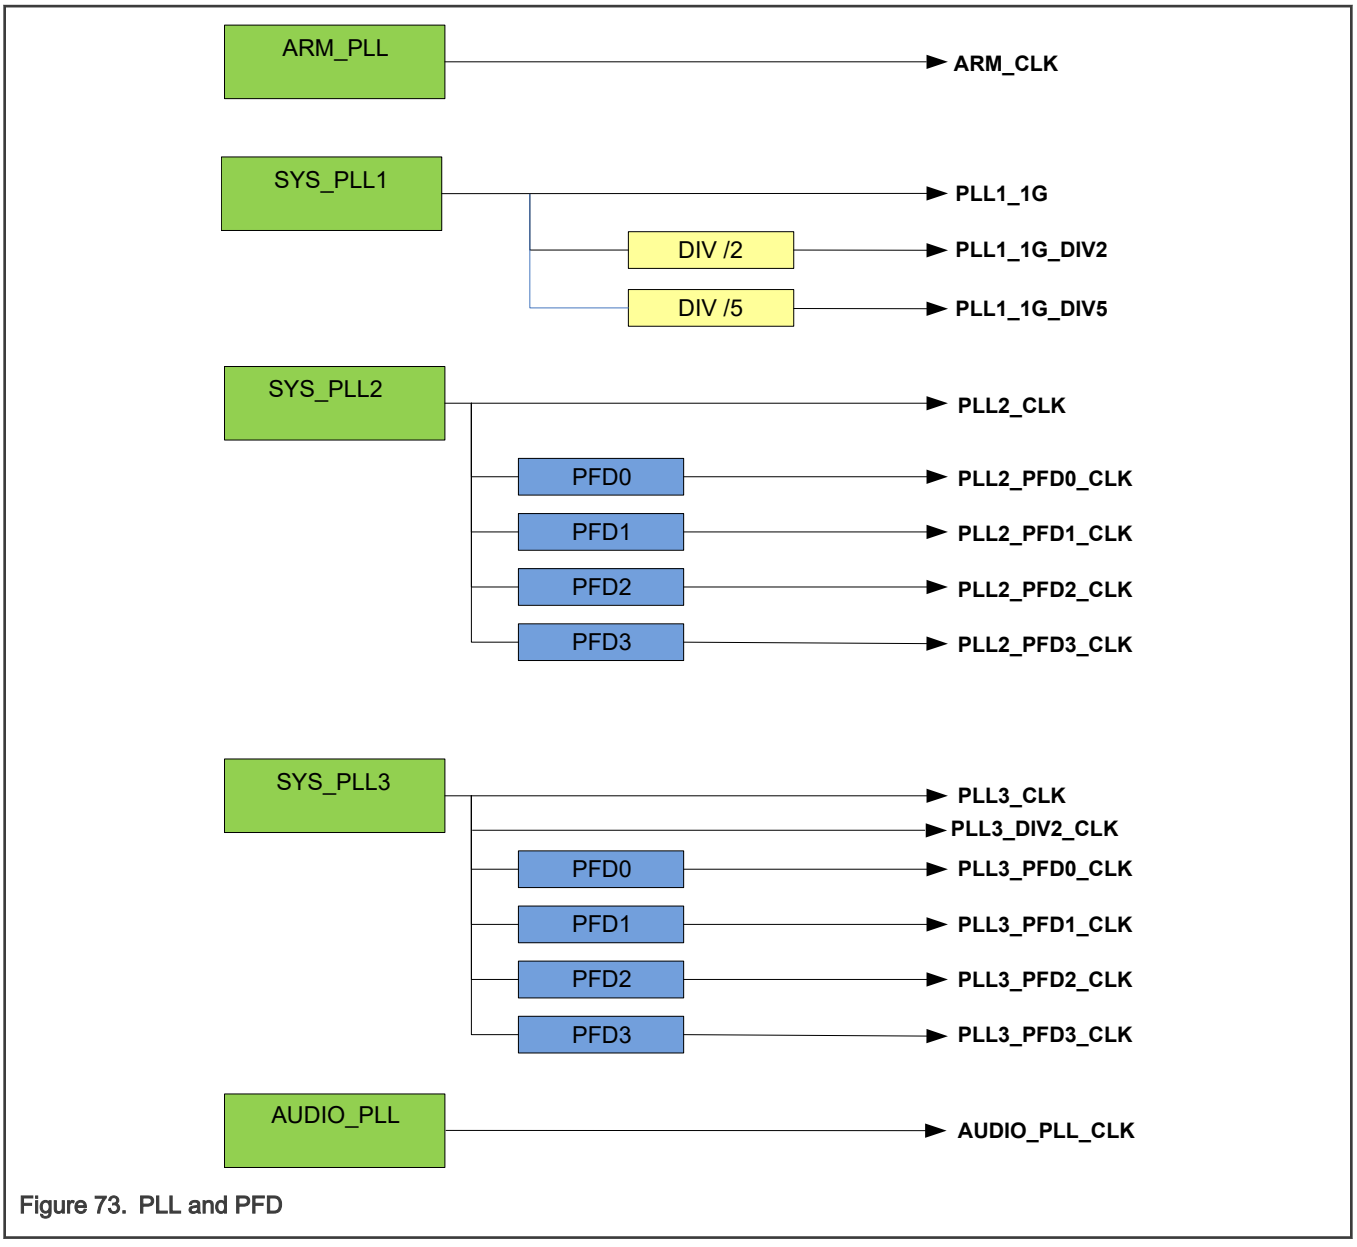

Figure 73. PLL and PFD

PLL configuration and control functions are accessible via configuration and status registers. The ANADIG block contains the detailed descriptions of the memory mapped registers, and control functions of the clock generation sub-module. See ANADIG for more information.

19.5.4 Clock Root Generation

Clock generation in the CCM creates clock roots for on-chip peripherals. Each clock root will have a dedicated clock slice. It takes the clock source from Oscillators, PLL/PFD or Pre-Dividers, and generate the clock root with required frequency.

The CCM can manage on-chip peripheral clocks by controlling the low power clock gating cells (LPCGs) before the clock roots enter the peripherals.

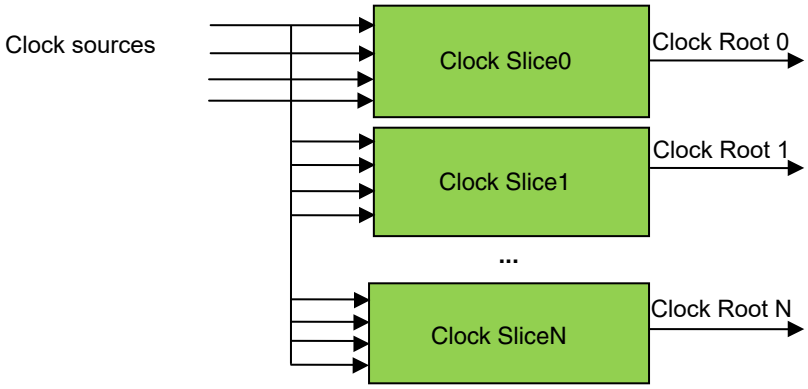

Figure 74. Clock Root Generation from Clock Slice

The LPCGs are implemented to control peripheral functions, and there could be several LPCGs for each function in a peripheral.

For details on the programming model, refer to CCM Memory Map/Register Definition.

19.5.5 Low Power Clock Gating (LPCG)

The clock roots generated inside CCM are distributed to the entire SoC through LPCG. The LPCG block receives the root clocks from CCM and splits them to clock branches for each functional block. The clock branches are individually gated clocks.

See the CCM chapter for more information about clock gating.

The memory map and register definition for PLLs exist in the ANADIG chapter. See the PLL Memory Map section in the ANADIG chapter for more information.

20.2 Overview

The Clock Control Module (CCM) manages the on-chip module clocks. The oscillators, PLLs, and Phase Fractional Dividers (PFD) will generate clock sources with fixed or variable frequencies.

20.2.1 Block diagram

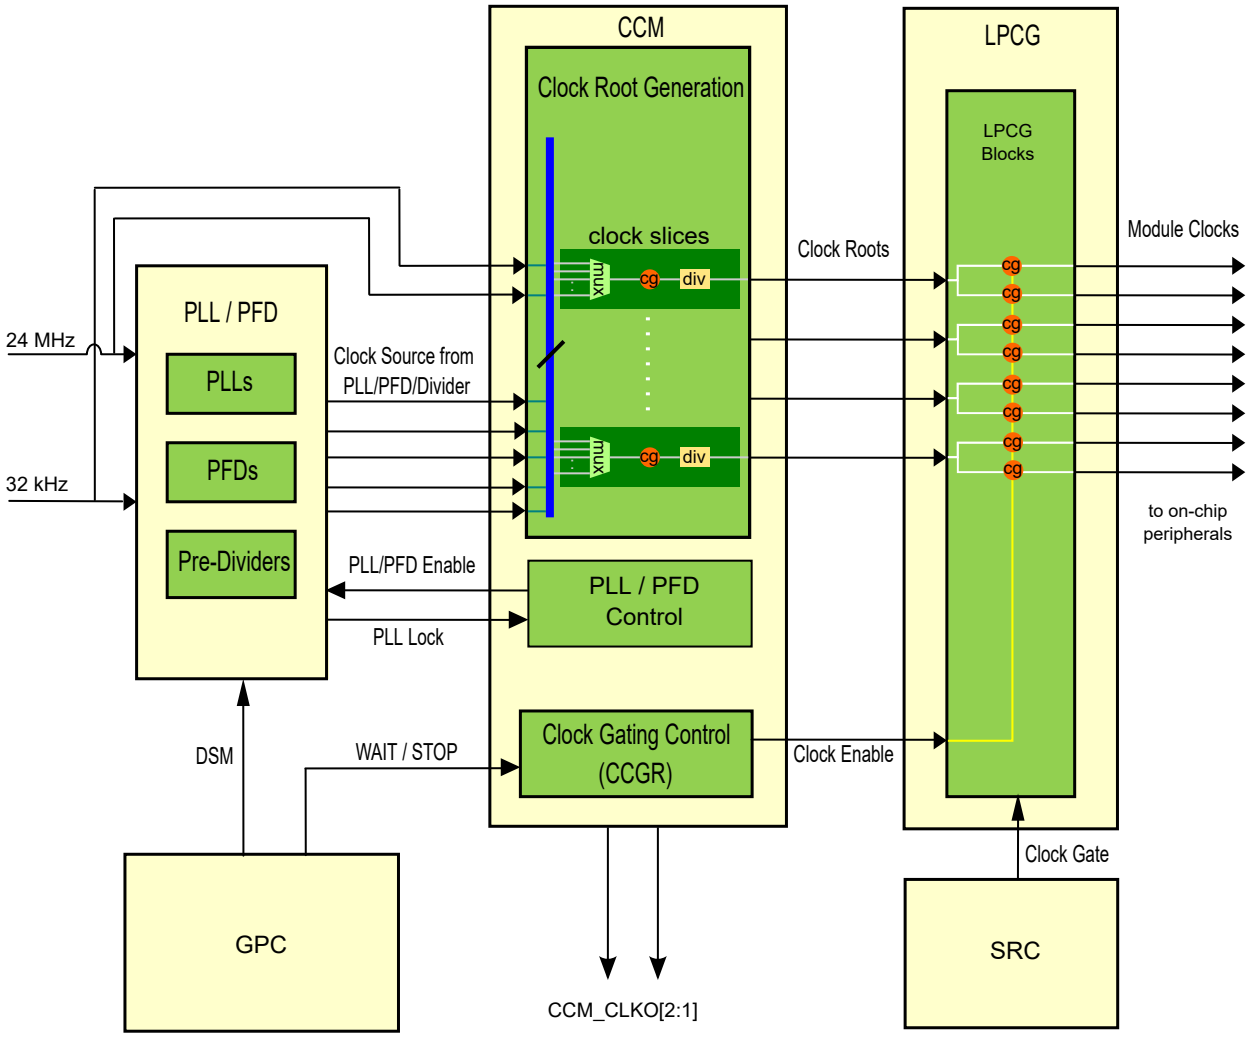

Figure 75. CCM block diagram

The clock root generation logic inside CCM will generate various clock roots required for core, bus, and peripheral blocks. These clock roots will be delivered to each module through Low Power Clock Gate (LPCG), which contains the clock gating logic for each clock.

The control signal for CCGRs in CCM will be the source for clock enable signals. Since some of the clocks need to be gated off during the reset, the System Reset Controller (SRC) will also send clock gate signals to the LPCG.

In low power mode, the General Power Controller(GPC) will drive the low power mode state signal to CCM, and CCM will enable clock gating based on the configuration. At the same time, CCM may also de-assert enable signals for PLLs, so these modules can be powered off during the low power mode.

20.2.2 Features

The CCM includes the following features:

- Clock Root
  - Up to 4 clock sources for each clock root

- 8-bit divider support up to divide by 256 in each clock root
- Each clock root can be shutdown by software

- Peripheral clock can be auto gated according to CPU work mode, software configurations, or system work mode
- PLLs and oscillators can be auto shutdown according to CPU work mode, software configurations, or system work mode
- Access Control
  - Two access control schemes: TrustZone, and Domain
  - Write access to each component can be protected independently
  - Independent setting for user, privileged, secure, non-secure
  - Domain mode access can be controlled by whitelist
  - Access control setting can be locked independently

20.3 System Clocks

The table found here shows the CCM output clocks' system-level connectivity.

20.4 Functional description

CCM is comprised of several functional blocks:

- Clock Root
- Clock Gate
- Clock Source
- General Purpose Registers (GPR)

These functions can be configured under various CCM modes. The first section will describe the ways to configure these functions under different CCM modes. And the other sections will describe these functions independently.

20.4.1 Configuration of Functions

CCM functional blocks support the following modes:

- Direct Configuration mode
- CPU Low Power mode
- Auto mode (only for clock sources)

The default CCM mode is Direct Configuration mode.

20.4.2 Clock Sources

Clock roots are generated from various clock sources, which can be either oscillators or PLLs. Clock source is implemented to control PLLs and oscillators, to be automatically turned OFF or ON on system low power actions.

The following table shows the clock sources for the CCM:

Table 137. Clock Sources

Clock Source	Description
OSC_RC_24M	24MHz RC OSC output
OSC_RC_400M	400MHz RC OSC output
OSC_24M	Crystal OSC 24MHz clock
ARM_PLL	ARM PLL VCO

Table continues on the next page...

Table 137. Clock Sources (continued)

Clock Source	Description
SYS_PLL2	System PLL2 VCO
SYS_PLL2_PFD0	System PLL2 PFD0 clock
SYS_PLL2_PFD1	System PLL2 PFD1 clock
SYS_PLL2_PFD2	System PLL2 PFD2 clock
SYS_PLL2_PFD3	System PLL2 PFD3 clock
SYS_PLL3	System PLL3 VCO
SYS_PLL3_DIV2	System PLL3 divided by 2 clock
SYS_PLL3_PFD0	System PLL3 PFD0 clock
SYS_PLL3_PFD1	System PLL3 PFD1 clock
SYS_PLL3_PFD2	System PLL3 PFD2 clock
SYS_PLL3_PFD3	System PLL3 PFD3 clock
SYS_PLL1	System PLL1 VCO
SYS_PLL1_DIV2	System PLL1 divided by 2 clock
SYS_PLL1_DIV5	System PLL1 divided by 5 clock
AUDIO_PLL	Audio PLL VCO

NOTE

The clock source calculates whether the clock is required for each CPU domain. If clock source is not needed for any domain, clock will be shutdown.

Clock Source blocks have 3 work mode: Direct Control mode, CPULPM mode and Auto mode. Direct Control mode is the default mode. After reset, all Clock Source blocks work in Direct Control mode.

All registers are readable for any domain in any mode, but write access is restricted for protection. TrustZone unauthenticated access will be ignored.

The OSCPLLn_AUTHEN and OSCPLLn_DIRECT registers can be changed in any mode, while the write access should be from the domain granted by OSCPLLn_AUTHEN[WHITE_LIST] and TrustZone authenticated. The default value of OSCPLLn_AUTHEN[WHITE_LIST] is 0xFFFF, which means all 16 domains are granted.

The OSCPLLn_LPM registers can only be written in CPULPM mode, otherwise the write access will be ignored. And the write access in CPULPM mode should also comply with the TrustZone access control.

In Direct Control mode, the ON/OFF of clock source is determined by OSCPLLn_DIRECT[ON] directly. The default state of OSCPLL is OFF.

In CPULPM mode, the ON/OFF of clock source is dependent on the settings in OSCPLLn_LPMs and the current mode every domain is in. There are 2-bit clock dependent level settings for each domain respectively. The bigger the 2-bit value is, the stronger the clock is dependent. Valid values are as follows:

- 0: Disable in any mode
- 1: Turn on in Run mode
- 2: Turn on in Run and Wait mode
- 3: Enable in Run, Wait, and Stop modes

In CPULPM mode, LPCG will calculate whether the clock is required by any CPU domain. If clock source is not needed for any domain, the clock will be shutdown.

In Auto mode, the specific clock source will be shut down automatically when all clock roots derived from this clock source are OFF, and the OSCPLLn_DIRECT[ON] is de-asserted.

20.4.3 Clock Root

CCM clock root generation contains multiple clock root channels. All clock roots are asynchronous each other, even all the clock root setting are the same.

Each clock channel contains an 4-to-1 MUX, and a 8-bit divider. The clock MUX selects 1 clock out of 4 clock inputs. The 8-bit divider can divide selected clock by up to 256. The clock output of the clock channel can be gated off.

The clock root channel setting can be changed from any value to any value, and at any time. If more than one setting is changed at the same time, internal logic will use a procedure to change the setting. The procedure will make sure the clock output is not faster than the current clock root setting or target clock root setting. If the application does care about the clock during transition, software will need to change the setting one field at a time. This typically happens when a clock must be faster than the given frequency. In this case, the application needs to change each field one at a time and wait for the field to take effect before changing the next field.

Although a clock root channel is designed to be able to switch clocks regardless of clock input status. When the current selected clock input is off, the application needs to avoid changing the clock MUX after the clock input is turned on. This will lead to unstable behavior for the clock root and loading peripherals. To avoid this scenario, the application can either switch the clock MUX before turning on the clock input, or wait until the clock input is stable before changing the MUX option.

The division factor of the divider is equal to CLOCK_ROOTn_CONTROL[DIV]+1.

All registers are readable for any domain in any mode, but write access are restricted. Unauthenticated write access will be ignored. Only the access from the domains on the whitelist can change the value of CLOCK_ROOTn_CONTROL register, after passing TrustZone authentication.

Table 138. Clock Roots

Clock Control Register	Clock Root	Max Freq (MHz)			Source Select CLOCK_ROOTn_CONTROL[MUX]
		HSRUN (High Speed Run mode)	RUN (Run mode)	UDRUN (Underdrive mode)	
CLOCK_ROOT0	m7_clk_root	800	600	360	00 - OSC_RC_24M 01 - OSC_RC_400M 10 - PLL_ARM 11 - PLL_480
CLOCK_ROOT1	m33_clk_root	240	240	100	00 - OSC_RC_24M 01 - OSC_RC_400M 10 - PLL_480 11 - PLL_ARM

NOTE

The frequency values of the cores are dependent on the part configuration. Please see the datasheet for supported core frequencies.

20.4.4 Clock Gate

Before a clock root goes to on-chip peripherals, the clock roots go through the Low Power Clock Gates (LPCG). These LPCG are implemented to perform automatic clock gating when a domain enters and leaves low-power states. The LPCGs are mapped to peripherals so software can be simplified. LPCGs are also implemented to control peripheral functions, and different LPCGs could interface different clocks of the peripheral.

Clock gates have 2 work modes: Direct Control mode and CPULPM mode. Direct Control mode is the implicit mode. After reset, all clock gates work in Direct Control mode.

All registers are readable for any domain in any mode, but write access is restricted for protection. TrustZone unauthenticated access will be ignored.

The LPCGn_AUTHEN and LPCGn_DIRECT registers can be changed in any mode, while the write access should be from the domain granted by LPCGn_AUTHEN[WHITE_LIST] and TrustZone authenticated. The default value of LPCGn_AUTHEN[WHITE_LIST] is 0xFFFF, which means all 16 domains are granted.

The LPCGn_LPM registers can only be written in CPULPM mode, otherwise the write access will be ignored. And the write access in CPULPM mode should also comply with the TrustZone access control.

In Direct Control mode, the ON/OFF of LPCG is determined by LPCGn_DIRECT[ON] directly. The default state of LPCG is OFF.

In CPULPM mode, the ON/OFF of LPCG is dependent on the settings in LPCGn_LPMs and the current mode every domain is in. There are 2-bit clock dependent level settings for each domain respectively. The bigger the 2-bit value is, the stronger the clock is dependent. Valid values are as follows:

- 0: this clock is not needed in any mode
- 1: this clock is needed in RUN mode, but not needed in WAIT, STOP mode
- 2: this clock is needed in RUN and WAIT mode, but not needed in STOP mode
- 3: this clock is needed in RUN, WAIT and STOP mode

In CPULPM mode, LPCG will calculate whether the clock is required by any CPU domain. If clock is not needed for any domain, the clock will be shutdown.

20.4.5 Clock Observe

The clock observe slices are used to observe on-chip clocks or signals by measurement or IO pins.

Each observe channel contains a 512-to-1 MUX, an inverter and an 8-bit divider. The clock MUX selects one observe signal out of 512 inputs.

The 8-bit divider can divide the selected clock by up to 256. The inverter is selectable by software. Raw MUX is used to bypass inverter and divider to observe selected signal directly.

There is also a reset control on for observe selection part. If RAW MUX, inverter signal select MUX or divide factor changed, a logic reset will be automatically reset. If all those setting are kept unchanged, a reset can be force reset by explicitly write "1" to RESET field.

The MUX options are listed in following table. The table listed each option signal name, and present or not in each part of the chip. Any option not shown in the table are tied to "0". Any a tied "0" option can be selected for saving power.

Observe slice can do frequency, width, and period measurement on selected signals or clocks. On each time observe signal selection change, all measurement data will be reset, and the measurement starts.

The software can explicitly issue a reset by write "1" to RESET filed. During measurement, the register value may change all the time, and read from registers may not be valid. To get the measurement result, software must turn OFF the observe slice before the measurement results are read.

For frequency measurement, 32K clock is used as time reference,and 32K will be divided to 64Hz. So the observe clock counts every 64Hz cycle. The resolution of frequency measurement is 64Hz. And measurement unit will also record maximum and minimum value ever occurred.

For pulse measurement, measurement unit use Ethernet PLL 1GHz clock, the resolution of pulse is 1ns. To observe, the clock need be divide to some frequency lower than 500MHz for correct result. Pulse measurement unit count every positive pulse, negative pulse, and cycle, and update measurement result. At the same time, pulse measurement unit will record maximum and minimum value ever occurred.

Observe signal can be directly read out from status register.

All registers of Clock Observe blocks are readable for any domain. But the write access should be granted by the OBSERVEn_AUTHEN[WHITELIST] and TrustZone authenticated.

20.4.6 General Purpose Registers (GPR)

The general purpose registers provide miscellaneous controls and data saving functions. The GPRs are divided in two regions - shared and private region.

In shared region, all CPU domains access the same registers. If any CPU updates the value in the shared region, all the other CPU domains can read out the new value. The registers have an access control bit field to protect it from being changed unexpectedly.

In private region, each CPU domain has its own register. A CPU domain can only access registers belonging to itself. Since all the registers share the same address, a CPU domain will not have access to registers belonging to another CPU domain.

Shared registers can be read by any domain at any time, while write access to shared registers must be from domains granted by GPR_SHAREDn_AUTHEN[WHITE_LIST] and TrustZone authenticated. Every shared register has independent whitelist.

Private registers can be and only can be read or written by corresponding domain with TrustZone authentication.

Shared registers have two work modes, Unassigned mode and Domain mode. Private registers work in only Unassigned mode. While list is ignored by private registers. Unassigned mode is an implicit mode, if a shared register is not assigned to domain mode. After reset, all registers work in unassigned mode.

GPR_SHAREDn_AUTHEN and GPR_PRIVATEn_AUTHEN registers can be read by any domain at any time, but the write access must be from domains granted by respective whitelist and TrustZone authenticated.

The following figure shows the structure of the CCM GPR shared registers.

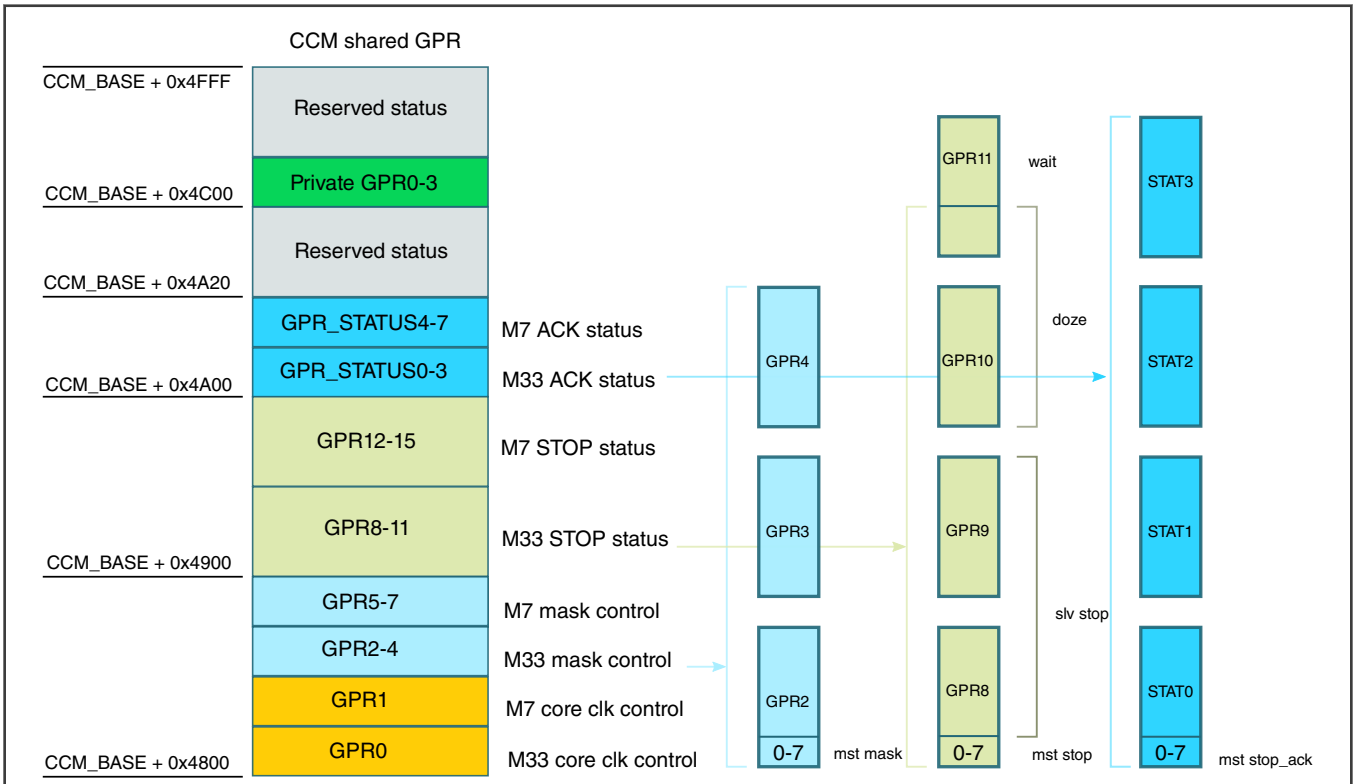

Figure 76. CCM GPR Structure

The following table shows the bitfields for each of the CCM GPR shared registers.

20.5 Reset

The reset of CCM will be released along with system early reset and clocks are provided during system reset. For each power domain, early reset of the power domain in which that clock gate resides, will be fed for correct power up and reset flow.

20.6 CCM Memory Map and Register definition

20.6.1 CCM register descriptions

20.6.1.1 D_IP_MXRTC_CCM_SYN memory map

CCM base address: 4445_0000h
