20.6.1.2 Clock Root Control Register (CLOCK_ROOT0_CONTROL - CLOCK_ROOT73_CONTROL)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

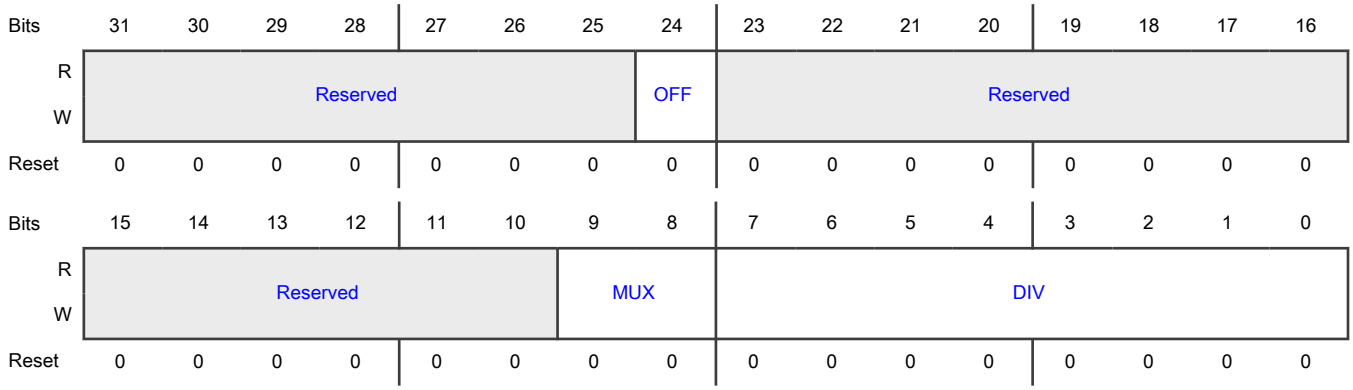
For a = 0 to 73:

Register	Offset	Description
CLOCK_ROOTa_CONTROL	0h + (a × 80h)	Clock Root Control Register
CLOCK_ROOTa_CONTROL_SET	4h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_CONTROL is 1
CLOCK_ROOTa_CONTROL_CLR	8h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_CONTROL is 0
CLOCK_ROOTa_CONTROL_TOG	Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in CLOCK_ROOTa_CONTROL

Function

This register controls clock root generation, including enable, MUX selection and division factor.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 OFF	Shutdown clock root. Turn off the generated clock root or not. 0b - Clock root is enabled 1b - Clock root is disabled
23-10 —	Reserved
9-8 MUX	Clock multiplexer. Select clock from 4 clock sources to generate the clock root. 00b - Select clock source 0 01b - Select clock source 1 10b - Select clock source 2 11b - Select clock source 3
7-0 DIV	Clock division fraction. The period of generated clock root is DIV + 1 times longer than selected clock source.

20.6.1.3 Clock root working status (CLOCK_ROOT0_STATUS0 - CLOCK_ROOT73_STATUS0)

Offset

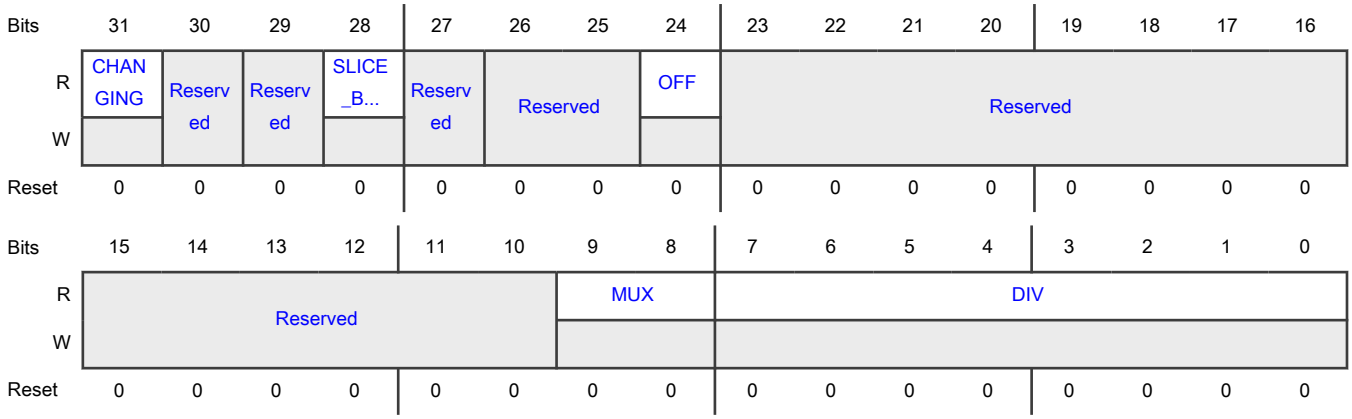
For a = 0 to 73:

Register	Offset
CLOCK_ROOTa_STATUS0	20h + (a × 80h)

Function

This register shows current clock root running status.

Diagram



Fields

Field	Function
31 CHANGING	Indication for clock root internal logic is updating. This status is a combination of UPDATE_FORWARD and SLICE_BUSY. 0b - Clock Status is not updating currently 1b - Clock generation logic is currently updating
30 —	Reserved
29 —	Internal status synchronization to clock generation logic Indication for clock status is synchronizing for clock root. 0b - Synchronization not in process 1b - Synchronization in process
28 SLICE_BUSY	Internal updating in generation logic Indication for clock generation logic is applying new setting. 0b - Clock generation logic is not busy 1b - Clock generation logic is applying the new setting
27 —	Reserved
26-25	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
24 OFF	Current clock root OFF setting Current running state of OFF field for clock root. 0b - Clock root is enabled 1b - Clock root is disabled
23-10 —	Reserved
9-8 MUX	Current clock root MUX setting Current running state of MUX field for clock root. See Clock Root for more info.
7-0 DIV	Current clock root DIV setting Current running state of DIV field for clock root. The 8-bit divider can divide selected clock by up to 256. The Divider value = DIV+1.

20.6.1.4 Clock root access control (CLOCK_ROOT0_AUTHEN - CLOCK_ROOT73_AUTHEN)

Offset

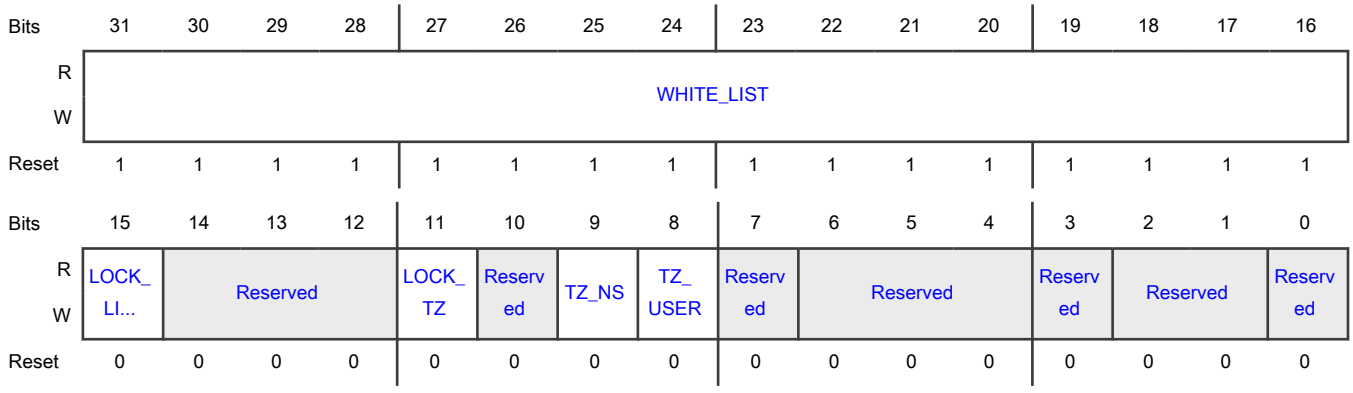
For a = 0 to 73:

Register	Offset
CLOCK_ROOTa_AUTHEN	30h + (a × 80h)

Function

This register controls the access to this Clock Root slice. The access control includes 2 parts: TrustZone control and domain based granting.

Diagram



Fields

Field	Function
31-16 WHITE_LIST	Whitelist settings Each bit in this field represent for one domain. Bit16~Bit31 represent for DOMAIN0~DOMAIN15 respectively. Only the domains the corresponding bit of which is set to 1 can change the registers of this Clock Root.
15 LOCK_LIST	Lock white list This bit locks whitelist of this Clock Root. When this bit is set, CLOCK_ROOTn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Whitelist is not locked. 1b - Whitelist is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone settings This bit locks TrustZone settings. When this bit is set, CLOCK_ROOTn_AUTHEN[TZ_USER] and CLOCK_ROOTn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - TrustZone settings is not locked. 1b - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission Whether the registers of this Clock Root can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this Clock Root. 0b - Cannot be changed in Non-secure mode. 1b - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this Clock Root can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this Clock Root. 0b - Clock Root settings cannot be changed in user mode. 1b - Clock Root settings can be changed in user mode.
7 —	Reserved
6-4	Reserved

20.6.1.5 Observe control (OBSERVE0_CONTROL - OBSERVE1_CONTROL)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

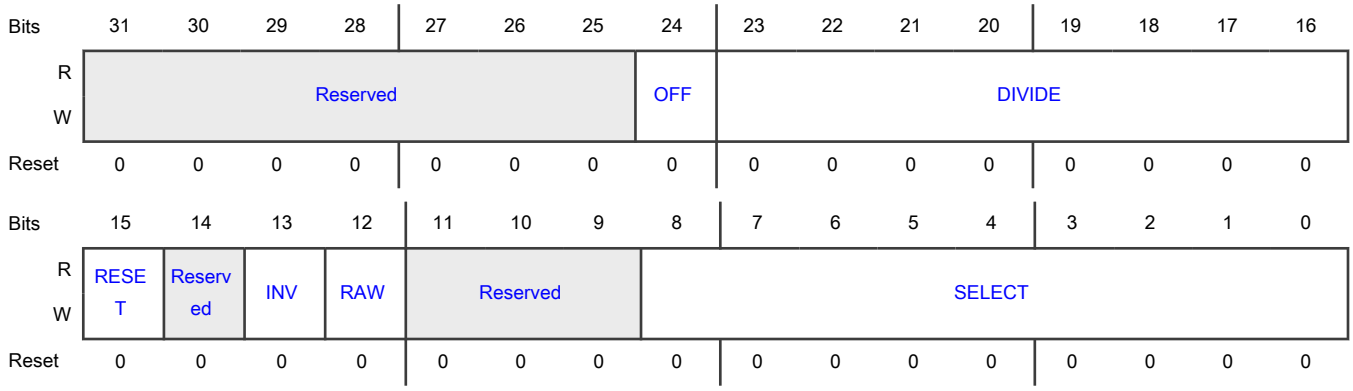
For a = 0 to 1:

Register	Offset	Description
OBSERVEa_CONTROL	4400h + (a × 80h)	Observe control
OBSERVEa_CONTROL_SET	4404h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in OBSERVEa_CONTROL is 1
OBSERVEa_CONTROL_CLR	4408h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in OBSERVEa_CONTROL is 0
OBSERVEa_CONTROL_TOG	440Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in OBSERVEa_CONTROL

Function

This register contains several control settings of observe slice, such as observed signal selection, disivion factor of the divider for the signals, software reset of the divider and the ON/OFF of observe slice.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 OFF	Turn off Turn off slice to save power. 0b - observe slice is on 1b - observe slice is off
23-16 DIVIDE	Division factor of the divider for observed signal This field sets the division factor of divider before measurement or send out to IO. The divison factor is equal to DIVIDE+1. **NOTE** If divider selected, first serveral toggles maynot be observed. Divider is typically used when observed signal is a continuous clock.
15 RESET	Reset observe divider Reset observe divider. Setting to 1 change will reset the observe divider. **NOTE** This bit is not self-clear, write 0 to release the divider. 0b - Reset deasserts 1b - Reset asserts
14 —	Reserved
13 INV	Invert input signal phase. 0b - Clock phase remain same. 1b - Invert clock phase before measurement or send to IO.
12 RAW	Observe raw signal Select from raw signal and divided signal. 0b - Select divided signal. 1b - Select raw signal.
11-9 —	Reserved
8-0 SELECT	Observe signal selector Selector that controls which observe signals will be selected and observed. The observe slice supports up to 512 signals.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The observe functionality is for debug purposes only, and the accuracy is not guaranteed. Use of this field should be limited to room temperature, and frequency limited to less than 400 MHz.

20.6.1.6 Observe status (OBSERVE0_STATUS - OBSERVE1_STATUS)

Offset

Register	Offset
OBSERVE0_STATUS	4420h
OBSERVE1_STATUS	44A0h

Function

This register contains several current settings of OBSERVEn_CONTROL, and another work status.

Diagram

Field	Function
12 RAW	Observe raw signal Select from raw signal and divided signal. 0b - Select divided signal. 1b - Select raw signal.
11-9 —	Reserved
8-0 SELECT	Observe signal selector Selector that controls which observe signals will be selected and observed.

20.6.1.7 Observe access control (OBSERVE0_AUTHEN - OBSERVE1_AUTHEN)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

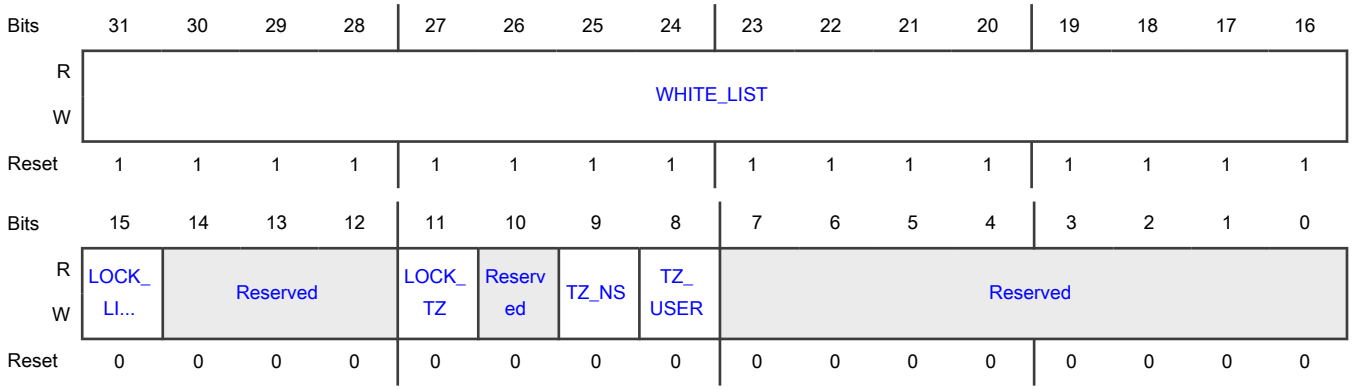
For a = 0 to 1:

Register	Offset	Description
OBSERVEa_AUTHEN	4430h + (a × 80h)	Observe access control
OBSERVEa_AUTHEN_SET	4434h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in OBSERVEa_AUTHEN is 1
OBSERVEa_AUTHEN_CLR	4438h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in OBSERVEa_AUTHEN is 0
OBSERVEa_AUTHEN_TOG	443Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in OBSERVEa_AUTHEN

Function

This register controls the access to this observe slice. The access control includes 2 parts: TrustZone control and domain based granting.

Diagram



Fields

Field	Function
31-16 WHITE_LIST	Whitelist settings Each bit in this field represent for one domain. Bit16~Bit31 represent for DOMAIN0~DOMAIN15 respectively. Only the domains the corresponding bit of which is set to 1 can change the registers of this observe slice. 0000_0000_0000_0000b - No domain can change. 0000_0000_0000_0001b - Domain 0 can change. 0000_0000_0000_0010b - Domain 1 can change. 0000_0000_0000_0011b - Domain 0 and domain 1 can change. 0000_0000_0000_0100b - Domain 2 can change. 0000_0000_0000_1111b - All domain can change.
15 LOCK_LIST	Lock white list This bit locks white list of this observe slice. When this bit is set, OBSERVEn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - White list is not locked. 1b - White list is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone setting This bit locks TrustZone settings. When this bit is set, OBSERVEn_AUTHEN[TZ_USER] and OBSERVEn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - TrustZone settings is not locked. 1b - TrustZone settings is locked.
10	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
9 TZ_NS	Non-secure access permission Whether the registers of this observe slice can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this observe slice. 0b - Cannot be changed in non-secure mode. 1b - Can be changed in non-secure mode.
8 TZ_USER	User access permission Whether the registers of this observe slice can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this observe slice. 0b - Observe slice settings cannot be changed in user mode. 1b - Observe slice settings can be changed in user mode.
7-0 —	Reserved

20.6.1.8 Current frequency detected (OBSERVE0_FREQUENCY_CURRENT - OBSERVE1_FREQUENCY_CURRENT)

Offset

Register	Offset
OBSERVE0_FREQUENCY_CURRENT	4440h
OBSERVE1_FREQUENCY_CURRENT	44C0h

Function

This register shows the current frequency detected since last update or reset.

NOTE

Frequency related measurment requires 32K crystal clock, and the gauged signal is generally a clock.

Diagram

Fields

Field	Function
31-0 FREQUENCY	Frequency Frequency of observed signal in Hz.

20.6.1.11 Current period time detected (OBSERVE0_PERIOD_CURRENT - OBSERVE1_PERIOD_CURRENT)

Offset

Register	Offset
OBSERVE0_PERIOD_CURRENT	4450h
OBSERVE1_PERIOD_CURRENT	44D0h

Function

This register shows the current period detected since last update or reset.

NOTE

Period related measurment requires 1G Hz PLL clock, and the measured signal is treated as a pulse.

Diagram

Fields

Field	Function
31-0 PERIOD	Period time Period time of observed signal in ns.

20.6.1.12 Minimum period time detected (OBSERVE0_PERIOD_MIN - OBSERVE1_PERIOD_MIN)

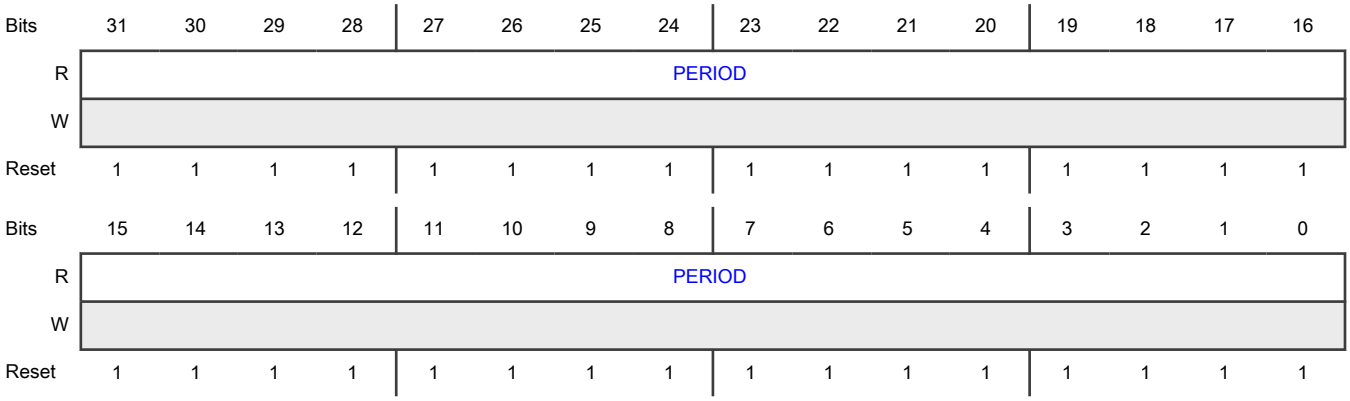
Offset

Register	Offset
OBSERVE0_PERIOD_MIN	4454h
OBSERVE1_PERIOD_MIN	44D4h

Function

This register shows the minimum period time detected since last update or reset.

Diagram



Fields

Field	Function
31-0 PERIOD	Period time Period time of observed signal in ns.

20.6.1.13 Maximum period time detected (OBSERVE0_PERIOD_MAX - OBSERVE1_PERIOD_MAX)

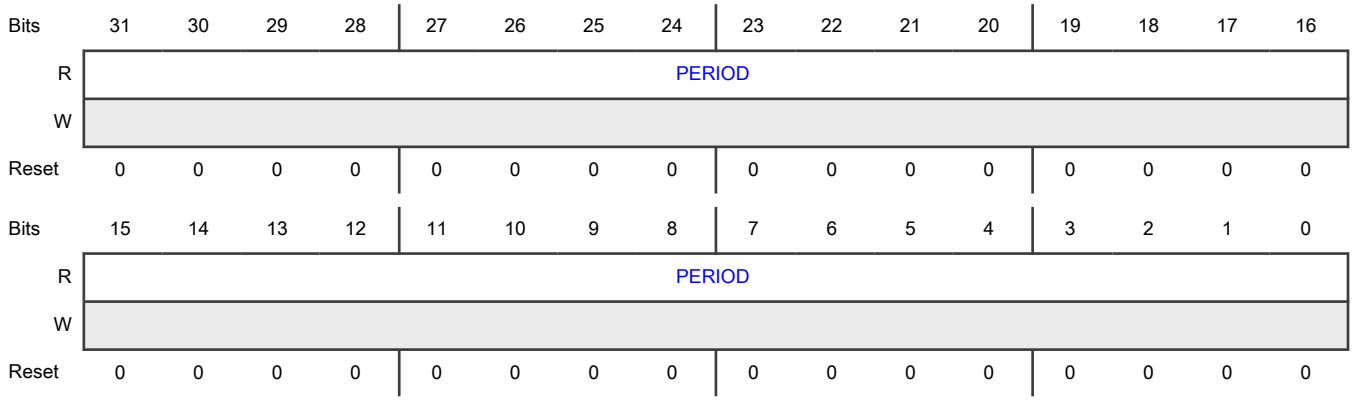
Offset

Register	Offset
OBSERVE0_PERIOD_MAX	4458h
OBSERVE1_PERIOD_MAX	44D8h

Function

This register shows the maximum period time detected since last update or reset.

Diagram



Fields

Field	Function
31-0 PERIOD	Period time Period time of observed signal in ns.

20.6.1.14 Current high level time detected (OBSERVE0_HIGH_CURRENT - OBSERVE1_HIGH_CURRENT)

Offset

Register	Offset
OBSERVE0_HIGH_CURRENT	4460h
OBSERVE1_HIGH_CURRENT	44E0h

Function

This register shows the current high level time detected since last update or reset.

NOTE

Period related measurment requires 1G Hz PLL clock, and the measured signal is treated as a pulse.

20.6.1.20 General Purpose Register (GPR_SHARED0)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED0	4800h	General Purpose Register
GPR_SHARED0_SET	4804h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0 is 1
GPR_SHARED0_CLR	4808h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0 is 0
GPR_SHARED0_TOG	480Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED0

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.21 GPR access control (GPR_SHARED0_AUTHEN - GPR_SHARED15_AUTHEN)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 15:

Register	Offset	Description
GPR_SHAREDa_AUTHEN	4810h + (a × 20h)	GPR access control
GPR_SHAREDa_AUTHEN_SET	4814h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHAREDa_AUTHEN is 1
GPR_SHAREDa_AUTHEN_CLR	4818h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHAREDa_AUTHEN is 0
GPR_SHAREDa_AUTHEN_TOG	481Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHAREDa_AUTHEN

Function

This register manages GPR access control. The access control includes 2 parts: TrustZone control and domain based granting.

2-0 —	Reserved

20.6.1.22 General Purpose Register (GPR_SHARED1)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED1	4820h	General Purpose Register
GPR_SHARED1_SET	4824h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED1 is 1
GPR_SHARED1_CLR	4828h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED1 is 0
GPR_SHARED1_TOG	482Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED1

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.23 General Purpose Register (GPR_SHARED2)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED2	4840h	General Purpose Register
GPR_SHARED2_SET	4844h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED2 is 1
GPR_SHARED2_CLR	4848h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED2 is 0
GPR_SHARED2_TOG	484Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED2

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.24 General Purpose Register (GPR_SHARED3)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED3	4860h	General Purpose Register
GPR_SHARED3_SET	4864h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED3 is 1
GPR_SHARED3_CLR	4868h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED3 is 0
GPR_SHARED3_TOG	486Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED3

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.25 General Purpose Register (GPR_SHARED4)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED4	4880h	General Purpose Register
GPR_SHARED4_SET	4884h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED4 is 1
GPR_SHARED4_CLR	4888h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED4 is 0
GPR_SHARED4_TOG	488Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED4

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.30 General Purpose Register (GPR_SHARED9)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED9	4920h	General Purpose Register
GPR_SHARED9_SET	4924h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED9 is 1

Table continues on the next page...

Table continued from the previous page...

Register	Offset	Description
GPR_SHARED9_CLR	4928h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED9 is 0
GPR_SHARED9_TOG	492Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED9

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.31 General Purpose Register (GPR_SHARED10)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED10	4940h	General Purpose Register
GPR_SHARED10_SET	4944h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED10 is 1
GPR_SHARED10_CLR	4948h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED10 is 0
GPR_SHARED10_TOG	494Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED10

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.32 General Purpose Register (GPR_SHARED11)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED11	4960h	General Purpose Register
GPR_SHARED11_SET	4964h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED11 is 1
GPR_SHARED11_CLR	4968h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED11 is 0
GPR_SHARED11_TOG	496Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED11

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.33 General Purpose Register (GPR_SHARED12)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED12	4980h	General Purpose Register
GPR_SHARED12_SET	4984h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED12 is 1
GPR_SHARED12_CLR	4988h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED12 is 0
GPR_SHARED12_TOG	498Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED12

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.34 General Purpose Register (GPR_SHARED13)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED13	49A0h	General Purpose Register
GPR_SHARED13_SET	49A4h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED13 is 1

Table continues on the next page...

Table continued from the previous page...

Register	Offset	Description
GPR_SHARED13_CLR	49A8h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED13 is 0
GPR_SHARED13_TOG	49ACh	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED13

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.35 General Purpose Register (GPR_SHARED14)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED14	49C0h	General Purpose Register
GPR_SHARED14_SET	49C4h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED14 is 1
GPR_SHARED14_CLR	49C8h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED14 is 0
GPR_SHARED14_TOG	49CCh	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED14

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

20.6.1.36 General Purpose Register (GPR_SHARED15)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED15	49E0h	General Purpose Register
GPR_SHARED15_SET	49E4h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED15 is 1
GPR_SHARED15_CLR	49E8h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED15 is 0
GPR_SHARED15_TOG	49ECh	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED15

Function

These registers are shared general purpose registers. See General Purpose Registers (GPR) and GPR Shared Control Registers (GPR_SHAREDn) for more information.

Fields

Field	Function
31-0 GPR_STATUS	Acknowledge indicators for low power handshake

20.6.1.45 General purpose register (GPR_PRIVATE0 - GPR_PRIVATE3)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

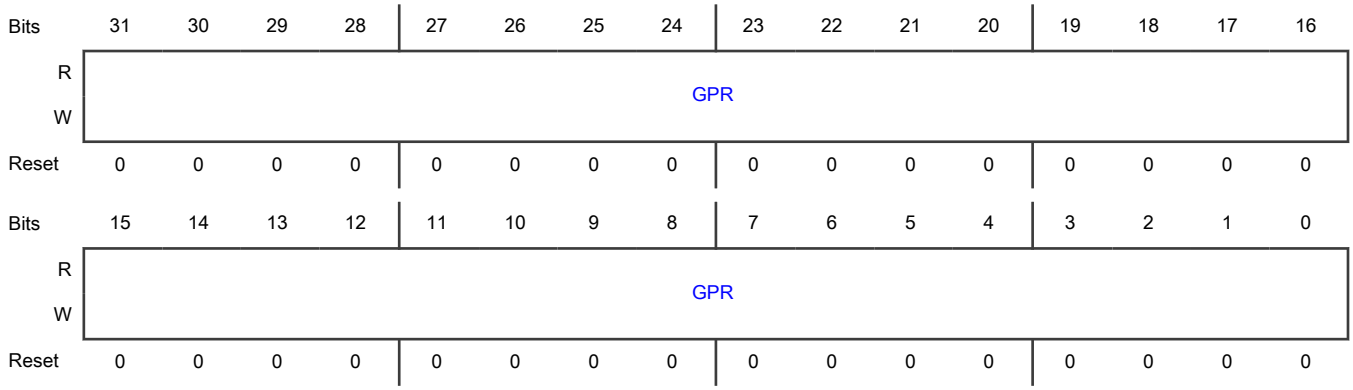
For a = 0 to 3:

Register	Offset	Description
GPR_PRIVATEa	4C00h + (a × 20h)	General purpose register
GPR_PRIVATEa_SET	4C04h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa is 1
GPR_PRIVATEa_CLR	4C08h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa is 0
GPR_PRIVATEa_TOG	4C0Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_PRIVATEa

Function

These registers are general purpose registers.

Diagram



Fields

Field	Function
31-0 GPR	GP register General purpose register. This register has dedicated bits for each domain.

20.6.1.46 GPR access control (GPR_PRIVATE0_AUTHEN - GPR_PRIVATE3_AUTHEN)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 3:

Register	Offset	Description
GPR_PRIVATEa_AUTHEN	4C10h + (a × 20h)	GPR access control
GPR_PRIVATEa_AUTHEN_SET	4C14h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa_AUTHEN is 1
GPR_PRIVATEa_AUTHEN_CLR	4C18h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa_AUTHEN is 0
GPR_PRIVATEa_AUTHEN_TOG	4C1Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_PRIVATEa_AUTHEN

Function

This register controls the access to this private GPR slice. The access control includes 2 parts: TrustZone control and domain based granting.

NOTE

The domain based granting only influence the access to GPR_PRIVATEn_AUTHEN.

Diagram

20.6.1.47 Clock source direct control (OSCPLL0_DIRECT - OSCPLL24_DIRECT)

Offset

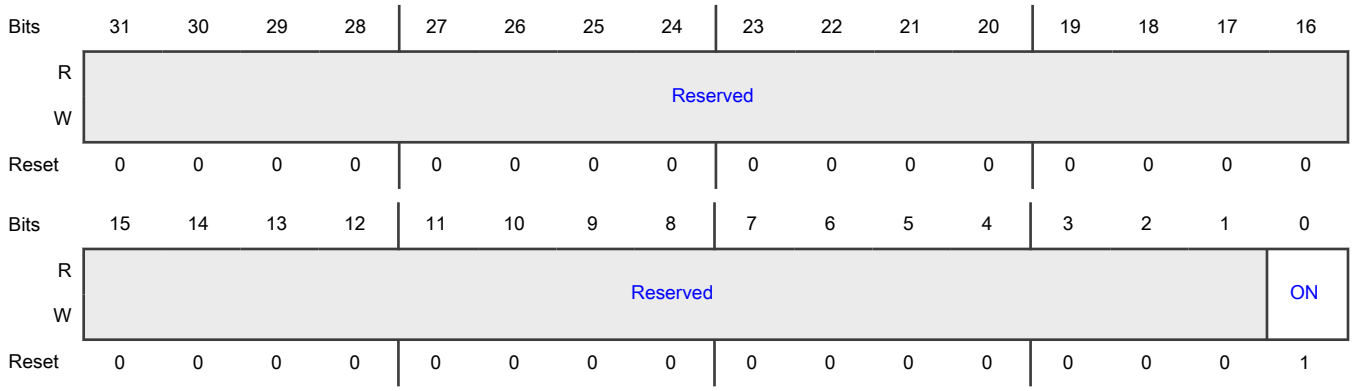
For a = 0 to 24:

Register	Offset
OSCPLLa_DIRECT	5000h + (a × 40h)

Function

This register controls the ON/OFF of clock source when clock source is working in Direct Control mode.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 ON	Turn on clock source This bit controls ON/OFF of clock source. 0b - Clock source is OFF. 1b - Clock source is ON.

20.6.1.48 Clock source low power mode setting (OSCPLL0_LPM0 - OSCPLL24_LPM0)

Offset

For a = 0 to 24:

Register	Offset
OSCPLLa_LPM0	5010h + (a × 40h)

Function

Clock source low power mode setting for DOMAIN0 ~ DOMAIM7.

NOTE

The settings in this register are valid only when this Clock Source slice is working in CPULPM mode.

20.6.1.50 LPM setting of current CPU domain (OSCPLL0_LPM_CUR - OSCPLL24_LPM_CUR)

Offset

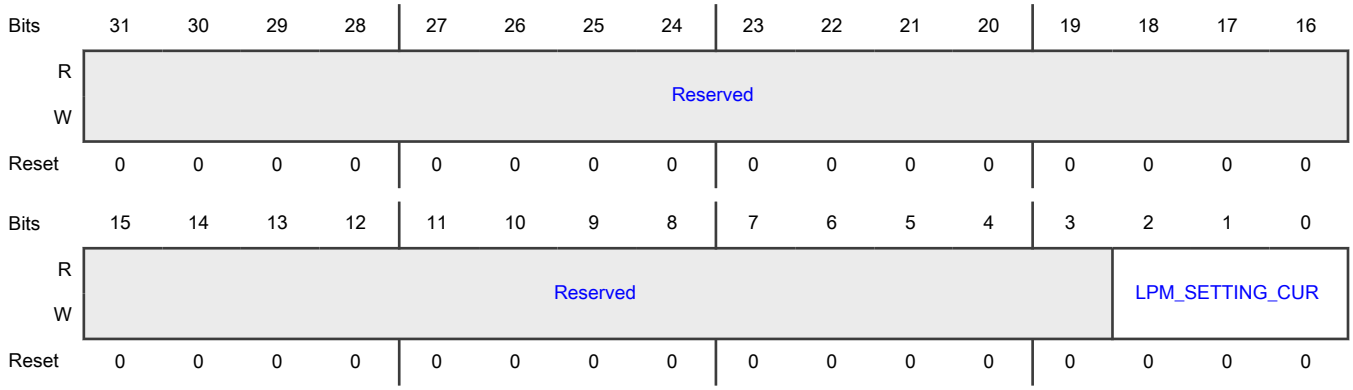
For a = 0 to 24:

Register	Offset
OSCPLLa_LPM_CUR	501Ch + (a × 40h)

Function

Reading this field will return OSCPLLn_LPM[LPM_SETTING_Dx], and x represent the CPU domain which launched the read access.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 LPM_SETTING_CUR	LPM settings value for current CPU domain that is reading this register. 000b - Clock Source will be OFF in any CPU mode. 001b - Clock Source will be ON in RUN mode, OFF in WAIT/STOP/SUSPEND mode. 010b - Clock Source will be ON in RUN/WAIT mode, OFF in STOP/SUSPEND mode. 011b - Clock Source will be ON in RUN/WAIT/STOP mode, OFF in SUSPEND mode.

20.6.1.51 Clock source working status (OSCPLL0_STATUS0 - OSCPLL24_STATUS0)

Offset

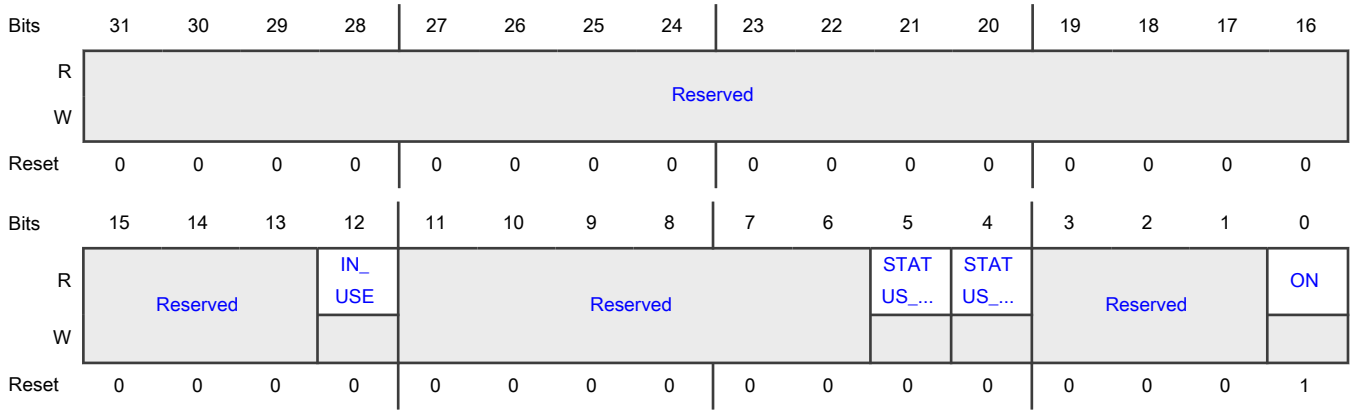
For a = 0 to 24:

Register	Offset
OSCPLLa_STATUS0	5020h + (a × 40h)

Function

This register shows current clock source running status.

Diagram



Fields

Field	Function
31-13 —	Reserved
12 IN_USE	This Clock Source is being used or not. This field will be 1, if any Clock Root derived from this Clock Source is enabled. 0b - Clock Source is not being used. 1b - Clock Source is being used.
11-6 —	Reserved
5 STATUS_LATE	Clock source ready This status bit indicates clock source is ready to use. 0b - Clock source is not ready to use 1b - Clock source is ready to use
4 STATUS_EARLY	Clock source active This status bit indicating clock source is active. 0b - Clock source is not active 1b - Clock source is active
3-1 —	Reserved
0 ON	Clock source current state Clock source running status. 0b - Clock source is OFF. 1b - Clock source is ON.

20.6.1.52 Clock source domain status (OSCPLL0_STATUS1 - OSCPLL24_STATUS1)

Offset

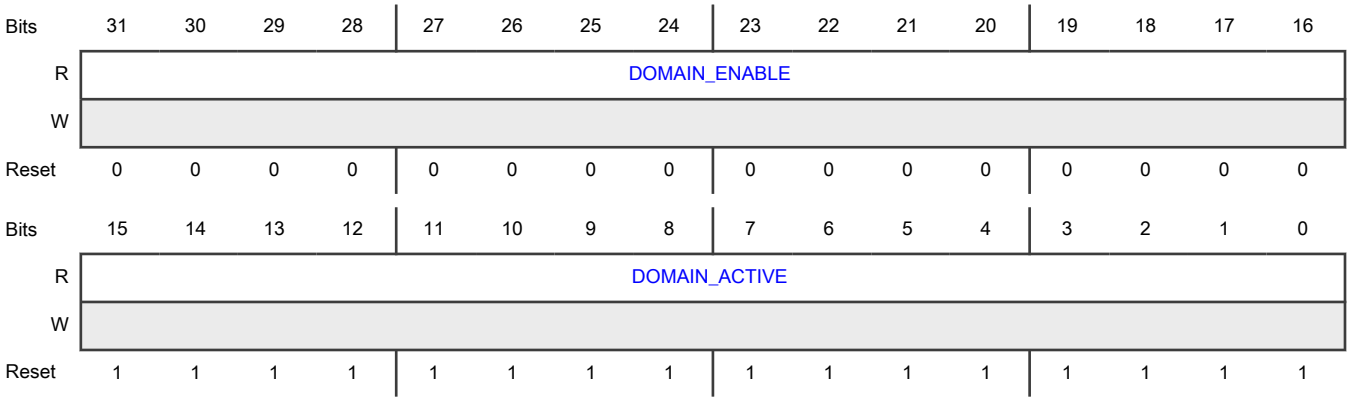
For a = 0 to 24:

Register	Offset
OSCPLLa_STATUS1	5024h + (a × 40h)

Function

This register shows domain status of clock source.

Diagram



Fields

Field	Function
31-16 DOMAIN_ENABLE	Domain enable Enable status for each domain. This clock source should be ON for DOMAINx. BIT16~BIT31 are corresponding with DOMAIN0~DOMAIN15.
15-0 DOMAIN_ACTIVE	Domain active This field is equal to OSCPLLn_AUTHEN[WHITE_LIST].

20.6.1.53 Clock Source access control (OSCPLL0_AUTHEN - OSCPLL24_AUTHEN)

Offset

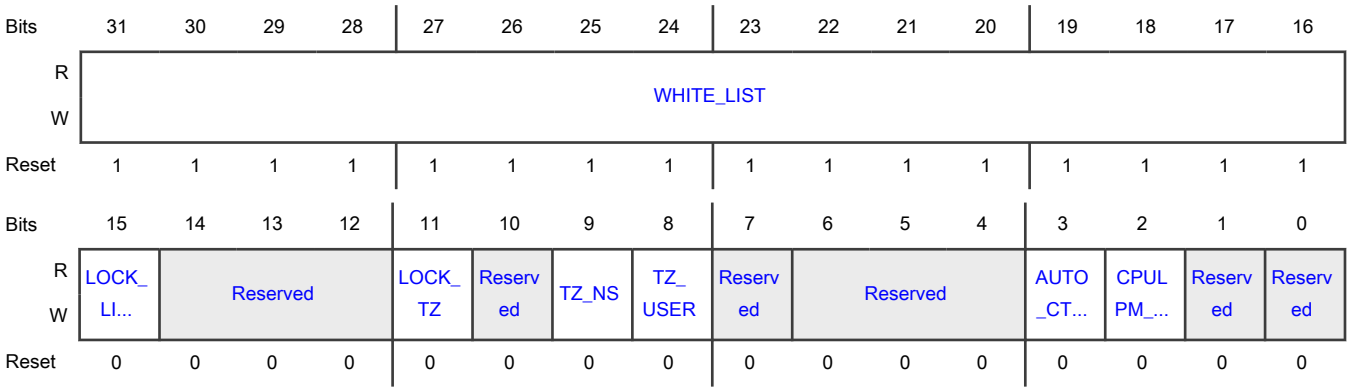
For a = 0 to 24:

Register	Offset
OSCPLLa_AUTHEN	5030h + (a × 40h)

Function

This register controls the access to this Clock Source slice. The access control includes 2 parts: TrustZone control and domain based granting.

Diagram



Fields

Field	Function
31-16 WHITE_LIST	Whitelist Each bit in this field represent for one domain. Bit16~Bit31 represent for DOMAIN0~DOMAIN15 respectively. Only the domains the corresponding bit of which is set to 1 can change the registers of this Clock Source.
15 LOCK_LIST	Lock white list This bit lock white list. When this bit is set, OSCPLLn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - Whitelist is not locked. 1b - Whitelist is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone settings This bit locks TrustZone settings. When this bit is set, OSCPLLn_AUTHEN[TZ_USER] and OSCPLLn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0b - TrustZone settings is not locked. 1b - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Whether the registers of this Clock Source can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this Clock Source. 0b - Cannot be changed in Non-secure mode. 1b - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this Clock Source can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this Clock Source. 0b - Clock Source settings cannot be changed in user mode. 1b - Clock Source settings can be changed in user mode.
7 —	Reserved
6-4 —	Reserved
3 AUTO_CTRL	Auto mode enable This field enables the Auto mode. Auto mode means if a clock source is used by any root, it will be automatically enabled. **NOTE** The actual working mode of this Clock Source is determined by OSCPLLn_AUTHEN[CPULPM_MODE] and OSCPLLn_AUTHEN[AUTO_CTRL]. 0b - Disable Auto mode 1b - Enable Auto mode
2 CPULPM_MODE	CPULPM mode enable This field enables the CPULPM mode. Once CPULPM mode is set, auto_ctrl is disabled. **NOTE** The actual working mode of this Clock Source is determined by OSCPLLn_AUTHEN[CPULPM_MODE] and OSCPLLn_AUTHEN[AUTO_CTRL]. 0b - Disable CPULPM mode. 1b - Enable CPULPM mode.

2 CLKOFF_ACK_TIMEOUT_EN	Clock off handshake timeout enable This bit enables time out mechanism for clock off handshake, when enabled, clock off acknowledge will be ignored and wait for 16-cycle IPG clock timeout, when disabled, wait for clock off acknowledge. 0b - disable 1b - enable
1 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 ON	Turn on LPCG This bit controls ON/OFF of LPCG. 0b - LPCG is OFF. 1b - LPCG is ON.

20.6.1.55 Clock source low power mode setting (LPCG0_LPM0 - LPCG148_LPM0)

Offset

For a = 0 to 148:

Register	Offset
LPCGa_LPM0	8010h + (a × 40h)

Function

Clock source low power mode setting for DOMAIN0 ~ DOMAIM7.

NOTE

The settings in this register are valid only when this Clock Source slice is working in CPULPM mode.

NOTE

The LPCG clock levels (LPM setting) of GPC, CCM, SRC and ANADIG should be set as 4 before CPU enter SUSPEND mode, otherwise CPU cannot be awakened once it entered SUSPEND mode.

20.6.1.56 clock source low power mode setting (LPCG0_LPM1 - LPCG148_LPM1)

Offset

For a = 0 to 148:

Register	Offset
LPCGa_LPM1	8014h + (a × 40h)

Function

Clock source low power mode setting for DOMAIN8 ~ DOMAIM15.

NOTE

The settings in this register are valid only when this Clock Source slice is working in CPULPM mode.

NOTE

The LPCG clock levels (LPM setting) of GPC, CCM, SRC and ANADIG should be set as 4 before CPU enter SUSPEND mode, otherwise CPU cannot be awakened once it entered SUSPEND mode.

21.2 Introduction

The General Power Controller (GPC) is the centralized power controller, which controls the power mode of the processor(s). The GPC takes the Wait For Interrupt (WFI) signal from CPU platforms, and wakeup events from peripherals, to determine the power mode based on the GPC power management policy. The GPC can also control the power mode transition.

GPC does not control the state of the resource directly. During power mode transition, it communicates with the resource controllers through the UPI (Unified Power Management Interface) to accomplish the power mode transition.

21.2.1 Block diagram

The GPC block consists of the following sub-modules:

- CPU Mode Control (CMC): It contains CPU mode controllers, one for each CPU platform. They control CPU mode of CPU platforms and their private resources.
- UPI CM Mapping: The connection between CMC and CPU platform is directly hard-wired, but CPU platform can be assigned to any domain in the system. This block is used to map CPU mode control signals into the correct domain.
- System Sleep Control (SSC): It is used to indicate resource controllers into and out of system sleep mode.

The figure below shows the block diagram of the General Power Controller.

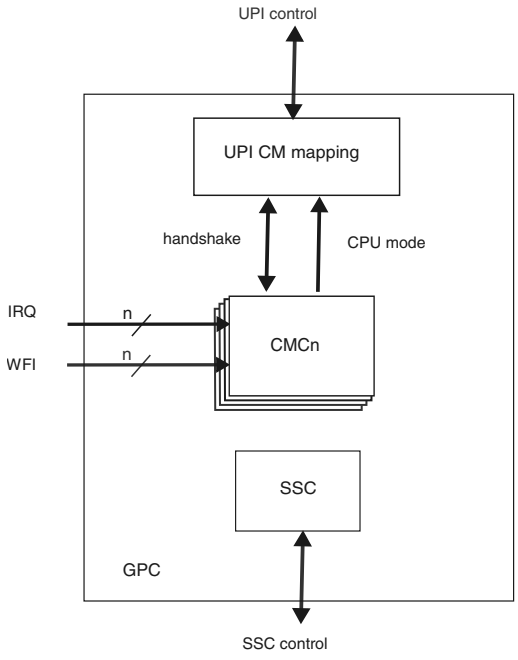

Figure 77. GPC block diagram

21.2.2 Features

The GPC includes the following features:

- Independent CPU modes for each CPU platform
- System sleep management
- Domain access control
- Controllable steps of sleep and wakeup sequence

21.3 Functional description

The following sections describe functional details of the GPC module.

21.3.1 CPU Mode Control (CMC)

The CPU mode is a power mode of the CPU platform. The following are the four CPU modes:

Table 145. CPU Modes

CPU Mode	Description
RUN	The CPU core is active and running under normal operation. All the blocks inside the CPU platform can be accessed when needed. The state of private resources are fully controlled by software configuration.
WAIT	The CPU is in WFI/WFE state, but can to get back to RUN mode with very short latency. In typical applications, the CPU will enter WAIT mode whenever there is no active thread running. In WAIT mode, the clock to the CPU core is gated off, the cache is clock gated, and the TCM is still active since there are other modules, such as DMA, that still needs access to it.

Table continues on the next page...

Table 145. CPU Modes (continued)

CPU Mode	Description
STOP	The CPU is in WFI/WFE state, and does not require an extremely short exit time. In STOP mode, the clocks to the CPU core, Cache, and TCM are all gated off. The clocks to the bus and peripherals are also gated off. This is the lowest power consumption mode without losing the state of the peripheral. When exiting from STOP mode, there is no need to re-initialize the peripherals.
SUSPEND	Entering SUSPEND mode is for lowest power consumption, and exit time is not critical. In SUSPEND mode, CPU, Cache, and peripherals are all power gated. The biggest difference between SUSPEND and STOP mode is the peripherals will be power gated. Because the peripherals are power gated, entering SUSPEND mode requires the CPU to save the state of the peripherals. When exiting from SUSPEND mode, the CPU needs to restore these states.

CPU Mode transitions happen when the following events occur:

- Sleep Event: CPU enters sleep state with WFI/WFE instruction
- Wakeup Event: Any unmasked IRQ wakeup

On a Sleep Event, the CPU has the option to enter WAIT/STOP/SUSPEND mode, or stay in RUN mode. The transition to WAIT/STOP/SUSPEND is called the sleep sequence, and the next state is configured by CM_MODE_CTRL[CPU_MODE_TARGET].

When CPU is in WAIT/STOP/SUSPEND mode, a wakeup request can wake the CPU, and bring it back to RUN mode. This is transition is called the wakeup sequence. The CM_IRQ_WAKEUP_MASK_n register selects which IRQs can wakeup the CPU platform. There are also non-IRQ requests, which can wakeup the CPU. These non-IRQ requests are configured by the CM_NON_IRQ_WAKEUP_MASK register.

During a CPU mode transition, the GPC communicates with the system resource controllers by sending the target CPU mode and transition step. Please see the UPI interface for more details.

If a resource is set as private to a single CPU platform, the resource's power state will change with the CPU platform's mode. If a resource is set as shared by multiple CPU platforms, the resource controller needs to look at all the current modes of the CPU platforms to determine the power state of the resource.

21.3.2 System Sleep Mode

System sleep mode is the second kind of low power mode besides CPU mode. System sleep mode is related to the state of all CPU platforms. When all CPU platforms are in low power mode, the system can further shut off some analog modules or put them into their own STANDBY mode. This chip status is called SYSTEM SLEEP. For details of each system sleep transition step, refer to Table 147.

The CMC can request send a system sleep when the CPU is in WAIT/STOP/SUSPEND modes by configuring the CM_SYS_SLEEP_CTRL[SS_WAIT, SS_STOP, SS_SUSPEND].

The SSC maintains the system sleep status. When all the CPU platforms send a system sleep request, the system is put into system sleep mode. Any interrupt can abort a system sleep sequence so that the system can be quickly woken up. If a CPU is disabled by FUSE, the GPC considers it to be always in the system sleep mode.

21.3.3 Unified Power Management Interface (UPI)

GPC does not control the state of the resource directly. During power mode transition, it communicates with the resource controllers through the UPI (Unified Power management Interface) to accomplish the power mode transition.

GPC and resource controllers implement a handshaking mechanism for mode transitions.

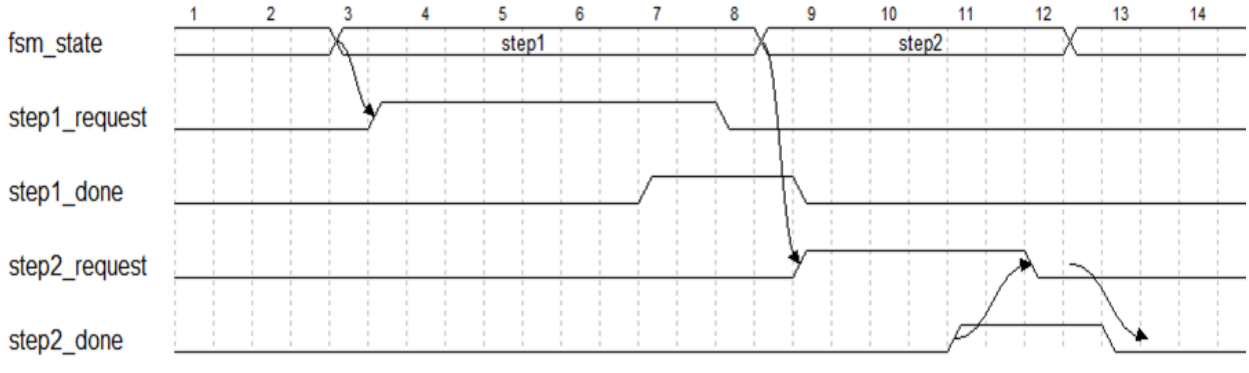

Figure 78. Handshake method

21.3.4 Low Power Sequence

21.3.4.1 CPU mode transition flow

There are two CPU mode control instances in iMX RT1180 GPC: CMC0 for CM33 and CMC1 for CM7. Each CMC has a state machine to control the sequence of CPU mode transition.

When CMC receives a sleep request from CPU platform, it starts the sleep sequence. The flow cannot be interrupted by a wakeup request until the SLEEP_POWER request completes. In SLEEP_SYS step, the SSC runs the system sleep transition flow. After the sleep sequence finishes, the CMC stays at IDLE_SLEEP and waits for a wakeup event to start wakeup sequence, which is shown in the left part of the diagram.

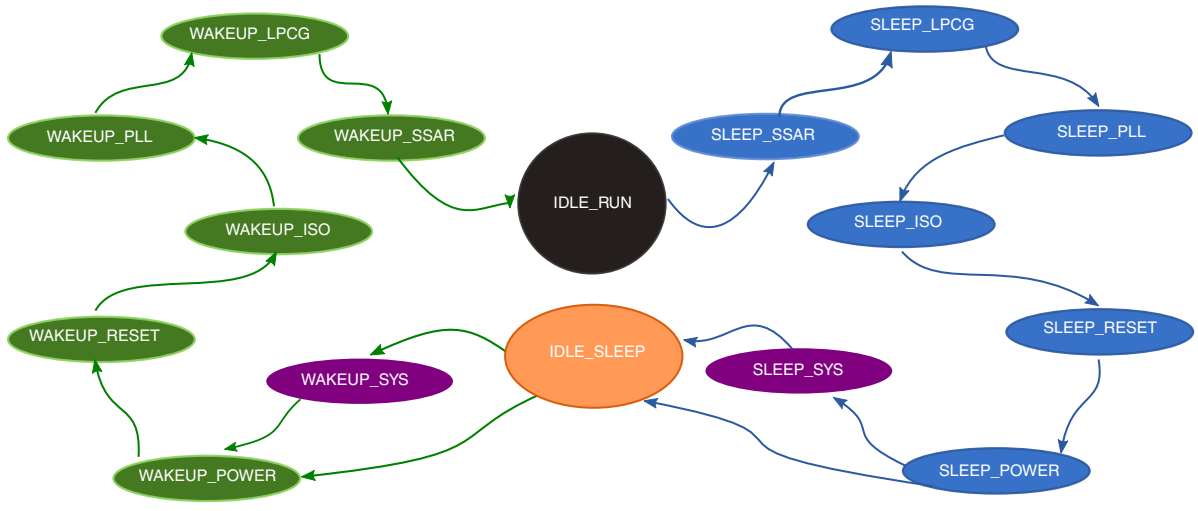

Figure 79. CPU mode transition flow

Table 146. CPU mode transition steps

State	Description
IDLE_RUN	CPU is in RUN mode

Table continues on the next page...

Table 146. CPU mode transition steps (continued)

State	Description
SLEEP_SSAR	GPC asserts command to SRC to implement handshake with ELE for power-off.
SLEEP_LPCG	GPC asserts command to CCM to disable LPCGs
SLEEP_PLL	GPC asserts command to CCM to turn PLLs off
SLEEP_ISO	GPC asserts command to SRC to enable isolation signals
SLEEP_RESET	GPC asserts command to SRC to assert reset signals
SLEEP_POWER	GPC asserts command to SRC to turn off power switch signals
SLEEP_SYS	SSC runs the system sleep transition flow
IDLE_SLEEP	CMC waits for wakeup event to start wakeup sequence
WAKEUP_SYS	SSC runs the wakeup flow
WAKEUP_RESET	GPC asserts command to SRC to turn on power switch signals
WAKEUP_POWER	GPC asserts command to SRC to de-assert reset signals
WAKEUP_ISO	GPC asserts command to SRC to disable isolation signals
WAKEUP_PLL	GPC asserts command to CCM to turn PLLs on
WAKEUP_LPCG	GPC asserts command to CCM to enable LPCGs
WAKEUP_SSAR	GPC asserts command to SRC to implement handshake with ELE for power-on.

21.3.4.2 System sleep transition flow

If all CPUs are in low power state and they all request system sleep mode, a system sleep sequence will be triggered.

There are two state machines in SSC: the first in 24MHz ROSC clock domain, the second in 32KHz clock domain. The first SSC state machine starts when CMC sends a system sleep request, it looks at all CMC system sleep status, if any CPU platform is not in sleep mode or not allow system sleep, this system sleep request will be refused. When this state machine transits to ROSC_OFF and there is no wakeup request, the second state machine starts. The system sleep in sequence can be aborted after any step completes because of wakeup time requirement. In the 24MHz state machine, step 0 is for BIAS, step 1 is for PLDO, step 2 is for BANDGAP, and step 3 is for LDO.

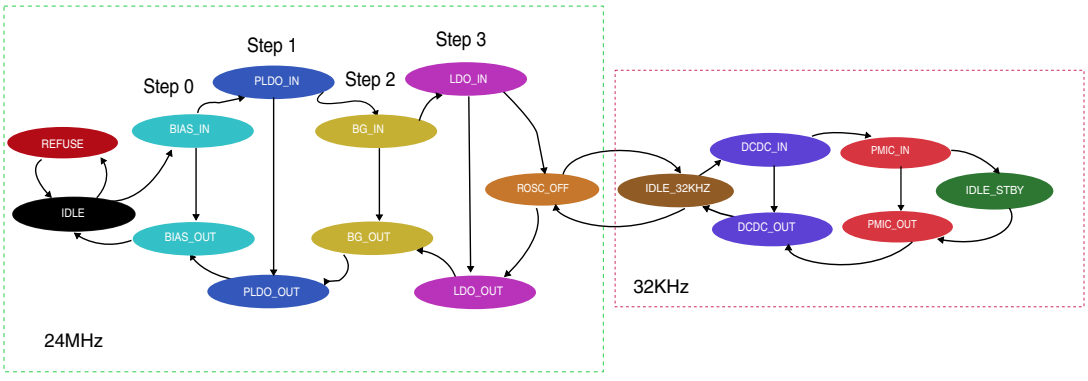

Figure 80. System sleep transition flow

Table 147. System sleep transition steps

State	Description
REFUSE	Condition for system sleep is not met. FSM goes to REFUSE state, then automatically returns to IDLE again.
IDLE	System sleep mode is not requested. 24MHz FSM is in IDLE mode.
BIAS_IN	GPC asserts command to disable BIAS.
PLDO_IN	GPC asserts command to disable PHY LDO.
BG_IN	GPC asserts command to power down BANDGAP.
LDO_IN	GPC asserts command to put LDO into low power mode.
ROSC_OFF	GPC asserts command to disable 24MHz OSC.
IDLE_32KHZ	32KHz FSM is in IDLE mode.
DCDC_IN	GPC asserts command to DCDC to select low power target trim value to analog part.
PMIC_IN	GPC asserts PMIC_STBY_REQ to external PMIC to adjust voltage.
IDLE_STBY	Chip is in SYSTEM SLEEP mode.
*_OUT	The steps named as *_OUT consist of a system sleep wakeup sequence.

21.3.5 System Domain

21.3.5.1 Domain assignment

Each CPU platform and the CMC connected to it can be assigned to the same domain.

The GPC_CPUn_DOMAIN[CPUn_DOMAIN] is used to select the domain assignments for CMCn.

Based on the domain assignment, a mapping mechanism between CPU platform and system domain is implemented inside GPC. The CMCn's power mode and each handshake step request will be mapped to all the domains it belongs to. When all its domains' Done response are asserted, the step handshake completes.

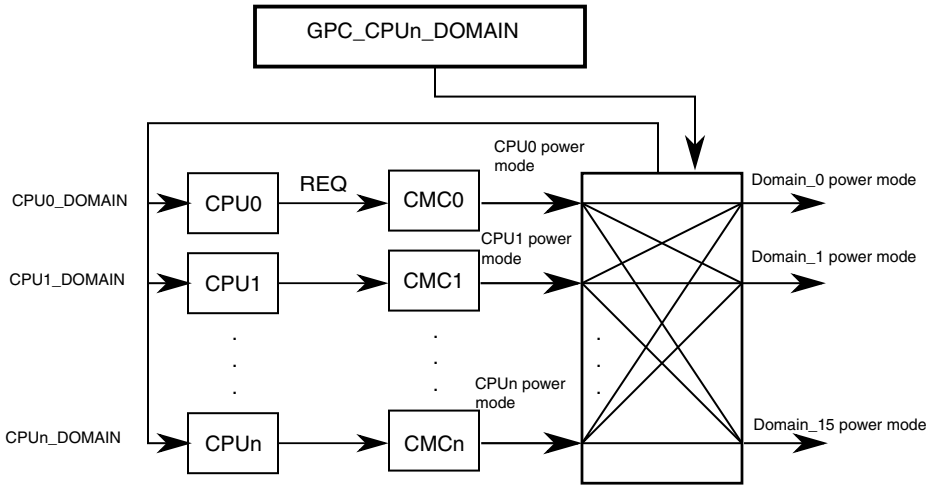

Figure 81. Domain Assignment

When more than one CMCs is assigned to same domain, a two stage priority selects which CMC can control the domain's UPI output. The first stage is CPUn_MASTER flag from GLOBAL which is enabled by register GPC_MASTER[CPUn_MASTER]. Only one CMC with CPUn_MASTER flag owns the domain UPI output. The second stage is for the case when more than one CMC has CPUn_MASTER flag or no CMC has this flag. In this case, the lower indexed CMC has higher priority.

21.3.5.2 Register Access Permissions

The GPC register access is controlled by the following registers and bitfields:

- CM_AUTHEN_CTRL register for CMC access permission
- SS_AUTHEN_CTRL register for SSC access permission
- GLOBAL_AUTHEN_CTRL register to control GLOBAL access permission
- x_AUTHEN_CTRL[WHITE_LIST] field configures which domain IDs can write to the registers
- x_AUTHEN_CTRL[USER] and x_AUTHEN_CTRL[NONSECURE] fields are used to set the privilege and security permission
- x_AUTHEN_CTRL[LOCK_CFG] locks configuration fields and should only be set at initialization
- x_AUTHEN_CTRL[LOCK_LIST] locks WHITE_LIST fields and should only be set at initialization

The GPC returns an error response when a register write access has any access violations.

21.3.6 Clocks

This section describes clocks and special clocking requirements of the GPC module.

Table 148. Clocks

Clock	Description
ipg_clk	Main GPC clock. This clock originates from RCOSC 24 MHz and can be turned off by setting GPC_ROSC_CTRL[ROSC_OFF_EN]. When the ROSC_OFF_EN = 1, the 24 MHz system sleep state machine transitions to the ROSC_OFF state and the GPC shuts off the ROSC 24 MHz block. The 32 KHz clock is then used for the 32 KHz state machine transition.
32k_clk	32 kHz clock used to wakeup GPC and RCOSC. The 32 kHz clock is not needed by ipg_clk since they are fully asynchronous

21.3.7 Interrupts

The interrupt inputs of CMC0 and CMC1 are independent and the same as the CPU platforms they are connected to. Each CMC has up to 256 IRQ input to wake up the core or system.

21.4 External Signals

The following table describes the GPC external signals.

Table 149. External Signals

Signal	Description	Direction
PMIC_STBY_REQ	Asserted by the GPC to the external PMIC to adjust the voltage.	Output
PMIC_READY	Indicates that the external PMIC is ready.	Input

21.5 Initialization

See Low Power Sequence for low power entry and exit flow and considerations.

21.5.1 CPU Sleep Hold

There is a certain delay between the time the core sleeps and when the core clock stops. If a wakeup IRQ appears inside this delay window, the core will process the IRQ and wake up, but the GPC sleep sequence is still shutting off the core clock. Since the sleep sequence is not interruptable, this scenario may lead to unpredictable behavior.

To avoid this scenario, a CPU Sleep Hold is implemented to hold the core in the sleep state until the sleep sequence is finished. The GPC will then send a signal to release the core. The CM_MISC[SLEEP_HOLD_EN] field is used to enable this function.

The core clock can also be gated by a WFI event without any GPC sequence. The GPC uses a signal to clear this gate when a wakeup trigger occurs.

21.6 Memory map and register definition

This section includes the GPC module memory map and detailed descriptions of all registers.

21.6.1 register descriptions

21.6.1.1 gpc_cpu_ctrl memory map

GPC_CPU_CTRL base address: 4447_0000h

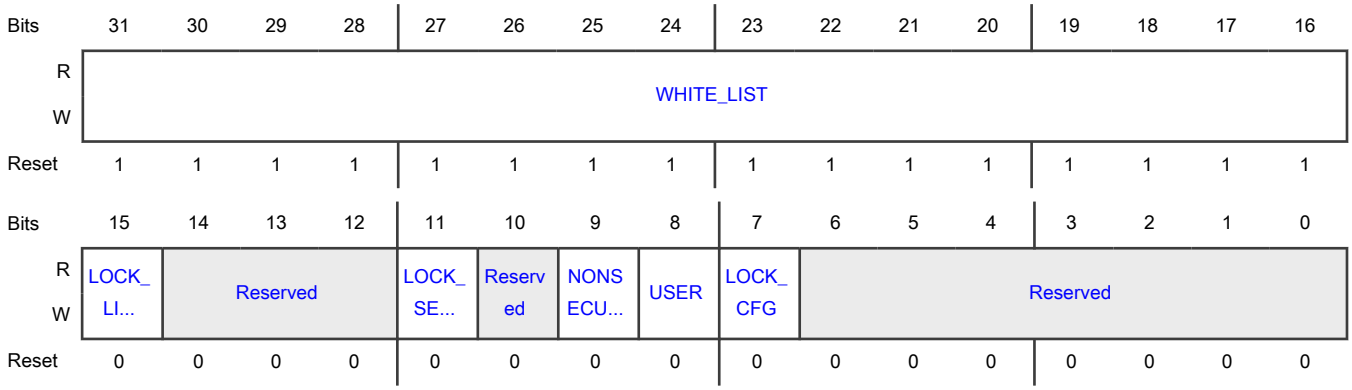
21.6.1.2 CM Authentication Control (CPU0_CM_AUTHEN_CTRL - CPU1_CM_AUTHEN_CTRL)

Offset

Register	Offset
CPU0_CM_AUTHEN_CTRL	4h
CPU1_CM_AUTHEN_CTRL	804h

Function
Authentication control for CMC.

Diagram



Fields

Field	Function
31-16 WHITE_LIST	Domain ID white list When bit is set to 1, the corresponding domain ID can access CPU mode control registers. bit[0] for Domain 0, bit[1] for Domain 1, bit[2] for Domain 2, and bit[3] for Domain 3. Multiple bits with a value of 1 is permitted.
15 LOCK_LIST	White list lock This bit locks the WHITE_LIST. When this bit is set, WHITE_LIST cannot be changed. Once this bit is set, it cannot be cleared until the next system reset. 0b - WHITE_LIST is not locked 1b - WHITE_LIST is locked
14-12 —	Reserved
11 LOCK_SETTING	Lock NONSECURE and USER This bit locks the NONSECURE and USER fields. When this bit is set, LOCK_SETTING cannot be changed. Once this bit is set, it cannot be cleared until the next system reset. 0b - NONSECURE and USER fields are not locked 1b - NONSECURE and USER fields are locked
10 —	Reserved
9 NONSECURE	Allow non-secure mode access 0b - Allow only secure mode to access CPU mode control 1b - Allow both secure and non-secure mode to access CPU mode control registers
8 USER	Allow user mode access 0b - Allow only privilege mode to access CPU mode control registers

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Allow both privilege and user mode to access CPU mode control registers
7 LOCK_CFG	Configuration lock This bit locks the value of low power configuration fields. Once this bit is set, it cannot be cleared until the next system reset. 0b - The value of low power configuration fields are not locked. 1b - The value of low power configuration fields are locked. It locks the CPUx_CM registers which are marked as "Locked by LOCK_CFG field" in the function field.
6-0 —	Reserved

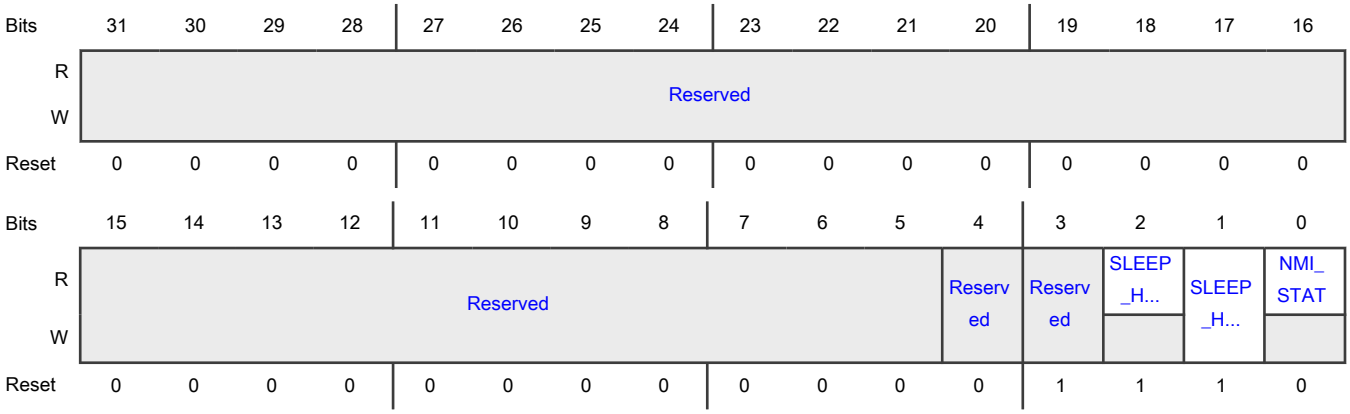
21.6.1.3 Miscellaneous (CPU0_CM_MISC - CPU1_CM_MISC)

Offset

Register	Offset
CPU0_CM_MISC	Ch
CPU1_CM_MISC	80Ch

Function
Miscellaneous register.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 —	Reserved
3 —	Reserved
2 SLEEP_HOLD_STAT	CPU sleep hold status 0b - CPU sleep hold is acknowledged 1b - CPU is not in sleep hold
1 SLEEP_HOLD_EN	Allow cpu_sleep_hold_req to assert during CPU low power status 0b - Disable cpu_sleep_hold_req 1b - Allow cpu_sleep_hold_req to assert during CPU low power status
0 NMI_STAT	Non-masked interrupt status 0b - NMI is not asserted 1b - NMI is asserted

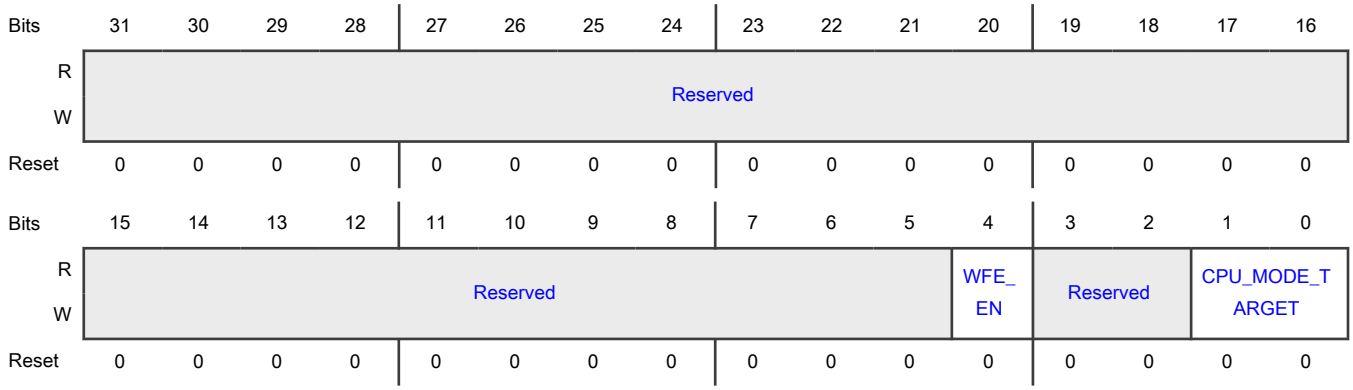
21.6.1.4 CPU mode control (CPU0_CM_MODE_CTRL - CPU1_CM_MODE_CTRL)

Offset

Register	Offset
CPU0_CM_MODE_CTRL	10h
CPU1_CM_MODE_CTRL	810h

Function
CPU mode control register.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 WFE_EN	WFE assertion can be sleep event 0b - WFE assertion can not trigger low power 1b - WFE assertion can trigger low power
3-2 —	Reserved
1-0 CPU_MODE_TARGET	The CPU mode the CPU platform should transit to on next sleep event Important: Core MUST re-configure this field EACH TIME before entering sleep 00b - Stay in RUN mode 01b - Transit to WAIT mode 10b - Transit to STOP mode 11b - Transit to SUSPEND mode

21.6.1.5 CM CPU mode Status (CPU0_CM_MODE_STAT - CPU1_CM_MODE_STAT)

Offset

Register	Offset
CPU0_CM_MODE_STAT	14h
CPU1_CM_MODE_STAT	814h

Function

CPU mode status register.

22.2 Overview

The DCDC Converter(DCDC) is a synchronous buck mode DCDC converter, which is used for generating the power supply for chip's core logic. It also includes a LDO which outputs 1.8V to supply for the analog module of DCDC itself and some of the other 1.8V domain blocks of the chip.

22.2.1 Block diagram

The block diagram of the DCDC module is provided below:

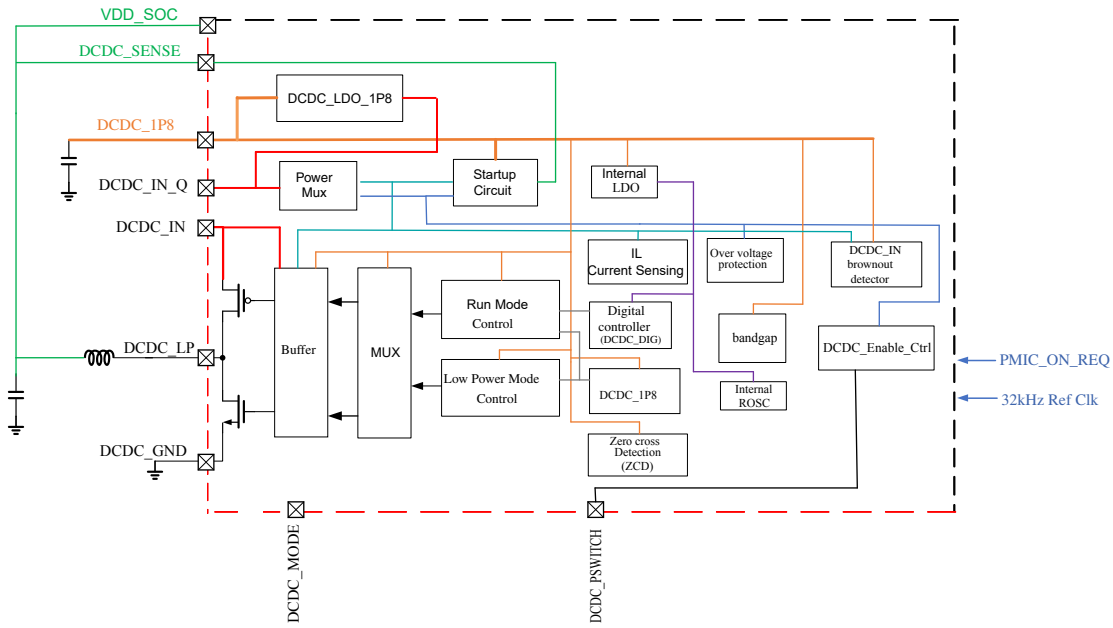

Figure 82. DCDC block diagram

22.2.2 Features

The DCDC module includes the following features:

- Buck mode only, 3.3V input with 1.0V output
- LDO with 3.3V input and 1.8V output
- DCDC_PSWITCH pin to turn on/off DCDC
- Continuous conduction mode (CCM) operation
- Automatic pulse skipping
- RUN mode and LP (low-power) mode
- RUN mode supports CCM
- Overcurrent and overvoltage protection
- Low-input voltage detection
- Low-input voltage warning

22.3 Functional description

The DCDC converter is a synchronous step-down converter with one output. In run mode, it can operate on continuous conduction mode or discontinuous conduction mode, depending on the level of the load current. Discontinuous conduction mode needs to be enabled through register configuration.

DCDC can be configured to operate in Low Power (LP) mode when the load current is less than 50mA. During the LP mode, the converter operates in pulse mode with a minimum quiescent current to maintain high efficiency.

22.3.1 Application Modes

DCDC has only one application mode, which is configured by DCDC_MODE:

- Application Mode 0: DCDC_IN is connected to 3.3V, DCDC outputs 1.0V and LDO output 1.8V. DCDC_MODE is tied to ground

22.3.2 Functional Modes

- Run Mode
  - Continuous Conduction Mode
  - Discontinuous Conduction Mode - improved efficiency and same working state as Continuous Conduction Mode
- Low-Power Mode
  - Improved efficiency
  - Ripple is a little bit higher than Run Mode

22.3.3 Operation

The DCDC is a synchronous buck converter. An illustration of the power switch arrangement is shown below.

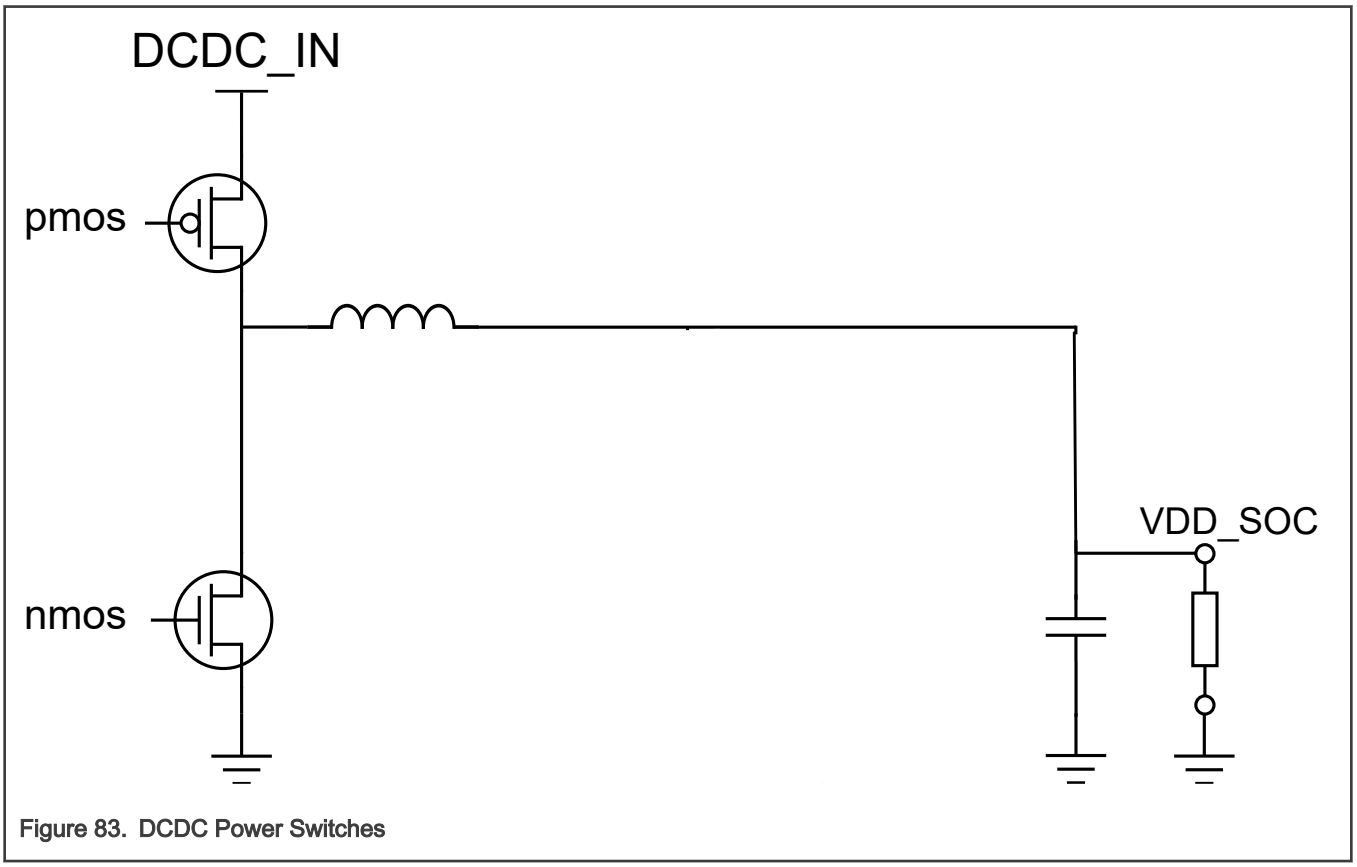

Figure 83. DCDC Power Switches

The DCDC features zero cross detection for Discontinuous Conduction Mode. This functionality is enabled by the REG0[PWD_ZCD] bit.

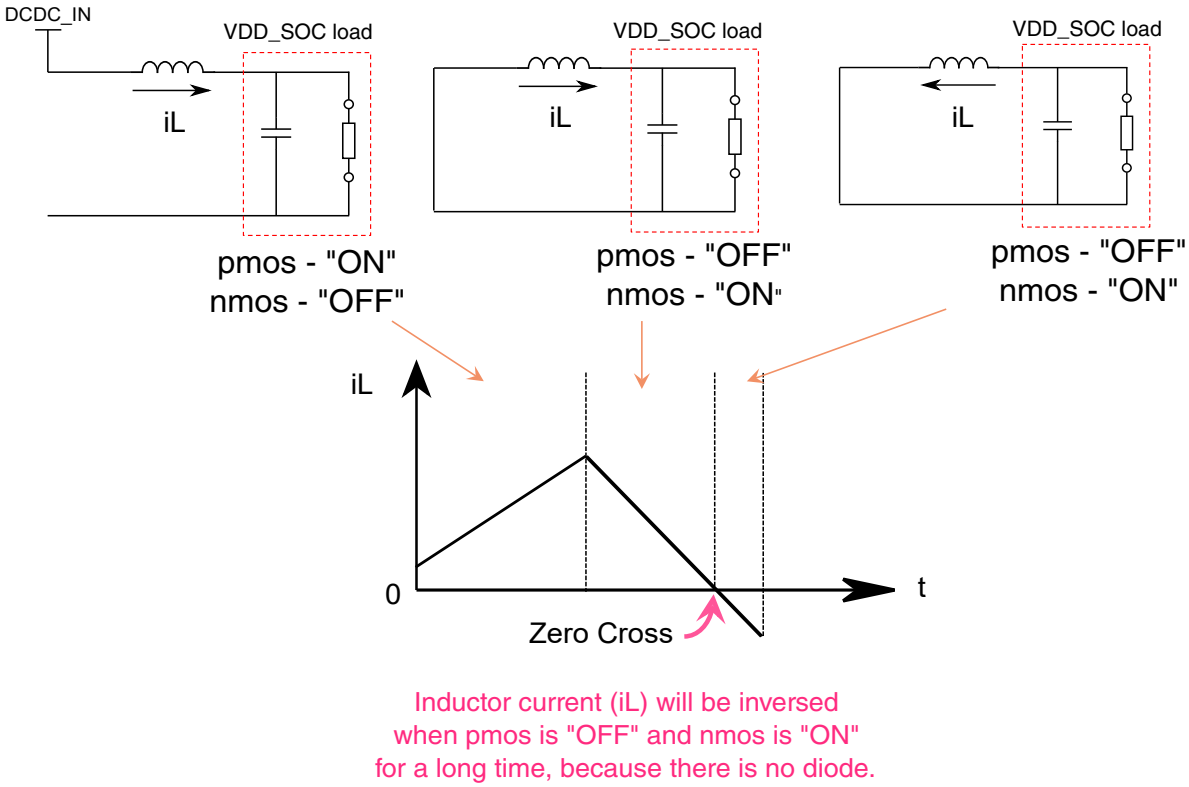

Figure 84. Zero Cross Detection

Working as the CCM, the inductor current (iL) will be inversed during the cycle of pmos is "OFF" and nmos is "ON" if the current loading is half of the current ripple of the inductor.

22.3.4 Overcurrent, Overvoltage, and Low Voltage Detection

DCDC supports the following three protection functions:

1. Overcurrent protection
   - In run mode, DCDC will shut down when detecting abnormal large current in the P-type power switch. See REG0[OVERCUR_TRIG_ADJ] for details.
   - In LP mode, DCDC will stop charging the inductor when detecting large current in the P-type power switch.
2. Overvoltage protection - DCDC will shut down when detecting high voltage on either of the two outputs.
3. Low-Voltage Detection - DCDC will shut down when detecting the input voltage is too low.
4. Low-Voltage Warning - DCDC will assert interrupt when detecting the input voltage below threshold.

NOTE

Please see the Chip Datasheet for the specified values.

22.3.5 Clocks

This section describes clocks and special clocking requirements for the DCDC module.

Table 151. Clocks

Clock	Description
ipg_clk	Peripheral Clock
clk_24M	24 MHz reference clock

Besides using an external 24 MHz clock from outside of DCDC. There is an internal 24 MHz clock inside the DCDC analog. If the internal 24 MHz clock is used, auto clock switching can be used. The diagram below illustrates how Select XTAL clock(24 MHz clock) works whenever auto clock switching is enabled or disabled:

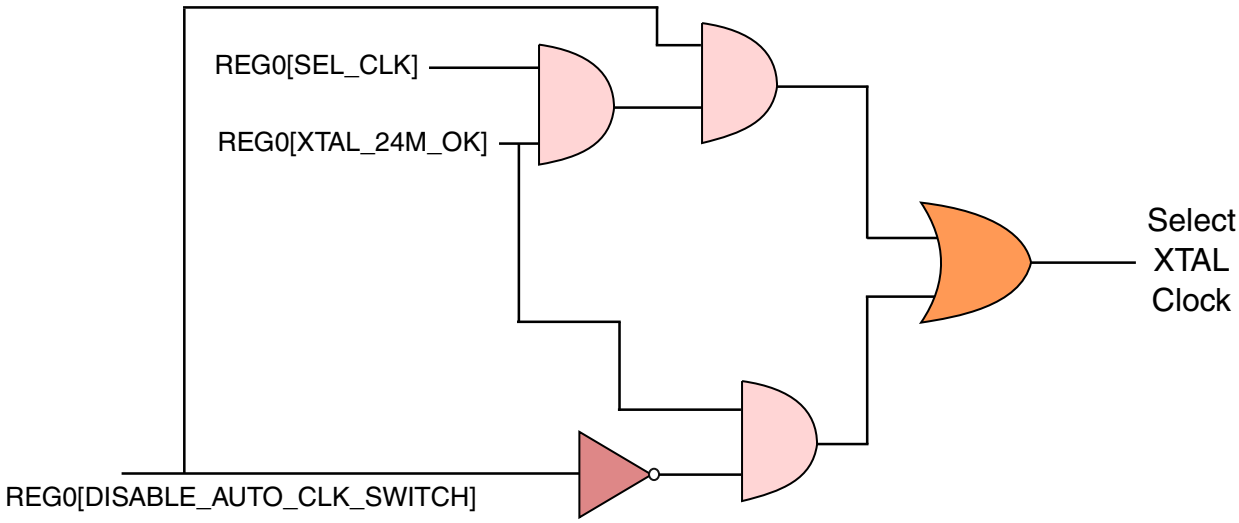

Figure 85. 24M Clock Selection

22.3.6 Interrupts

Please see the IRQ chapter for any assigned interrupts.

22.4 External Signals

Table 152. External Signals

External Signals	Power Domain	Description	Direction
DCDC_1P8	DCDC_1P8	The PAD used to provide 1.8 V power to DCDC analog module and some of the other 1.8V domain blocks of the chip.. It is connected to the 1.8 V LDO output.	O
DCDC_SENSE	VDD_SOC	Connected to DCDC_SENSE PAD, provide the sense point of DCDC output voltage for the feedback loop.	I
DCDC_IN	DCDC_IN	The DCDC input which is connected to the power switch of DCDC	I
DCDC_LP	DCDC_IN	The PAD connected to one terminal of the external inductor on the board.	IO

Table continues on the next page...

Table 152. External Signals (continued)

External Signals	Power Domain	Description	Direction
DCDC_GND	DCDC_IN	Ground PAD which is connected to DCDC power switch	O
DCDC_IN_Q	DCDC_IN	Analog power supply used by some analog modules of DCDC. It is from the same source as DCDC_IN, but is split from DCDC_IN, in order to make it more quiet.	I
DCDC_PSWITCH	DCDC_IN	The PAD which can bypass the DCDC	I
DCDC_MODE	DCDC_IN	The PAD which is used to distinguish between application mode “0” and “1”. Please refer to the Application Mode section for more information.	I

22.5 Initialization

To enable DCDC, the following conditions must be met:

1. Power supply VDD_BBSM_IN and DCDC_IN are available
2. 32 kHz clock in the VDD_BBSM_IN domain is available
3. Provide DCDC with 1ms of reset time after DCDC_IN powers up
4. PMIC_ON_REQ && DCDC_PSWITCH

The Power up sequence is:

- Power VDD_BBSM_IN
- DCDC_IN powered up
- Delay 1 ms reset time. Ensure DCDC_PSWITCH to 0 during 1 ms reset time.
- PMIC_ON_REQ && DCDC_PSWITCH
- DCDC startup

22.6 Application information

This section describes applications supported by the DCDC module.

22.6.1 Typical Application

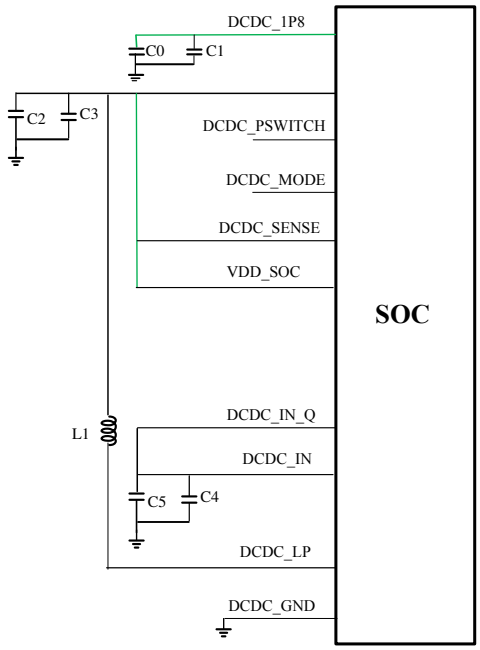

Figure 86. DCDC Typical Application

Table 153. DCDC Component List

Component	Description	Recommendation
L1	Inductance needed by DCDC	4.7uH with low DC resistance (less than 0.1 ohm ESR) inductor to minimize conduction losses.
C0	High-frequency decoupling capacitor	At least 0.1uF.
C1	Filter capacitor on DCDC_1P8 output	A 10uF with ESR less than 0.1 ohm capacitor for small ripple.
C2	High frequency decoupling capacitor	At least 0.1uF.
C3	Filter capacitors of DCDC output for VDD_SOC	A 33uF with low ESR (less than 0.02 ohm ESR) capacitor for small ripple.
C4	High-frequency decoupling capacitor for DCDC_IN	At least 0.1uF. The parasitic inductance of the routing from C4 to DCDC_IN, of the chip on the board, should be less than 0.5nH.
C5	Filter capacitor of DCDC_IN.	A 10uF (or greater) with low ESR capacitor. Increase capacitance (no limit) for better input-voltage filtering.

NOTE

It is very important to place C0, C1, C2, C3, C4 as close to the associated BGA power supply ball as possible.

NOTE

Please see the chip datasheet for specification details.

22.6.2 Recommended configuration

To improve loading ability under heavy load:

- Set CTRL0[DEBUG_BITS] = 0x1

22.7 Memory Map and register definition

This section includes the DCDC module memory map and detailed descriptions of all registers.

22.7.1 DCDC register descriptions

22.7.1.1 DCDC memory map

Fields

Field	Function
31 STS_DC_OK	DCDC Output OK This is the status bit indicates if the DCDC output voltage is stable. The lock time depends on the loading and the DCDC mode. 0b - DCDC is settling 1b - DCDC already settled
30 —	Reserved
29 XTAL_24M_OK	24M XTAL OK This bit determines if the DCDC uses the internal ring oscillator or the xtal 24 M. See Figure 85 for details. 0b - DCDC uses internal ring OSC 1b - DCDC uses xtal 24M
28 —	Reserved
27 XTALOK_DISABLE	Disable xtalok detection circuit This is a debug bit which should not be changed in real case. This bit disables and bypasses the clock 24 MHz reference clock detector. 0b - Enable xtalok detection circuit 1b - Disable xtalok detection circuit and always outputs OK signal "1"
26 PWD_CMP_OFFSET	power down the out-of-range detection comparator The out-of-range comparator monitors the output voltage of DCDC. When the DCDC output voltage is out of range, this comparator will speed up DCDC control loop in an attempt to bring the DCDC output voltage back in range.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	PWD_CMP_OFFSET must be set to 0 (out-of-range comparator on) if LOOPCTRL_EN_RCSCALE is to be used to speed up the transient response. 0b - Out-of-range comparator powered up 1b - Out-of-range comparator powered down
25 —	Reserved
24-18 —	Reserved
17 PWD_HIGH_VDD1P0_DET	Power Down High Voltage Detection for VDD1P0 Power down overvoltage detection comparator for the VDD1P0 output. 0b - Overvoltage detection comparator for the VDD1P0 output is enabled 1b - Overvoltage detection comparator for the VDD1P0 output is disabled
16 PWD_HIGH_VDD1P8_DET	Power Down High Voltage Detection for VDD1P8 Power down overvoltage detection comparator for the VDD1P8 output. 0b - Overvoltage detection comparator for the VDD1P8 output is enabled 1b - Overvoltage detection comparator for the VDD1P8 output is disabled
15-12 —	Reserved
11 PWD_CMP_DCDC_IN_DET	Set to "1" to power down the low voltage detection comparator. Set and clear this bit can reset this comparator and its 2 output flags: 1. IN_BROWNOUT; 2 IN_BROWNOUT_WARN. 0b - Low voltage detection comparator is enabled 1b - Low voltage detection comparator is disabled
10-9 OVERCUR_TRIG_ADJ	Overcurrent Trigger Adjust Set the threshold of overcurrent detector in run mode and LP mode, if the peak current of the inductor exceeds the threshold, the current detector will assert. OVERCUR_TRIG_ADJ[1] is used to set overcurrent threshold in RUN mode - 0 is 1.5 A, 1 is 2 A. OVERCUR_TRIG_ADJ[0] is used to set overcurrent threshold in LP(low-power) mode - 0 is 150 mA, 1 is 130 mA. 00b - In Run Mode, 1.5 A. In LP Mode, 150 mA 01b - In Run Mode, 1.5 A. In LP Mode, 130 mA 10b - In Run Mode, 2 A. In LP Mode, 150 mA

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - In Run Mode, 2 A. In LP Mode, 130 mA
8 PWD_OVERCUR_DET	Power down overcurrent detection comparator 0b - Overcurrent detection comparator is enabled 1b - Overcurrent detection comparator is disabled
7-4 —	Reserved
3 PWD_OSC_INT	Power down internal osc Only set this bit when 24 MHz crystal osc is available. 0b - Internal oscillator powered up 1b - Internal oscillator powered down
2 SEL_CLK	Select Clock Select 24 MHz Crystal clock for DCDC, **when DISABLE_AUTO_CLK_SWITCH is set.** If DISABLE_AUTO_CLK_SWITCH is set to 0 and 24M xtal is OK, the clock source will switch from internal ring OSC to 24M xtal automatically. If DISABLE_AUTO_CLK_SWITCH is set to 1, SEL_CLK will determine which clock source the DCDC uses: if SEL_CLK=0, DCDC will use internal ring OSC, if SEL_CLK=1, DCDC will use 24M xtal. See Figure 85 for details. 0b - DCDC uses internal ring oscillator 1b - DCDC uses 24M xtal
1 DISABLE_AUTO_CLK_SWITCH	Disable Auto Clock Switch Disable automatic clock switch from internal osc to xtal clock. 0b - If DISABLE_AUTO_CLK_SWITCH is set to 0 and 24M xtal is OK, the clock source will switch from internal ring OSC to 24M xtal automatically 1b - If DISABLE_AUTO_CLK_SWITCH is set to 1, SEL_CLK will determine which clock source the DCDC uses
0 PWD_ZCD	Power Down Zero Cross Detection Power down the zero cross detection function for discontinuous conductor mode. 0b - Zero cross detection function powered up 1b - Zero cross detection function powered down

22.7.1.3 DCDC Register 1 (REG1)

Offset

Register	Offset
REG1	4h

Function

DCDC register 1

Fields

Field	Function
31 —	Reserved
30 LOOPCTRL_EN_DF_HYST	Enable hysteresis in switching converter differential mode analog comparators. This feature will improve transient supply ripple and efficiency 0b - Disable hysteresis in switching converter differential mode analog comparators 1b - Enable hysteresis in switching converter differential mode analog comparators
29 LOOPCTRL_EN_CM_HYST	Enable hysteresis in switching converter common mode analog comparators. This feature will improve transient supply ripple and efficiency 0b - Disable hysteresis in switching converter common mode analog comparators 1b - Enable hysteresis in switching converter common mode analog comparators
28 LOOPCTRL_DF_HST_THRESH	Increase Threshold Detection Increase the threshold detection for differential mode analog comparators. 0b - Disable increase the threshold detection for differential mode analog comparators.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable increase the threshold detection for differential mode analog comparators.
27 LOOPCTRL_CM_HST_THRESH	Increase Threshold Detection Increase the threshold detection for common mode analog comparators. 0b - Disable increase the threshold detection for common mode analog comparators. 1b - Enable increase the threshold detection for common mode analog comparators.
26-20 —	Reserved
19-13 NEGLIMIT_IN	Negative duty cycle limit of DC-DC converter
12-11 —	Reserved
10-6 VBG_TRIM	Trim Bandgap Voltage Trim step is 3mV. 00000 - 0.452V 10000 - 0.5V 11111 - 0.545V
5 —	Reserved
4 RLOAD_REG_EN	Resistor Load of Regulator Enable This controls the load resistor of the internal regulator of DCDC. Connecting the load resistor to the internal LDO in RUN mode, improves the startup ripple of the LDO, but the load resistor will consume additional current. Once the REG0[STS_DC_OK] asserts, the load resistor can be disconnected to save the current caused by the resistor loading. 0b - Resistor load disconnected 1b - Resistor load connected
3-0 —	Reserved

22.7.1.4 DCDC Register 2 (REG2)

Offset

Register	Offset
REG2	8h

Function

DCDC register 2

This register controls various high-level functions of the DCDC

Diagram

Fields

Field	Function
31 —	Reserved
30 LOOPCTRL_TOGGLE_DIF	Set high to enable supply stepping to change only after the differential control loop has toggled as well. This should eliminate any chance of large transients when supply voltage changes are made. 0b - Disable supply stepping to change. 1b - Enable supply stepping to change.
29 —	Reserved
28 —	Reserved
27-26 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
25-16 BATTMONITOR_BATT_VAL	Software should be configured to place the battery voltage in this register measured with an 8-mV LSB resolution through the ADC. This value is used by the DC-DC converter and must be correct before setting BATTMONITOR_EN_BATADJ.
15 BATTMONITOR_EN_BATADJ	This bit enables the DC-DC to improve efficiency and minimize ripple using the information from the BATTMONITOR_BATT_VAL field. It is very important that the BATTMONITOR_BATT_VAL contain accurate information before setting BATTMONITOR_EN_BATADJ. 0b - Disable the improvement function. 1b - Enable the improvement function.
14 —	Reserved
13 LOOPCTRL_HYST_SIGN	Invert the sign of the hysteresis in DC-DC analog comparators. 0b - Disable the invert function. 1b - Enable the invert function.
12 LOOPCTRL_RCSCALE_THRSH	Increase the threshold detection for RC scale circuit. 0b - Disable increasing the threshold detection function. 1b - Enable increasing the threshold detection function.
11-9 LOOPCTRL_EN_RCSCALE	Enable RC Scale This enables the analog circuit of the DCDC to respond faster under transient load conditions. Higher the value, faster the response. 0x5 is the highest setting. 0x6 - 0x7: Not available
8-6 LOOPCTRL_DC_FF	Two's complement feed forward step in duty cycle in the switching DC-DC converter. Each time this field makes a transition from 0x0, the loop filter of the DC-DC converter is stepped once by a value proportional to the change. This can be used to force a certain control loop behavior, such as improving response under known heavy load transients.
5-2 LOOPCTRL_DC_R	Magnitude of proportional control parameter in the switching DC-DC converter control loop.
1-0 LOOPCTRL_DC_C	Ratio of integral control parameter to proportional control parameter in the switching DC-DC converter, and can be used to optimize efficiency and loop response.

22.7.1.5 DCDC Register 3 (REG3)

Offset

Register	Offset
REG3	Ch

Function

DCDC register 3

This register controls various high-level functions of the DCDC

29 VDD1P0CTRL_DISABLE_STEP	Disable Step for VDD1P0 Disable stepping for VDD1P0. Must set this bit before entering low power modes. 0b - Enable stepping for VDD1P0 1b - Disable stepping for VDD1P0
28 —	Reserved
27 MISC_DELAY_TIMING	Miscellaneous Delay Timing Adjust delay to reduce ground noise. 0b - Disable the function. 1b - Enable the function.

Table continues on the next page...

Table continued from the previous page...

Field	Function
26 MINPWR_HALF_FETS	Use half switch FET 0b - Donot use half switch FET. 1b - Use half switch FET.
25-24 —	Reserved
23-22 REG_FBK_SEL	Select the feedback point of the internal regulator. No need to change this field in user mode.
21 DOUBLE_IBIAS_CMP_LP	Double the bias current of the comparator for low-voltage detector in LP (low-power) mode. 0b - Disable the function. 1b - Enable the function.
20 DISABLE_IDLE_SKIP	The DCDC will be idle when out-of-range comparator detects the output voltage is higher than the target by 25mV. This function requires the out-of-range comparator to be enabled (PWD_CMP_OFFSET=0). 0b - Enable the idle skip function. 1b - Disable the idle skip function.
19 DISABLE_PULSE_SKIP	Disable Pulse Skip 0 - Stop charging if the duty cycle is lower than what is set by REG1[NEGLIMIT_IN] 1 - Enable charging if the duty cycle is lower than what is set by REG1[NEGLIMIT_IN]
18 ENABLE_FF	Enable feed-forward (FF) function that can speed up transient settling. 0b - Enable the FF function. 1b - Disable the FF function.
17-14 —	Reserved
13-10 —	Reserved
9 IN_BROWNOUT_WARN	The voltage on DCDC_IN is lower than 2.8V 0b - The voltage on DCDC_IN raises up to 2.8V. 1b - The voltage on DCDC_IN is lower than 2.8V. Once this bit sets, the bit must be cleared by software write one clear action while the voltage on DCDC_IN raises up to 2.8V. Writing "0" to this bit has no effect. Writing "1" to this bit has no effect while it's "0".
8-0 —	Reserved

22.7.1.6 DCDC Control Register 0 (CTRL0)

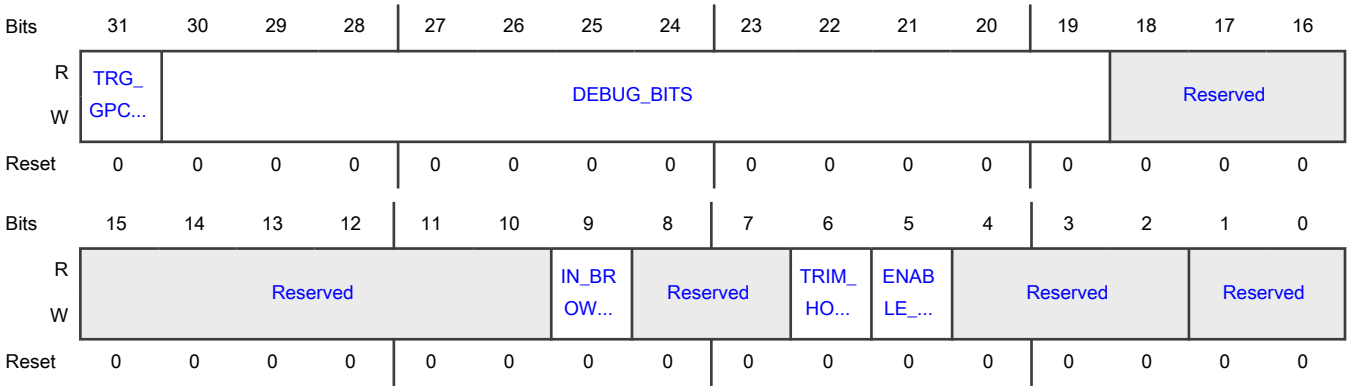
Offset

Register	Offset
CTRL0	10h

Function

DCDC Control register 0

Diagram



Fields

Field	Function
31 TRG_GPC_EN	TRG_GPC_EN: used to enable TRG_GPC_* value or not. 0b - No matter there is GPC stby request or not, value in TRG_SW_* register will always be used as DCDC analog target value. 1b - When there is a GPC stby request, value in TRG_GPC_* register will be used as DCDC analog target value instead of TRG_SW_*'s
30-19 DEBUG_BITS	Set to 0x1: To improve loading ability under heavy load.
18-10 —	Reserved
9 IN_BROWNOUT_WARN_EN	IN_BROWNOUT_WARN_EN 0b - Disable IN_BROWNOUT_WARN int flag bit output to CORE as an interrupt resource. 1b - Enable IN_BROWNOUT_WARN int flag bit output to CORE as an interrupt resource.
8-7 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 TRIM_HOLD	Hold trim input 0b - Sample trim value from FUSE or value from REG1[VBG_TRIM] depending on FUSE select bit. 1b - Use value from REG1[VBG_TRIM] as trim value.
5 ENABLE_OK_CNT	Enable internal count for DCDC_OK timeout 0b - Wait DCDC_OK for ACK 1b - Enable internal count for DCDC_OK timeout
4-2 —	Reserved
1-0 —	Reserved

22.7.1.7 OK CNT (OK_CNT)

Offset

Register	Offset
OK_CNT	14h

Function

This register value is only used when CTRL0[ENABLE_OK_CNT] bit is 1. This register is internal counter initial value. When this counter decreases to 0 by 32KHz clock rising edge, DCDC state machine will jump to next state instead of waiting for DCDC analog's status OK hardware acknowledge. Reset value is (0xA4)164*0.030517=5ms.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	OK_COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	OK_COUNT															
Reset	0	0	0	0	0	0	0	0	1	0	1	0	0	1	0	0

Fields

Field	Function
31-0 OK_COUNT	OK_COUNT Internal count for dcdc_ok timeout The value smaller than 8 is forbidden to write to this register. When this happens, 8 will be written to this register.

22.7.1.8 CURRENT TARGET VALUE for DCDC ANALOG (CURRENT_TRG)

Offset

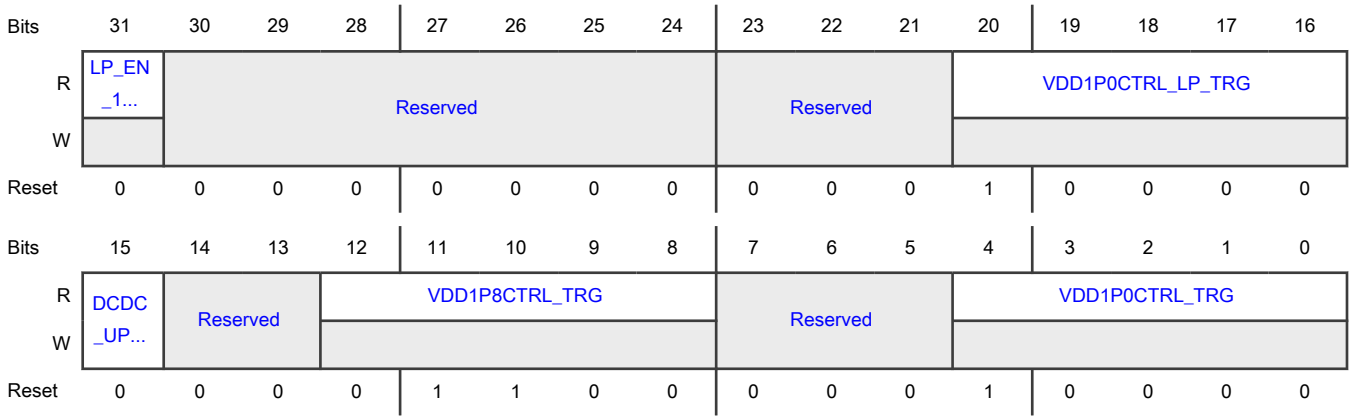
Register	Offset
CURRENT_TRG	18h

Function

This register value is current value used by DCDC analog. Since both TRG_SW_0 and TRG_SW_1 can control DCDC analog, hardware implements an arbitration strategy between them. For voltage target value, only the higher value between TRG_SW_0 and TRG_SW_1 can take effect. For LP_EN_1P0, only the lower value between them can take effect.

Notice: TRG_GPC_0 and TRG_GPC_1 also use this strategy to control DCDC analog when CTRL0[TRG_GPC_EN]=1 and there is a GPC stby request. But when TRG GPC takes effect, we can not get current value used by DCDC analog through reading this register. Because CORE is always in wait or stop mode at this time.

Diagram



Fields

Field	Function
31 LP_EN_1P0	This value comes from the smaller one between TRG_SW_0 and TRG_SW_1. This bit only controls 1P0. 1P8 is always controlled by VDD1P8CTRL_TRG

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - DCDC 1P0 works in run mode. Its output voltage is controlled by VDD1P0CTRL_TRG. 1b - DCDC 1P0 works in low power mode. Its output voltage is controlled by VDD1P0CTRL_LP_TRG and its output current is less than 50mA.
30-24 —	Reserved
23-21 —	Reserved
20-16 VDD1P0CTRL_LP_TRG	This value is only valid when LP_EN_1P0 =1. The value comes from the bigger one between TRG_SW_0 and TRG_SW_1.
15 DCDC_UPDATING	Notice: Only if the time of the bit's 1 is too long(more than several seconds) and REG0[STS_DC_OK]=1, then you can write 1 to clear it. Else writing to this bit is forbidden. Writing to this bit is only for debug. 0b - Last DCDC change has been done. New value can be written to TRG register to trigger a new change of DCDC voltage. 1b - Last DCDC change is still not done. New value should not be written to TRG register to trigger a new change of DCDC voltage.
14-13 —	Reserved
12-8 VDD1P8CTRL_TRG	This value is current value used by DCDC analog. The value comes from the bigger one between TRG_SW_0 and TRG_SW_1.
7-5 —	Reserved
4-0 VDD1P0CTRL_TRG	This value is current value used by DCDC analog. The value comes from the bigger one between TRG_SW_0 and TRG_SW_1.

22.7.1.9 FILTER CNT (FILTER_CNT)

Offset

Register	Offset
FILTER_CNT	1Ch

Function

Control dcdc_sts_ok signal's filter function. This register can force DCDC analog status output signal dcdc_sts_ok to 0. Cannot write value smaller than 2.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	FILTER_CNT_CFG															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	FILTER_CNT_CFG															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Fields

Field	Function
31-0 FILTER_CNT_CFG	FILTER_CNT_CFG Filter counter timeout value. Any DCDC change requirement can trigger filter counter begin to count by 32K clock, and it will stop at this value and go back to 0 at next clock cycle. When this counter is not 0, dcdc_sts_ok will be forced to 0, otherwise dcdc_sts_ok will be released to its original value.

22.7.1.10 TRG_0 Authentication Control (TRG_0_AUTHEN)

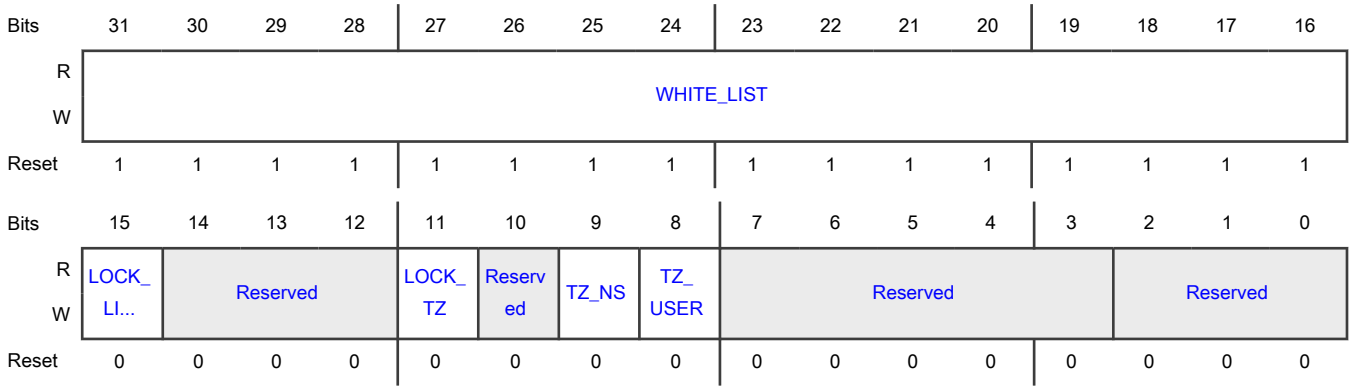
Offset

Register	Offset
TRG_0_AUTHEN	20h

Function

This register controls TRG_SW_0, TRG_GPC_0 and its own access control for different CORE.

Diagram



Fields

Field	Function
31-16 WHITE_LIST	Domain ID white list Each master(Core or non Core) can be assigned to any domains among domain0~domain15 by TRDC. Once its domains are assigned, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit16~bit31 represent for domain0~domain15 respectively. Only the domains whose corresponding bits are 1 can write TRG_0 registers. Write violation will fail without any exception or information. Read violation can still get read data. 0000_0000_0000_0001b - Core with domain ID=0 can write TRG_0 registers. 0000_0000_0000_0010b - Core with domain ID=1 can write TRG_0 registers. 0000_0000_0000_0100b - Core with domain ID=2 can write TRG_0 registers. 0000_0000_0000_1000b - Core with domain ID=3 can write TRG_0 registers. 0000_0000_0001_0000b - Core with domain ID=4 can write TRG_0 registers. 0000_0000_0010_0000b - Core with domain ID=5 can write TRG_0 registers. 0000_0000_0100_0000b - Core with domain ID=6 can write TRG_0 registers. 0000_0000_1000_0000b - Core with domain ID=7 can write TRG_0 registers. 0000_0001_0000_0000b - Core with domain ID=8 can write TRG_0 registers. 0000_0010_0000_0000b - Core with domain ID=9 can write TRG_0 registers. 0000_0100_0000_0000b - Core with domain ID=10 can write TRG_0 registers. 0000_1000_0000_0000b - Core with domain ID=11 can write TRG_0 registers. 0001_0000_0000_0000b - Core with domain ID=12 can write TRG_0 registers. 0010_0000_0000_0000b - Core with domain ID=13 can write TRG_0 registers. 0100_0000_0000_0000b - Core with domain ID=14 can write TRG_0 registers. 1000_0000_0000_0000b - Core with domain ID=15 can write TRG_0 registers.
15 LOCK_LIST	White list lock This field can lock itself and WHITE_LIST.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - WHITE_LIST value can be changed. 1b - LOCK_LIST and WHITE_LIST value cannot be changed.
14-12 —	Reserved

The TMPSNS analog registers are in the ANADIG chapter. The TEMPSNS_OTP_TRIM_VALUE[TEMPSNS_TEMP_VAL] in ANADIG is used in the temperature equation.

23.2 Overview

TMPSNS implements a temperature sensor and conversion function based on a temperature-dependent voltage-to-time conversion.

23.2.1 Block diagram

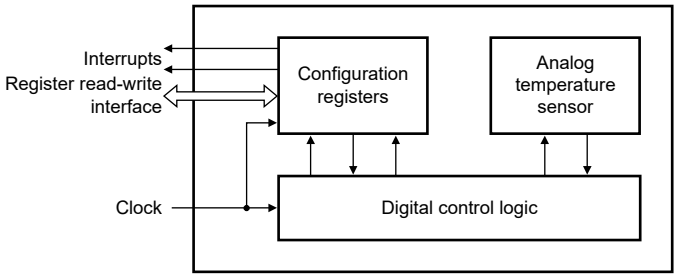

Figure 87. Block diagram

23.2.2 Features

- Single Measurement mode
  - Performs one measurement for each start indication from software
  - Asserts STATUS0[FINISH] on every measurement completion
- Continuous Measurement mode
  - Performs continuous measurements after being initiated by software
  - Allows frequency of measurements to be programmed by software
  - Asserts STATUS0[FINISH] on every measurement completion, if previously cleared
- Contains temperature alarm interrupts to indicate if the temperature is beyond programmed thresholds
  - Supports three tier alarms: Low, High, Panic

23.3 Functional description

TMPSNS features alarm functions that can raise independent interrupt signals if the temperature is above either of two high-temperature thresholds, or below a low-temperature threshold. These temperature thresholds are programmable and designated as low, high, and panic temperatures.

The panic threshold is a special programmable threshold. If the temperature increases above this value and the temperature-panic-reset interrupt is enabled in the System Reset Controller, then the hardware assumes that software no longer has control over the thermal situation and initiates a reset of the chip. In order to avoid resets initiated by a false panic temperature, the panic alarm is not triggered until the temperature panic condition has been met for four consecutive conversion cycles. You can also program a self-repeating mode that executes a temperature-sensing operation based on a programmed delay.

Because the high and low temperature thresholds are programmable, they form a sliding temperature bracket that can be tailored to the needs of each application. For example, at startup, you can set the low-temperature threshold to the minimum temperature code, and the high-temperature threshold to a maximum operating temperature for the chip.

The chip can then use TMPSNS to monitor the on-die temperature and take appropriate action, such as throttling back the core frequency when the high-temperature interrupt is set. After you have set the high-temperature interrupt, the chip can program the low-temperature threshold to a desired cool-down temperature. The chip can then switch to monitoring the low-temperature alarm and wait for its interrupt to be set.

With this scheme, after the low-temperature interrupt is set, TMPSNS can determine that the temperature has cooled down to a safe level. The process can then be repeated.

23.3.1 Modes of operation

The following modes are supported in TMPSNS:

- Single Measurement mode
  - Performs one measurement per start indication from software.
  - Asserts STATUS0[FINISH] on completion of every measurement.
- Continuous Measurement mode
  - Performs continuous measurements (after being initiated by software) at the rate defined by CTRL1[FREQ].
  - Allows you to program the frequency of measurements through software.
  - Asserts STATUS0[FINISH] on every measurement completion, if previously cleared.

23.3.2 Temperature sensing

Use Equation 1 to calculate the initial value of the temperature in *C.

$$temp_{diode} = \frac{[-ts_{21} - \sqrt{ts_{21}^2 - 4 \times ts_{22} \times (ts_{20} + ts_{25C} - ts_{meas})}]}{[2 \times ts_{22}]}$$

Where:

$ts_{21} = -5.39$
$ts_{22} = 0.002$
$ts_{20} = 133.6$

ts_{meas} = the measured code output from the temperature sensor
$ts_{25C} = ts_{offset} + 1915$, where ts_{offset} is a value in two's-complement format that comes from fuses

Equation 1. Temperature formula

23.3.3 Clocking

Clock	Description
TEMP_24MCLK	Reference clock

23.3.4 Reset

All resets are controlled through the Analog IP (AI) interface.

23.3.5 Interrupts

All interrupts are controlled through the Analog IP (AI) interface.

23.4 External signals

TMPSNS has no external signals.

23.5 Initialization

There are no special considerations for initializing TMPSNS. Use CTRL1[PWD] and CTRL1[PWD_FULL] to power down the temperature sensor.

23.6 Application information

23.6.1 Configuration for Single Measurement mode

1. Write the appropriate threshold values in Range 0 (RANGE0) and Range 1 (RANGE1) for the Panic, High, and Low Temperature alarms to trigger. See Temperature sensing to determine the value to program, based on the selected temperature value.
2. Enable appropriate interrupts by writing 1 to the corresponding interrupt enable fields in Control 1 (CTRL1).
3. Power up the analog section by writing 0 to CTRL1[PWD] and CTRL1[PWD_FULL].
4. Ensure that CTRL1[FREQ] = 0.
5. Enable the measurement process by writing 1 to CTRL1[START].
6. Determine the completion of the measurement by polling STATUS0[FINISH].
7. Read the measured value in STATUS0[TEMP_VAL].
8. Clear CTRL1[FINISH_IE] by writing 1 to it.
9. Clear CTRL1[START] by writing 0 to it.

Repeat steps 4–8 to start another measurement cycle.

23.6.2 Configuration for Multiple Measurement mode

1. Write the appropriate threshold values in Range 0 (RANGE0) and Range 1 (RANGE1) for the Panic, High, and Low Temperature alarms to trigger. See Temperature sensing to determine the value to program, based on the selected temperature value.
2. Enable appropriate interrupts by writing 1 to the corresponding interrupt enable fields in Control 1 (CTRL1).
3. Power up the analog section by writing 0 to CTRL1[PWD] and CTRL1[PWD_FULL].
4. Set the selected frequency of measurement by writing a non-zero value to CTRL1[FREQ]. This field determines the number of idle clock cycles between two conversions. The next measurement starts after counting these clock cycles.
5. Enable the measurement process by writing 1 to CTRL1[START].
6. Determine the completion of the measurement by polling STATUS0[FINISH].
7. Read the measured value in STATUS0[TEMP_VAL].
8. Clear CTRL1[FINISH_IE] by writing 1 to it.
9. Repeat steps 5 to 7 to continue receiving continuous measurements.
10. To exit Multiple Measurement mode, write 0 to CTRL1[START].

23.7 Memory map and register definitions

23.7.1 TMPSNS register descriptions

TMPSNS memory consists of 32-bit–aligned registers that can be accessed only via 8-, 16-, or 32-bit accesses. Write access to reserved locations generates a transfer error. Read access to reserved locations also generates a transfer error, and the read data bus shows all zeros.

TMPSNS does not check for correctness of programmed values in the registers. You must program software to ensure that the values are valid.

NOTE

All register fields are shadowed except for those in Status 0 (STATUS0). You can change shadowed fields only when CTRL1[START] = 0 or CTRL1[PWD] = 1. Changing shadowed fields at any other time will take effect only when CTRL1[START] is toggled from 0 to 1, or CTRL1[PWD] is toggled from 1 to 0. You can change any STATUS0 field regardless of the values of CTRL1[START] and CTRL1[PWD].

23.7.1.2 Control 1 (CTRL1)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL1	10h	Control 1
CTRL1_SET	14h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL1 is 1
CTRL1_CLR	18h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL1 is 0
CTRL1_TOG	1Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL1

Function

Configures the digital temperature sensor control and mode of operation (Single Read or Continuous Read).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 PWD_FULL	Power Down Powers down TMPSNS. If this field = 0, TMPSNS is active. If this field = 1, TMPSNS is powered down. 0b - Active 1b - Inactive
30-24 —	Reserved
23 PWD	Power Down Except Bias Current Powers down TMPSNS except for the bias current. If this field = 0, TMPSNS is active. If this field = 1, TMPSNS is powered down except for the bias current. 0b - Active 1b - Inactive
22 START	Start Temperature Measurement Initiates the temperature reading in either Single Read mode or Continuous Read mode. For single reading, you must write 0 this field and then write 1 for every read. For continuous reading, this field must remain 1. Write 0 to this field when you want to stop measurement. 0b - No read 1b - New read
21-20 —	Reserved
19 PANIC_TEMP_IE	Panic Temperature Interrupt Enable Enables assertion of an interrupt when the measured temperature is greater than or equal to the programmed panic temperature value. 0b - Disable 1b - Enable
18 HIGH_TEMP_IE	High Temperature Interrupt Enable Enables assertion of an interrupt when the measured temperature is greater than or equal to the programmed high temperature value. 0b - Disable 1b - Enable
17 LOW_TEMP_IE	Low Temperature Interrupt Enable Enables assertion of an interrupt when the measured temperature is lower than or equal to the programmed low temperature value. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
16 FINISH_IE	Measurement Finished Interrupt Enable Enables assertion of an interrupt when the temperature measurement is complete. 0b - Disable 1b - Enable
15-0 FREQ	Temperature Measurement Frequency Represents the number of clock cycles of the 24 MHz clock that TMPSNS counts between two temperature readings. If this field = 0, TMPSNS works in Single Reading mode, where a new temperature reading is available every time START = 1. For non-zero values of this field, TMPSNS works in Continuous Reading mode, where it initiates a new temperature reading when the programmed period expires after the end of the current temperature reading. The value of START must remain 1 for continuous conversion. 0000_0000_0000_0000b - Single Reading Mode. A new reading is available every time you change START from 0 to 1. 0000_0000_0000_0001b-1111_1111_1111_1111b - Continuous Reading Mode. TMPSNS takes the next temperature reading when it completes the programmed number of cycles after the current reading.

23.7.1.3 Range 0 (RANGE0)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
RANGE0	20h	Range 0
RANGE0_SET	24h	Writing 1 to a bit in this register ensures that the corresponding bit in RANGE0 is 1
RANGE0_CLR	28h	Writing 1 to a bit in this register ensures that the corresponding bit in RANGE0 is 0
RANGE0_TOG	2Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in RANGE0

Function

Configures the ranges for generation of High and Low temperature alarms.

Diagram

Fields

Field	Function
31-28 —	Reserved
27-16 HIGH_TEMP_VAL	High Temperature Threshold Value Contains the high temperature threshold value (number of clock counts) below which you must write 1 to STATUS0[HIGH_TEMP].
15-12 —	Reserved
11-0 LOW_TEMP_VAL	Low Temperature Threshold Value Contains the low temperature threshold value (number of clock counts) above which you must set STATUS0[LOW_TEMP].

23.7.1.4 Range 1 (RANGE1)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
RANGE1	30h	Range 1
RANGE1_SET	34h	Writing 1 to a bit in this register ensures that the corresponding bit in RANGE1 is 1
RANGE1_CLR	38h	Writing 1 to a bit in this register ensures that the corresponding bit in RANGE1 is 0
RANGE1_TOG	3Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in RANGE1

Function

Configures the ranges for generation of a Panic temperature alarm.

24.2 Overview

The ANADIG block contains the Power Management Unit (PMU), Crystal Oscillator (XTALOSC), Temp Sensor (TMPSNS), PLL controls for CCM, and several other miscellaneous system-level control and status registers.

NOTE

AON_ANA_LDO and AON_1P8_LDO is used interchangeably throughout this document.

24.2.1 Block Diagram

The following shows a block diagram of ANADIG.

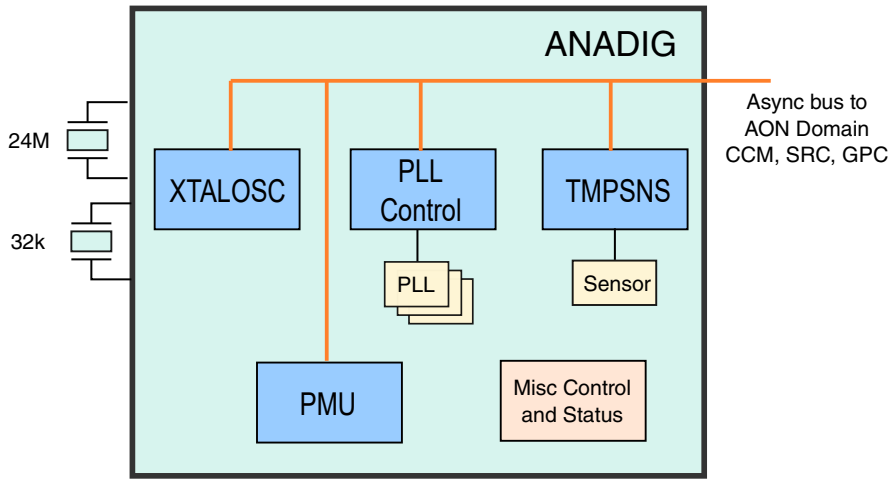

Figure 88. ANADIG Block Diagram

24.2.2 Features

Main features of ANADIG are:

- Integrated crystal ,RC oscillators and PLLs for system generation
- Integrated Power Management Unit (PMU) analog component: LDOs and Power Switches
- Integrated Temperature Monitor for system over heat detection

24.3 Functional Description

The following sections describe the XTALOSC, PMU, PLL, and TMPSNS modules.

24.3.1 Crystal Oscillator (XTALOSC)

This chip contains two crystal oscillators for clock generation: 24 MHz and 32 kHz. In addition, it also contains three RC oscillators: 24 MHz, 32 kHz and 400 MHz.

24.3.1.1 XTALOSC Block Diagram

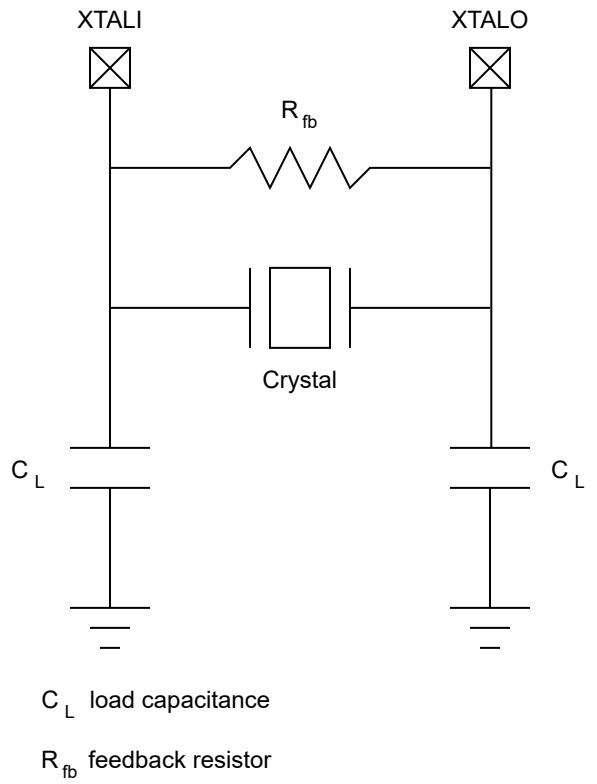

Figure 89. Crystal Oscillator block diagram

NOTE

The Rfb resistor is used in high gain mode. It is not used in low power mode.

24.3.1.2 XTALOSC Functional Description

This section details the oscillator clock sources to the chip.

24.3.1.2.1 Crystal Oscillators

The XTALOSC has two external crystal oscillators:

- **24 MHz XTAL oscillator**
  - Primary clock source for all PLLs that generate the clocks for the CPU, bus, and high-speed interfaces.
  - This clock source can be bypassed by the user, and replaced with another external clock source.
- **32 kHz XTAL oscillator**
  - Primary clock source for RTC as well as low-speed clock source for CCM/SRC/GPC.

24.3.1.2.1.1 Bypass configuration (24 MHz XTAL oscillator)

If it is desired to drive the chip with an external clock source, then it should be connected to XTALI and OSC_24M_CTRL[BYPASS_EN] should be set to 1. XTALO should be left externally floating.

24.3.1.2.2 RC Oscillators

The XTALOSC is supported by RC oscillators (RCOSC). This chip has three RCOSC:

- **24 MHz RC oscillator**
  - Generates the 24MHz clock source for the chip during start-up when the external 24 MHz crystal is not ready.
  - Alternative 24 MHz clock source in low power mode when the crystal oscillator is turned off, or in system which does not have any crystal oscillator.
- **32 kHz RC oscillator**
  - 32 kHz clock source for the chip during start-up when the external 32 kHz crystal is not ready.
  - Alternative 32 kHz clock source when the external 32 kHz crystal oscillator is not stable, or in system which does not have any crystal oscillator.
- **400 MHz RC oscillator**
  - Clock source during chip boot up before PLL is enabled or in low-power mode when PLL is turned off.

NOTE

- The switch from external 32 kHz XTALOSC to internal 32 kHz RCOSC is controlled by hardware and occurs automatically when the system detects a loss of 32 kHz crystal clock.
- To properly switch between 24 MHz XTALOSC and 24 MHz internal RCOSC, ensure the PLL is powered down before the switch. After switching the clock, power up PLL.

24.3.1.3 XTALOSC External Signals

The table found here describes the external signals of XTALOSC:

Table 156. XTALOSC External Signals

Signal	Description	Pad	Mode	Direction
RTC_XTALI	Real-time clock crystal oscillator input	RTC_XTALI	No muxing	I
RTC_XTALO	Real-time clock crystal oscillator output	RTC_XTALO	No muxing	O
XTALI	Crystal oscillator input signal	XTALI	No muxing	I
XTALO	Crystal oscillator output signal	XTALO	No muxing	O

24.3.1.4 XTALOSC Initialization

In software control mode, the enable sequence for OSC24M is:

1. Set OSC_24M_CTRL[OSC_EN] = 1
2. Wait for OSC_24M_CTRL[OSC_24M_STABLE] = 1
3. Set OSC_24M_CTRL[OSC_24M_GATE] = 0

The disable sequence for OSC24M is:

1. Set OSC_24M_CTRL[OSC_24M_GATE] = 1
2. Set OSC_24M_CTRL[OSC_EN] = 0

In software control mode, the enable sequence for RC_24M is:

- Set OSC_RC24M_CTRL[TEN] = 1

The disable sequence for RC_24M is:

- Set OSC_RC24M_CTRL[TEN] = 0

In hardware control mode, the power-on/power-off of the oscillators are fully controlled by CCM/GPC. The other settings remain under the control of XTALOSC.

24.3.1.5 XTALOSC Memory Map and register definition

Please see the OSC Memory Map section in this ANADIG chapter for more information about the XTALOSC registers.

NOTE

For related IPS Domain Slot control, see IPS Domain Registers in this chapter.

24.3.2 Power Management Unit (PMU)

The Power Management Unit (PMU) is designed to simplify the external power interface.

24.3.2.1 PMU Block Diagram

The power architecture of the chip is illustrated in the figure below, which shows the typical use case of a single 3.3V power supply and a coin cell battery. Depending on the application, different power supply schemes can apply (for example, DCDC bypassed).

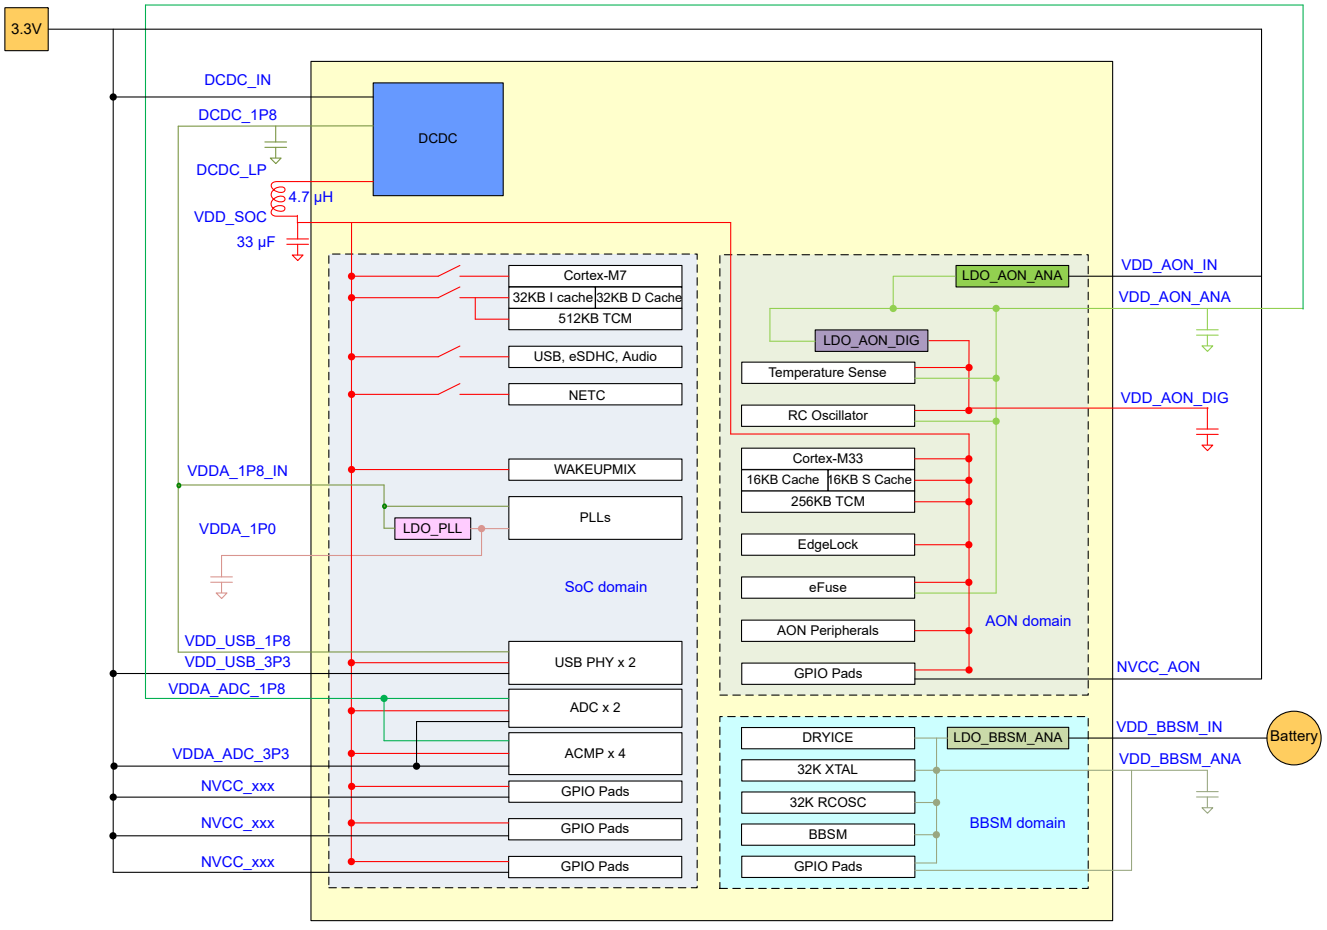

Figure 90. Power system overview

24.3.2.2 PMU Overview

The PMU has the following components integrated for power management:

- One DCDC to generate core power supply, with dynamic voltage scaling capability
- LDOs to generate power for internal logics
- Multiple Power Switches for sophisticated power mode management

24.3.2.3 PMU Functional Description

The PMU operations are detailed in the sections below.

24.3.2.3.1 PMU LDO Regulators

The PMU has four LDO regulators. Two LDOs are in the AON Domain covering the 1.8 V Analog source (LDO_AON_ANA) and 1.0 V Digital source (LDO_AON_DIG). One LDO covers the SoC PLLs in the SoC Domain, and one LDO in the BBSM domain, which is supplied by the VDD_BBSM_IN rail from the battery backed source.

24.3.2.3.2 PMU Well-Bias configuration

The well-bias configuration is shown below. The PWELL is an adaptive, quiescent consumption, positive voltage tracker, switched regulator. The PWELL regulator is biased as FBB. The PWELL regulator is connected to a LVT transistors.

- For low-voltage threshold (LVT), FBB is supported. It provides enhanced SoC core performance at a cost of higher leakage.

The VDD_SOC_IN and VDD_AON_ANA supplies need to be settled before the well-bias regulator is turned on (WB_EN) for FBB.

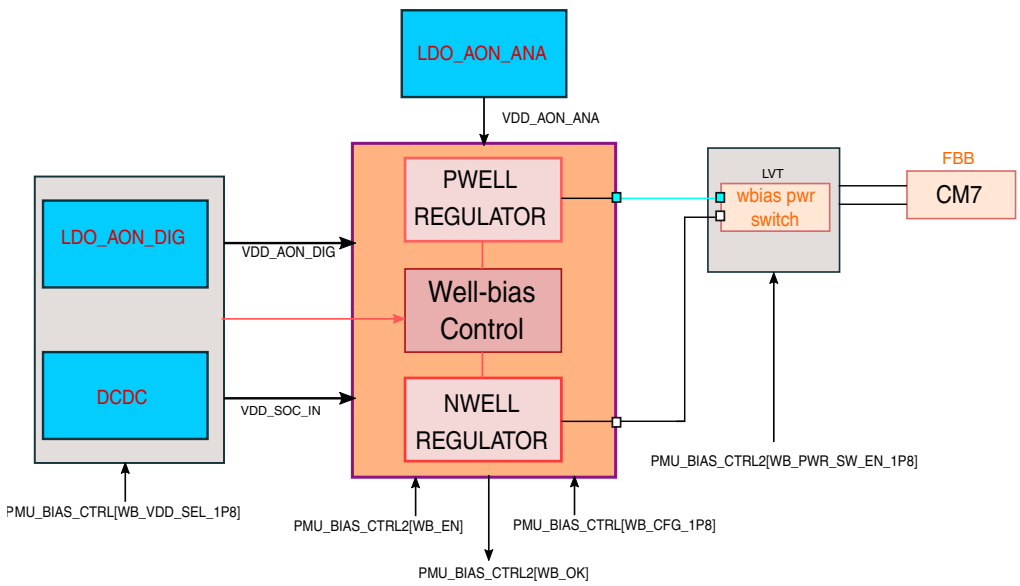

Figure 91. Well-Biasing Block Diagram

NOTE

The VDD selection (WB_VDD_SEL_1P8) needs to be done before enabling well-bias.

24.3.2.3.2.1 Body Biasing

Forward Body Biasing (FBB)is implemented to boost performance. The implementation of FBB is listed below:

- FBB is implemented in Cortex-M7 Platform in order to achieve higher performance

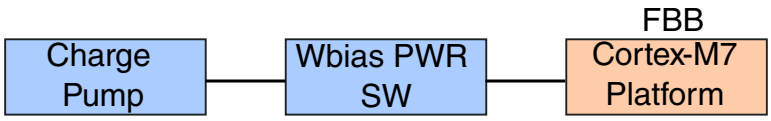

Figure 92. Body Biasing Diagram

24.3.2.3.3 PMU Control Mode

The PMU supports two control modes that can be configured by x_CONTROL_MODE fields. These two modes are Software control mode and Hardware control mode.

- The Software control mode enables LDOs, switches and bandgap to be fully configured by registers.
- The Hardware control mode enables the ON/OFF of the LDOs, LDO bypass switches and bandgap to be configured by GPC. The voltage of AON_DIG and operation modes of LDOs (lp_mode) are also configured by GPC. The other settings remain unchanged.

The following table shows the functions controlled by GPC:

Table 157. Functions controlled by GPC

IP	ON/OFF Control	Operation Mode	Tracking Mode	Bypass Mode (Switch ON/ OFF)	Standby Mode (Low Power Mode)	Voltage Control
LDO_PLL	Y	-	-	-	Y	-
AON_ANA	-	HP/LP	Y	Y	HP/LP	-
AON_DIG	-	HP/LP	Y	Y	HP/LP	Y
REFTOP (Bandgap)	Y	-	-	-	Y	-
FBB M7	Y	-	-	-	Y	-

Each time there is a change, there will be two steps of requests - voltage down and voltage up. The new target is compared with the current setting to check if the voltage change should happen at each step. When there is a change request, the 'done' signals will be generated until all the settings have been changed. When there is a sleep in request, the acknowledge signal will be held high until the set modules are put into low-power mode. When there is sleep out request, the acknowledge signal will held high until the modules are brought back from low power mode.

24.3.2.3.3.1 PMU ON/OFF Control Mode

The ON/OFF control for LDOs:

- When LDO_x_CONTROL_MODE = 0 (Software control mode), LDO_x_ENABLE controls the ON/OFF

Bandgap ON/OFF Control:

- When REF_CONTROL_MODE = 0 (Software control mode), REF_ENABLE controls the ON/OFF of the bandgap

NOTE

Software mode supports flexible control, but care and consideration should be followed in regards to analog dependencies and power structure sequences. In GPC mode, everything is handled precisely by hardware.

24.3.2.3.3.2 PMU Well Bias Enable Sequence

The following sequence should be followed to enable Well Bias:

- Set well bias setting (voltage, LVT)
  - PMU_BIAS_CTRL[1] is set to 1 (NWELL is configured to supply and LVT CORE, FBB)
  - PMU_BIAS_CTRL[12] is set to 1 to enable FBB correctly
  - All the other bits are set to 0
- Turn on CM7 FBB switch, and well bias (must be executed in the same step)
  - PMU_BIAS_CTRL2[WB_EN] is set to 1
  - PMU_BIAS_CTRL2[WB_PWR_SW_EN_1P8] is set to 1
  - All other bits set to 0
- Check the PMU_BIAS_CTRL2[WB_OK] bit to confirm Well Bias is stable

24.3.2.4 Clocks

The PMU doesn't have any relevant application clock sources.

24.3.2.5 PMU External Signals

See the supply contact assignments in the data sheet for more information.

24.3.2.6 PMU Memory Map and register definition

Please see the PMU Memory Map section in this ANADIG chapter for more information about the PMU registers.

24.3.3 Phase Locked Loops (PLLs) - Programming Guidelines

This chip contains the following Fractional and Integer PLLs:

- Fractional PLLs:
  - SYS_PLL1 (1G_PLL)
  - AUDIO_PLL
- Integer PLLs:
  - SYS_PLL2 (528_PLL)
  - SYS_PLL3 (480_PLL)
  - ARM_PLL

The PLLs can work in either GPC mode or Software mode (default). In GPC mode, GPC configures the PLLs. In Software mode, the users can configure all the registers.

The equations given below help to calculate the output frequency for PLLs based on the mode (Software or GPC) and type of PLL (Fractional or Integer).

- During Software mode (default):
  - For Fractional PLLs (SYS_PLL1, AUDIO_PLL):

- Output frequency = Fref*(CTRL0[DIV_SELECT]+(NUMERATOR[NUM]/DENOMINATOR[DENOM]))/ 2^CTRL0[POST_DIV_SEL]

— For Integer PLLs (SYS_PLL2):

- Output frequency = Fref * (MFI+MFN/MFD)

— For Integer PLLs (SYS_PLL3):

- Output frequency = Fref * div_sel

— For Integer PLLs (ARM_PLL):

- Output frequency = Fref * ARM_PLL_CTRL[DIV_SELECT]/2 * ARM_PLL_CTRL[POST_DIV_SELECT]

- During GPC mode:

— For Fractional PLLs (SYS_PLL1, AUDIO_PLL):

- Output frequency = Fref * (SYS_PLLx_DIV_SELECT[DIV_SELECT] + (SYS_PLLx_NUMERATOR[NUM]/ SYS_PLLx_DENOMINATOR[DENOM]))

— For Integer PLLs (SYS_PLL2):

- Output frequency = Fref * (MFI+MFN/MFD)

— For Integer PLLs (SYS_PLL3):

- Output frequency = Fref * div_sel

— For Integer PLLs (ARM_PLL):

- Output frequency = Fref * ARM_PLL_CTRL[DIV_SELECT]/2 * ARM_PLL_CTRL[POST_DIV_SELECT]

Fref is the PLL Reference Frequency sourced from 24 MHz.

NOTE

For SYS_PLL2, MFI is a fixed value of 22 and for SYS_PLL3, div_sel is a fix value of 20.

24.3.3.1 PLL - Spread Spectrum Parameters

The SYS_PLL1, SYS_PLL2, AUDIO_PLL and the related PFDs support spread spectrum (down spread). The equations given below help to calculate spread spectrum range, and modulation frequency based on the mode (Software or GPC) and type of PLL (Fractional or Integer).

- During Software mode (default):

— For Fractional PLLs (SYS_PLL1, AUDIO_PLL):

- Spread spectrum range = Fref * SPREAD_SPECTRUM[STOP]/DENOMINATOR[DENOM]
- Modulation frequency = Fref * SPREAD_SPECTRUM[STEP]/(2*SPREAD_SPECTRUM[STOP])

— For Integer PLL (SYS_PLL2):

- Spread spectrum range = Fref * SYS_PLL2_SS[STOP]/SYS_PLL2_MFD[MFD]
- Modulation frequency= Fref * SYS_PLL2_SS[STEP]/(SYS_PLL2_SS[STOP] *2)

- During GPC mode:

— For Fractional PLLs (SYS_PLL1, AUDIO_PLL):

- Spread spectrum range = Fref * SYS_PLLx_SS[STOP]/SYS_PLLx_DENOMINATOR[DENOM]
- Modulation frequency = Fref * SYS_PLLx_SS[STEP]/(2*SYS_PLLx_SS[STOP])

— For Integer PLL (SYS_PLL2):

- Spread spectrum range = Fref * SYS_PLL2_SS[STOP]/SYS_PLL2_MFD[MFD]
- Modulation frequency= Fref * SYS_PLL2_SS[STEP]/(SYS_PLL2_SS[STOP] *2)

Fref is the PLL Reference Frequency sourced from 24MHz.

The spread range indicates how much frequency the PLL will sweep down. For example, a spread range of 6MHz would mean that the PLL will sweep from 'Target_frequency' to 'Target_Frequency - 6MHz' and sweep back.

24.3.4 TMPSNS temperature trim value

The ANADIG TEMPSENSOR registers contain the temperature value at 25C. This is a read-only value that comes from the fuses.

Other TMPSNS information can be found in the TMPSNS chapter.

24.4 Memory Map and register definition

The memory map register definition for XTALOSC, LDOs, PLLs, TMPSNS (analog), and IPS Domain Slot controls are shown below.

24.4.1 RT1180_ANADIG_REGISTER register descriptions

24.4.1.1 LDO_BBSM memory map

ANADIG base address: 4448_0000h

Offset	Register	Width (In bits)	Access	Reset value
4740h	PMU_LDO_AON_ANA_REGISTER (PMU_LDO_AON_ANA)	32	RW	0000_0108h
4760h	PMU_LDO_AON_DIG_REGISTER (PMU_LDO_AON_DIG)	32	RW	0130_1C05h

24.4.1.2 MISC memory map

ANADIG base address: 4448_0000h

Offset	Register	Width (In bits)	Access	Reset value
4800h	Chip Silicon Version Register (MISC_DIFPROG)	32	R	0090_0200h

24.4.1.3 OSC memory map

ANADIG base address: 4448_0000h

Offset	Register	Width (In bits)	Access	Reset value
4310h	24MHz RCOSC Control Register (OSC_RC24M_CTRL)	32	RW	0079_01F2h

The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
29-24 PFD3_FRAC	PFD3_FRAC This field controls the fractional divide value. The resulting frequency shall be 528*18/PFD3_FRAC where PFD3_FRAC is in the range 13-35.
23 PFD2_DIV1_CLKGATE	PFD2_CLKGATE 0b - PFD2 fractional divider clock is enabled. 1b - Fractional divider clock (reference PFD2) is off (power savings)
22 PFD2_STABLE	PFD2_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
21-16 PFD2_FRAC	PFD2_FRAC This field controls the fractional divide value. The resulting frequency shall be 528*18/PFD2_FRAC where PFD2_FRAC is in the range 13-35.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 PFD1_DIV1_CLKGATE	PFD1_CLKGATE 0b - PFD1 fractional divider clock is enabled. 1b - Fractional divider clock (reference PFD1) is off (power savings)
14 PFD1_STABLE	PFD1_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
13-8 PFD1_FRAC	PFD1_FRAC This field controls the fractional divide value. The resulting frequency shall be 528*18/PFD1_FRAC where PFD1_FRAC is in the range 13-35.
7 PFD0_DIV1_CLKGATE	PFD0_CLKGATE 0b - PFD0 fractional divider clock is enabled. 1b - Fractional divider clock (reference PFD0) is off (power savings)
6 PFD0_STABLE	PFD0_STABLE This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into clock-gated state.
5-0 PFD0_FRAC	PFD0_FRAC This field controls the fractional divide value. The resulting frequency shall be 528*18/PFD0_FRAC where PFD0_FRAC is in the range 13-35.

24.4.1.15 SYS_PLL2_MFN_REGISTER (SYS_PLL2_MFN)

Offset

Register	Offset
SYS_PLL2_MFN	4080h

Function

SYS_PLL2_MFN PLL output frequency=Fref*(MFI+MFN/MFD)

Refer to Programming Guidelines for more details.

Table continued from the previous page...

Field	Function
WB_VDD_SEL_1P8	0b - VDD_LV1. VDD_LV1 supplies the power stage and NWELL sampler (DCDC) 1b - VDD_LV2. VDD_LV2 supplies the power stage and NWELL sampler (AON_DIG_LDO)
13 —	Reserved
12-0 WB_CFG_1P8	wb_cfg_1p8 Well Bias Configuration 1P8. For bit 0 : • 0 PWELL and NWELL is turned on when wb_en_1p8 is set; • 1 PWELL regulator is turned on only when wb_en_1p8 is set. NWELL is kept disabled. For bit 1 : Body bias • 0 NWELL is configured to supply and RVT CORE - RBB. • 1 NWELL is configured to supply and LVT CORE - FBB. For bit 2-4 : Select size of bias area • 000 Imax = 180uA; Areamax-RVT = 6.00mm2 at 125C • 001 Imax = 150uA; Areamax-RVT = 5.00mm2 at 125C • 010 Imax = 120uA; Areamax-RVT = 4.00mm2 at 125C • 011 Imax = 90uA; Areamax-RVT = 3.00mm2 at 125C • 100 Imax = 60uA; Areamax-RVT = 2.00mm2 at 125C • 101 Imax = 45uA; Areamax-RVT = 0.15mm2 at 125C • 110 Imax = 30uA; Areamax-RVT = 1.0mm2 at 125C • 111 Imax = 15uA; Areamax-RVT = 0.50mm2 at 125C For bit 5 : Adaptive function • 1 Adaptive frequency disabled. Frequency determined by wb_cfg_1p8[8:6]. • 0 Frequency change after each half cycle Minimum frequency determined by wb_cfg_1p8[8:6] For bit 6-8 : Oscillator bits • 000 typical frequency = osc_freq/128 • 001 typical frequency = osc_freq/64 • 010 typical frequency = osc_freq/32 • 011 typical frequency =osc_freq/16 • 100 typical frequency = osc_freq/8 • 110 typical frequency = osc_freq/2 • 111 typical frequency = oscillator Frequency (osc_freq)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For bit 9 : TRIM BUS. It is used to set an internal adaptive configuration. It configures the adaptive clock source. The options are: 1) the oscillator clock 2) clock synchronous with the Charge Pump clock. These 2 signals have the same frequency, but delayed one to other. It determines if the adaptive control signal changes the frequency in the same or in the next oscillator cycle. • 0 The option is the oscillator clock • 1 The option is clock synchronous with the Charge Pump clock For bit 10 - 11 : TRIM BUS • 00 no frequency reduction • 01 30% frequency reduction due to cap. increment. • 10 40% frequency reduction due to cap. increment. • 11 50% frequency reduction due to cap. increment. For bit 12 : • 1 Pull down option is enabled. • 0 Pull down option is disabled.

24.4.1.26 PMU_BIAS_CTRL2_REGISTER (PMU_BIAS_CTRL2)

Offset

Register	Offset
PMU_BIAS_CTRL2	4610h

Function

Well Bias IP control register

This register defines the test mode function for wb bias.

24-20 VOLTAGE_SELECT	VOLTAGE_SELECT VOLTAGE SELECT for AON_DIG For aon_dig voltage switch to different voltage In SW mode, software is responsible to take care of the stepping time. In HW mode, hardware is responsible to take care of the stepping time. During the mode transition, in case the aon_dig voltage is out of table, software is responsible to take care of the stepping time (i.e. mode transist), software calculates the steps difference multiply the stepping requirement, after the voltage is stable. GPC mode transition is allowed. The values below are the stable voltage with the range in parentheses (e.g. Stable Voltage (Range)V). 0_0000b - Stable Voltage (range). 0.631 (+0.039)V 0_0001b - Stable Voltage (range). 0.65 (+0.041)V 0_0010b - Stable Voltage (range). 0.67 (+0.041)V 0_0011b - Stable Voltage (range). 0.689 (+0.043)V 0_0100b - Stable Voltage (range). 0.709 (+0.044)V 0_0101b - Stable Voltage (range). 0.728 (+0.045)V 0_0110b - Stable Voltage (range). 0.748 (+0.046)V 0_0111b - Stable Voltage (range). 0.767 (+0.047)V 0_1000b - Stable Voltage (range). 0.786 (+0.049)V 0_1001b - Stable Voltage (range). 0.806 (+0.05)V

16 ALLOW_NONSECURE	Allow non-secure write access to this domain control register or domain register 0b - Do not allow non-secure write access 1b - Allow non-secure write access
15 DOMAIN_LOCK	Lock domain ID of this slot 0b - Do not lock the domain ID 1b - Lock the domain ID
14-4 —	Reserved
3-0 LOCKED_DOMAIN_ID	Domain ID of the slot to be locked Domain id3~0 maps to bit3~0. It indicates whether related domain can write to domain register or not. The slot can be accessed only when ips_domain_id is same with the value of these bits

24.5 About this module

24.5.1 Block diagram

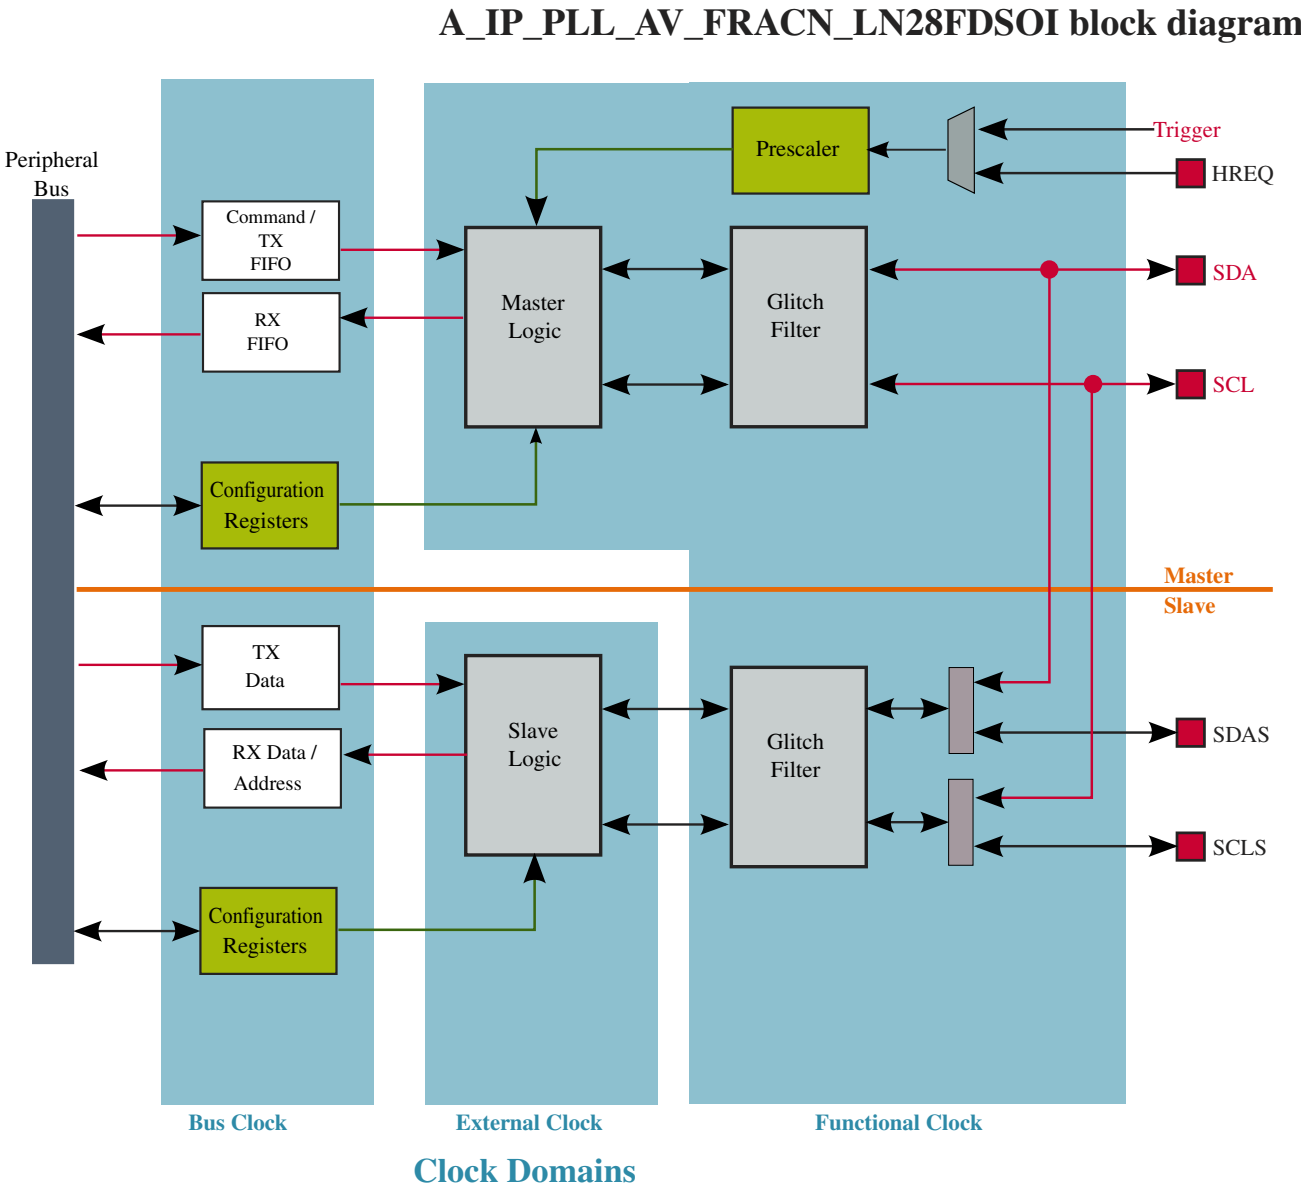

Figure 93. Fractional PLL block diagram

24.6 External signals

This table describes the module's external signals.

Signal	I/O	Description
ATRIG0	I	CFIFO 0 Auxiliary Trigger–Used only for CFIFO 0 when it's in one of the single-scan or continuous-scan edge hardware trigger modes and streaming is enabled (EQADC_CFCR0_1[STRME0] is 1b). Receives auxiliary triggers that assert the EN_TRIG0 and ADVANCE0 flags to control the streaming operation of CFIFO 0.
EWM_out_B	O	Reset Out–Gates an external circuit (application specific) that controls critical safety functions. Remains deasserted when the EWM is being regularly serviced by the CPU within the programmable service window, indicating that the application code is executed as expected.
INA_ADC1_0	I	Integration-Assigned Single-Ended ADC 1 Analog Input 0–Supplies a continuously variable voltage directly to the associated ADC for single-ended conversions to discrete positive digital values
TRIG1[7:0]	I/O	CFIFO 1 Standard Trigger–Receives triggers that initiate transfers from the associated CFIFO to the ADC command buffers. The EQADC filters this signal to prevent interpreting short-lived, noise-related state changes as valid state changes. You can change the digital filter length for all standard triggers by changing the value of EQADC_ETDFR[DFL].
VDDA	I/O	Analog Positive Power Supply–Supplies power to the integrated ADCs.

24.7 Memory Map and register definition

This section includes the Fractional PLL module memory map and detailed descriptions of all registers.

24.7.1 Fractional PLL register descriptions

24.7.1.1 FRACTIONAL_PLL memory map

AUDIO_PLL base address: 4448_4280h

ETHERNET_PLL base address: 4448_4180h

24.7.1.2 Fractional PLL Control Register (CTRL0)

Offset

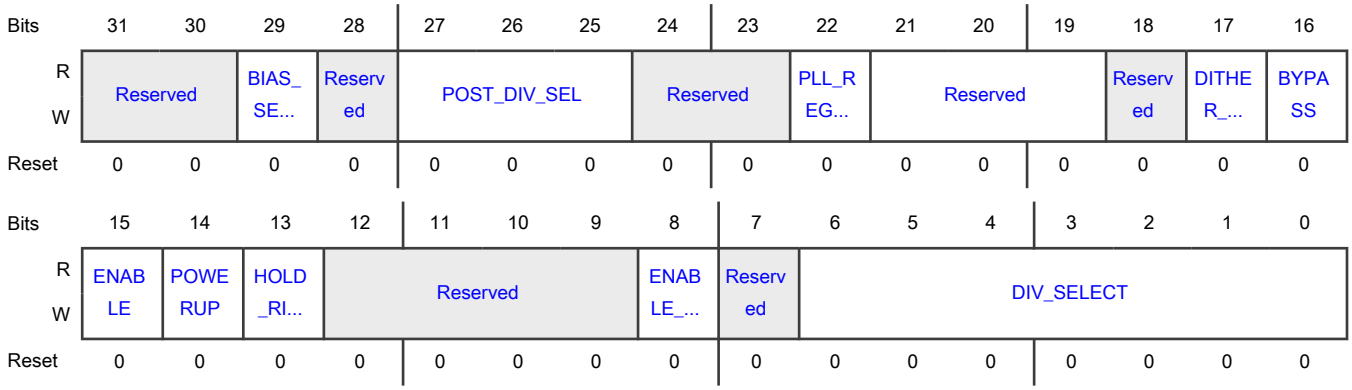
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL0	0h	Fractional PLL Control Register
CTRL0_SET	4h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL0 is 1
CTRL0_CLR	8h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL0 is 0
CTRL0_TOG	Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL0

Function

This register contains fractional pll control registers.

Diagram



Fields

Field	Function
31-30 —	Reserved
29 BIAS_SELECT	BIAS_SELECT Selects which input bias current is expected by the PLL. 0b - Used in SoCs with a bias current of 10uA 1b - Used in SoCs with a bias current of 2uA
28 —	Reserved
27-25 POST_DIV_SEL	Post Divide Select Fractional PLL Post Divider Select (glitchless clock mux) 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32
24-23 —	Reserved
22 PLL_REG_EN	PLL_REG_EN Enables the internal PLL regulator. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-19 —	Reserved
18 —	Reserved
17 DITHER_EN	DITHER_EN Enables dither in the fractional modulator calculation. 0b - Disable Dither 1b - Enable Dither
16 BYPASS	BYPASS Byapss the PLL. Output is the PLL reference clock source 0b - No Bypass 1b - Bypass the PLL
15 ENABLE	ENABLE 0b - Disable the clock output 1b - Enable the clock output
14 POWERUP	POWERUP 0b - Power down the PLL 1b - Power Up the PLL
13 HOLD_RING_OFF	PLL Start up initialization This field should be set to 1 every time during PLL lock, and cleared after a certain delay. 0b - Normal operation 1b - Initialize PLL start up
12-9 —	Reserved
8 ENABLE_ALT	ENABLE_ALT 0b - Disable the alternate clock output 1b - Enable the alternate clock output which is the output of the post_divider, and cannot be bypassed
7 —	Reserved
6-0	DIV_SELECT

Table continues on the next page...

Table continued from the previous page...

Field	Function
DIV_SELECT	This field controls the pll loop divider. Valid range for DIV_SELECT divider value: 27-54 decimal.

24.7.1.3 Fractional PLL Spread Spectrum Control Register (SPREAD_SPECTRUM)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
SPREAD_SPECTRUM	10h	Fractional PLL Spread Spectrum Control Register
SPREAD_SPECTRUM_SET	14h	Writing 1 to a bit in this register ensures that the corresponding bit in SPREAD_SPECTRUM is 1
SPREAD_SPECTRUM_CLR	18h	Writing 1 to a bit in this register ensures that the corresponding bit in SPREAD_SPECTRUM is 0
SPREAD_SPECTRUM_TOG	1Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in SPREAD_SPECTRUM

Function

This register contains fractional pll spread spectrum control registers.

Fields

Field	Function
31-16 STOP	Stop Spread Spectrum Stop Register. Frequency change = step/MFD*24MHz.
15	Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ENABLE	This bit enables the spread spectrum modulation. 0b - Disable 1b - Enable
14-0 STEP	Step Spread Spectrum Step The max frequency change = stop/MFD*24MHz.

24.7.1.4 Fractional PLL Numerator Control Register (NUMERATOR)

Offset

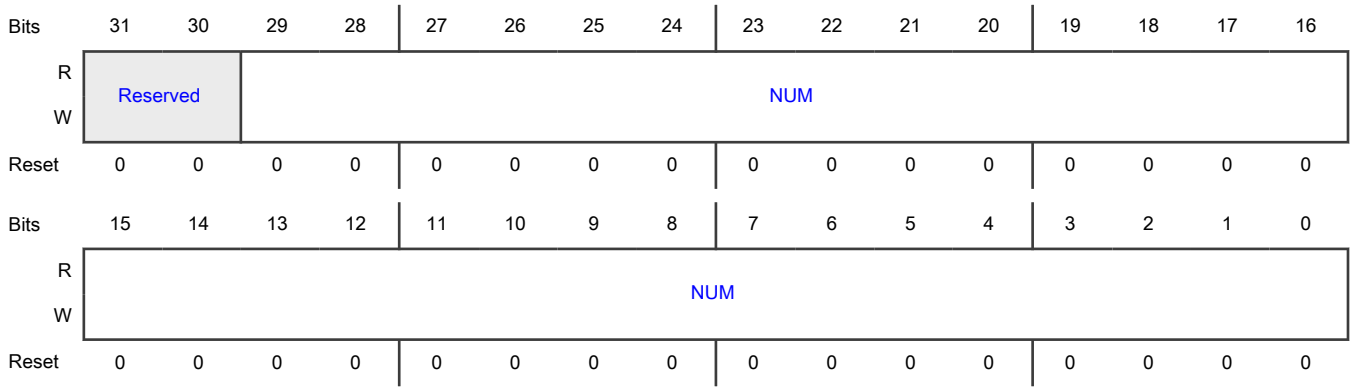
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
NUMERATOR	20h	Fractional PLL Numerator Control Register
NUMERATOR_SET	24h	Writing 1 to a bit in this register ensures that the corresponding bit in NUMERATOR is 1
NUMERATOR_CLR	28h	Writing 1 to a bit in this register ensures that the corresponding bit in NUMERATOR is 0
NUMERATOR_TOG	2Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in NUMERATOR

Function

This register contains fractional pll numerator control registers.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-0 NUM	Numerator Numerator of PLL Fractional Loop Divider. 2's complement .

24.7.1.5 Fractional PLL Denominator Control Register (DENOMINATOR)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
DENOMINATOR	30h	Fractional PLL Denominator Control Register
DENOMINATOR_SET	34h	Writing 1 to a bit in this register ensures that the corresponding bit in DENOMINATOR is 1
DENOMINATOR_CLR	38h	Writing 1 to a bit in this register ensures that the corresponding bit in DENOMINATOR is 0
DENOMINATOR_TOG	3Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in DENOMINATOR

Function

This register contains fractional pll denominator control registers.

24.8.2 Analog Control Register CTRL0 (CTRL0)

Offset

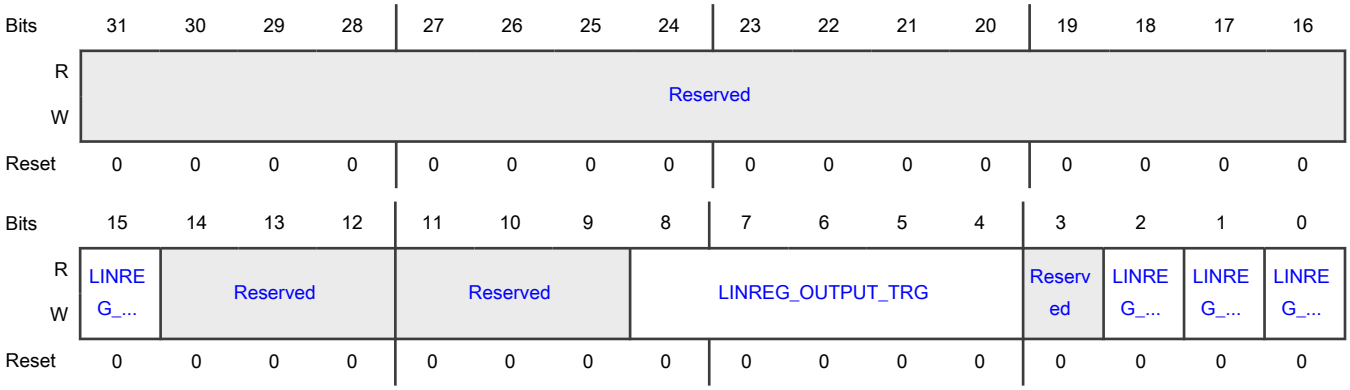
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL0	0h	Analog Control Register CTRL0
CTRL0_SET	4h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL0 is 1
CTRL0_CLR	8h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL0 is 0
CTRL0_TOG	Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL0

Function

This register contains analog control bits.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 LINREG_PHY_ISO_B	Isolation control for attached PHY load This control bit is to be used by the system controller to isolate the attached PHY load when the LinReg is powered down. During a power-up event of the regulator it is expected that this control signal is set high at least 100us after the main regulator is enabled. During a power-down event of the regulator it is expected that this control signal is set low before the main regulator is disabled/power-down.
14-12 —	Reserved
11-9 —	Reserved
8-4 LINREG_OUTPUT_TRG	LinReg output voltage target setting LinReg output voltage target setting. The nominal voltage step per code is 25mV. Setting the output voltage beyond the technology reliability limit is not recommended.
3 —	Reserved
2 LINREG_ILIMIT_EN	LinReg current-limit enable LinReg current-limit enable. Setting this bit will enable the current-limiter in the regulator.
1	LinReg power-up load disable LinReg power-up load disable control bit.

Table continues on the next page...

Field	Function
LINREG_PWR UPLOAD_DIS	0b - Internal pull-down enabled 1b - Internal pull-down disabled
0 LINREG_EN	LinrReg master enable LinReg master enable. Setting this bit will enable the regulator.

24.8.3 Analog Status Register STAT0 (STAT0)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
STAT0	50h	Analog Status Register STAT0
STAT0_SET	54h	Writing 1 to a bit in this register ensures that the corresponding bit in STAT0 is 1
STAT0_CLR	58h	Writing 1 to a bit in this register ensures that the corresponding bit in STAT0 is 0
STAT0_TOG	5Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in STAT0

Function

This register contains analog status bits.

24.9.2 Analog Control Register CTRL0 (CTRL0)

Offset

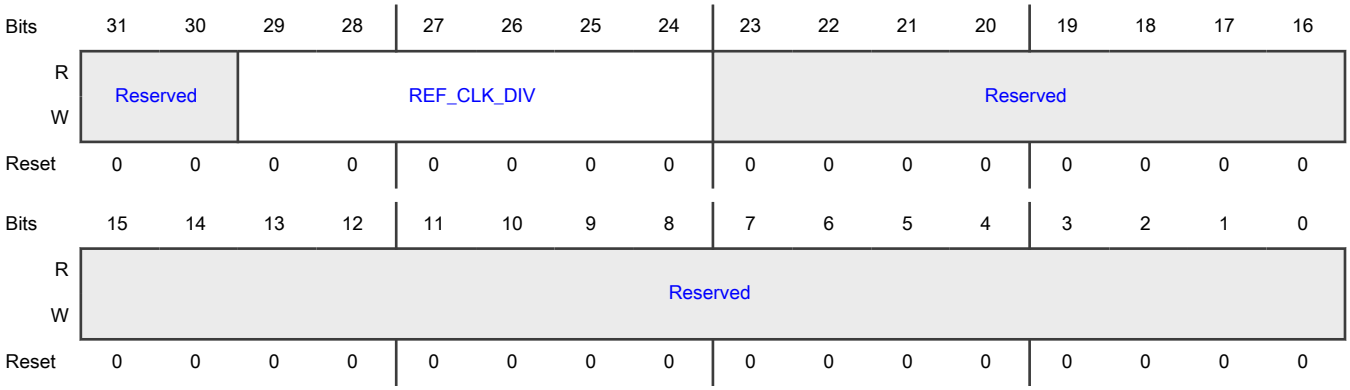
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL0	0h	Analog Control Register CTRL0
CTRL0_SET	4h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL0 is 1
CTRL0_CLR	8h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL0 is 0
CTRL0_TOG	Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL0

Function

This register contains analog control bits.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 REF_CLK_DIV	Divide value for ref_clk to generate slow_clk. Divide value for ref_clk to generate slow_clk. 0: divide by 1 1-63: corresponding division by 1-63.
23-0 —	Reserved

24.9.3 Analog Control Register CTRL1 (CTRL1)

Offset

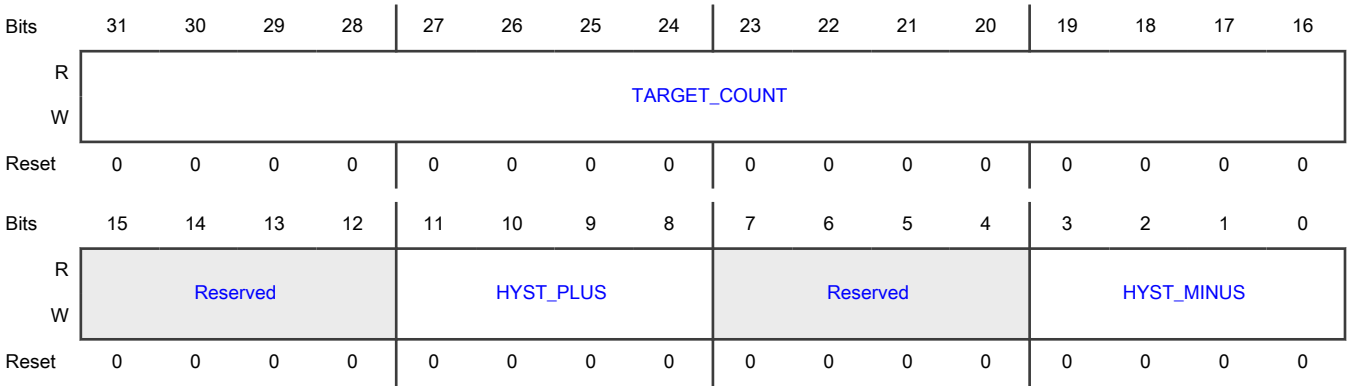
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL1	10h	Analog Control Register CTRL1
CTRL1_SET	14h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL1 is 1
CTRL1_CLR	18h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL1 is 0
CTRL1_TOG	1Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL1

Function

This register contains analog control bits.

Diagram



Fields

Field	Function
31-16 TARGET_COUNT	Target count for the fast clock. Desired target for the fast clock(osc_out_400m). Value in no. of clock cycles of the fast_clk(osc_out_400m) per divided ref_clk.
15-12 —	Reserved
11-8 HYST_PLUS	Positive hysteresis value for the tuned clock. Positive hysteresis value for the tuned clock. Set this value after the clock is tuned. Value in no. of clock cycles of the fast clock(osc_out_400m).
7-4	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
3-0 HYST_MINUS	Negative hysteresis value for the tuned clock. Negative hysteresis value for the tuned clock. Set this value after the clock is tuned. Value in no. of clock cycles of the fast clock(osc_out_400m).

24.9.4 Analog Control Register CTRL2 (CTRL2)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL2	20h	Analog Control Register CTRL2
CTRL2_SET	24h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL2 is 1
CTRL2_CLR	28h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL2 is 0
CTRL2_TOG	2Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL2

Function

This register contains analog control bits.

31-24	Program the oscillator frequency.

Table continues on the next page...

Table continued from the previous page...

Field	Function
OSC_TUNE_VAL	These bits determine the frequency of oscillator when tuning is not enabled. Frequency varies with PVT. 0 - Lowest frequency. 255 - Highest frequency.
23-15 —	Reserved
14 TUNE_START	Start/Stop tuning. 0: Stop tuning and reset the tuning logic. Oscillator runs using programmed OSC_TUNE_VAL. 1: Start tuning.
13 —	Reserved
12 TUNE_EN	Freeze/Unfreeze the tuning value. 0: Freezes the tuning at the current tuned value. Oscillator runs at the frozen tuning value. 1: Unfreezes and continues the tuning operation.
11 —	Reserved
10 TUNE_BYP	Bypass the tuning logic 0: Use the output of tuning logic to run the oscillator. 1: Bypass the tuning logic and use the programmed OSC_TUNE_VAL to run the oscillator.
9 —	Reserved
8 TUNE_INV	Inverse tuning direction. 0: Normal tuning. 1: Inverse the direction of tuning. For DEBUG only.
7-0 —	Reserved

24.9.5 Analog Control Register CTRL3 (CTRL3)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL3	30h	Analog Control Register CTRL3
CTRL3_SET	34h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL3 is 1

Table continues on the next page...

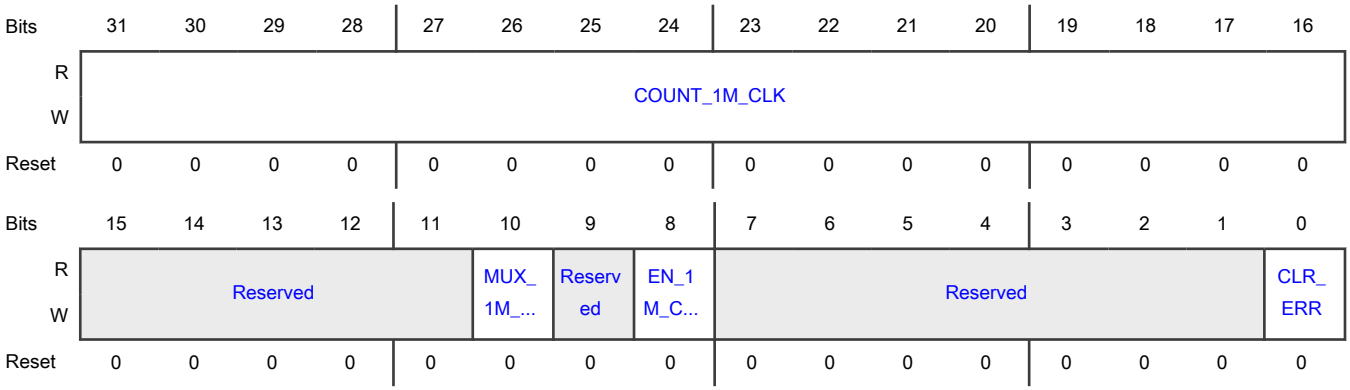
Table continued from the previous page...

Register	Offset	Description
CTRL3_CLR	38h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL3 is 0
CTRL3_TOG	3Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL3

Function

This register contains analog control bits.

Diagram



Fields

Field	Function
31-16 COUNT_1M_CLK	Count for the locked clk_1m_out. Desired target for the locked clk_1m_out. Value in no. of clock cycles of the fast_clk(osc_out_400m) per divided ref_clk. This value should be 4 to 8 counts less than TARGET_COUNT-HYST_MINUS.
15-11 —	Reserved
10 MUX_1M_CLK	Select free/locked 1MHz output 0: Select free-running 1MHz to be put out on clk_1m_out. 1: Select locked 1MHz to be put out on clk_1m_out.
9 —	Reserved
8 EN_1M_CLK	1: Disable clk_1m_out. 0: Enables the output clk_1m_out. Though the name is EN_1M_CLK, it's funtion is inverted in analog to make this clock enabled by default. 1: Disable the output clk_1m_out.
7-1	Reserved

Table continues on the next page...

25.2 Overview

BBNSM serves as non-volatile logic and storage for the system.

25.2.1 Block diagram

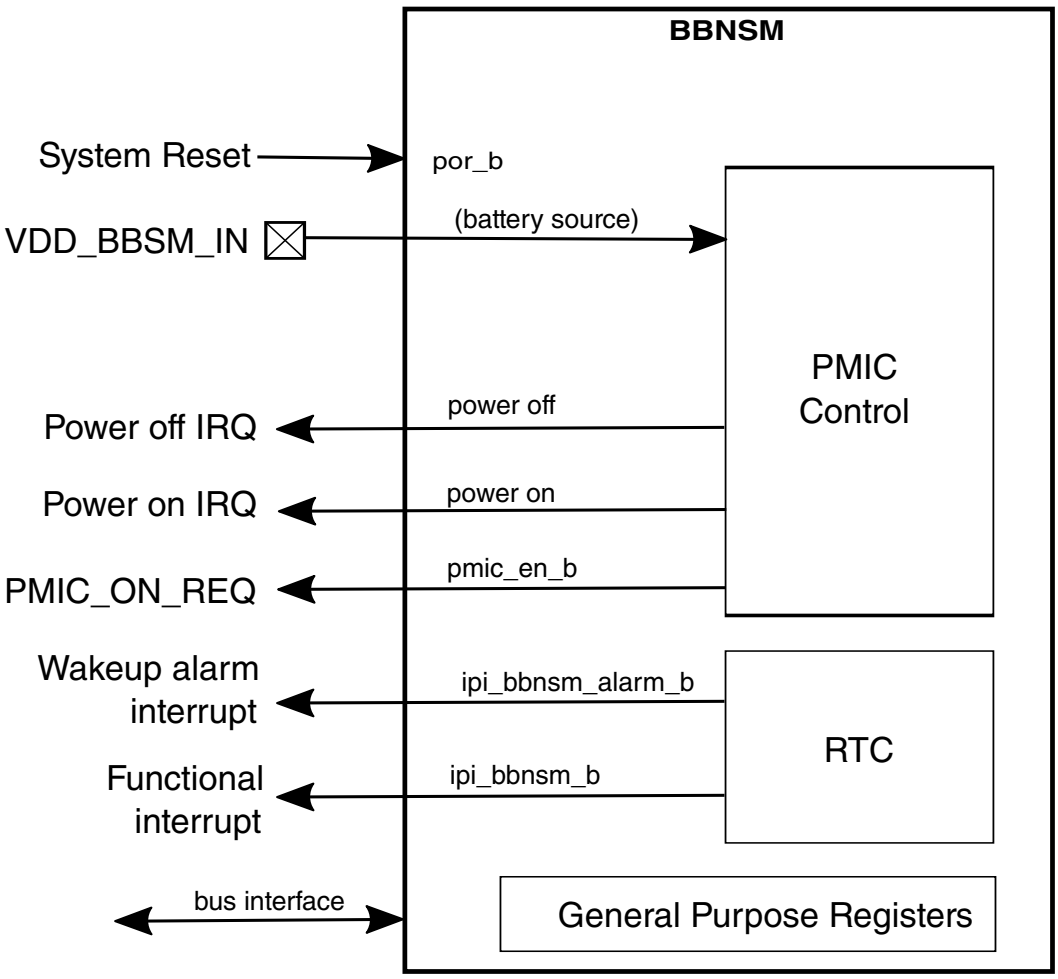

Figure 94. BBNSM block diagram

25.2.2 Features

BBNSM implements the following features:

Table 161. BBNSM feature list

Feature	Description
Non-volatile storage and logic (PMIC logic)	• If the BBNSM power input is connected to an uninterrupted power supply: — BBNSM register values are maintained even when the main SoC is powered off — BBNSM logic continues to operate even when the main SoC is powered off

Table continues on the next page...

Table 161. BBNSM feature list (continued)

Feature	Description
General-purpose register	• The general-purpose register is available to software to store data. It is 8 registers of 32 bits each by default.
Real-time counter (RTC)	• Triggers an interrupt if the RTC reaches its maximum value. • A time alarm can be programmed to generate an interrupt at a specific time.
On/Off Control	• Allows connectivity to a Power Management Integrated Circuit (PMIC) or other voltage regulator devices. • Configurable debounce support for button presses.

25.3 Functional description

The following sections describe functional details of the BBNSM module.

25.3.1 Real-Time Counter (RTC)

BBNSM implements a real-time counter that:

- Retains its state and continues counting even when the main chip is powered down. The BBNSM power input is connected to an uninterrupted power supply
- Generates an interrupt when it reaches the maximum value of all ones. It will then rollover and continue to count
- Generates a functional interrupt request at a particular time by setting the desired time in the Time Alarm register and setting BBNSM_CTRL[TA_EN]
- Can be written at any time
- Can be calibrated so that its count frequency tracks some other time source
- Can be configured to capture the time of a security violation

25.3.1.1 Time Counter Calibration

The real-time counter accuracy may suffer from a drift in the clock, which is used to increment the RTC register. To compensate for this drift, a clock calibration mechanism can adjust the RTC value. It is up to the system processor to decide whether calibration is required or not. If RTC correction is required, enable the mechanism and set the calibration value in the control register. The calibration value (BBNSM_CTRL[CAL_VAL]) includes the sign bit, which is implemented in twos' complement.

If the calibration mechanism is enabled, the calibration value is added or subtracted from the RTC on a periodic basis, once per 32768 cycles of the RTC clock.

The following table shows the available correction range.

Table 162. Real-time counter calibration settings

Calibration setting (BBNSM_CTRL[CAL_VAL])	Correction in counts per 32768 cycles of the counter clock
01111	+15
...	...
00010	+2

Table continues on the next page...

Table 162. Real-time counter calibration settings (continued)

Calibration setting (BBNSM_CTRL[CAL_VAL])	Correction in counts per 32768 cycles of the counter clock
00001	+1
00000	0
11111	-1
11110	-2
...	...
10001	-15
10000	-16

25.3.1.2 Time Alarm

A time alarm is generated once the most significant 32 bits of the real-time counter match the value in the Time Alarm register. The time alarm can generate interrupts to alert the host processor and can wake up the host processor from one of its low-power modes. This alarm can also wake up the entire system in the power-down mode by asserting the wake-up external output signal.

25.3.2 On/Off Control

The on/off logic inside the BBNSM allows for connecting directly to a PMIC or other voltage regulator device. The module has a button input signal and a wakeup request input signal. It also has two interrupts (power off and power on) and an active-low PMIC enable (pmic_en_b) output. The module can function in two different modes of operation (Dumb PMIC mode and Smart PMIC mode).

25.3.2.1 Smart PMIC Mode

In Smart PMIC mode, BBNSM can generate interrupt outputs (power off and power on) like in Dumb PMIC mode. However, the pmic_en_b signal is a pulse and active-high signal in Smart PMIC mode instead of a level and active-low signal in Dumb PMIC mode. The only configuration option available for this mode is the debounce configuration, which is used for the power off and power on interrupts in the same way as Dumb PMIC mode.

25.3.2.1.1 Smart PMIC Enable Control

The active-high pmic_en_b output asserts if either condition occurs:

- the button input signal asserts
- the wakeup alarm triggers when system power has failed (isolation enable is asserted)

25.3.2.2 Dumb PMIC Mode

In Dumb PMIC mode, BBNSM can generate interrupt outputs (power off and power on) and control the active-low PMIC enable output (pmic_en_b).

25.3.2.2.1 Dumb PMIC Enable Control

The pmic_en_b signal is active (ON state) at reset. In the ON state, the pmic_en_b is deactivated (to OFF state) if either condition occurs:

- the button input signal asserts longer than the BBNSM_CTRL[BTN_TIMEOUT] configuration
- the BBNSM_CTRL[TOSP] bit is set

In the OFF state, the pmic_en_b is activated (to ON state) if either condition occurs:

- the button input signal asserts longer than the BBNSM_CTRL[TURN_ON_TIME] configuration
- the external wakeup request signal asserts
- the wakeup alarm triggers from programming the time alarm and enabling the real-time counter

The behavior of the pmic_en_b signal is described in the state machine below.

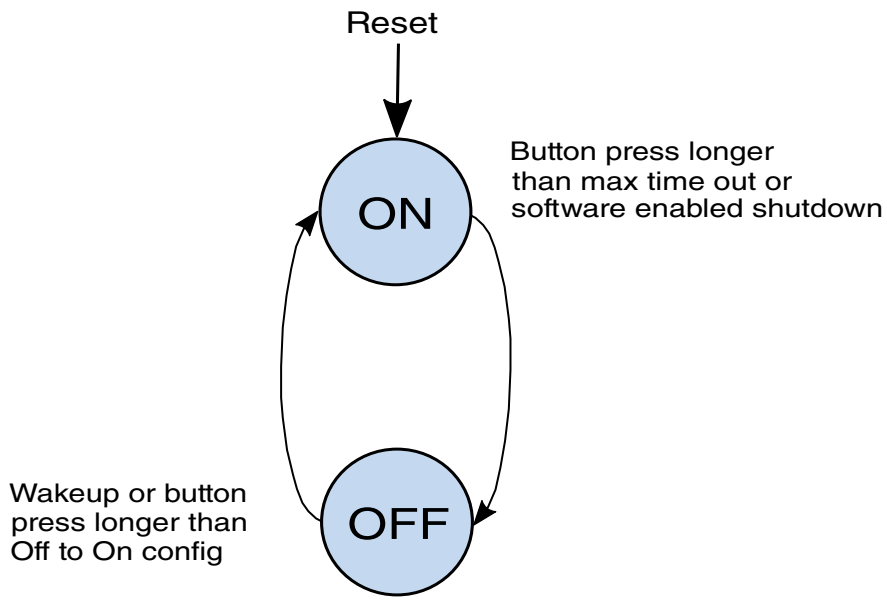

Figure 95. PMIC Enable State Machine (Dumb PMIC Mode)

25.3.3 Clocking

Table 163. BBNSM Clock

Clock	Description
32kHZ RTC clock	Clock is used by BBNSM real-time counter. This clock does not need to be synchronous with other clocks

25.3.4 Reset

Table 164. BBNSM Reset

Reset	Description
por_b	Power-on reset

25.3.5 Interrupts and Alarms

BBNSM provides the following interrupts and alarms:

Table 165. Interrupts and alarms summary

Interrupt/Violation	Event	Default configuration[1]	Configuration options
Functional interrupt (ipi_bbnsm_b)	RTC rollover	Disable	Enable/disable
Wakeup alarm interrupt (ipi_bbnsm_alarm_b)	RTC time alarm	Disable	Enable/disable
Power off interrupt	Button input signal	50 msec debounce	Debounce time
Power on interrupt	Button input signal	50 msec debounce	Debounce time

1. Default configuration refers to the state after reset.

25.3.5.1 PMIC Interrupts

The interrupts behave identically in Smart and Dumb PMIC modes.

The power on asserts if:

- system power has failed (isolation enable is asserted), **and**
- the button input signal asserts longer than the BBNSM_CTRL[DEBOUNCE] configuration

The power off asserts if:

- system power has not failed (isolation enable is not asserted), **and**
- the button input signal asserts longer than the BBNSM_CTRL[DEBOUNCE] configuration

25.4 External Signals

The table below lists the external signals to the BBNSM.

Table 166. BBNSM external signals

Signal	Description	Direction
ONOFF (btn)	Active-high external on/off button	Input
PMIC_ON_REQ (pmic_en_b)	PMIC on request signal. Active-low supply enable in dumb PMIC mode, active-high pulse in smart PMIC mode	Output

25.5 Initialization

There are no initialization steps.

25.6 Memory Map and register definition

This section includes the BBNSM module memory map and detailed descriptions of all registers.

25.6.1 BBNSM register descriptions

25.6.1.1 BBNSM memory map

BBNSM base address: 4444_0000h

25.6.1.2 BBNSM Version ID Register (BBNSM_VID)

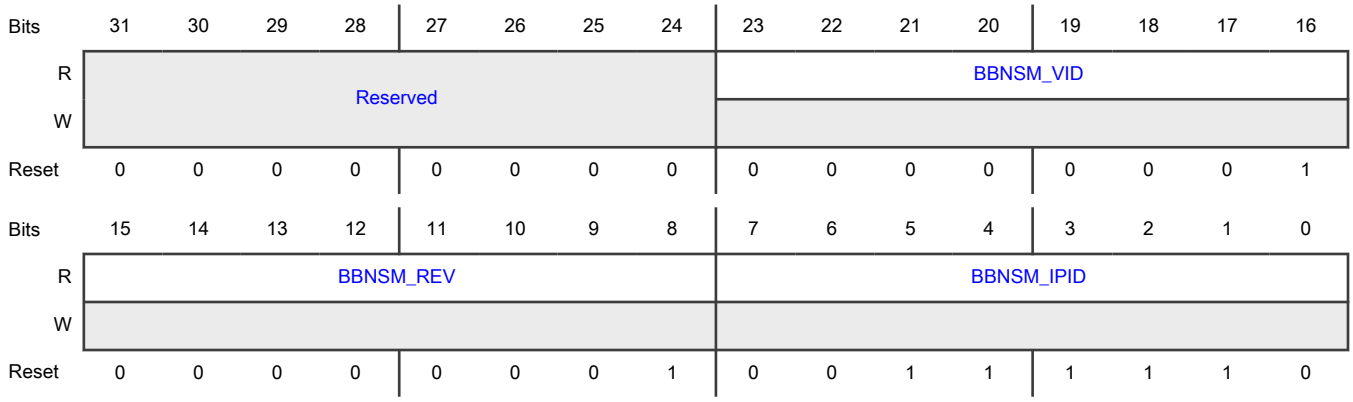
Offset

Register	Offset
BBNSM_VID	0h

Function

The BBNSM Version ID register can be used by software to differentiate between different versions of the BBNSM and determine what options are implemented in this version of BBNSM. The bit assignments of this register appear below.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 BBNSM_VID	BBNSM Version ID Version identifier or major version ID of the BBNSM.
15-8 BBNSM_REV	BBNSM Revision Revision number or minor version ID of the BBNSM.
7-0 BBNSM_IPID	BBNSM IP ID Identifier for the Battery-Backed Non-Secure Module.

25.6.1.3 BBNSM Features Register (BBNSM_FEATURES)

Offset

Register	Offset
BBNSM_FEATURES	4h

Function

The BBNSM Features register indicates which optional features are implemented in this version of BBNSM. The bit assignments of this register appear below.

Table continued from the previous page...

Field	Function
28-26 —	Reserved
25 TOSP	Turn Off System Power When set, a signal is sent to the PMIC to turn off the system power. This bit will clear once power is off. This bit is only valid when Dumb PMIC is enabled. 0b - Leave system power on. 1b - Turn off system power when Dumb PMIC is enabled.
24 DP_EN	Dumb PMIC Enable When set, software can control the system power. When cleared, the system requires a Smart PMIC to automatically turn power off. 0b - Smart PMIC is enabled. 1b - Dumb PMIC is enabled.
23 PK_OVR	PMIC On Request Override The value written to PK_OVR will be asserted on output signal bbnsm_pk_override. That signal is used to override the IOMUX control for the PMIC I/O pad. 0b - PMIC On Request Override is disabled. 1b - PMIC On Request Override is enabled.
22 PK_EN	PMIC On Request Enable The value written to PK_EN will be asserted on output signal bbnsm_pk_en. That signal is used to turn off the pullup/pulldown circuitry in the PMIC I/O pad. 0b - PMIC On Request is disabled. 1b - PMIC On Request is enabled.
21-20 TURN_ON_TIME	Turn-On Time Amount of time that button is pressed before pmic_en_b is asserted to turn on the SoC power. 00b - 500 milliseconds. 01b - 50 milliseconds. 10b - 100 milliseconds. 11b - 0 milliseconds.
19-18 DEBOUNCE	Debounce Time Amount of debounce time for the BTN input signal. 00b - 50 milliseconds. 01b - 100 milliseconds.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - 500 milliseconds. 11b - 0 milliseconds.
17-16 BTN_TIMEOUT	Button Press Timeout Time it takes to hold the button to request a power down. 00b - 5 seconds. 01b - 10 seconds. 10b - 15 seconds. 11b - Timeout disabled. Long button presses will not request a power down.
15-13 —	Reserved
12-8 CAL_VAL	Calibration Value Defines signed calibration value for the RTC. This field can be programmed only when RTC calibration is disabled. This is a 5-bit twos' complement value. Hence, the allowable calibration values are in the range from -16 to +15 counts per 32768 ticks of the counter clock. 0_0000b - +0 counts per each 32768 ticks of the counter clock. 0_0001b - +1 counts per each 32768 ticks of the counter clock. 0_0010b - +2 counts per each 32768 ticks of the counter clock. 0_1111b - +15 counts per each 32768 ticks of the counter clock. 1_0000b - -16 counts per each 32768 ticks of the counter clock. 1_0001b - -15 counts per each 32768 ticks of the counter clock. 1_1110b - -2 counts per each 32768 ticks of the counter clock. 1_1111b - -1 counts per each 32768 ticks of the counter clock.
7-5 —	Reserved
4 CAL_EN	Calibration Enable Enables the RTC calibration mechanism when set. This bit cannot be changed once set. 0b - RTC Time calibration is disabled. 1b - RTC Time calibration is enabled.
3-2 TA_EN	Time Alarm Enable 01b - Disable the time alarm. 10b - Enable the time alarm. A time alarm event occurs if the value in the real-time counter register is equal to the value in the time alarm register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1-0 RTC_EN	Real-Time Counter Enable 01b - Disable the real-time counter. 10b - Enable the real-time counter.

25.6.1.5 BBNSM Interrupt Enable Register (BBNSM_INT_EN)

Offset

Register	Offset
BBNSM_INT_EN	10h

Function

The BBNSM Interrupt Enable Register is used to enable interrupt generation when a status event has occurred in BBNSM. Interrupts supported include RTC rollover and time alarm. The bit assignments of this register appear below.

Diagram

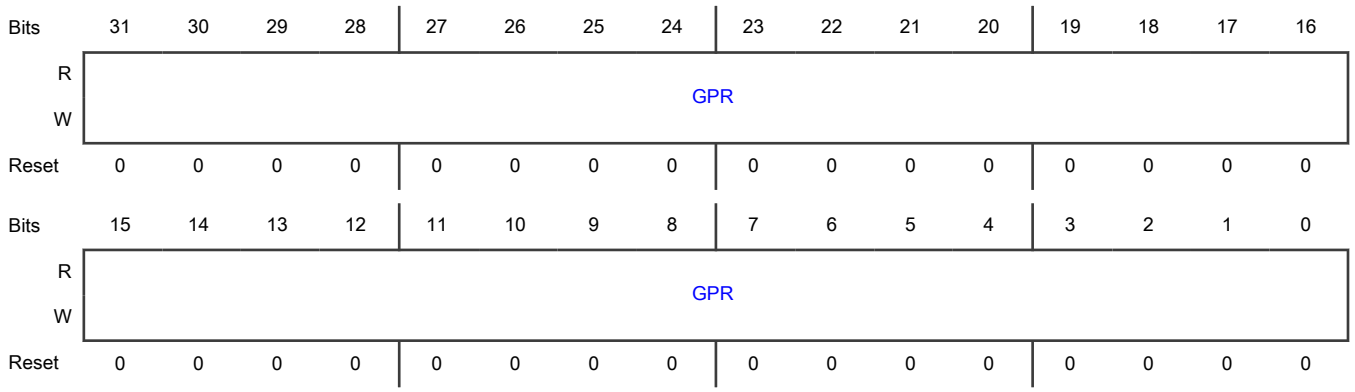
GPRa	300h + (a × 4h)

Function

The GPR register array holds data whose value is retained across power cycles of the SoC. The words of the array can be used to store general purpose data.

It is up to ELKe firmware to determine how the space in the array is allocated.

Diagram



Fields

Field	Function
31-0 GPR	32 bits of the GPR.

Chapter 26
Fusemap

26.1 Overview

This section details the various fuses and their associated configuration settings. This chapter also describes various modes and the selection of the required boot devices.

NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only, or are security related. Customers must not attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'. Security-related fuses are described in the Security Reference Manual (SRM) for this device.

26.1.1 Lock bits

There are three bits per lock, read, write, and overwrite.

The write lock bits are used by the controller to control writing/programming of the fuse bits and the shadow registers (which hold the value read from the fuses). Each word can be write locked independently, which means that it can no longer be programmed. If the word is write locked, only read is permitted and the overwriting of the shadow registers is not permitted. If the word is not locked, then it can be read sensed and programmed and the shadow registers can be overwritten (to allow emulation of programming without actually blowing fuses). The supplemental array of fuses are always override locked.

Read lock bits are a specific set of fuses that give you the ability to block bus access to specific words. Read locks are on parts of the array consisting of multiple words. The bits for these are stored in the supplementary array section in the last word.

Table 167. Lock Fuses

Fuse Word Index	Fuse Bit Index	# of fuses	Fuse Lock	Function	Setting	Used By
0	0	3	BOOT_CFG_LOCK	Boot Configuration Lock	000 - Unlocked (fuses can be read, sensed, burned or over-ridden in the corresponding OTP shadow register) xx1 - WP (Write Protect, the controlled field can not be burned) x1x - OP (Over-ride Protect, the controlled field shadow registers can not be over-written) 1xx - RP (Read Protect, the controlled field can be sensed only, but can't be read from shadow registers)	ELE
0	12	3	LOCK_CFG_LOCK	Lock for Fuse Lock bits	000 - Unlocked (fuses can be read, sensed, burned or over-ridden in the corresponding OTP shadow register)	ELE

26.2 Boot Fusemap

This section describes the various modes and the selection of the required boot devices. A separate map is given for each and every boot device. The device select is specified by the BOOT_CFG0[2:0] fuses.

Table 168. Boot device select

Boot Device	BOOT_CFG0[2]	BOOT_CFG0[1]	BOOT_CFG0[0]
FlexSPI (Serial NOR)	0	0	0
FlexSPI (Serial NAND)	0	0	1
MMC/eMMC	0	1	0
SD	0	1	1
SEMC SLC (NAND)	1	0	0
Serial Boot	1	0	1

NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only. Customers **must not** attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'. Security-related fuses are described in the Security Reference Manual (SRM) for this device.

The Fuse Word Index and Fuse Bit Index mapping for the BOOT_CFGn fuses is provided in the following table.

The following table applies for all boot devices.

Table 169. Configuration fuses

Fuse Word Index [Fuse Bit Index]	7	6	5	4	3	2	1	0
24 [775:768]	FORCE_BT_FROM_FUSE	BT_FUSE_SEL 0 - BOOT_MO	DIS_SDMMC_MFG_BOOT 0 - Enable	RECOVERY_BOOT_EN	Reserved	BOOT_MODE_FROM_FUSE 0 - FlexSPI NOR 1 - FlexSPI NAND

26.3 Fusemap Descriptions Table

This section provides the chip fusemap descriptions.

NOTE

All fuse programming operations go through ELE.

NOTE

Also see the EdgeLock Secure Enclave (ELE) API Reference Guide.

The following two mechanism are used by the fuse block to ensure that its values are correct:

- Redundancy (RED) mode: In this case only 16 of the 32 bits are available (bits 15:0 are automatically copied to bits 31:16) and checked on read. Each pair of bits can be programmed at different times. This allows for multiple programming operations on a word, so bits can be configured at different times.
- ECC mode: The ECC is generated for the whole word. The whole word must be setup at one time and individual bits cannot be modified independently.

Table 177. Fusemap Descriptions

Fuse Word Index	Fuse Bit Index	# of fuses	Fuse Name	Function	Comments	Read Locked by	ECC/RED

27.2 Overview

SRC is responsible for the generation of all the system reset signals and boot argument latching. Its main functions are as follows:

- Deals with all global system reset sources from other modules, and generates global system reset.
- Responsible for power gating of MIXs (slices) and their memory low power control. To make sure the chip's function while turning off some MIXs or memory power, SRC uses a fixed sequence to power off/on MIXs.

27.2.1 Block diagram

There are two major sub-modules in SRC according to its main functions, as shown in the block diagram.

- Global system reset control: collects all reset sources from other modules to generate global system reset to the whole chip.
- Six slices or MIXs: implements UPI handshake with GPC, and generates MIX Edgelock handshake, isolation, reset and power off signals, and MIX memory low power control signals, based on GPC's request.

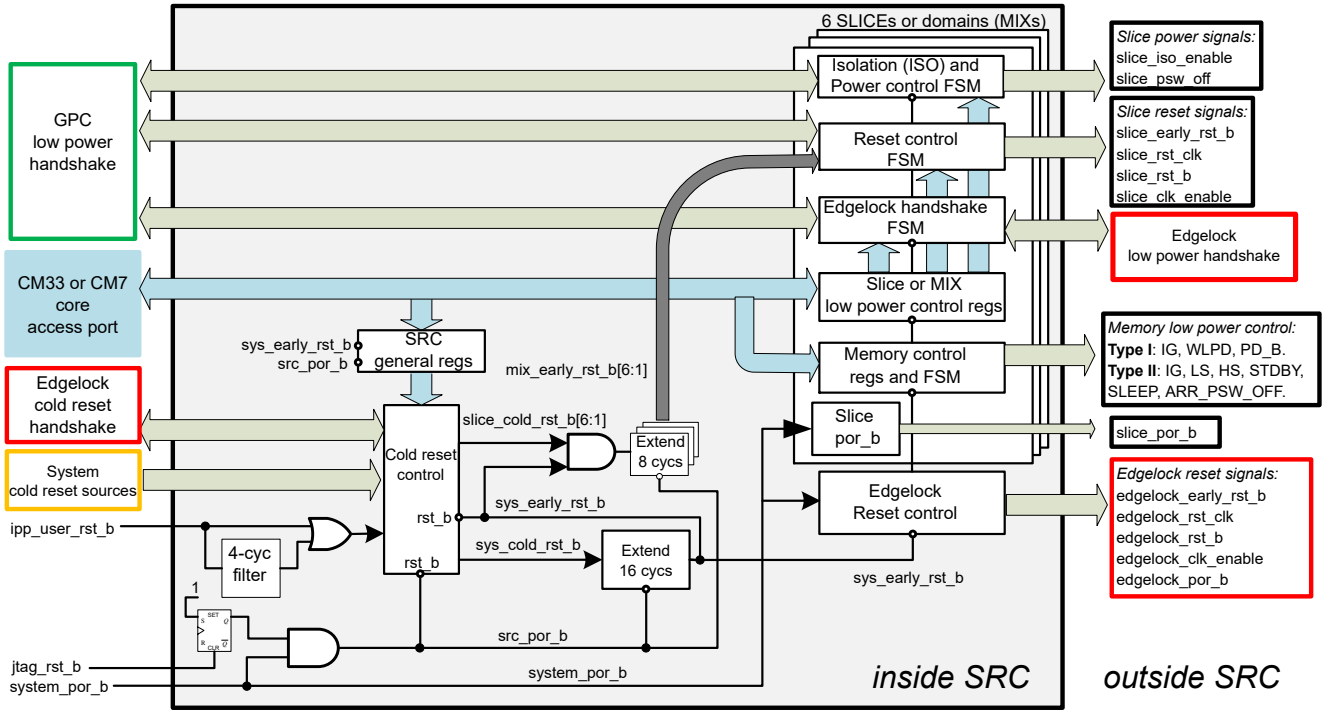

Figure 96. SRC block diagram

27.2.2 Features

SRC includes the following features:

- Receives and handles global system reset sources from other modules
- Saves the active reset source flag into the reset status register, in both DCDC and BBSM power domains
- Latches the IPP_BOOT_MODE pins from the chip top pads
- Automatic power domain control (MIXs power off/on), based on GPC's low power request
- Software power domain control (MIXs power off/on)
- Programmable registers to adjust low power sequence timing
- Programmable memory power domain control (MIXs memory power off/on and low power mode)

27.3 Functional description

The reset control determines the source and type of reset, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire chip.

The boot argument latching includes the IPP_BOOT_MODE pins latch, when the system comes out of reset.

27.3.1 Reset and Power Scheme

The chip presumes the following system reset and power schemes. See the power management chapter for more details on the specific power sources, controls, and domains.

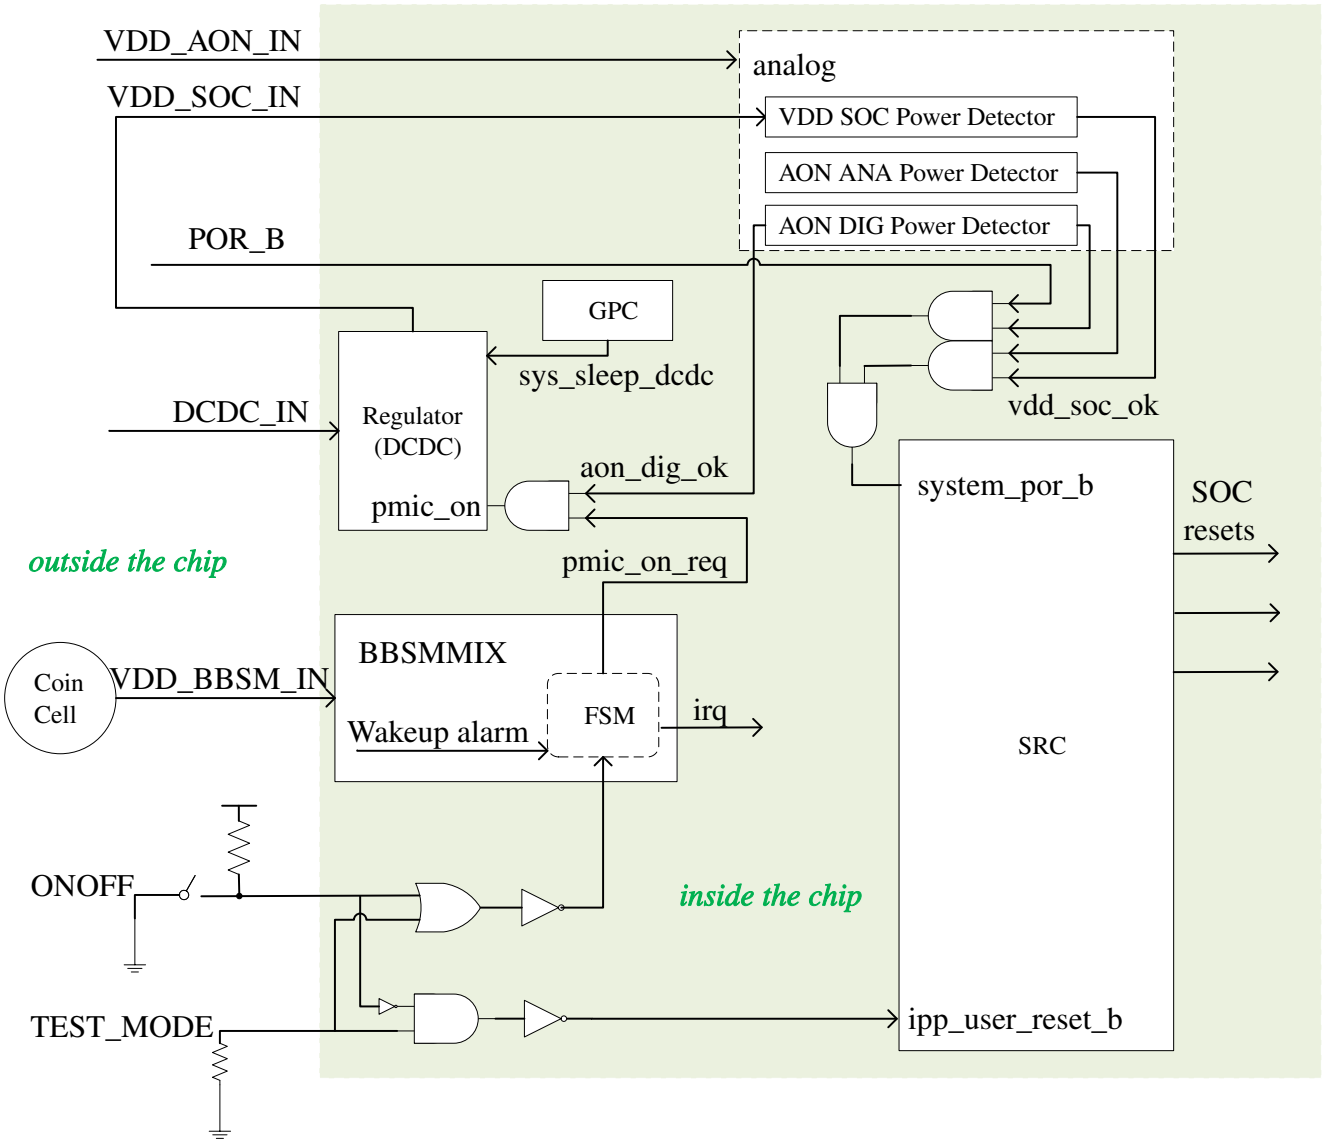

Figure 97. Chip Reset with on-chip DCDC

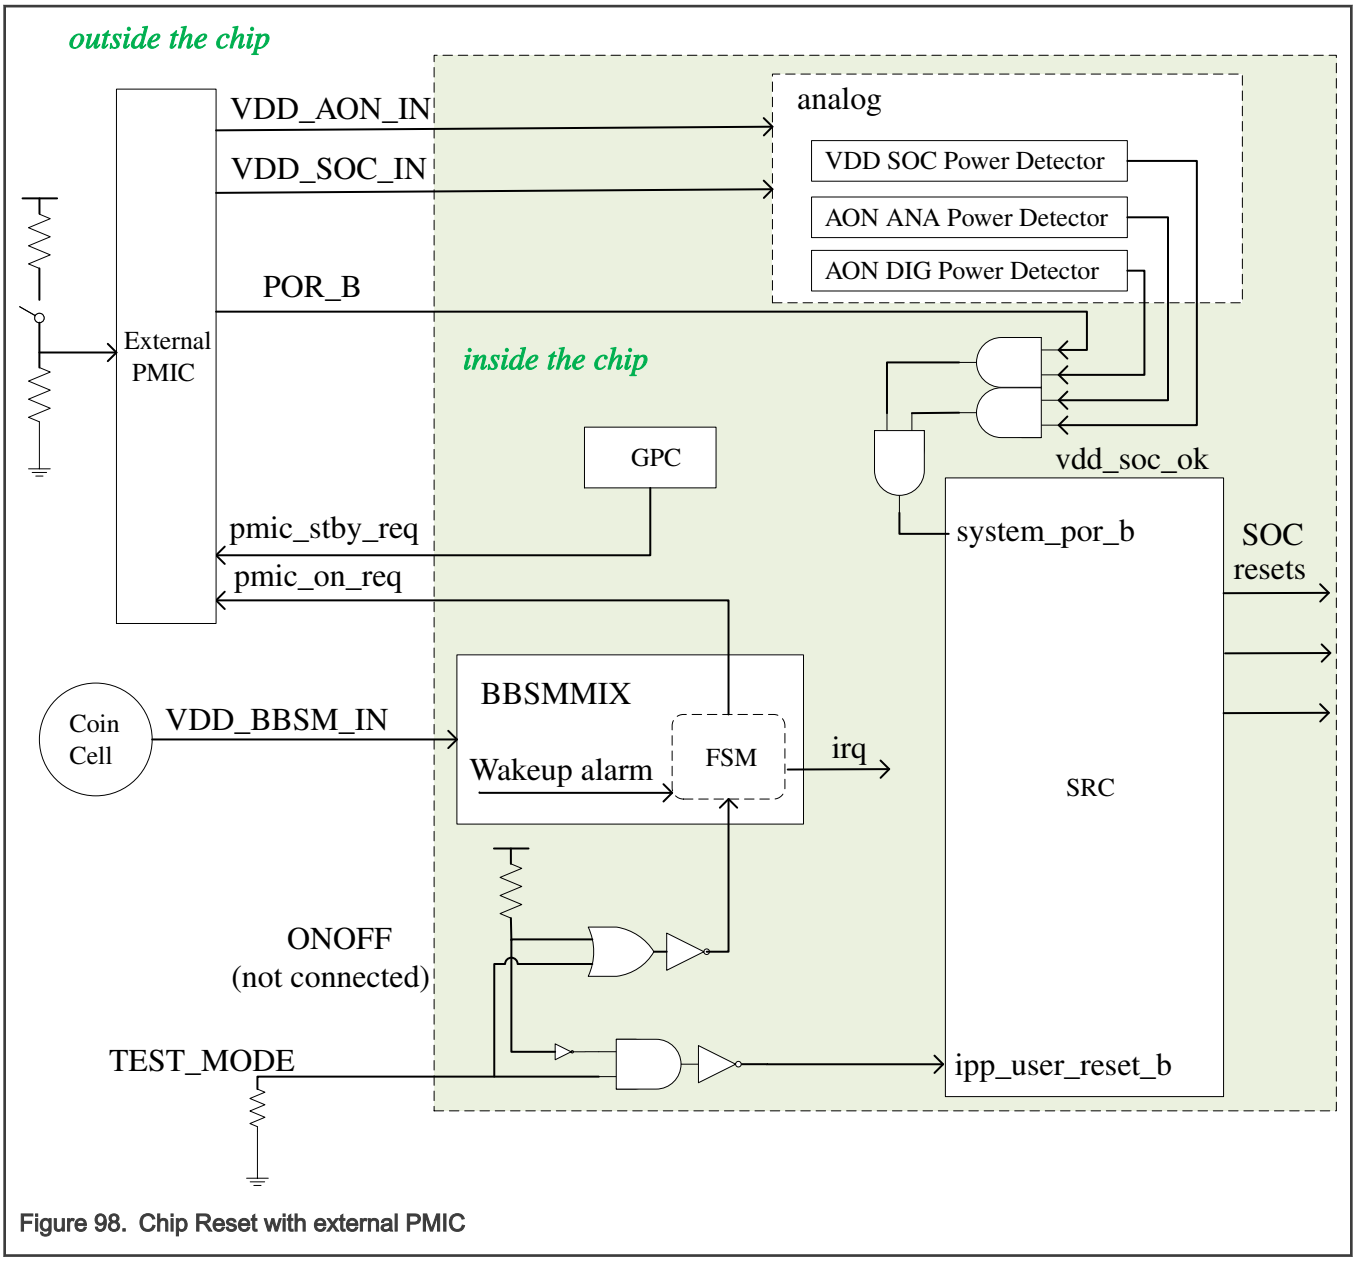

Figure 98. Chip Reset with external PMIC

27.3.2 Finite State Machine (FSM)

The FSM operation of SRC is illustrated below. The details of the states are explained in the table as well.

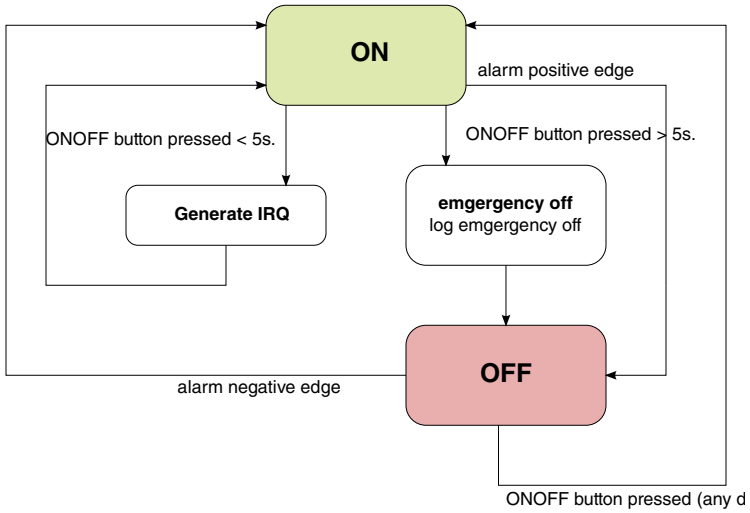

Figure 99. FSM Operation

The following table describes the ON-OFF state mechanism:

State	Configuration with external PMIC	Configuration with on-chip DCDC
ON, first time	1. BBSM is powered, PMIC_ON_REQ goes to logic '1'. 2. When PMIC button is pressed, PMIC powers on.	1. BBSM is powered, PMIC_ON_REQ goes to logic '1'. 2. VDD_AON_IN and DCDC_IN are powered. 3. Drive DCDC_PSWITCH to high, 1ms after DCDC_IN is powered. 4. DCDC regulator is enabled.
Normal ON to OFF, by button (PMIC or ONOFF)	1. PMIC button is pressed (short duration) on the external PMIC. 2. IRQ is sent to SoC from the external PMIC. 3. SoC is programing PMIC for power off when PMIC_STBY_REQ is asserted. 4. In low-power mode, the PMIC_STBY_REQ is asserted according to the GPC configuration. PMIC gates SoC supplies.	1. ONOFF button is pressed (short duration, less than 5s). 2. IRQ is sent to SoC from FSM. 3. Alarm timer is set by software routine and started. 4. Upon wakeup alarm assertion to logic '1', PMIC_ON_REQ goes to logic '0'. 5. DCDC regulator goes OFF.
Emergency On to OFF, by button (PMIC or ONOFF)	1. PMIC button is pressed long way on the external PMIC. 2. PMIC is powering off.	1. ONOFF button is pressed for longer than 5s on the SoC. 2. FSM validates ONOFF button pressed for 5s.

Table continues on the next page...

Table continued from the previous page...

State	Configuration with external PMIC	Configuration with on-chip DCDC
		3. Emergency power off is logged, PMIC_ON_REQ goes to logic '0'. 4. DCDC regulator goes OFF.
OFF to ON, by button (PMIC or ONOFF)	1. PMIC button is pressed on the external PMIC. 2. PMIC is powering on.	1. ONOFF button is pressed on the SoC. 2. PMIC_ON_REQ goes to logic '1'. 3. DCDC regulator powers ON.
OFF to ON, by timer alarm	1. Timer alarm in BBSM is programmed by software before SoC goes OFF. 2. SoC enters OFF mode. 3. Upon timer limit, wake up alarm goes to logic '0'. PMIC_ON_REQ goes to logic '1'. 4. PMIC receives assertion of PMIC_ON_REQ and wakes up.	1. Timer alarm in BBSM is programmed by software before SoC goes OFF. 2. SoC enters OFF mode. 3. Upon timer limit, wakeup alarm goes to logic '0'. PMIC_ON_REQ goes to logic '1'. 4. DCDC regulator is enabled by PMIC_ON_REQ=1.

27.3.3 Reset Control

This section describes the reset control of this device. Any of the following sources can cause a reset event:

- power-on reset (POR),
- global system reset request,
- low-power mode transition.

27.3.3.1 Reset behavior of POR

POR reset occurs when any of the following conditions is met. It resets the whole chip, except the BBSM domain, as shown in the "Power Architecture" diagram (see the "Clock and Power Overview" chapter).

- VDD_AON_IN is not supplied (**Note**: BBSM power supply must be earlier than VDD_AON_IN, or at least at the same time.)
- VDD_SOC_IN power signal not OK, indicated by the chip internal analog power detector
- LDO_AON_DIG output power signal not OK, indicated by the chip internal analog power detector
- LDO_AON_ANA output power signal not OK, indicated by the chip internal analog power detector
- Chip POR_B pad = 0
- Chip internal module JTAGC output signal jtag_reset_b = 0 (**Note**: this is not applicable in the user mode.)

NOTE

The boot argument latching is the IPP_BOOT_MODE value latching. The value of IPP_BOOT_MODE[5:3] is tied to 3'b100. And the value of IPP_BOOT_MODE[2:0] comes from the chip top pads GPIO_AON_02, GPIO_AON_01 and GPIO_AON_00. The value on chip top pads is latched to IPP_BOOT_MODE[2:0] when the chip comes out of POR reset one 32kHz clock cycle later. And the latched value cannot be changed by global system reset or slice reset.

27.3.3.2 Reset behavior of the global system reset request

As shown in the following table, global system reset sources can trigger system reset or not:

- Global system reset request can reset the whole chip, except BBSM domain, CM33 debug and trace, CM7 debug and trace, IOMUXC, reset control logic and GPR in SRC.
- Global system reset source can be masked by setting relative bits in SRC RESET MASK register. (By default, only Edgelock's global system reset source can trigger global system reset, while other reset sources are masked.)

Table 179. Global System Reset Sources

Reset sources	Description
ecat_rsto	Asserts when EtherCat outputs a reset request
dcdc_ovvt	Asserts when DCDC output power 1.0V (over 1.5V) or 1.8V (over 2.5V) voltage is too high
cm7_req_rst	Asserts when software writes SYSRESETREQ bit of register APPLICATION_INTERRUPT_CONTROL_REGISTER in CM7
cm7_lockup_rst	Asserts when CM7 lock up
cm33_req_rst	Asserts when software writes SYSRESETREQ bit of register APPLICATION_INTERRUPT_CONTROL_REGISTER in CM33
cm33_lockup_rst	Asserts when CM33 lock up
jtag_sw_b	Asserts when the debugger asserts software reset by JTAG
edgelock_rst	Asserts when Edgelock secure violation happens
tempsense_rst	Asserts when the Temper Sensor requests a reset
wdog*n*_rst	Asserts when the peripheral WDOG*n* timeouts

27.3.3.3 Reset behavior under the low-power mode transition

The reset step is one of the four steps in the low-power mode transition. After the MIX goes through power off and power on, the MIX is reset (all registers in the MIX also reset). See the following section "low-power mode transition", for more details.

NOTE

When CM7 Platform is reset, its debug and trace logic will not be reset. Only the POR reset can reset this debug and trace logic.

27.3.4 Low-power mode transition

Among the several MIXs, MEGA MIX, NETC MIX and CM7P MIX can be powered off. A fixed power off/on sequence is adopted in this chip.

The fixed power-off sequence is as follows:

1. Edgelock handshake for power-off
2. isolation asserted
3. reset asserted
4. power off MIXs or its memory

And the fixed power-on sequence is as follows:

1. power on MIXs or its memory
2. reset released
3. isolation released
4. Edgelock handshake for power-on

27.3.4.1 Control of MIX power-off

There are two ways to power off a MIX.

- GPC mode (by setting AUTHEN_CTRL[LPM_MODE] = 1)
- software (SW) mode (by setting AUTHEN_CTRL[LPM_MODE] = 0, If user fully knows how to control the power-off sequence)

NOTE

Do not change AUTHEN_CTRL[LPM_MODE] value, when the MIX is in power off/on sequence or is already in power off state.

In the GPC mode, SRC powers off the MIX under the control of GPC.

In the chip, each Core can be mapped to any of the 16 domains by TRDC. For example, CM33 Core can be mapped to both domain2 and domain15. In SRC, each MIX can be assigned to any of the 16 domains via AUTHEN_CTRL[WHITE_LIST] bits. When the bit is set, the domain's mapped Core's power state transition is considered as a low power trigger, else the transition is ignored. In each MIX, there is 16 LPM_SETTING_Dx in LPM_SETTING_1 and LPM_SETTING_2, via this software mode, configuring LPM_SETTING_Dx to select what Core power state triggers the MIX's power off/on request.

Because a MIX can be assigned to 16 domains at most, a unified arbitration rule is defined for each MIX.

- The MIX enters power-off sequence with the last active Core power state transition, if several cores (of MIX's assigned domains' mapping Cores) request the MIX to power off.
- The MIX enters power-on sequence with the first active Core power state transition, if any one core (of MIX's assigned domains' mapping Cores) requests the MIX to power on while the MIX is in power-off status.

For example, CM7P MIX can be assigned to the CM7 Core. After CM7 core requests MIX to power off/on, CM7P MIX enters power off/on sequence with CM7 Core power state transition. For comparison, MEGA MIX can be assigned to both CM33 and CM7 Cores. If only one Core requests the MIX to power off, MEGA MIX keeps in power on status. If CM33 requests the MIX to power off, and CM7 requests the MIX to power off later, then MEGAMIX enters power-off sequence with CM7 Core's power state transition. When MEGA MIX is already in power-off status, after any Core requests the MIX to power on, MEGA MIX enters power-on sequence with the Core's power state transition.

NOTE

If the MIX enters power-off/on sequence, it goes through all the four steps[1] and cannot be interrupted. So during the power-off sequence, any Core's power-on request has to be delayed until the completion of MIX's power-off sequence. During the power-on sequence, any Core's power-off request has to be delayed until the completion of MIX's power-on sequence.

27.3.4.2 MIX power-off and power-on sequence

After the initial power-up of the entire chip, all MIXs in the chip are powered on, unless the chip's CM7P MIX or NETC MIX is fused out. So each MIX must be firstly powered off before it can be powered on.

The power-off sequence of MEGA MIX, NETC MIX and CM7P MIX is as follows:

1. CPU WFI.
2. GPC sends the domain's power state change request and the Core's current low power state. SRC controls the MIX's low power sequence based on its AUTHEN_CTRL[LPM_MODE] , AUTHEN_CTRL[WHITE_LIST] and LPM_SETTING_x values.

[1] See the "Low-power mode transition" section.

- if GPC mode is adopted, then go to the next step.
- If SW mode is adopted, software can use the UPI status to check GPC's *req*. Also the software can use Slice software control to begin the whole low power sequence by one bit, or begin some or one step of the sequence.

3. GPC sends *stop clock req* to CCM, to halt the clock.
4. GPC sends *Edgelock handshake req* to SRC, to implement handshake with Edgelock.
5. GPC sends *ISO assert req* to SRC, to isolate the MIX intended to power off.
6. GPC sends *reset assert req* to SRC, to assert reset to the MIX intended to power off.
7. GPC sends *power off req* to SRC, to power off the intended MIX.

The power-on sequence of MEGA MIX, NETC MIX and CM7P MIX is as follows:

1. CPU gets interrupt to wake up from low power state.
2. GPC sends the domain's power state transition request and the Core's low power state of current domain. SRC controls the MIX's low power sequence based on its AUTHEN_CTRL[LPM_MODE] , AUTHEN_CTRL[WHITE_LIST] and LPM_SETTING_x values.
   - if GPC mode is adopted, then go to the next step.
   - if SW mode is adopted, software can use the UPI status to check GPC's *req*. Also the software can use Slice software control to begin the whole low power sequence by one bit, or begin some or one step of the sequence.
3. GPC sends *power on req* to SRC, to power on the intended MIX.
4. GPC sends *reset release req* to SRC, to release reset to the MIX intended to power on.
5. GPC sends *ISO release req* to SRC, to release isolation of the MIX intended to power on
6. GPC sends *Edgelock handshake req* to SRC, to implement handshake with Edgelock.
7. GPC sends *enable clock req* to CCM, to resume the clock.

Edgelock handshake: EDGELOCK_HDSK_CTRL and EDGELOCK_HDSK_CNT_CFG can be used to control the Edgelock handshake step. EDGELOCK_HDSK_CTRL[POFF_CNT_MODE] and EDGELOCK_HDSK_CTRL[PON_CNT_MODE] can control how *ack* affects the FSM of Edgelock handshake. FSM can wait *ack* or ignore *ack*, or use internal delay counter.

Isolation (ISO) and power switch (PSW): ISO_DLY_PRE can control the delay from ISO change request to the actual ISO change on the MIX. PSW_DLY_PRE_HF/LF can control the delay from power change request to the actual power change on the MIX. Also PSW_CTRL and PSW_CNT_CFG_HF/LF can control how *ack* affects the FSM of power change. FSM can wait *ack* or ignore *ack*, or use internal delay counter.

The following timing diagram shows an example in which a power-off sequence is seen, with UPI handshake to GPC.

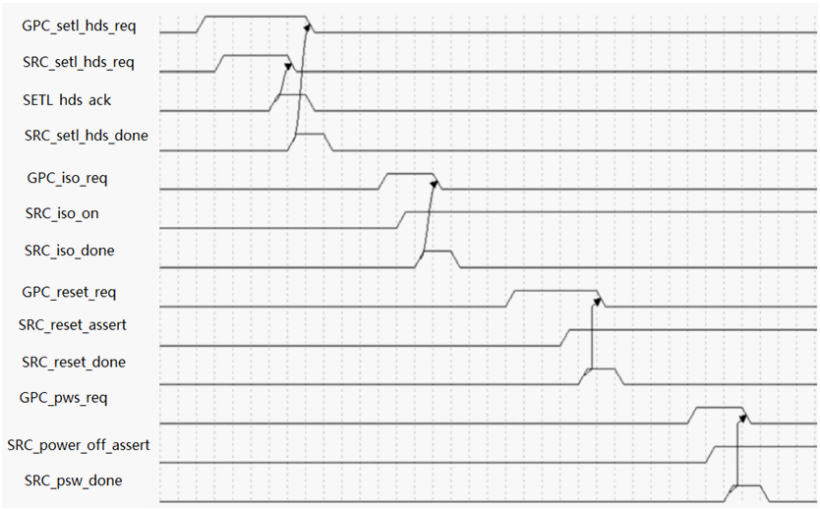

Figure 100. Power-off sequence, with UPI handshake to GPC

27.3.5 Memory low power control

Each MIX contains two kinds of memory type: MEM type I and MEM type II. Because their low power control signals are different, SRC has two types of controllers designed accordingly.

- For MEM type I, the signals (HS, LS, IG, STDBY, SLEEP and ARR_PDN) to control low power mode. [2]
- For MEM type II, the signals (IG, PD_B and WLPD) to control low power mode.

User can control the memory low power mode in either HW way or SW way. When the CM7P MIX enters power-off sequence, the memory in the MIX can change its memory power state automatically, which is the HW way (For MEGA MIX and NETC MIX, because its MIX and memory use the same power switch, its memory is powered off/on with the MIX's power off/on). Also there is a SW way to change memory power state. MEM_LP_TRIG_CTRL register selects either way.

There are two memory low power controllers in each MIX: one for cache and the other for local TCM. If there is no cache and local TCM in the MIX, then the former one controls MEM type I and the latter controls MEM type II.

MIX	Cache memory	TCM memory
AON MIX	MEM Type I	MEM Type II
WAKEUP MIX	MEM Type I	MEM Type II
MEGA MIX	MEM Type I	MEM Type II
NETC MIX	MEM Type I	MEM Type II
CM33P MIX	MEM Type I	MEM Type I
CM7P MIX	MEM Type I	MEM Type I with PSW

In HW way, set one of 8 levels of low power depth for each signal before the low power sequence, via the MEM_LP_CFG register, and let them take effect when SRC low power sequence starts. There are 8 low power levels, as shown in the following table.

In SW way, users can make their own strategy by changing values of the MPL_CTRL bits in MEM Type I and II. No matter a MIX enters power off/on sequence or a software trigger happens, the level value is always used to select one of 8 values in the MPL_CTRL bits in MEM Type I and II, and then to change the memory low power control signals accordingly.

[2] See the "Memory map and register definition" section for detailed descriptions of control signals.

Table 180. Reset value of memory low power control

Signal	Level7	Level6	Level5	Level4	Level3	Level2	Level1	Level0
LS	0	0	0	0	0	0	0	0
HS	0	0	0	0	0	0	**1**	0
IG	0	0	0	**1**	0	0	0	0
STDBY	0	0	0	0	0	0	0	0
SLEEP[1]	**1**	**1**	0	0	0	0	0	0
ARR_PDN[1]	**1**	**1**	0	0	0	0	0	0
IG	0	0	0	**1**	0	0	0	0
WLPD	0	0	0	0	0	**1**	**1**	0
PD_B	0	0	0	**1**	**1**	0	**1**	**1**

1. only for CM7 TCM

27.3.5.1 CM7 TCM content retention

The memory content usually gets lost after the memory is powered off. CM7 TCM memory can still be alive when CM7P MIX is powered off. So its memory content can be retained in this case.

In HW mode, change the value of MEM_LP_CFG[MLPL_HW_PDN_LMEM] to 0x0~0x5 (**not** the default value 0x7) in CM7PLATFORM_MIX_SLICE, because the value 0x6 or 0x7 means CM7 TCM memory is powered off with CM7P MIX power-off together.

In SW mode (if you want to control memory power by programing), it has to be **noted** there are two low power control signals: SLEEP and ARR_PDN. SLEEP is an isolation signal between the memory array power domain and the CM7P MIX power domain. SLEEP must be asserted before ARR_PDN changes to 1, and also kept asserted, until both power domains are powered on.

- In the memory array power-on and CM7P MIX power-off case, SLEEP signal can be asserted high automatically, and there is no need for software intervention.
- In the memory array power-off and CM7P MIX power-on case, SLEEP signal must be asserted ahead via setting MIF_MPL_SLEEP[SW_SLEEP] by software, and then assert memory array power off signal MIF_MPL_ARR_PDN[SW_ARR_PDN]. If later the software needs to power on CM7 TCM, it must clear MIF_MPL_ARR_PDN[SW_ARR_PDN] at first to power on the memory array, and then clear MIF_MPL_SLEEP[SW_SLEEP] to deassert the SLEEP signal.

27.3.6 Clocking

The following table describes the relevant SRC clock sources.

Table 181. SRC Clocks

Clock name	Description
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock. This clock is typically the same source as the ipg_clk.

NOTE

See the clock controller chapter for clock setting, configuration, and gating information.

27.4 External Signals

The following table describes the SRC external signals.

Table 182. External Signals

Signal	Description	Direction
POR_B	Power on reset input pin, active low.	I
IPP_BOOT_MODE[2:0] {GPIO_AON_02, GPIO_AON_01, GPIO_AON_00}	Boot configuration pins. The values are sampled during system reset and can be read in the SBMR1 register. See the boot chapter for specific boot configuration settings, and the pin mux chapter for pin assignments.	I

27.5 Initialization

27.5.1 Notes of power sequencing in POR

The following conditions must be met for power-up:

- VDD_BBSM_IN supply must be turned on before any other power supply, or be connected (shorted) with DCDC_IN supply.
- If a coin cell is used to power VDD_BBSM_IN, then ensure that it is connected before any other supply is switched on.
- When the internal DCDC is enabled, DCDC_IN and VDD_AON_IN must be supplied. And an external delay circuit is required to delay the DCDC_PSWITCH signal at least 1ms after DCDC_IN is stable.
- User can choose not using POR_B and just tie it to high. Else if it is expected to release the chip by POR_B signal, the POR_B input must be immediately asserted at power-up, and kept asserted until the last power rail reaches its working voltage.

Similarly, for power-down, the following conditions must be met:

- VDD_BBSM_IN supply must be turned off after any other power supply, or be connected (shorted) with DCDC_IN supply.
- If a coin cell is used to power VDD_BBSM_IN, then ensure that it is removed after any other supply is switched off.

27.6 Memory map and register definition

The SRC registers can be separated into three groups:

1. General registers, which control reset sources from other modules to generate global system reset or not.
2. MIX registers, which control MIX power off/on sequence.
3. MIX memory registers, which control MIXs memory low power functions.

NOTE

For SRC register access, the register AUTHEN_CTRL is used to control access permission. The general registers and MIX registers have their own AUTHEN_CTRL to control access permission, non-secure or secure access, and lock configuration for each MIX.

27.6.1 SRC General register descriptions

27.6.1.1 SRC general registers memory map

SRC_GENERAL_REG base address: 4446_0000h

Fields

Field	Function
31-16	Domain ID white list

Table continues on the next page...

Table continued from the previous page...

Field	Function
WHITE_LIST	Each master (Core or non-Core) can be assigned to any domains among domain0~domain15 by TRDC. Once its domains are assigned, then its accesses will have its unique domain ID. Each bit in this field represents for one domain. Bit16~bit31 represent for domain0~domain15 respectively. Only the domains whose corresponding bits are 1 can write the General registers. Write violation will fail without any exception or information. Read violation can still get read data. 0000_0000_0000_0001b - Core with domain ID=0 can write General registers. 0000_0000_0000_0010b - Core with domain ID=1 can write General registers. 0000_0000_0000_0100b - Core with domain ID=2 can write General registers. 0000_0000_0000_1000b - Core with domain ID=3 can write General registers. 0000_0000_0001_0000b - Core with domain ID=4 can write General registers. 0000_0000_0010_0000b - Core with domain ID=5 can write General registers. 0000_0000_0100_0000b - Core with domain ID=6 can write General registers. 0000_0000_1000_0000b - Core with domain ID=7 can write General registers. 0000_0001_0000_0000b - Core with domain ID=8 can write General registers. 0000_0010_0000_0000b - Core with domain ID=9 can write General registers. 0000_0100_0000_0000b - Core with domain ID=10 can write General registers. 0000_1000_0000_0000b - Core with domain ID=11 can write General registers. 0001_0000_0000_0000b - Core with domain ID=12 can write General registers. 0010_0000_0000_0000b - Core with domain ID=13 can write General registers. 0100_0000_0000_0000b - Core with domain ID=14 can write General registers. 1000_0000_0000_0000b - Core with domain ID=15 can write General registers.
15 LOCK_LIST	White list lock This field can lock itself and WHITE_LIST. 0b - WHITE_LIST value can be changed. 1b - LOCK_LIST and WHITE_LIST values cannot be changed.
14-12 —	Reserved
11 LOCK_TZ	Lock Trust Zone Non Secure(TZ_NS) and Trust Zone User(TZ_USER) bits This field can lock itself, TZ_NS and TZ_USER. 0b - TZ_NS and TZ_USER values can be changed. 1b - LOCK_TZ, TZ_NS and TZ_USER values cannot be changed.
10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 TZ_NS	Allow non-secure mode access Allows either secure mode or non-secure mode to write general registers. 0b - General registers can only be written in secure mode. 1b - General registers can be written either in secure mode or non-secure mode.
8 TZ_USER	Allow user mode write Allows either privilege mode or user mode to write general registers. 0b - General registers can only be written in privilege mode. 1b - General registers can be written either in privilege mode or user mode.
7 LOCK_CFG	Configuration lock This field can lock itself and some registers in the General registers: i.e. SRTMR and SRMASK. 0b - General registers are not locked. 1b - LOCK_CFG and registers in the list are locked.
6-0 —	Reserved

27.6.1.3 SRC Control Register (SCR)

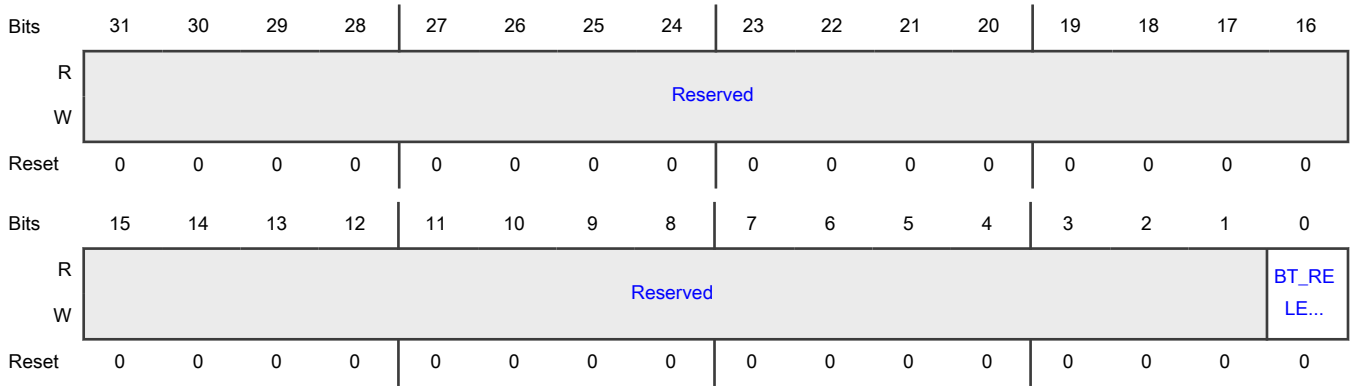
Offset

Register	Offset
SCR	10h

Function

Contains bits that control operation of the reset controller. Reset by global system reset.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 BT_RELEASE_M7	Boot release M7 0b - Holds M7 Core reset. 1b - Releases M7 Core reset and let it run. After this bit is set, it cannot be cleared by SW write.

27.6.1.4 SRC Reset Trigger Mode Register (SRTMR)

Offset

Register	Offset
SRTMR	14h

Function
Reset by POR not global system reset.

27.6.1.7 SRC Boot Mode Register 2 (SBMR2)

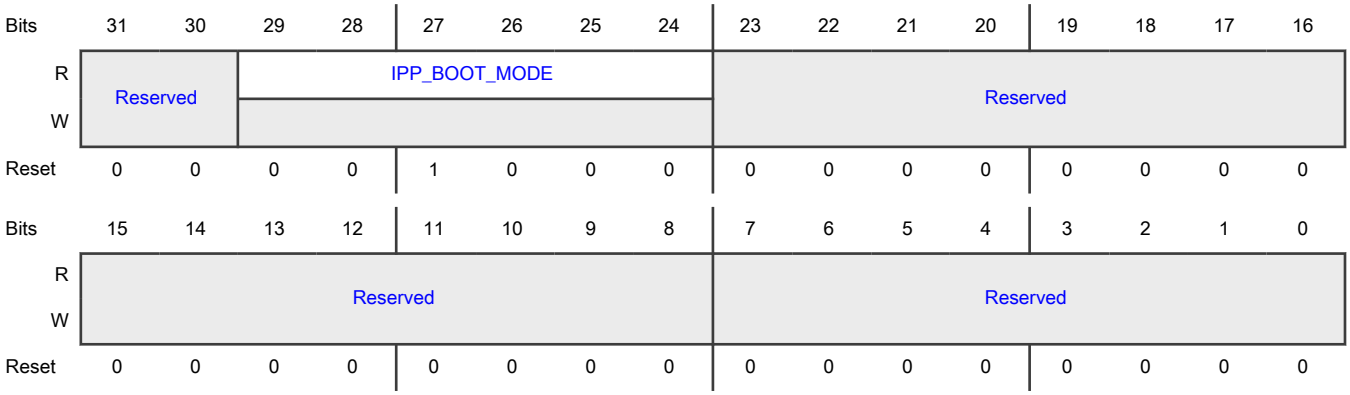
Offset

Register	Offset
SBMR2	44h

Function

Contains bits that reflect the status of Boot Mode Pins of the chip. Reset by POR not global system reset

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 IPP_BOOT_MODE	IPP_BOOT_MODE[5:4] reserved. Ties to 0. IPP_BOOT_MODE[3] ties to 1, which means CM33 boot mode selected. IPP_BOOT_MODE[2:0] value is latched from chip top PADS at 2nd 32KHz clock rising edge after POR reset. IPP_BOOT_MODE[2:0] selects boot devices. The map table for this chip is as below: 00_0000b - Boot from internal Fuses 00_0001b - Serial Downloader: USB1 or LPUART1 00_0010b - USDHC1 8-bit eMMC 5.1 00_0011b - USDHC2 4-bit SD 3.0 00_0100b - FlexSPI Serial NOR with SFDP (JESD-216) discoverable parameters 00_0101b - FlexSPI Serial NAND 2k page 00_0110b - FlexSPI Serial NAND 4k page 00_0111b - Test mode/Infinite loop mode
23-8 —	Reserved
7-0 —	Reserved

27.6.1.8 SRC Reset Status Register backup in BBSM domain (SRSR_BBSM)

Offset

Register	Offset
SRSR_BBSM	4Ch

Function

Records the source of the reset events for the chip. Writing zero does not have any effect. Writing one to the bit clears the corresponding bit to 0.

NOTE

This register is only reset by BBSM power-on reset, not POR or global system reset.

Diagram

9 CM33_REQUEST	Indicates whether reset was the result of cm33 reset request 0b - Reset is not a result of cm33 reset request. 1b - Reset is a result of cm33 reset request.
8 JTAG_SW_RST	JTAG software reset. Indicates whether the reset was the result of software reset from JTAG. 0b - Reset is not a result of software reset from JTAG. 1b - Reset is a result of software reset from JTAG.
7 EDGELOCK_RESET_B	Indicates whether the reset was the result of the Edgelock's reset input. 0b - Reset is not a result of the Edgelock's reset event. 1b - Reset is a result of the Edgelock's reset event.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 TEMPSENSE_RST_B	Temper Sensor software reset. Indicates whether the reset was the result of software reset from on-chip Temperature Sensor. 0b - Reset is not a result of software reset from Temperature Sensor. 1b - Reset is a result of software reset from Temperature Sensor.
5 WDOG5_RST_B	Time-out reset. Indicates whether the reset was the result of the watchdog5 time-out 0b - Reset is not a result of the watchdog time-out event. 1b - Reset is a result of the watchdog time-out event.
4 WDOG4_RST_B	Time-out reset. Indicates whether the reset was the result of the watchdog4 time-out 0b - Reset is not a result of the watchdog time-out event. 1b - Reset is a result of the watchdog time-out event.
3 WDOG3_RST_B	Time-out reset. Indicates whether the reset was the result of the watchdog3 time-out 0b - Reset is not a result of the watchdog3 time-out event. 1b - Reset is a result of the watchdog3 time-out event.
2 WDOG2_RST_B	Time-out reset. Indicates whether the reset was the result of the watchdog2 time-out event. 0b - Reset is not a result of the watchdog time-out event. 1b - Reset is a result of the watchdog time-out event.
1 WDOG1_RST_B	Time-out reset. Indicates whether the reset was the result of the watchdog1 time-out event. 0b - Reset is not a result of the watchdog time-out event. 1b - Reset is a result of the watchdog time-out event.
0 POR_RST	Indicates whether the reset was the result of POR. 0b - Reset is not a result of POR. 1b - Reset is a result of POR.

27.6.1.10 SRC General Purpose Register (GPR0 - GPR19)

Offset

For a = 0 to 19:

Register	Offset
GPRa	54h + (a × 4h)

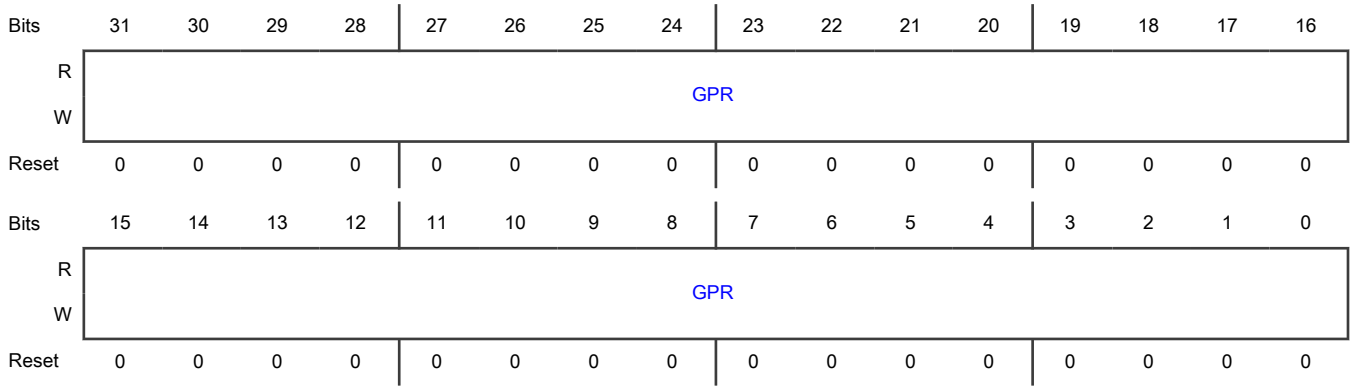
Function

The registers of GPR0, GPR1, GPR2, GPR3 and GPR9 are used by the ROM code and should not be used by user application. Reset by POR only, not by global system reset.

NOTE

The reset values of GPR0, GPR1, GPR2, GPR3 and GPR9 may not be logic 0, because ROM code runs first after the system reset.

Diagram



Fields

Field	Function
31-0 GPR	General Purpose Register. GPR0, GPR1, GPR2, GPR3 and GPR9 are used by the ROM code. User application should not use them.

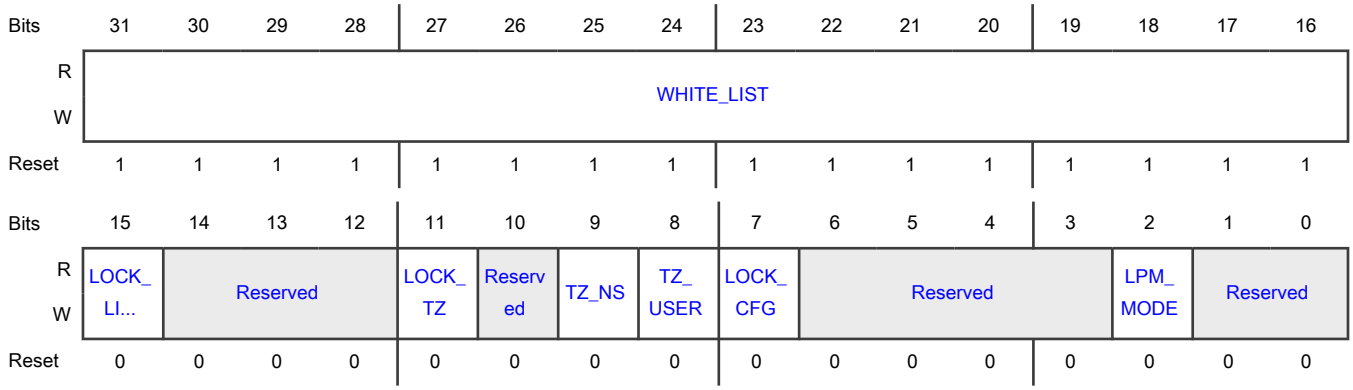
Offset

Register	Offset
AUTHEN_CTRL	4h

Function

Reset by global system reset.

Diagram



Fields

Field	Function
31-16 WHITE_LIST	Domain ID white list This field has functions as below: • Each master (Core or non-Core) can be assigned to any domains among domain0~domain15 by TRDC. Once its domains are assigned, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit16~bit31 represent for domain0~domain15 respectively. Only the domains whose corresponding bits are 1 can write the MIX SLICE registers and its MEM Type I/II registers. Write violation will fail without any exception or information. Read violation can still get read data. • When the bit is 1, LPM_SETTING value with corresponding domain ID will be used to compare with the relative Core's low power state bits. If Core's low power state value is not smaller than the LPM_SETTING value, then low power sequence will be triggered. When this bit is 0, relative Core's low power state value will be ignored, and the MIX SLICE will always be in normal run mode. 0000_0000_0000_0001b - Core with domain ID=0 can write SRC MIX SLICE registers. 0000_0000_0000_0010b - Core with domain ID=1 can write SRC MIX SLICE registers. 0000_0000_0000_0100b - Core with domain ID=2 can write SRC MIX SLICE registers. 0000_0000_0000_1000b - Core with domain ID=3 can write SRC MIX SLICE registers. 0000_0000_0001_0000b - Core with domain ID=4 can write SRC MIX SLICE registers. 0000_0000_0010_0000b - Core with domain ID=5 can write SRC MIX SLICE registers. 0000_0000_0100_0000b - Core with domain ID=6 can write SRC MIX SLICE registers. 0000_0000_1000_0000b - Core with domain ID=7 can write SRC MIX SLICE registers. 0000_0001_0000_0000b - Core with domain ID=8 can write SRC MIX SLICE registers. 0000_0010_0000_0000b - Core with domain ID=9 can write SRC MIX SLICE registers. 0000_0100_0000_0000b - Core with domain ID=10 can write SRC MIX SLICE registers. 0000_1000_0000_0000b - Core with domain ID=11 can write SRC MIX SLICE registers. 0001_0000_0000_0000b - Core with domain ID=12 can write SRC MIX SLICE registers.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0010_0000_0000_0000b - Core with domain ID=13 can write SRC MIX SLICE registers. 0100_0000_0000_0000b - Core with domain ID=14 can write SRC MIX SLICE registers. 1000_0000_0000_0000b - Core with domain ID=15 can write SRC MIX SLICE registers.
15 LOCK_LIST	White list lock Can lock itself and WHITE_LIST. 0b - WHITE_LIST value can be changed. 1b - LOCK_LIST and WHITE_LIST value cannot be changed.
14-12 —	Reserved
11 LOCK_TZ	Lock TZ_NS and TZ_USER Can lock itself, TZ_NS and TZ_USER. 0b - TZ_NS and TZ_USER value can be changed. 1b - LOCK_TZ, TZ_NS and TZ_USER value cannot be changed.
10 —	Reserved
9 TZ_NS	Allow non-secure mode access Allows either secure mode or non-secure mode to write the MIX SLICE registers and its MEM Type I/II registers. 0b - The MIX SLICE registers and its MEM Type I/II registers can only be written in secure mode. 1b - The MIX SLICE registers and its MEM Type I/II registers can be written either in secure mode or non-secure mode.
8 TZ_USER	Allow user mode write Allows either privilege mode or user mode to write the MIX SLICE registers and its MEM Type I/II registers. 0b - The MIX SLICE registers and its MEM Type I/II registers can only be written in privilege mode. 1b - The MIX SLICE registers and its MEM Type I/II registers can be written either in privilege mode or user mode.
7 LOCK_CFG	Configuration lock Can lock itself and LPM_MODE fields. Also it can lock EDGELOCK_HDSK_CTRL, EDGELOCK_HDSK_CNT_CFG, ISO_DLY_PRE, PSW_DLY_PRE_HF, PSW_DLY_PRE_LF, PSW_CTRL, PSW_CNT_CFG_HF and PSW_CNT_CFG_LF registers. 0b - Registers are not locked.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Fields and registers in the list are locked.
6-3 —	Reserved
2 LPM_MODE	HW low power mode Controls whether low power works in Hardware(GPC) mode or Software mode. If it works in Software mode, all GPC's change state request will be acknowledged at once. This value can be locked by LOCK_CFG. 0b - Low power mode controlled by software. SLICE_SW_CTRL register can be updated. LPM_SETTING_0 register cannot be updated. 1b - Low power mode controlled by GPC. SLICE_SW_CTRL register cannot be updated. LPM_SETTING_0 register can be updated.
1-0 —	Reserved

27.6.2.3 SLICE Software Control (SLICE_SW_CTRL)

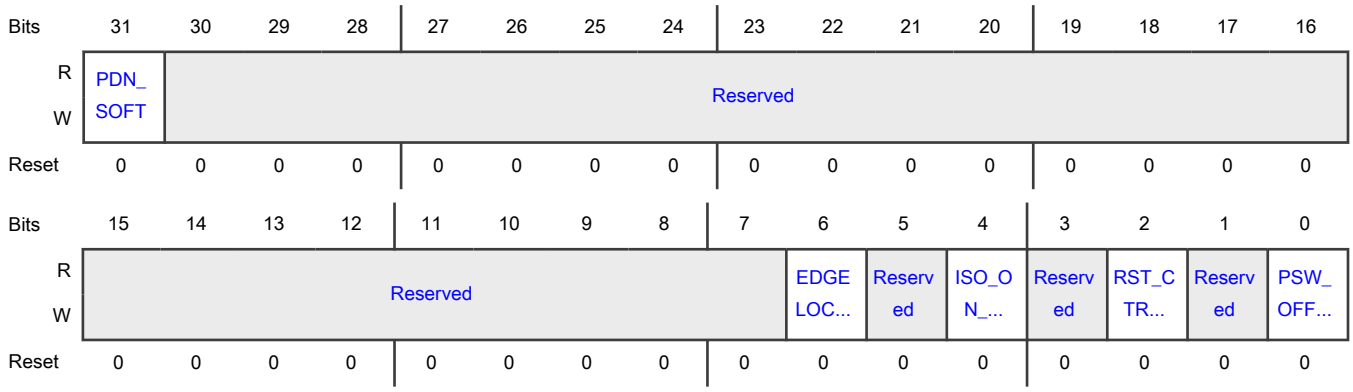
Offset

Register	Offset
SLICE_SW_CTRL	10h

Function

Controls the whole slice.

Diagram



Fields

Field	Function
31 PDN_SOFT	By flow sequence, Software power down sequence includes Edgelock handshake for power down, isolation on, reset assert, power off; Software power up sequence includes power up, reset deassert, isolation off, Edgelock handshake for power up. This bit can only be updated while LPM_MODE=0. 0b - Clear to 0 to trigger a power up sequence. 1b - Write 1 to trigger a power down sequence.
30-7 —	Reserved
6 EDGELOCK_HDSK_SOFT	Software Edgelock handshake control. This field can only be updated while LPM_MODE=0. 0b - Clear to 0 to trigger Edgelock handshake for power on. 1b - Write to 1 to trigger Edgelock handshake for power off.
5 —	Reserved
4 ISO_ON_SOFT	Software isolation on control. This field can only be updated while LPM_MODE=0. 0b - Clear to 0 to trigger isolation off 1b - Write 1 to trigger isolation on
3 —	Reserved
2 RST_CTRL_SOFT	Software reset control. This field can only be updated while LPM_MODE=0. **NOTE** Do not reset a target MIX slice if it has been in low power sequence, no matter it is in Edgelock, ISO, reset or Power off phase. 0b - Clear to 0 to trigger reset deassert 1b - Write 1 to trigger reset assert
1 —	Reserved
0 PSW_OFF_SOFT	Software power off control. This field can only be updated while LPM_MODE=0. 0b - Clear to 0 to trigger power switch on 1b - Write 1 to trigger power switch off

27.6.3.4 MIF MLPL control of LS (MIF_MLPL_LS)

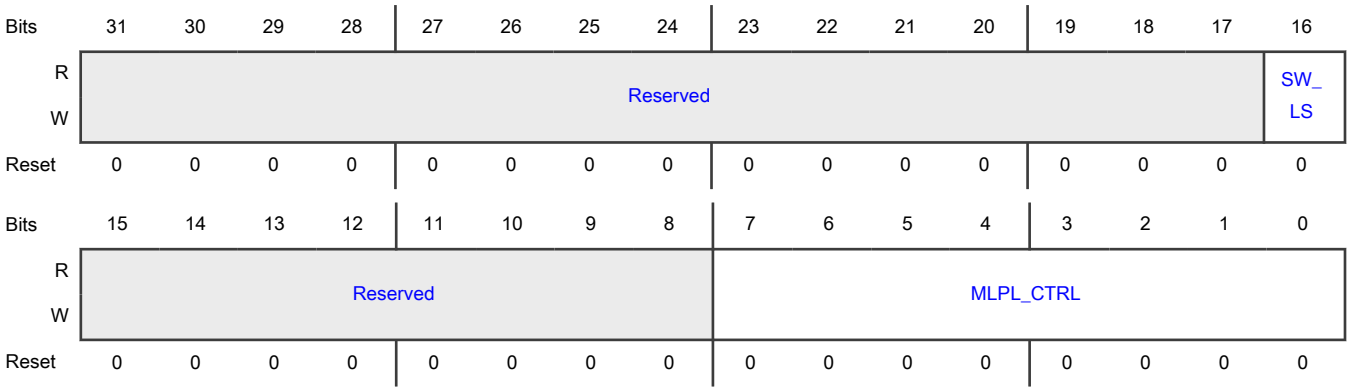
Offset

Register	Offset
MIF_MLPL_LS	10h

Function

Speed mode provides the flexibility to boost speed and gain dynamic power by controlling memory LS/HS pins depending on operating voltage. This option enables the user to operate memory in different speed modes. LS pin can be constraint to H only for low voltages, and LS = L at higher voltage will boost speed and reduce dynamic power. In conjunction with LS = L, HS = H with specific voltage constraints will further boost speed.

Diagram



Fields

Field	Function
31-17 —	Reserved

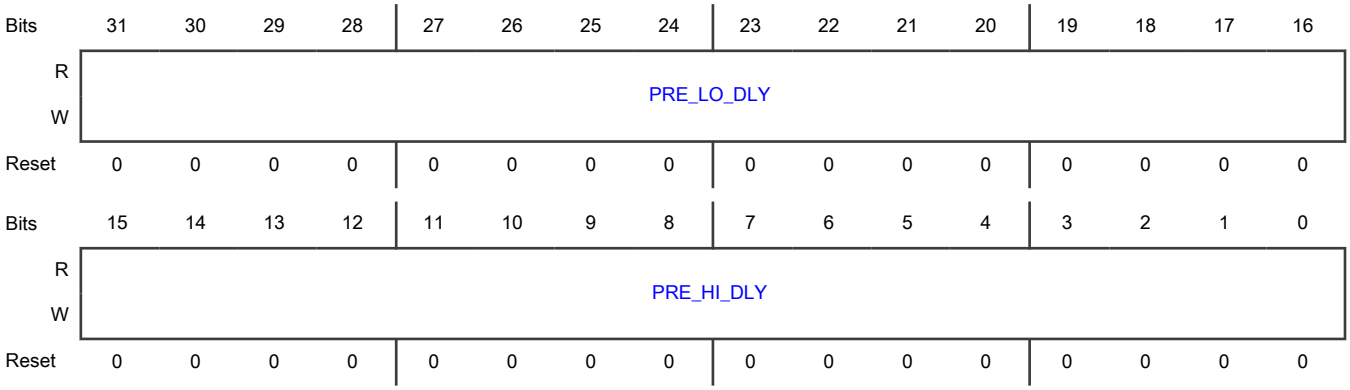
MIF Delay of IG register

Diagram



Fields

Field	Function
31-16 PRE_LO_DLY	Delay before de-asserting signal to low, locked by LOCK_CFG field This field is only valid when SW_CTRL_PIN is 0. It controls the delay time from SRC start MIX slice power switch to change the IG signal to low.
15-0 PRE_HI_DLY	Delay before asserting signal to high, locked by LOCK_CFG field This field is only valid when SW_CTRL_PIN is 0. It controls the delay time from SRC start MIX slice power switch to change the IG signal to high.

27.6.3.10 MIF MLPL control of STDBY (MIF_MLPL_STDBY)

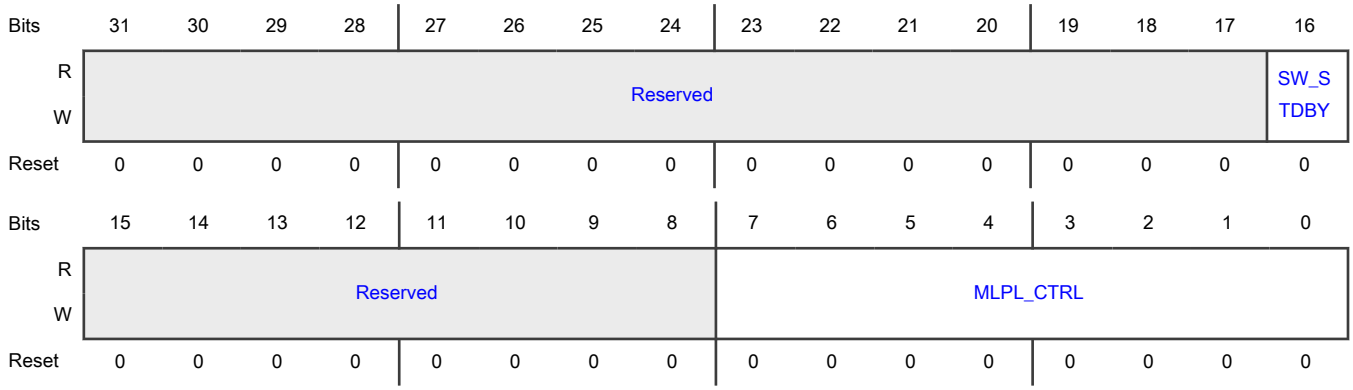
Offset

Register	Offset
MIF_MLPL_STDBY	40h

Function

To reduce the static power without changing the external supply, STDBY pin is provided. This pin gates the power supply to word-line final driver that is the leakiest part of the memory periphery. For the dual-rail memory, this mode reduces the static power of vddma supply. For large number of rows instances and consequently word-line final drivers, this mode can provide a good static power saving.

Diagram



Fields

Field	Function
31-17 —	Reserved

27.6.4.4 MIF MLPL control of LS (MIF_MLPL_LS)

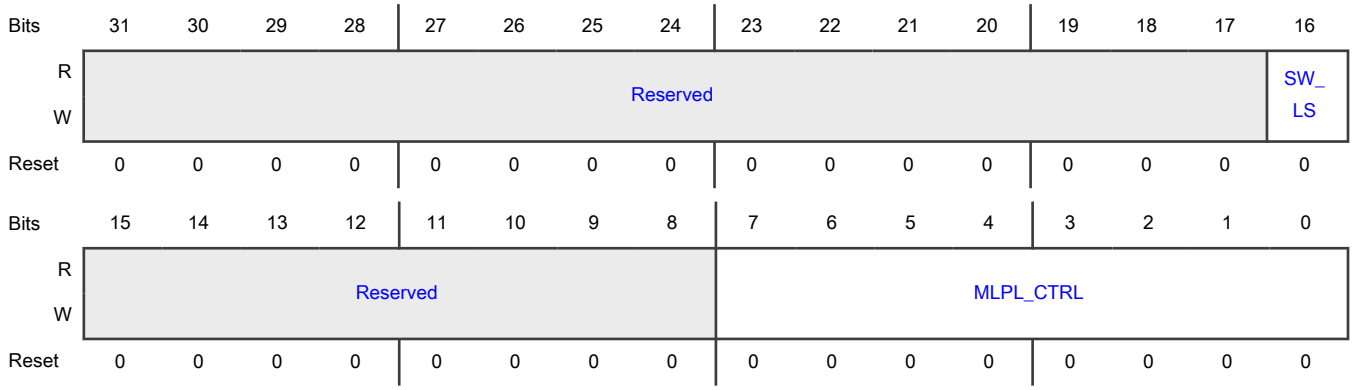
Offset

Register	Offset
MIF_MLPL_LS	10h

Function

Speed mode provides the flexibility to boost speed and gain dynamic power by controlling memory LS/HS pins depending on operating voltage. This option enables the user to operate memory in different speed modes. LS pin can be constraint to H only for low voltages and LS = L at higher voltage will boost speed and reduce dynamic power. In conjunction with LS = L, HS = H with specific voltage constraints will further boost speed.

Diagram



Fields

Field	Function

31-16	Delay before de-asserting signal to low, locked by LOCK_CFG field

Table continues on the next page...

Table continued from the previous page...

Field	Function
PRE_LO_DLY	This field is only valid when SW_CTRL_PIN is 0. It controls the delay time from SRC start MIX slice power switch to change the IG signal to low.
15-0 PRE_HI_DLY	Delay before asserting signal to high, locked by LOCK_CFG field This field is only valid when SW_CTRL_PIN is 0. It controls the delay time from SRC start MIX slice power switch to change the IG signal to high.

27.6.4.10 MIF MLPL control of STDBY (MIF_MLPL_STDBY)

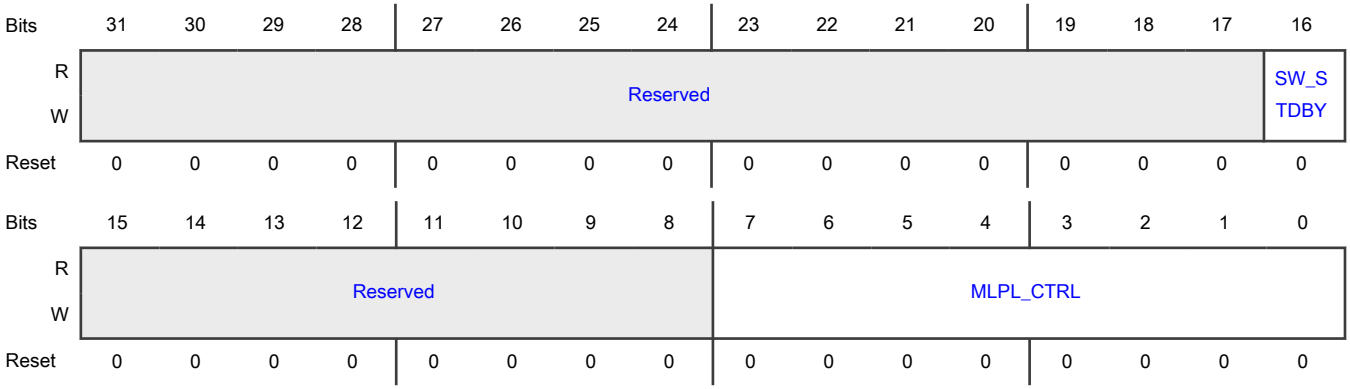
Offset

Register	Offset
MIF_MLPL_STDBY	40h

Function

To reduce the static power without changing the external supply, STDBY pin is provided. This pin gates the power supply to word-line final driver that is the leakiest part of the memory periphery. For the dual-rail memory, this mode reduces the static power of vddma supply. For large number of rows instances and consequently word-line final drivers, this mode can provide a good static power saving.

Diagram



Fields

Field	Function

27.6.5.6 MIF MLPL control of WLPD (MIF_MLPL_WLPD)

Offset

Register	Offset
MIF_MLPL_WLPD	30h

Function

The word-line power down feature will gate off the power supply to the word-line drivers. When asserted, wlpd=1, the word-line drivers will be power gated and the memory will be prevented from performing any normal functional mode operations. Assertion of wlpd enables leakage power savings on the vdda supply.

15-0 PRE_HI_DLY	Delay before asserting signal to high, locked by LOCK_CFG field This field is only valid when SW_CTRL_PIN is 0. It controls the delay time from SRC start MIX slice power switch to change the PD_B signal to high.

Chapter 28
External Memory Controllers

28.1 Overview

This section lists the external memory interfaces and controllers.

This chip has these external memory interfaces and controllers:

- Smart External Memory Controller (SEMC)
- eSD/eMMC/SDIO Interface
- Flexible Serial Peripheral Interface (FlexSPI)
- Flexible Serial Peripheral Interface Follower (FlexSPI_FLR)
- FPGA interface (SRAMC)

28.2 Smart External Memory Controller (SEMC)

The SEMC is a multi-standard memory controller optimized for both high-performance and low pin-count. It can support multiple external memories in the same application with shared address and data pins. The interface supported includes SDRAM, NOR Flash, SRAM and NAND Flash, as well as 8080 display interface.

The key features of the SEMC include:

- Support up to 12 memory regions up to 512 Mbit per region which can be configured to be memory space of SDRAM, NOR Flash, NAND Flash, SRAM or 8080 display frame buffer
- Chip Select (CS) signals
- Support Address Latch Enable (ALE)
- SDRAM interface
  - Supports both 8-bit, 16-bit, and 32-bit modes
  - Max 200 MHz
  - Up to 512Mb per each Chip Select (CS) and up to 4x CS
- NOR Flash and SRAM interface
  - Supports both 8-bit and 16-bit modes
  - Asynchronous and Synchronous mode
  - Address and Data Multiplexing (ADM)
  - Maximum 128Mb per each Chip Select (CS)
  - Support NOR Flash program via IPBus configuration
- 8080 display interface
  - Supports both 8/16/24-bit modes
  - Up to 100MHz
  - Without tearing effect support
- NAND Flash
  - 8/16-bit NAND FLASH
  - Asynchronous and Synchronous mode
  - Only supports device which is capable of cache read/write operations

  - Only supports page based operation
- Dynamic I/O sharing which enables multiple external memory device in parallel
- Multi-device access pattern scheduler
  - 8 entries scheduler
  - QoS priority, latency and efficiency adjustable arbitration scheme
- SDRAM access pattern optimization
  - 8 entries command reordering queue
  - QoS priority, latency and efficiency adjustable arbitration scheme

28.3 eMMC/eSD/SDIO

This chip has two Ultra Secured Digital Host Controller (uSDHC) modules for SD/eMMC interface. It provides the interface between the host system and the SD/SDIO/MMC cards.

The key features include:

- Support SD/SDIO standard, up to version 3.0
- Support MMC standard, up to version 5.1
- Support 3.3V and 1.8V operation.
- uSDHC1 supports maximum 4bit interface, uSDHC2 supports maximum 8bit interface

28.4 Flexible Serial Peripheral Interface (FlexSPI)

i.MX RT1180 has two FlexSPI host controllers - FlexSPI1 and FlexSPI2. Each FlexSPI host controller supports two SPI ports - A and B. Each port supports up two chip select outputs. Each port of FlexSPI1 supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines), while each port of FlexSPI2 supports Single/ Dual/Quad mode data transfer (1/2/4 bidirectional data lines).

The key features include:

- Support both SDR mode and DDR mode
- Support Individual/Parallel mode
- HyperBus device (HyperFlash/HyperRAM)
- Support On-The-Fly AES Decryption (OTFAD) with 4 keys

28.5 Flexible Serial Peripheral Interface Follower (FlexSPI_FLR)

The FlexSPI follower provides a FlexSPI interface, so that the i.MX RT1180 can act as a FlexSPI device. The FlexSPI follower module acts as a gasket between an external FlexSPI and the AXI bus. As AXI leader, the FlexSPI follower can access all memory mapped registers and memory in the i.MX RT1180.

The FlexSPI module provides basic hardware to process access control by high level software or protocol. By default, the FlexSPI AXI leader is disabled, external FlexSPI leader can access limited registers in the FlexSPI follower module. The FlexSPI follower module contains three kind of registers:

- GCR: General Control Register, read/write by IPS bus
  - Defines Command Set, Base Address, dummy cycles that necessary for FlexSPI transfer
  - Enable AXI leader
- CSR: Control and Status Register, read/write by IPS bus, read by FlexSPI leader via FlexSPI register read command
  - Indicate status of FlexSPI follower module, transfer fail, busy, AXI write in progress

  - Handshake, such as grant or reject FlexSPI leader access to RT1180 memory mapped register or SRAM
- GPR: General purpose Register, read by IPS bus, clean by Control and Status Register, read/write by FlexSPI leader via FlexSPI register read/write command
  - Can trigger interrupt once FlexSPI leader write GPR registers
  - 8 words in size
  - It depends on software or high level protocol to define the detailed format of SRAMCR0 and SRAMCR1, such as, but not limited to:
    - FlexSPI leader authentication
    - Define Base address that FlexSPI leader request to access
    - Define Command Set that FlexSPI leader should use

28.6 FPGA SRAM Interface (SRAMC)

This chip provides a memory mapped SRAMC to CM7 AHBP to achieve fast access:

- Support both A/D mux or non-A/D mux interfacing with FPGA
- Support Async SRAM timing
- WAIT signal is not supported
- 4 CS signal, each CS cover 128KB memory space, total 512KB
- Memory mapped, start from 0x43880000
- Support 8/16 mode

Chapter 29
Smart External Memory Controller (SEMC)

29.2 Overview

The SEMC is a multi-standard memory controller optimized for both high-performance and low pin-count. It can support multiple external memories in the same application with shared address and data pins. The interfaces supported include SDRAM, NOR Flash, SRAM, NAND Flash, and 8080 display interface.

29.2.1 Block Diagram

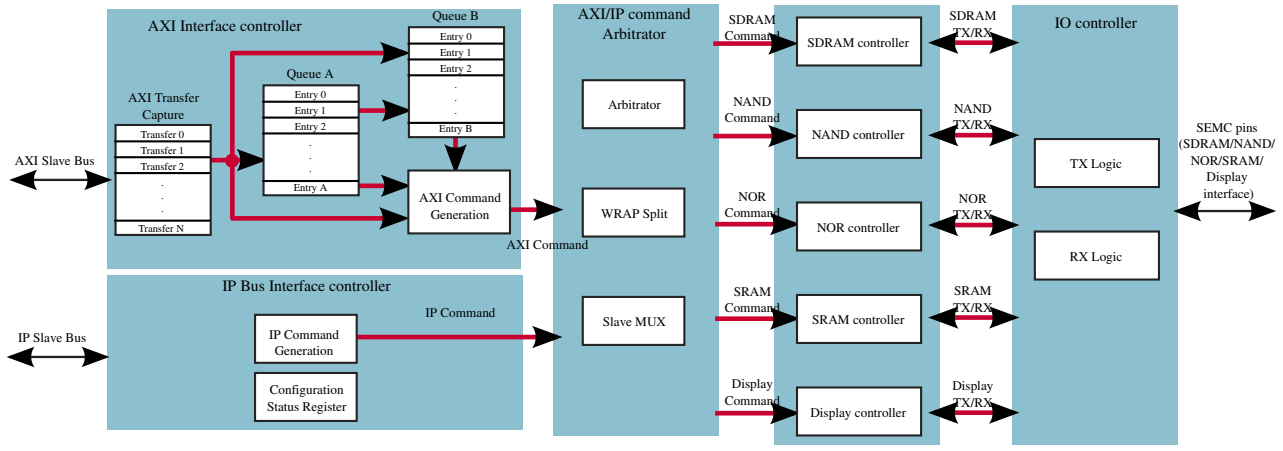

Figure 101. SEMC Block Diagram

29.2.2 Features

The SEMC includes the following features:

- Memory space:
  - Supports 12 memory regions:
    - Region #0 for SDRAM CS0 device
    - Region #1 for SDRAM CS1 device
    - Region #2 for SDRAM CS2 device
    - Region #3 for SDRAM CS3 device
    - Region #4 and #8 for NAND device (IP command and AXI command use different region to avoid large region address range on AXI interface)
    - Region #5 for NOR device
    - Region #6 for SRAM CS0 device
    - Region #7 for 8080 display frame buffer
    - Region #9 for SRAM CS1 device
    - Region #10 for SRAM CS2 device
    - Region #11 for SRAM CS3 device
  - Each region is configurable for base address, memory size and valid bit
- AXI slave interface
  - Supports 16 outstanding transfers (total including both reads and writes)
    - Supports 8 outstanding write transfers
    - Supports 16 outstanding read transfers
  - Multi-device access pattern optimization with Queue A
    - 8 entries command reordering in Queue A
    - Adjustable arbitration scheme based on QoS priority, latency and efficiency

  - SDRAM access pattern optimization with Queue B
    - 8 entries command reordering in Queue B
    - Adjustable arbitration scheme based on QoS priority, latency and efficiency
  - Memory-mapped AXI interface for read and write access
  - Supports 32/16/8 bit access
- IP Bus interface
  - Internal configuration register access
  - Trigger device access such as device initialization/configuration/read/write (IP command)
- SDRAM interface
  - Supports 8/16/32 bit modes
  - Supports 4 Chip Select (CS) and each CS up to 1024Mb
- NAND Flash interface
  - Supports 8/16 bit modes
  - Supports hardware ECC
  - Supports device which is capable of cache read/write operations
  - Supports page based read/write operation
  - Supports 32 bit transfer size for AXI write operation
  - Up to 512GB
- NOR Flash interface
  - Supports 8/16 bit modes
  - Supports ADMUX, AADM and Non-ADMUX modes
  - NOR Flash write access is supported only by IP command
  - Up to 4096Mb memory size

NOTE

- For 16 bit devices, up to 4096Mb memory size
- For 8 bit devices, up to 2048Mb memory size

- SRAM interface
  - Supports SRAM and Pseudo SRAM
  - Supports 8/16 bit modes
  - Supports ADMUX, AADM and Non-ADMUX modes
  - Up to 4 Chip Select (CS)
  - Up to 4096Mb memory size

NOTE

- For 16 bit devices, up to 4096Mb memory size
- For 8 bit devices, up to 2048Mb memory size

- 8080 display interface
  - Supports 8/16 bit modes
  - No tearing effect support

- Misc
  - Dynamic I/O sharing which enables multiple external memory device in parallel
  - Up to 7 Chip Select (CS) signals
  - Supports Address Latch Enable (ALE) for SRAM/NOR device

29.3 Functional Description

The following sections describe functional details of the SEMC module.

29.3.1 Operations

The following sections describe operations of the SEMC module.

29.3.1.1 Modes of Operation

The SEMC supports the following operation modes:

- Module Disable mode

  In module disable mode, the internal clock is gated for low power, but access to configuration and status registers is available.

  This mode is entered by setting MCR[MDIS], and exited by clearing MCR[MDIS]. Software should poll STS0[IDLE] to make sure there are no pending transactions before entering module disable mode.

- Stop mode

  When the system requires the SEMC to enter stop mode, the SEMC waits for all transactions to complete (STS0[IDLE]=1) and returns acknowledge handshake to system. The system can gate off the SEMC clock after the stop acknowledge handshake is returned. There is no clock gating within the SEMC module.

  The SEMC exits this mode immediately when the system stop mode request is negated.

- Normal mode

  Access to external devices and internal registers are available in normal mode. The SEMC clock is not gated internally.

29.3.1.2 Device Access by AXI Command

Devices can be accessed by AXI bus access directly. AXI command is the device access sequence triggered by AXI bus access. The device access sequence for AXI commands is described in the following sections.

NOTE

- The AXI bus memory map for each device is defined by Base Registers.
- There is no software configuration or polling needed for AXI command.
- AXI command is the first choice to access device memory. IP command is suitable for other access, such as device register/OTP space access, device initialization, etc.
- IP command can be used to access memory like AXI command, but it is not recommended if AXI command is available. IP command access is low efficiency.

29.3.1.2.1 Bus Master Control Registers (BMCRn) Configuration

BMCRn can be used to balance external memory access efficiency, urgency and latency based on the requirements of a specific application.

29.3.1.2.1.1 BMCR0 Register Configuration

For Queue A controlled by BMCR0, the arbitration logic adopts a weight based algorithm that assigns each command in the reordering queue with a final score.

The arbitration logic calculates a SCORE for each command based on the formula below, where the weighting factor for each parameter is controlled by the BMCR0 configuration. The command with the highest SCORE is served first.

SCORE = QOS*WQOS + AGE*WAGE/4 + WSH + WRWS

1. QOS stands for AxQOS of AXI bus, and WQOS is the weight factor of QOS.
2. AGE stands for the wait period for each command in queue, and WAGE is the weight factor of AGE.
3. WSH stands for weight of slave hit without read/write switch scenario.
4. WRWS stands for weight of slave hit with read/write switch scenario.

Recommend to set BMCR0 with 0x0 for applications that require restrict sequence of transactions, such as stack is allocated in SDRAM. The write and read transactions to the same address might be reordered if transactions in the queue is reordered, and it might crash the routine. WQOS can be non-zero value if needed, meanwhile WAGE must be non-zero value as well. In any case, WBR, WRWS, and WPH should be 0x0.

29.3.1.2.1.2 BMCR1 Register Configuration

For Queue B controlled by BMCR1, the arbitration logic adopts a weight based algorithm that assigns each command in the reordering queue with a final score.

The arbitration logic calculates SCORE for each SDRAM command based on the formula below. The command with the highest SCORE is served first.

SCORE = QOS*WQOS + AGE*WAGE/4 + WPH + WBR + WRWS

1. QOS stands for AxQOS of AXI bus, and WQOS is the weight factor of QOS.
2. AGE stands for the wait period for each command in queue, and WAGE is the weight factor of AGE.
3. WPH stands for weight of page hit scenario.
4. WBR stands for weight of bank rotation/switch scenario.
5. WRWS stands for weight of slave hit without read/write switch scenario.

Recommend to set BMCR1 with 0x0 for applications that require restrict sequence of transactions, such as stack is allocated in SDRAM. The write and read transactions to the same address might be reordered if transactions in the queue is reordered, and it might crash the routine. WQOS can be non-zero value if needed, meanwhile WAGE must be non-zero value as well. Anyway, WRWS, WBR and WPH should be 0x0.

29.3.1.3 Device Access by IP Command

Devices can be accessed (initialized/configured/read/written) by IP bus access also. IP command is the device access sequence triggered by IP bus access. The device access sequence for IP command is described in the following sections.

Device access can be triggered by IP command using the following steps:

1. Set IPCR0/IPCR1/IPCR2/IPTXDAT registers for device address, data size, write mask and write data.
2. Set IPCMD register with valid command code (IPCMD[CMD]) and command key (IPCMD[KEY]).
3. Wait for IP command done (INTR[IPCMDDONE] sets).
4. Read the device data from IPRXDAT register. This is for read access only.

NOTE

- If device address or command code setting is not valid, an IP command error interrupt is generated (INTR[IPCMDERR]) and no device access occurs.
- If another IP command is triggered when the previous IP command has not finished yet, an IP command error interrupt is generated.
- IPCR0/IPCR1/IPCR2/IPTXDAT registers are protected when an IP command is in progress. Any write access to these registers is ignored until the IP command completes.
- The IPCR0 slave address field must be configured even if the memory does not require an address for the selected command (such as WRITE ENABLE command). The SEMC determines the slave device by decoding the device address.
- The slave device is limited to NAND when IPCMD[KEY] is 0x5AA5.

29.3.1.4 SDRAM Controller Operations

This section describes the operations of SDRAM controller.

29.3.1.4.1 SDRAM Address Multiplexing

SDRAMs use a multiplexed address split into rows, columns, and banks. Figure 102 shows how the bits of the linear address sent to the SEMC are split up into the row, column, and bank addresses sent to the SDRAM memory device.

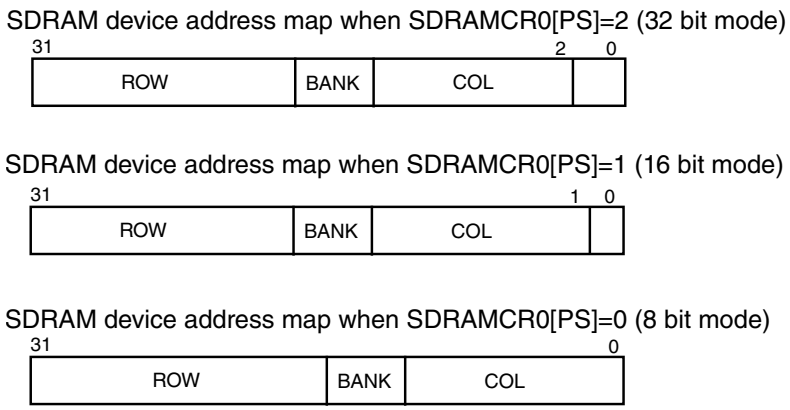

Figure 102. SDRAM Device Address Multiplexing

NOTE

- SDRAM address consists of row, bank and column address bits.
- Column address bits offset is bit 0 if SDRAMCR0[PS]=0, bit 1 if SDRAMCR0[PS]=1, bit 2 if SDRAMCR0[PS]=2. Column address bit width is determined by SDRAMCR0[COL] and SDRAMCR0[COL8].
- Bank address bits offset is determined by SDRAMCR0[PS], SDRAMCR0[COL] and SDRAMCR0[COL8]. Bank address bit width is determined by SDRAMCR0[BANK2].
- Row address bits offset is determined by SDRAMCR0[PS], SDRAMCR0[COL], SDRAMCR0[COL8] and SDRAMCR0[BANK2]. Row address bit width is determined by external SDRAM device.
- SDRAM device base address on SoC is configured by BR0, BR1, BR2 and BR3 registers.

29.3.1.4.2 SDRAM Access by IP Command

Table 184 lists the SDRAM access types that are triggered by IP commands.

Table 184. SDRAM IP Command

Command	Code	Comment
EXTENDED MODE REGISTER SET	0x5	Writes the extended mode register inside the SDRAM memory
DEEP POWER DOWN	0x6	Puts the SDRAM into deep power down mode
READ	0x8	Reads from the SDRAM memory
WRITE	0x9	Writes to the SDRAM memory
MODE REGISTER SET	0xA	Writes the mode register inside the SDRAM memory
ACTIVE	0xB	Sends a new bank and row address to the memory
AUTO REFRESH	0xC	Auto refresh
SELF REFRESH	0xD	Puts the SDRAM into low power data retention mode. The memory cannot be accessed while in self refresh mode.
PRECHARGE	0xE	Closes the currently active row for the specified bank
PRECHARGE ALL	0xF	Closes the active rows for all banks

29.3.1.4.2.1 READ

When an IP command is triggered with command code - READ, the SEMC will send a READ command to the SDRAM device.

Figure 103 shows the sequence for IP command - READ.

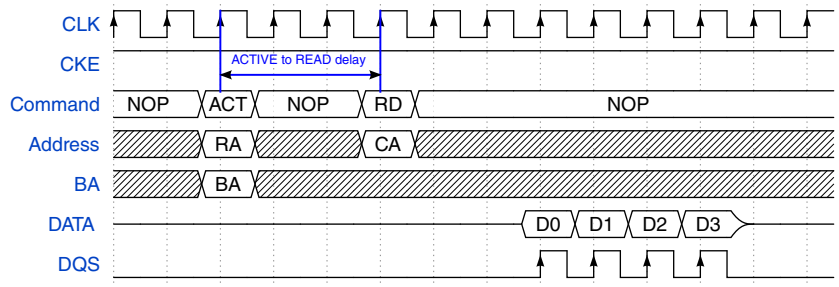

Figure 103. IP Command - SDRAM READ

NOTE

- It is supported but not recommended to send READ command with IP command trigger. The SEMC should read SDRAM device by AXI command.
- Read address is from IPCR0 register, read data is sent to IPRXDAT register.
- For this example:
  - ACTIVE to READ/WRITE delay is 3 (SDRAMCR1[ACT2RW]=2)

29.3.1.4.2.2 WRITE

When an IP command is triggered with command code - WRITE, the SEMC will send a WRITE command to the SDRAM device.

Figure 104 shows the sequence for IP command - WRITE.

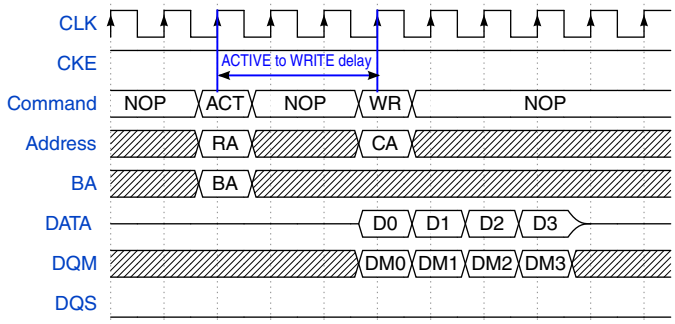

Figure 104. IP Command - SDRAM WRITE

NOTE

- It is supported but not recommended to send WRITE command with IP command trigger. The SEMC should write SDRAM device by AXI command.
- Write address is from IPCR0 register, write data is from IPTXDAT register, write mask is from IPCR2 register.
- For this example:
  - ACTIVE to READ/WRITE delay is 3 (SDRAMCR1[ACT2RW]=2)

29.3.1.4.2.3 MODE REGISTER SET

When an IP command is triggered with command code - MODE REGISTER SET, the SEMC will send a MODE REGISTER SET command to the SDRAM device.

Figure 105 shows the sequence for IP command - MODE REGISTER SET.

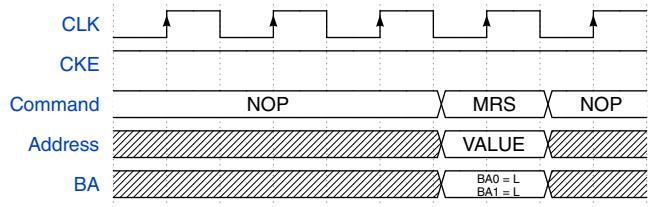

Figure 105. IP Command - SDRAM MODE REGISTER SET

NOTE

- MODE REGISTER SET command triggered by IP command should be used for SDRAM device initialization only.
- The "Value" of Address comes from IPTXDAT[12:0] register.

29.3.1.4.2.4 EXTENDED MODE REGISTER SET

When an IP command is triggered with command code - EXTENDED MODE REGISTER SET, the SEMC will send an EXTENDED MODE REGISTER SET command to the SDRAM device.

Figure 106 shows the sequence for IP command - EXTENDED MODE REGISTER SET.

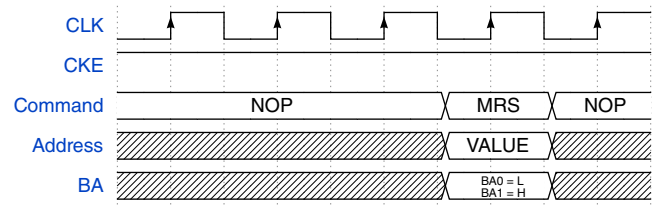

Figure 106. IP Command - EXTENDED SDRAM MODE REGISTER SET

NOTE

- EXTENDED MODE REGISTER SET command triggered by IP command should be used for SDRAM device initialization only.
- The "Value" of Address comes from IPTXDAT[12:0] register.

29.3.1.4.2.5 DEEP POWER DOWN

When an IP command is triggered with command code - DEEP POWER DOWN, the SEMC will send a DEEP POWER DOWN command to the SDRAM device.

Figure 107 shows the sequence for IP command - DEEP POWER DOWN.

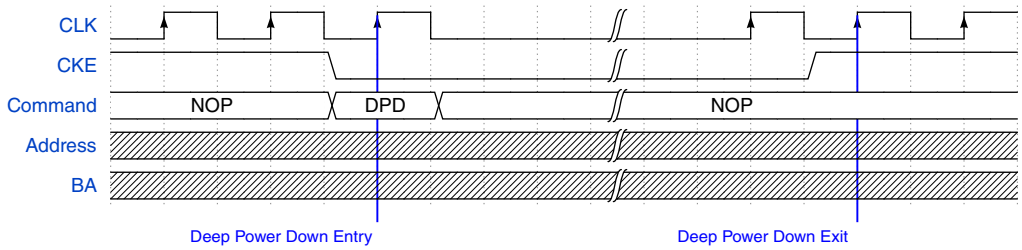

Figure 107. IP Command - DEEP POWER DOWN

NOTE

- The SEMC sends PRECHARGE ALL command to close any opened page on device before sending DEEP POWER DOWN command. There is no PRECHARGE ALL command if no pages on the selected device are open.
- Deep Power Mode is exited by any IP or AXI command.

29.3.1.4.2.6 ACTIVE

When an IP command is triggered with command code - ACTIVE, the SEMC will send an ACTIVE command to the SDRAM device.

Figure 108 shows the sequence for IP command - ACTIVE.

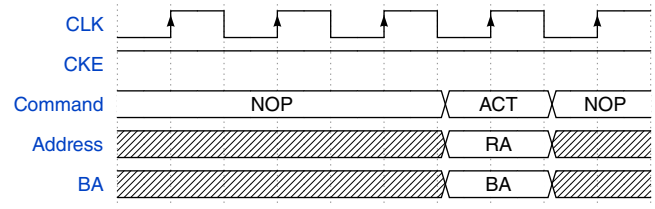

Figure 108. IP Command - SDRAM ACTIVE

NOTE

- It is supported but not recommended to send ACTIVE command with an IP command trigger. The SEMC can handle page management for READ/WRITE/AUTO REFRESH/SELF REFRESH etc.

29.3.1.4.2.7 AUTO REFRESH

When an IP command is triggered with command code - AUTO REFRESH, the SEMC will send an AUTO REFRESH command to the SDRAM device.

Figure 109 shows the sequence for IP command - AUTO REFRESH.

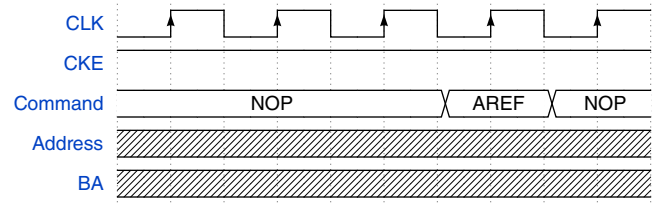

Figure 109. IP Command - SDRAM AUTO REFRESH

NOTE

- There is only one AUTO REFRESH command sent when triggered by IP command and only one device is accessed.
- The SEMC sends PRECHARGE ALL command to close any opened page on device before sending AUTO REFRESH command. There is no PRECHARGE ALL command if no pages on the selected device are open.
- AUTO REFRESH command triggered by IP command should be used for SDRAM device initialization only. For entering auto refresh during normal operation, set SDRAMCR3[REN] to 1 and the SEMC will send AUTO REFRESH command automatically.

29.3.1.4.2.8 SELF REFRESH

When a SELF REFRESH IP command is requested for any SDRAM device, the SEMC will send a SELF REFRESH command to all SDRAM devices. After the SELF REFRESH command is completed, all SDRAM devices should be in self refresh mode and the SEMC keeps this mode on SDRAM interface (SEMC_CKE=0 and SEMC_CLK=0).

The SEMC brings all SDRAM devices out of self refresh mode when there is any new IP command or AXI command triggered to an SDRAM device.

Figure 110 shows the sequence for self refresh entering and exiting by AXI command.

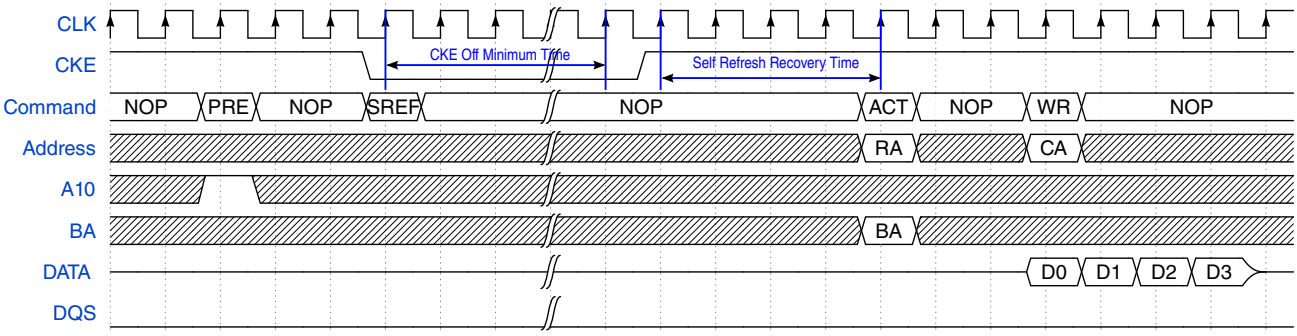

Figure 110. IP Command - SDRAM SELF REFRESH

NOTE

- The SEMC sends PRECHARGE ALL command to close any opened page on device before entering self refresh mode. There is no PRECHARGE ALL command if no page is opened at any device.
- SELF REFRESH command sends to all devices.
- It is not recommended to put device into self refresh mode by IP command triggering although it is supported. Recommend to put device into self refresh mode by the SEMC STOP mode instead.
- Disable the SEMC auto refresh enable bit (SDRAMCR3[REN]=0) before entering self refresh mode, otherwise the SEMC may bring devices out of self refresh mode.
- For this example:
  - Self refresh recovery time is 4 clock cycles (SDRAMCR2[SRRC]=3)
  - CKE off minimum time is 4 clock cycles (SDRAMCR1[CKEOFF]=3)
  - The SEMC brings SDRAM out of self refresh mode when an AXI write command is triggered.

29.3.1.4.2.9 PRECHARGE

When an IP command is triggered with command code - PRECHARGE, The SEMC will send a PRECHARGE command to the SDRAM device.

Figure 111 shows the sequence for IP command - PRECHARGE.

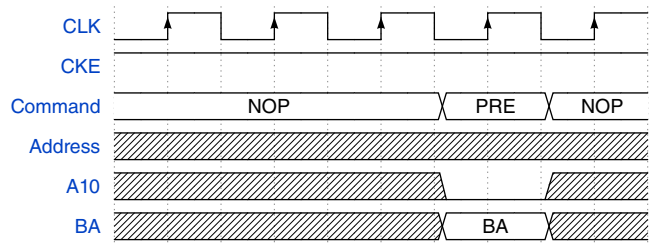

Figure 111. IP Command - SDRAM PRECHARGE

NOTE

- It is not recommended to send PRECHARGE command triggered by IP command although it is supported. The SEMC can handle page management for READ/WRITE/AUTO REFRESH/SELF REFRESH etc.

29.3.1.4.2.10 PRECHARGE ALL

When an IP command is triggered with command code - PRECHARGE ALL, the SEMC will send a PRECHARGE ALL command to the SDRAM device.

Figure 112 shows the sequence for IP command - PRECHARGE ALL.

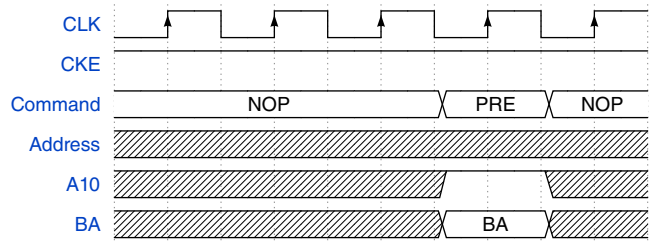

Figure 112. IP Command - SDRAM PRECHARGE ALL

NOTE

- It is not recommended to send PRECHARGE ALL command triggered by IP command although it is supported. The SEMC can handle page management for READ/WRITE/AUTO REFRESH/SELF REFRESH etc.
- PRECHARGE ALL command triggered by IP command should be used for SDRAM device initialization only.

29.3.1.4.2.11 Combination of IP Commands

Figure 113 shows a combination sequence of IP commands, that includes AUTO REFRESH, ACTIVE, WRITE and PRECHARGE IP commands.

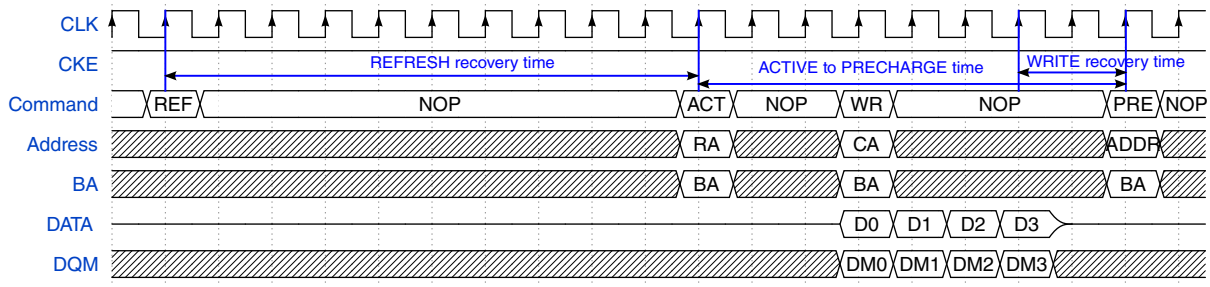

Figure 113. IP Command - AUTO REFRESH, ACTIVE, WRITE and PRECHARGE

NOTE

- For this example:
  - REFRESH recovery time is 10 clock cycles (SDRAMCR1[RFRC]=9)
  - WRITE recovery time is 2 clock cycles (SDRAMCR1[WRC]=1)
  - ACTIVE to PRECHARGE minimum time is 6 clock cycles (SDRAMCR1[ACT2PRE]=5). Current ACTIVE to PRECHARGE time is 8 clock cycles by the limitation of WRITE burst beats and recovery time.

29.3.1.4.3 SDRAM Device Access by AXI Command

SDRAM device read/write access can be triggered by AXI Command. For AXI read access, the SEMC will send READ commands to SDRAM device automatically and return data on AXI bus. For AXI write access, the SEMC will save AXI bus write data and send WRITE commands to the SDRAM device automatically.

29.3.1.4.3.1 Read Access

Figure 114 shows an SDRAM read triggered by an AXI command.

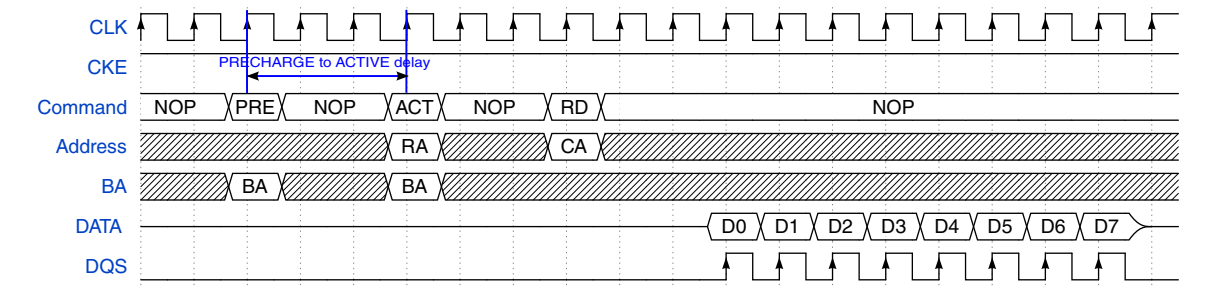

Figure 114. AXI Command - SDRAM READ

NOTE

- The SEMC opens/closes pages automatically for current AXI command.
- For this example:
  - CAS latency is 3 (SDRAMCR0[CL]=3)
  - Burst length is 8 (SDRAMCR0[BL]=3)
  - PRECHARGE to ACTIVE delay is 3 clock cycles (SDRAMCR1[PRE2ACT]=2)

29.3.1.4.3.2 Write Access

Figure 115 shows an SDRAM write triggered by an AXI command.

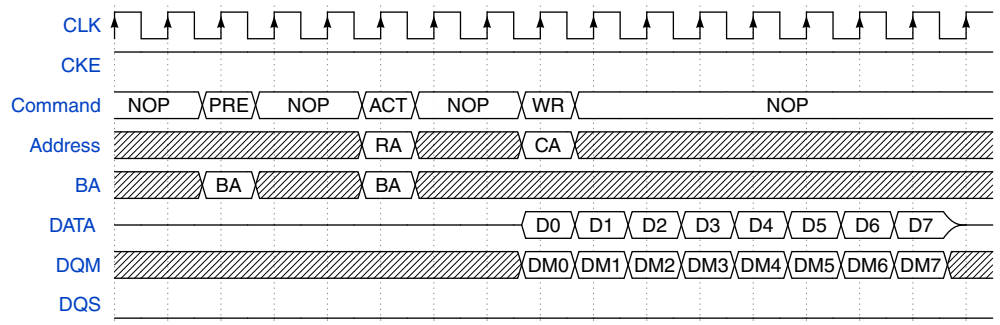

Figure 115. AXI Command - SDRAM WRITE

NOTE

- The SEMC opens/closes pages automatically for current AXI command.
- SDRAM device burst length is 8 in this example. The SEMC may send multiple WRITE commands if AXI burst size is larger than SDRAM burst length.

29.3.1.4.3.3 Pipelined Access

Figure 116 shows an SDRAM pipelined read access that is triggered by AXI bus read access.

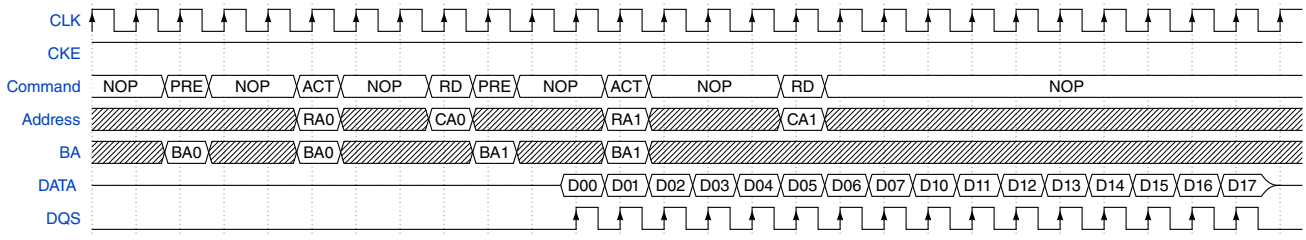

Figure 116. AXI Command - Pipelined SDRAM Read

NOTE

- The SEMC opens/closes pages automatically for next AXI command during SDRAM Read burst.
- Data D0x is from CA0, and data D1x is from CA1. This naming rule is also applied to the following SDRAM figures.

Figure 117 shows the SDRAM device pipelined write access that triggered by AXI bus write access.

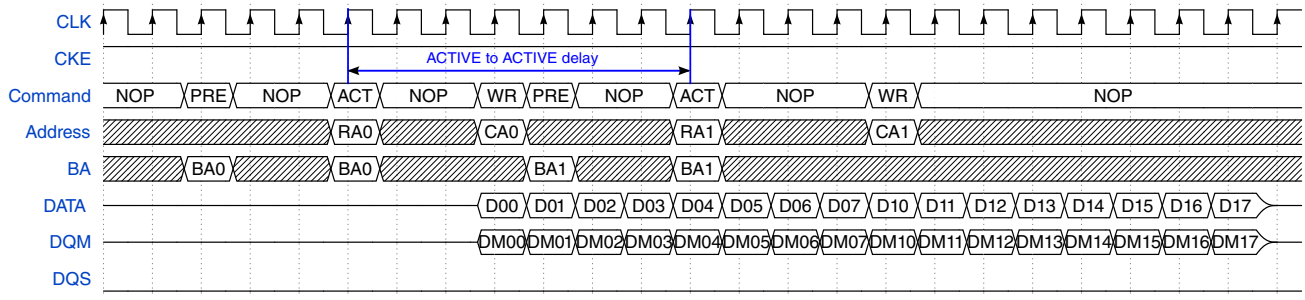

Figure 117. AXI Command - Pipelined SDRAM Write

NOTE

- The SEMC opens/closes pages automatically for next AXI command during SDRAM Write burst.

29.3.1.4.3.4 SDRAM Back-to-Back Access

This section describes the SDRAM back-to-back access.

29.3.1.4.3.4.1 Read-to-Read Access

Figure 118 shows SDRAM read-to-read access timing when CL=1.

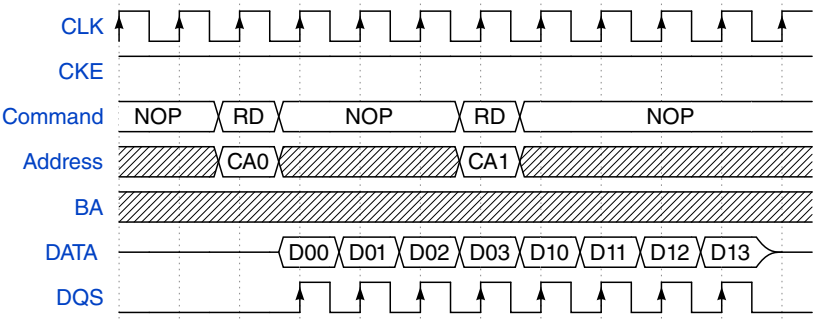

Figure 118. SDRAM Read-to-Read Access (CL=1)

Figure 119 shows SDRAM read-to-read access timing when CL=2.

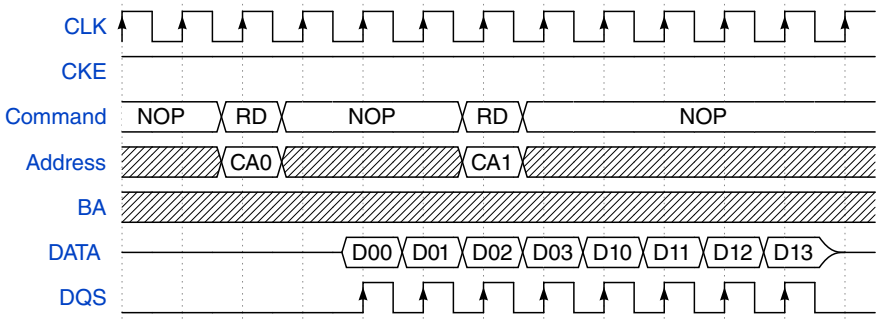

Figure 119. SDRAM Read-to-Read Access (CL=2)

Figure 120 shows SDRAM read-to-read access timing when CL=3.

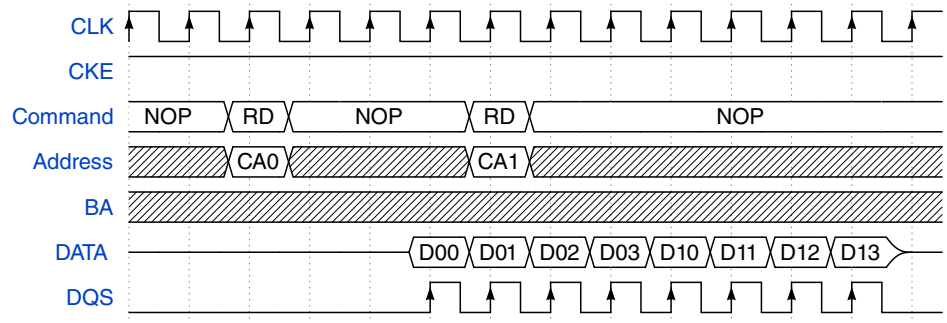

Figure 120. SDRAM Read-to-Read Access (CL=3)

29.3.1.4.3.4.2 Read-to-Write Access

Figure 121 shows SDRAM read-to-write access timing when CL=1.

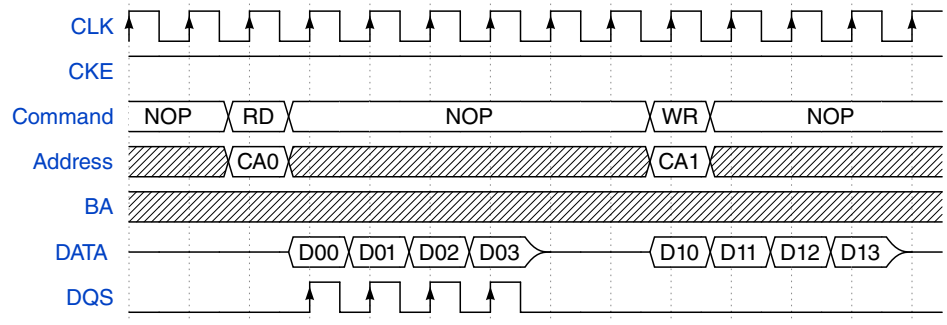

Figure 121. SDRAM Read-to-Write Access (CL=1)

Figure 122 shows SDRAM read-to-write access timing when CL=2.

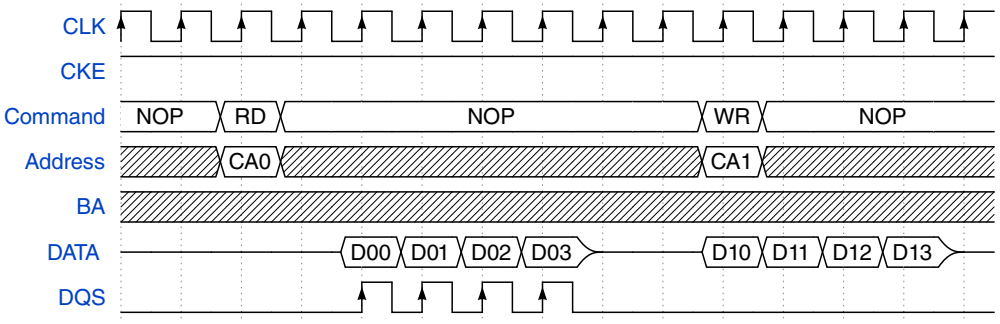

Figure 122. SDRAM Read-to-Write Access (CL=2)

Figure 123 shows SDRAM read-to-write access timing when CL=3.

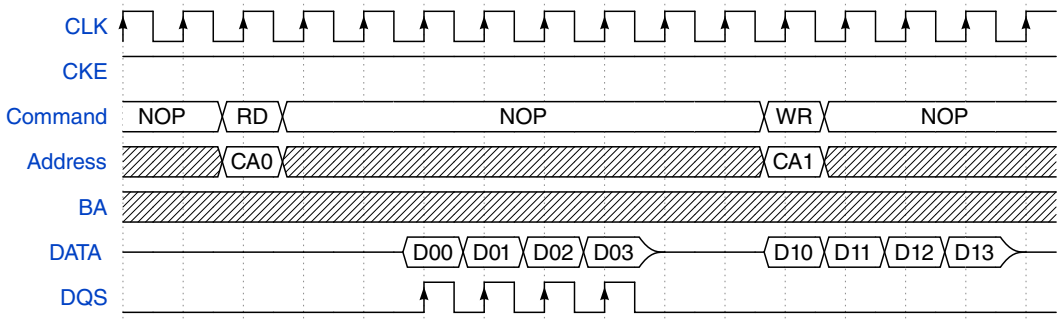

Figure 123. SDRAM Read-to-Write Access (CL=3)

29.3.1.4.3.4.3 Write-to-Write Access

Figure 124 shows SDRAM write-to-write access timing.

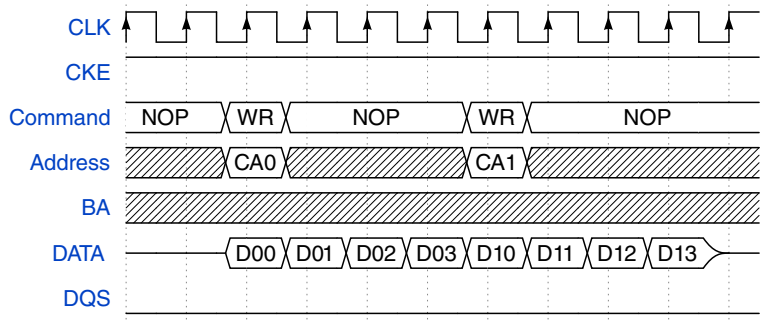

Figure 124. SDRAM Write-to-Write Access

29.3.1.4.3.4.4 Write-to-Read Access

Figure 125 shows SDRAM write-to-read access timing when CL=1.

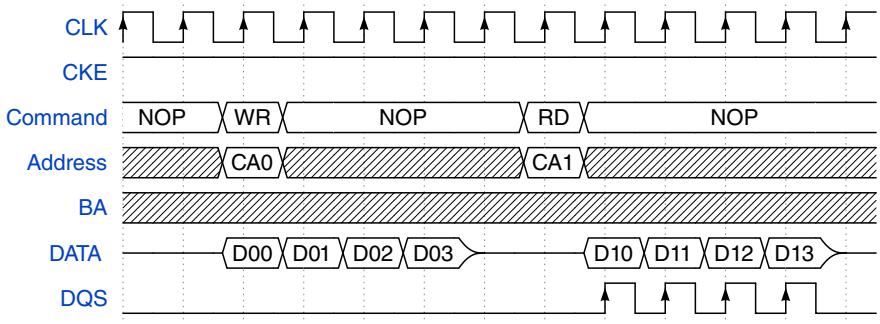

Figure 125. SDRAM Write-to-Read Access (CL=1)

Figure 126 shows SDRAM write-to-read access timing when CL=2.

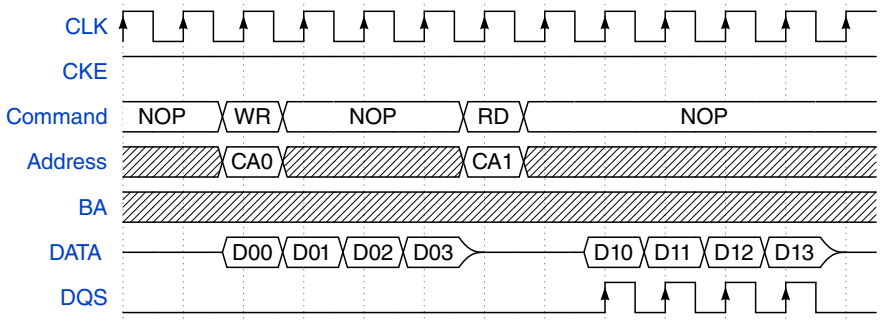

Figure 126. SDRAM Write-to-Read Access (CL=2)

Figure 127 shows SDRAM write-to-read access timing when CL=3.

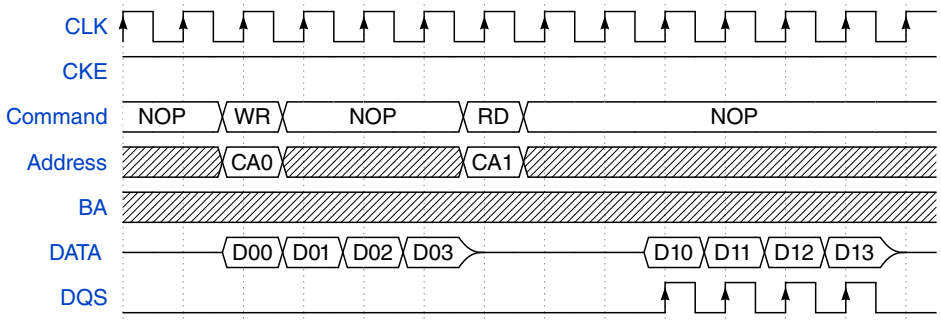

Figure 127. SDRAM Write-to-Read Access (CL=3)

29.3.1.4.4 Refresh Command - SDRAM AUTO REFRESH

When SDRAM refresh is enabled (SDRAMCR3[REN]=1), the SEMC will send an AUTO REFRESH command to all SDRAM devices whenever the refresh timer expires. Multiple AUTO REFRESH commands can be sent if refresh burst is not set to one (SDRAMCR3[REBL]!=0).

The refresh timer's count cycle is controlled by UT, RT and PRESCALE bits in SDRAMCR3.

Figure 128 shows the sequence of AUTO REFRESH Command.

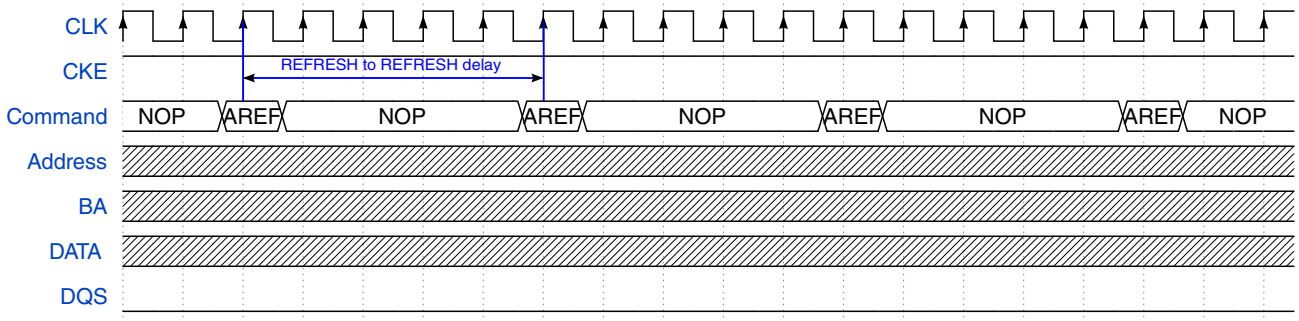

Figure 128. Refresh Command - SDRAM AUTO REFRESH

NOTE

- AUTO REFRESH command is sent to all devices.
- For this example:
  - Refresh to refresh delay is 5 clock cycles (SDRAMCR2[REF2REF]=4)
  - Refresh burst length is 4 (SDRAMCR3[REBL]=3)

29.3.1.4.5 SDRAM Low Power Feature

This section describes the low power feature that is implemented for SDRAM.

29.3.1.4.5.1 SDRAM Stop Mode

The SEMC puts SDRAM to self refresh mode automatically when the system enters STOP mode. The SEMC brings SDRAM out of self refresh mode when the system exits STOP mode.

Figure 129 shows the sequence of STOP mode entering and exiting.

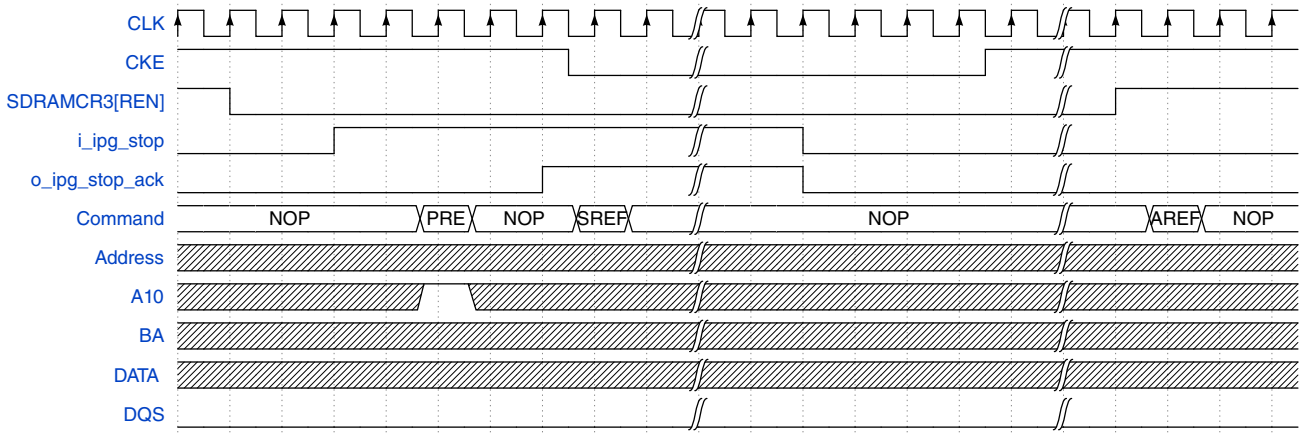

Figure 129. SDRAM Stop Mode Enter and Exit

NOTE

- The SEMC sends PRECHARGE ALL command to close any opened page on device before entering self refresh mode. There is no PRECHARGE ALL command if no page is opened at any device.
- SELF REFRESH command is sent to all devices.
- Disable the SEMC auto refresh bit (SDRAMCR3[REN]=0) before entering STOP mode, otherwise the SEMC may bring devices out of self refresh mode.

29.3.1.4.5.2 SDRAM Bus Idle

When there are no pending IP, AXI, or refresh commands, SDRAM interface will in the idle state. When the SDRAM interface bus idle timer expires, the SEMC closes all opened pages on all SDRAM devices. Refer to SDRAMCR2[ITO] for more information.

29.3.1.4.6 SDRAM Page Management

This section describes the SDRAM page management.

The SEMC will save row addresses for up to 8 opened pages: 4 pages for CS0/CS2 (4 banks), 4 pages for CS1/CS3 (4 banks). Device CS0 and CS2 pages are never opened at the same time. Before the SEMC opens pages on CS2, it closes all opened pages on CS0. This is similar for CS1/CS3.

The SEMC closes all pages on all CS by issuing a PRECHARGE ALL command in following cases:

1. SELF REFRESH triggered by IP command
2. SELF REFRESH triggered by stop mode entry
3. The idle time on AXI bus and SDRAM interface is longer than SDRAM idle timeout time (SDRAMCR2[ITO]).

NOTE

The SEMC will not send out PRECHARGE ALL command if there are no pages opened on any bank/CS.

The SEMC will close all pages on one CS in following cases:

1. PRECHARGE ALL command triggered by IP command
2. AUTO REFRESH command triggered by IP command
3. ACTIVE/WRITE/READ command triggered by IP command and CS miss
4. WRITE/READ command triggered by current AXI command and CS miss
5. WRITE/READ command triggered by next AXI command (not accepted yet), CS miss and not same CS as current AXI command

NOTE

One example for CS miss: current IP command access CS2 but there is page opened on CS0 already.

The SEMC will close one page on one CS in following cases:

1. PRECHARGE command triggered by IP command and this bank is opened
2. ACTIVE/READ/WRITE command triggered by IP command, this bank is opened and page missed.
3. WRITE/READ command triggered by current AXI command, this bank is opened and page missed.
4. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is opened, page missed and different bank accessed with current AXI command.

NOTE

One example for page miss: current bank is opened but the opened page row address is different with current SDRAM command access.

The SEMC will open one page on one CS in following cases:

1. ACTIVE/READ/WRITE command triggered by IP command, this bank is not opened.
2. WRITE/READ command triggered by current AXI command, this bank is not opened.
3. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is not opened and different bank accessed with current AXI command.

29.3.1.5 NAND Flash Controller Operations

This section describes the operations of NAND Flash controller.

29.3.1.5.1 NAND Flash Address Multiplexing

The NAND Flash controller uses a multiplexed address split into rows and columns. Figure 130 shows how the bits of the linear address sent to the SEMC are split up into the row and column addresses sent to the NAND Flash memory device.

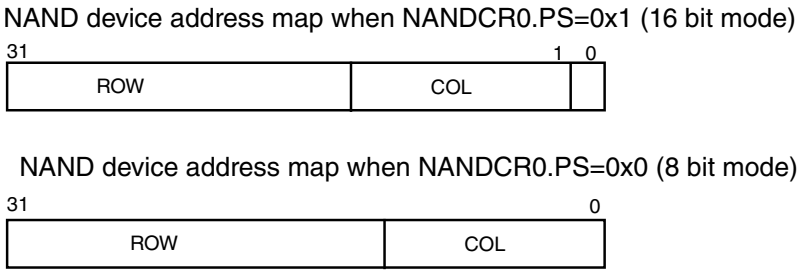

Figure 130. NAND Flash Address Multiplexing

NOTE

- NAND address bits consist of row and column address bits.
- Column address bits offset is bit 0 if NANDCR0[PS]=0, the offset is bit 1 if NANDCR0[PS]=1. Column address bit width is determined by NANDCR0[COL].
- Column bit number should cover all page size. For example, column bit number should be 14 if NAND Flash page size is 8192 + 448 (main + spare) bytes.
- Row address bits offset is determined by NANDCR0[PS] and NANDCR[COL].
- NAND device base address on SoC is configured by BR4 and BR8 registers.

29.3.1.5.2 NAND Flash Data Map

Table 185 lists the data map when NAND controller using NAND buffer.

Table 185. Buffer to Physical Mappings Examples

Flash page size (main+spare)	ECC Mode	Sector Number	Sector Size in Buffer	Sector Size in Flash	Mapping
512+16	0	1	528	528	Buffer_0[527:0]=Flash[527:0]
512+16	0	1	512	512	Buffer_0[511:0]=Flash[511:0]
512+16	1	1	512	520	Buffer_0[511:0]=Flash[511:0]
512+16	2	1	512	528	Buffer_0[511:0]=Flash[511:0]
2048+64	0	1	2112	2112	Buffer_0[2111:0]=Flash[2111:0]
2048+64	0	1	2048	2048	Buffer_0[2047:0]=Flash[2047:0]
2048+64	1	1	2048	2056	Buffer_0[2047:0]=Flash[2047:0]
2048+64	2	1	2048	2064	Buffer_0[2047:0]=Flash[2047:0]
2048+64	1	4	512	520	Buffer_0[511:0]=Flash[511:0] Buffer_1[511:0]=Flash[1031:520] Buffer_2[511:0]=Flash[1551:1040] Buffer_3[511:0]=Flash[2071:1560]
2048+64	2	4	512	528	Buffer_0[511:0]=Flash[511:0] Buffer_1[511:0]=Flash[1039:528] Buffer_2[511:0]=Flash[1567:1056] Buffer_3[511:0]=Flash[2095:1584]

NOTE

- Sector Size in Buffer stands for NANDCR0[SECTOR_SIZE]
- Sector Size in Flash = Sector Size in Buffer + ECC bytes
- If ECC Mode is 0, then ECC bytes is 0, and Sector Size in Flash = Sector Size in Buffer
- If ECC Mode is 1, then ECC bytes is 8, and Sector Size in Flash = Sector Size in Buffer + 8
- If ECC Mode is 2, then ECC bytes is 16, and Sector Size in Flash = Sector Size in Buffer + 16

29.3.1.5.3 NAND Flash Access Sequences

NAND Flash controller supports program and read operations by IPS and AXI bus. It has internal 2112 bytes NAND buffer to support encoding or decoding of ECC schemes. The NAND buffer must be enabled (NANDCR0[BUFEN]=1) if ECC function is required, otherwise it is not mandatory. Some program and read sequences are listed as below:

29.3.1.5.3.1 NAND Flash IPS Program Sequence

IPS program operation with buffer enabled (NANDCR0[BUFEN]=1):

1. Configure NANDCR0 register for ECC mode, sector number and size.
2. Configure IPCR0/IPCR1/IPCR2 registers for device address, data size and write mask.
3. Send Flash command "PROGRAM PAGE first command (80h)".
4. Configure NDBA register with proper NAND buffer start address, recommend 0.
5. Write data to NDBD register. IPCR1[DATSZ] should be 4 bytes, then the write pointer of buffer address increases 4 by each write action. It can not exceed (sector size)*(sector number).
6. Send IP command "NAND Buffer Write".
7. Repeat steps 4 - 6 if NAND device's main page space is more than 2048 bytes, otherwise go to step 8.
8. Send Flash command "PROGRAM PAGE second command (10h)".
9. Wait program sequence done.

IPS program operation with buffer disabled (NANDCR0[BUFEN]=0):

1. Configure IPCR0/IPCR1/IPCR2 registers for device address, data size and write mask.
2. Send Flash command "PROGRAM PAGE first command (80h)".
3. Write data to IPTXDAT register.
4. Send IP command "NAND Write".
5. Repeat steps 3 - 4 to write more data in the page, otherwise go to step 6.
6. Send Flash command "PROGRAM PAGE second command (10h)".
7. Wait program sequence done.

NOTE

- Be caution that erased data is not protected by ECC scheme.

29.3.1.5.3.2 NAND Flash IPS Read Sequence

IPS read operation with buffer enabled (NANDCR0[BUFEN]=1):

1. Configure NANDCR0 register for ECC mode, sector number and size.
2. Configure IPCR0/IPCR1/IPCR2 registers for device address, data size and write mask.

3. Send Flash command "PAGE READ".
4. Wait read data ready.
5. Send IP command "NAND Buffer Read".
6. Configure NDBA register with proper NAND buffer start address.
7. Read data from NDBD register. IPCR1[DATSZ] should be 4 bytes, then the read pointer of buffer address increases 4 by read action. It can not exceed (sector size)*(sector number).
8. Repeat steps 5 - 7 if NAND device's main page space is more than 2048 bytes.

IPS read operation with buffer disabled (NANDCR0[BUFEN]=0):

1. Configure IPCR0/IPCR1/IPCR2 registers for device address, data size and write mask.
2. Send Flash command "PAGE READ".
3. Wait read data ready.
4. Send IP command "NAND Read".
5. Read data from IPRXDAT register.
6. Repeat steps 4 - 5 to read more data in the page.

29.3.1.5.3.3 NAND Flash AXI Program Sequence

AXI program operation with buffer enabled (NANDCR0.BUFEN=1):

1. Configure NANDCR0 register for ECC mode, sector number and size.
2. Configure IPCR0/IPCR1/IPCR2 registers for device address, data size and write mask.
3. Send Flash command "PROGRAM PAGE first command (80h)".
4. Write data by AXI bus with valid address, the address offset can not exceed (sector size)*(sector number).
5. Send IP command "NAND Buffer Write".
6. Repeat steps 4 - 5 if NAND device's main page space is more than 2048 bytes, otherwise go to step 7.
7. Send Flash command "PROGRAM PAGE second command (10h)".
8. Wait program sequence done.

AXI program operation with buffer disabled (NANDCR0[BUFEN]=0):

1. Configure IPCR0/IPCR1/IPCR2 registers for device address, data size and write mask.
2. Send Flash command "PROGRAM PAGE first command (80h)".
3. Write data by AXI bus with valid address.
4. Repeat step 3 to write more data in the page, otherwise go to step 5.
5. Send Flash command "PROGRAM PAGE second command (10h)".
6. Wait program sequence done.

29.3.1.5.3.4 NAND Flash AXI Read Sequence

AXI read operation with buffer enabled (NANDCR0[BUFEN]=1):

1. Configure NANDCR0 register for ECC mode, sector number and size.
2. Configure IPCR0/IPCR1/IPCR2 registers for device address, data size and write mask.
3. Send Flash command "PAGE READ".

4. Wait read data ready.
5. Send IP command "NAND Buffer Read".
6. Read data by AXI bus with valid address, the read address can not exceed (sector size)*(sector number).
7. Repeat steps 5 - 6 if NAND device's main page space is more than 2048 bytes.

AXI read operation with buffer disabled (NANDCR0[BUFEN]=0):

1. Configure IPCR0/IPCR1/IPCR2 registers for device address, data size and write mask.
2. Send Flash command "PAGE READ".
3. Wait read data ready.
4. Send IP command "NAND Read".
5. Read data by AXI bus with valid address, the read address can not exceed page size.
6. Repeat step 5 to read more data.

29.3.1.5.4 NAND Flash Access Address Type

Table 186 lists the NAND address types that are triggered by IP commands.

Table 186. NAND Address Types

Address Type	IPCMD[7:4]
Five Bytes Row/Column Address	0x0
One Byte Column Address	0x1
Two Bytes Column Address	0x2
One Byte Row Address	0x3
Two Bytes Row Address	0x4
Three Bytes Row Address	0x5

For IP command, address type is determined by IPCMD register. For AXI command, address type is fixed to "Two Bytes Column Address" because AXI access is limited in opened NAND page.

29.3.1.5.4.1 Five Bytes Row/Column Address

Figure 131 shows the Five Bytes Row/Column Address type access timing.

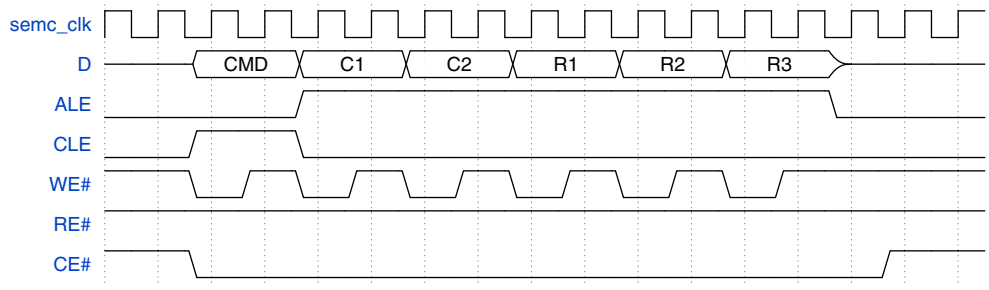

Figure 131. NAND Flash Access Address Type - Five Bytes Row/Column Address

There are some option bits to support different NAND address types in the Five Bytes Row/Column Address type. Table 187 lists all the combinations of address types.

Table 187. Address Bytes Order for five Bytes Row/Column Address Mode

NANDCR3[NDOPT3]	NANDCR3[NDOPT2]	NANDCR3[NDOPT1]	Address byte order
0	0	0	C1/C2/R1/R2/R3
0	0	1	C1/R1/R2/R3
0	1	0	C1/C2/R1/R2
0	1	1	C1/R1/R2
1	-	0	C1/C2/R1
1	-	1	C1/R1

29.3.1.5.4.2 One Byte Column Address

Figure 132 shows the One Byte Column Address type access timing.

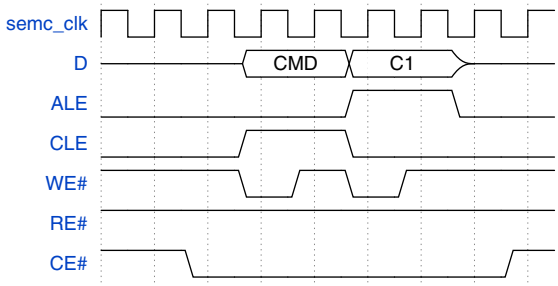

Figure 132. NAND Flash Access Address Type - One Byte Column Address

29.3.1.5.4.3 Two Bytes Column Address

Figure 133 shows the Two Bytes Column Address type access timing.

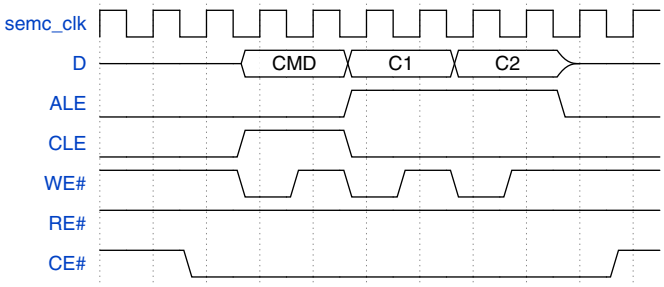

Figure 133. NAND Flash Access Address Type - Two Bytes Column Address

29.3.1.5.4.4 One Byte Row Address

Figure 134 shows the One Byte Row Address type access timing.

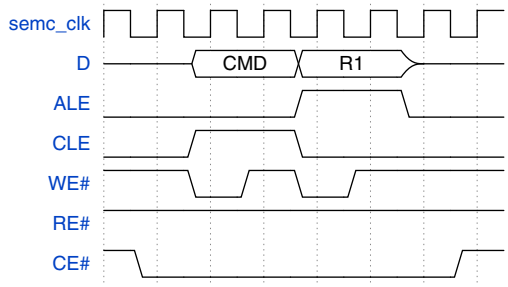

Figure 134. NAND Flash Access Address Type - One Byte Row Address

29.3.1.5.4.5 Two Bytes Row Address

Figure 135 shows the Two Bytes Row Address type access timing.

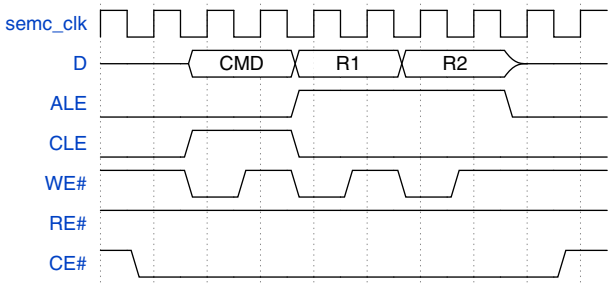

Figure 135. NAND Flash Access Address Type - Two Bytes Row Address

29.3.1.5.4.6 Three Bytes Row Address

Figure 136 shows the Three Bytes Row Address type access timing.

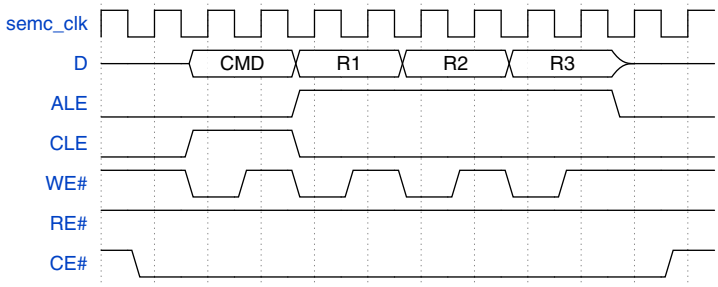

Figure 136. NAND Flash Access Address Type - Three Bytes Row Address

29.3.1.5.5 NAND Flash Access Command Type

NAND Flash access support following command types:

1. Command Phase
2. Command + Wait Phase
3. Command + Address Phase
4. Command + Address + Wait Phase

5. Command + Address + Read Phase
6. Command + Address + Write Phase (for IP command)
7. Command + Write Phase
8. Command + Read Phase
9. Write Phase
10. Read Phase
11. Command + Address + Command + Read Phase (for AXI command - Read)
12. Command + Address + Write Phase (for AXI command - Write)

29.3.1.5.5.1 Command Phase

Figure 137 shows the NAND Flash Command Phase access timing.

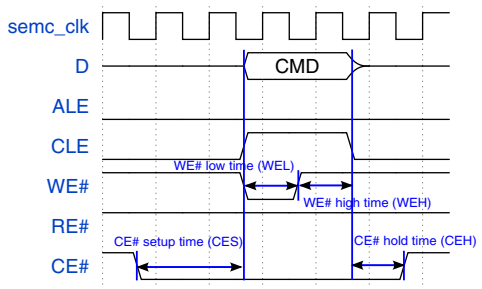

Figure 137. NAND Flash Access Command Type - Command Phase

NOTE

- semc_clk is the SEMC functional clock.
- For this example:
  - CE# setup time is 2 clock cycles (NANDCR1[CES]=1)
  - WE# low time is 1 clock cycle (NANDCR1[WEL]=0)
  - WE# high time is 1 clock cycle (NANDCR1[WEH]=0)
  - CE# hold time is 1 clock cycle (NANDCR1[CEH]=0)

29.3.1.5.5.2 Command + Wait Phase

Figure 138 shows NAND Flash Command + Wait Phase access timing

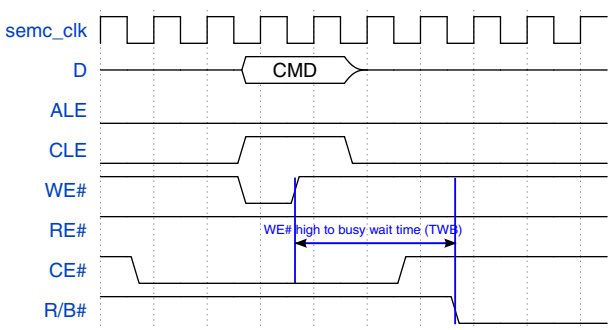

Figure 138. NAND Flash Access Command Type - Command + Wait Phase

NOTE

- For this example:
  - WE# high to busy time is 3 clock cycles (NANDCR1[TWB]=2)

29.3.1.5.5.3 Command + Address Phase

Figure 139 shows the NAND Flash Command + Address Phase access timing.

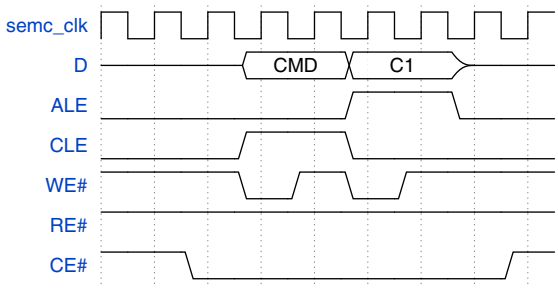

Figure 139. NAND Flash Access Command Type - Command + Address Phase

29.3.1.5.5.4 Command + Address + Wait Phase

Figure 140 shows NAND Flash Command + Address + Wait Phase access timing.

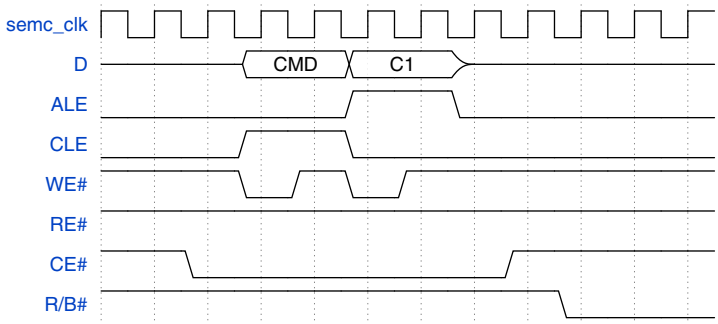

Figure 140. NAND Flash Access Command Type - Command + Address + Wait Phase

29.3.1.5.5.5 Command + Address + Read Phase

Figure 141 shows NAND Flash Command + Address + Read Phase access timing.

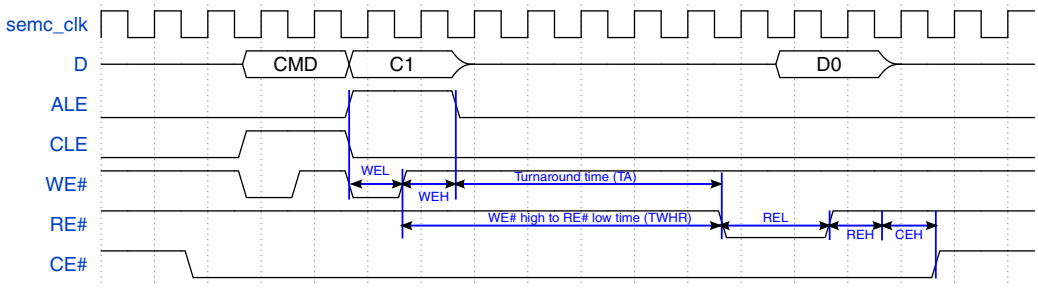

Figure 141. NAND Flash Access Command Type - Command + Address + Read Phase

NOTE

- For this example:
  - WE# low time is 1 clock cycle (NANDCR1[WEL]=0)
  - WE# high time is 1 clock cycle (NANDCR1[WEH]=0)
  - RE# low time is 2 clock cycles (NANDCR1[REL]=1)
  - RE# high time is 1 clock cycle (NANDCR1[REH]=0)
  - Turnaround time is 5 clock cycles (NANDCR1[TA]=4)
  - WE# high to RE# low time is 6 clock cycles (NANDCR2[TWHR]=5)
  - CE# hold time is 1 clock cycle (NANDCR1[CEH]=0)

29.3.1.5.5.6 Command + Address + Write Phase (for IP Command)

Figure 142 shows NAND Flash Command + Address + Write Phase access timing.

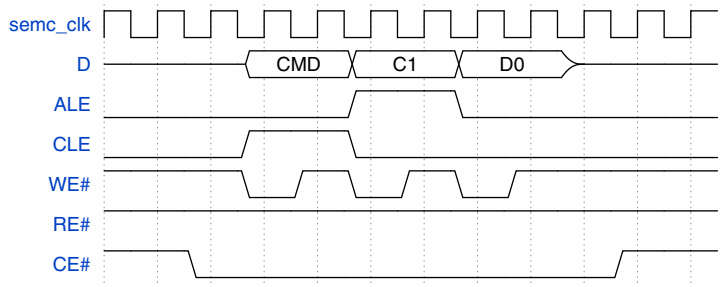

Figure 142. NAND Flash Access Command Type - Command + Address + Write Phase

29.3.1.5.5.7 Command + Read Phase

Figure 143 shows NAND Flash Command + Read Phase access timing.

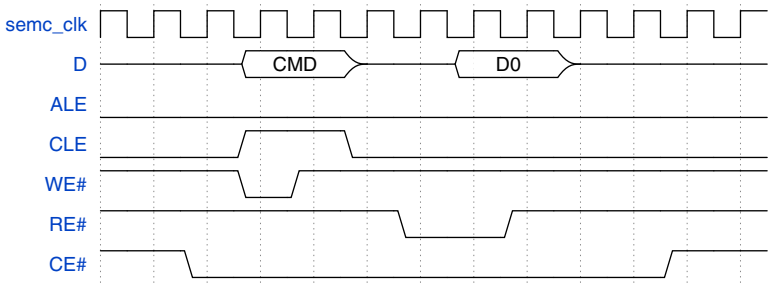

Figure 143. NAND Flash Access Command Type - Command + Read Phase

29.3.1.5.5.8 Command + Write Phase

Figure 144 shows NAND Flash Command + Write Phase access timing.

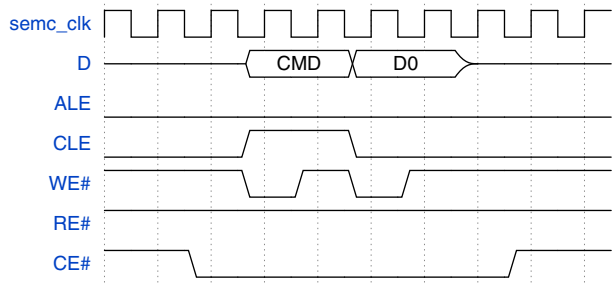

Figure 144. NAND Flash Access Command Type - Command + Write Phase

29.3.1.5.5.9 Read Phase

Figure 145 shows NAND Flash Read Phase access timing.

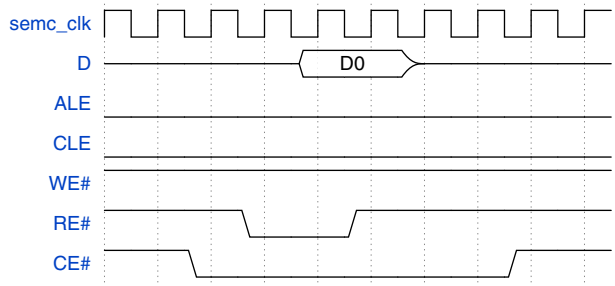

Figure 145. NAND Flash Access Command Type - Read Phase

29.3.1.5.5.10 Write Phase

Figure 146 shows the timing of NAND Flash Write Phase access.

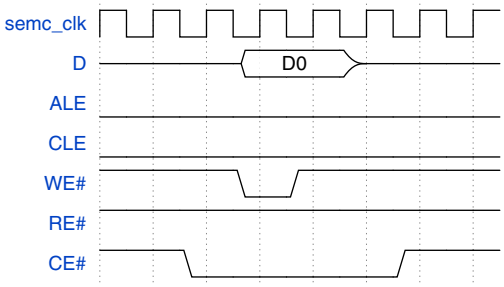

Figure 146. NAND Flash Access Command type - Write Phase

29.3.1.5.5.11 Command + Address + Command + Read Phase

Figure 147 shows the NAND Flash Command + Address + Command + Read Phase access timing.

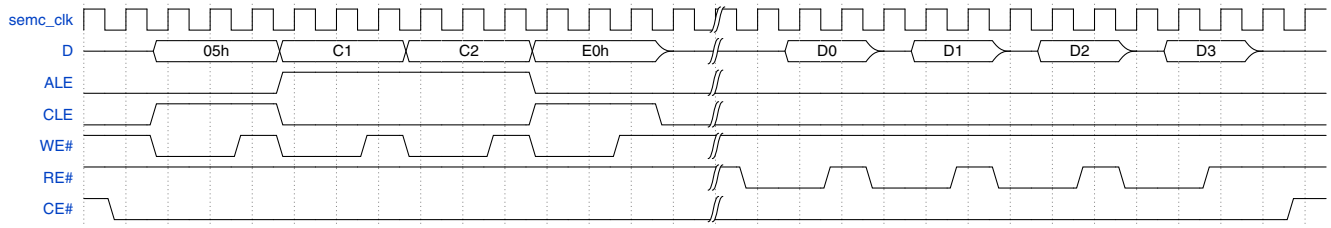

Figure 147. NAND Flash Access Command Type - Command + Address + Command + Read Phase

NOTE

- This command type is for AXI command only
- The command code in this command type is fixed value (Change Column Address) to support ONFI NAND device. The first byte command code is 05h, and second byte command code is E0h.
- The address type in this command type is fixed to two byte column address.

29.3.1.5.5.12 Command + Address + Write Phase (for AXI command)

Figure 148 shows the NAND Flash Command + Address + Write Phase access timing.

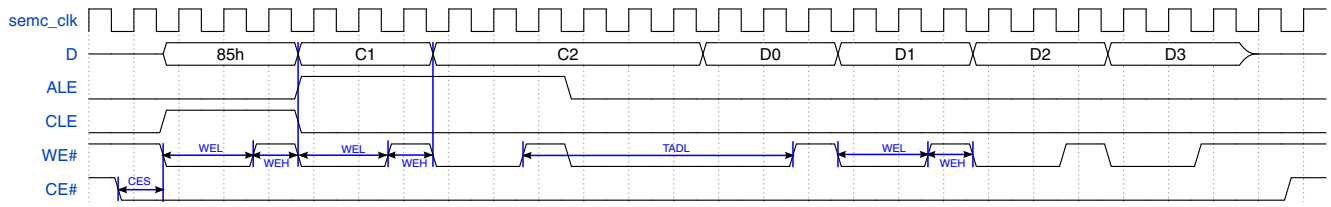

Figure 148. NAND Flash Access Command Type - Command + Address + Write Phase

NOTE

- This command type is for AXI command only
- The command code in this command type is fixed value (85h - Change Write Column Address) to support ONFI NAND device.
- The address type in this command type is fixed to two byte column address.
- For this example:
  - WE# low time is 2 clock cycles (NANDCR1[WEL]=1)
  - WE# high time is 1 clock cycle (NANDCR1[WEH]=0)
  - Address cycle to data loading time is 6 clock cycles (NANDCR2[TADL]=5)

29.3.1.5.6 NAND Flash Read Access in EDO and non-EDO Mode

NAND Flash support both EDO and non-EDO modes. Figure 149 shows the access timing of EDO mode.

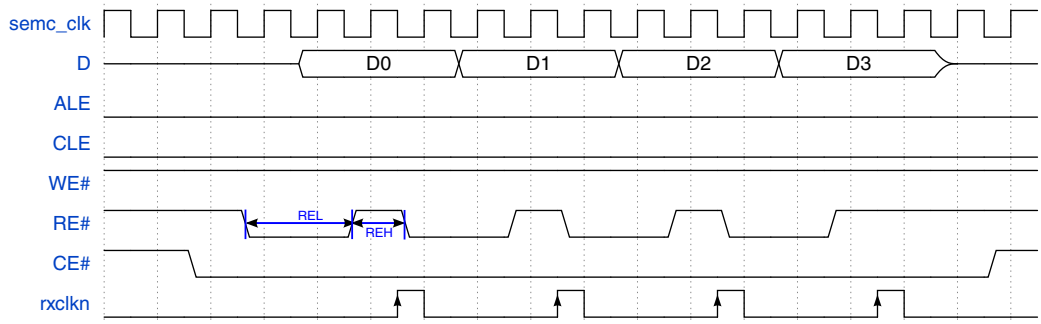

Figure 149. NAND Flash Read Access in EDO mode

NOTE

- rxclkn is the SEMC internal clock to sample read data. It is close to falling edge of RE#.
- For this example:
  - RE# low time is 2 clock cycles (NANDCR1[REL]=1)
  - RE# high time is 1 clock cycle (NANDCR1[REH]=0)

Figure 150 shows the access timing of non-EDO mode.

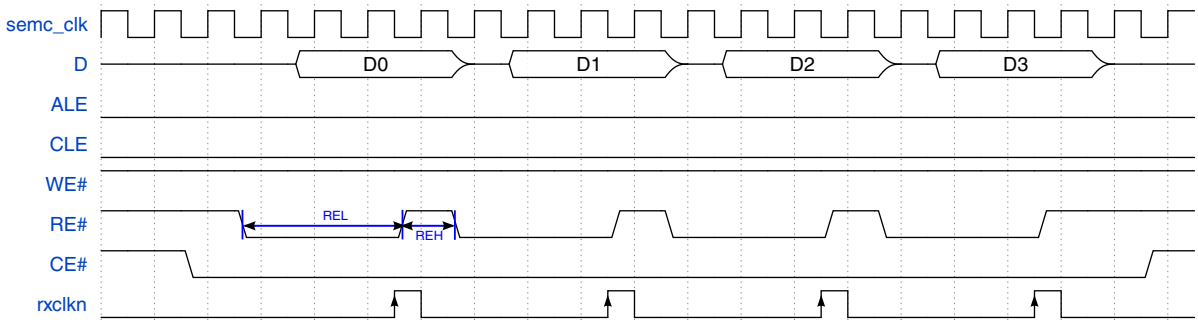

Figure 150. NAND Flash Read Access in non-EDO mode

NOTE

- rxclkn is the SEMC internal clock to sample read data. It is close to rising edge of RE#.
- For this example:
  - RE# low time is 3 clock cycles (NANDCR1[REL]=2)
  - RE# high time is 1 clock cycle (NANDCR1[REH]=0)

29.3.1.5.7 NAND Flash Access in SYNC Mode

NAND Flash supports SYNC mode, the following chapters describes the access timings.

29.3.1.5.7.1 NAND Command + Address + Command + Read Operation in SYNC Mode

Figure 151 shows NAND Command + Address + Command + Read operation in SYNC mode.

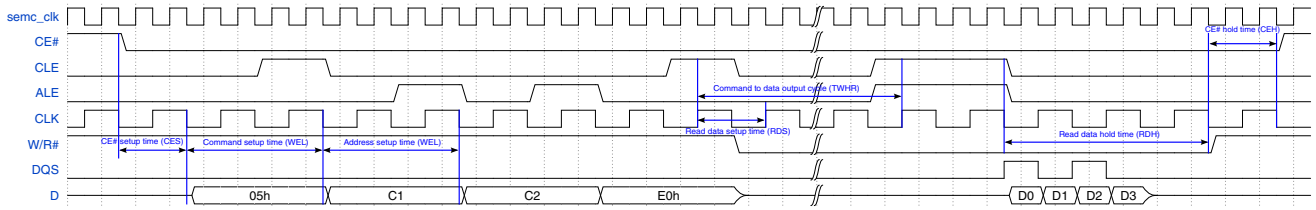

Figure 151. NAND Command + Address + Command + Read in SYNC Mode

NOTE

- semc_clk is the SEMC internal functional clock. CLK is the synchronous clock to latch command and address cycles. The frequency of CLK is half of semc_clk. For example, if semc_clk frequency is 200 MHz, the CLK frequency is 100 MHz.
- For this example:
  - CE# setup time is 2 clock cycles (NANDCR1[CES]=1)
  - Command/Address setup time is 4 clock cycles (NANDCR1[WEL]=2)
  - NANDCR3[RDS] and NANDCR2[TWHR] control the timing from command to data read phase. In general, NANDCR3[RDS] controls the minimum delay before data read phase. In this figure, NANDCR3[RDS]=0.
  - Read data hold time is 6 clock cycles (NANDCR3[RDH]=4)
  - CE# hold time is 2 clock cycles (NANDCR1[CEH]=1)

29.3.1.5.7.2 NAND Command + Address + Write Operation in SYNC Mode

Figure 152 shows NAND Command + Address + Write operation in SYNC mode.

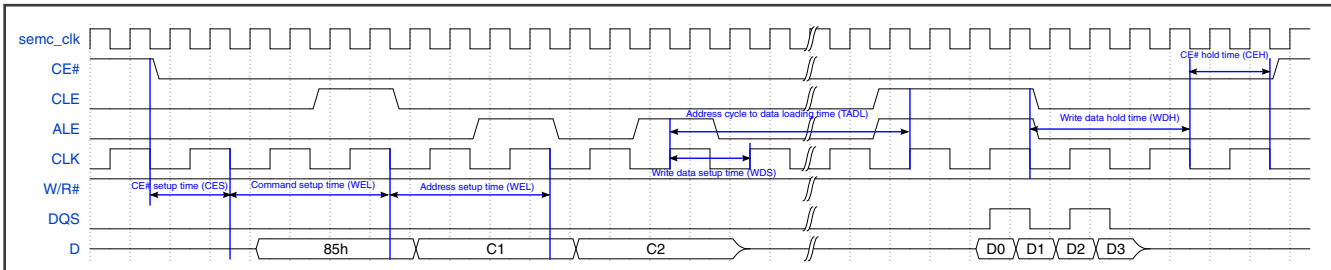

Figure 152. NAND Command + Address + Write in SYNC Mode

NOTE

- For this example:
  - CE# setup time is 2 clock cycles (NANDCR1[CES]=1)
  - Command/Address setup time is 4 clock cycles (NANDCR1[WEL]=2)
  - NANDCR3[WDS] and NANDCR2[TADL] control the timing from command to data write phase. In general, NANDCR3[WDS] controls the minimum delay before data write phase. In this figure, NANDCR3[WDS]=0.
  - Write data hold time is 4 clock cycles (NANDCR3[WDH]=2)
  - CE# hold time is 2 clock cycles (NANDCR1[CEH]=1)

29.3.1.6 NOR Flash Controller Operations

This section describes the operations of NOR Flash controller.

29.3.1.6.1 NOR Flash Address Multiplexing

NOR Flash use a multiplexed address split into rows and columns. Figure 153 shows how the bits of the linear address sent to the SEMC are split up into the row and column addresses sent to the NOR Flash memory device.

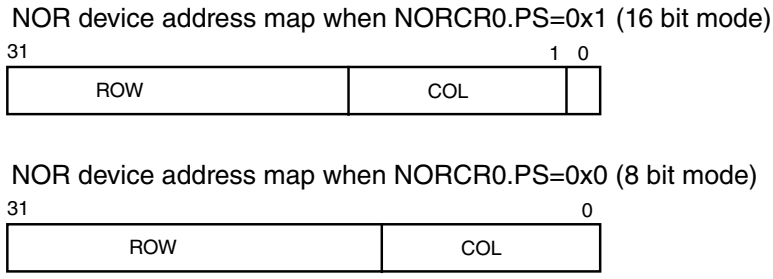

Figure 153. NOR Flash Address Multiplexing

NOTE

- NOR address bits consist of row and column address bits.
- Column address bits offset is bit 0 if NORCR0[PS]=0 and bit 1 if NORCR0[PS]=1. Column address bit width is determined by NORCR0[COL].
- Row address bits offset is determined by NORCR0[PS] and NORCR0[COL].
- NOR device base address on SoC is configured by BR5 register.
- Write data should be 16 bit aligned when connecting to 16 bit NOR device.

29.3.1.6.2 NOR Flash Read Operation in ASYNC Mode

NOR Flash controller supports following address modes, which setting by NORCR0[AM].

Figure 154 shows the ASYNC NOR Flash read in Non-ADMUX address mode.

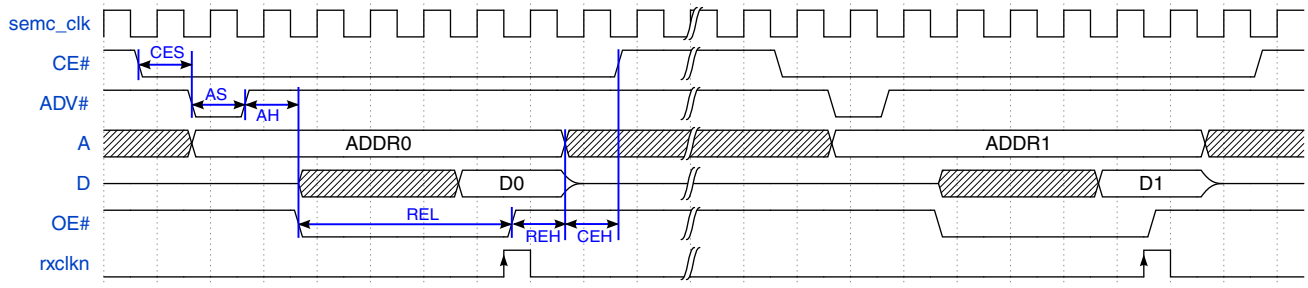

Figure 154. ASYNC NOR Flash Read in Non-ADMUX Address Mode

NOTE

- semc_clk and rxclkn are the internal signals. semc_clk is the SEMC functional clock. rxclkn is the clock to sample data from NOR Flash.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 1 clock cycle (NORCR1[AS]=0)
  - Address hold time is 1 clock cycle (NORCR1[AH]=0)
  - OE# low time is 4 clock cycles (NORCR1[REL]=3)
  - OE# high time is 1 clock cycle (NORCR1[REH]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 155 shows the ASYNC NOR Flash read in ADMUX address mode.

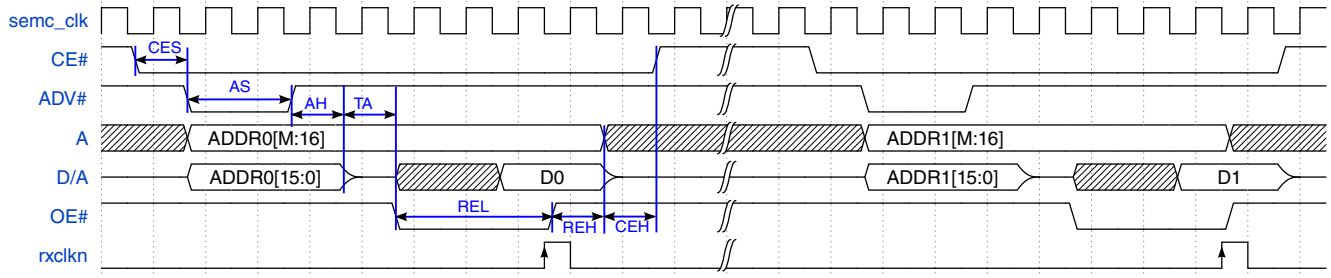

Figure 155. ASYNC NOR Flash Read in ADMUX Address Mode

NOTE

- semc_clk and rxclkn are the internal signals. semc_clk is the SEMC functional clock. rxclkn is the clock to sample data from NOR Flash.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 2 clock cycles (NORCR1[AS]=1)
  - Address hold time is 1 clock cycle (NORCR1[AH]=0)
  - Turnaround time is 1 clock cycle (NORCR2[TA]=0)
  - OE# low time is 3 clock cycles (NORCR1[REL]=2)
  - OE# high time is 1 clock cycle (NORCR1[REH]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 156 shows the ASYNC NOR Flash read in AADM address mode.

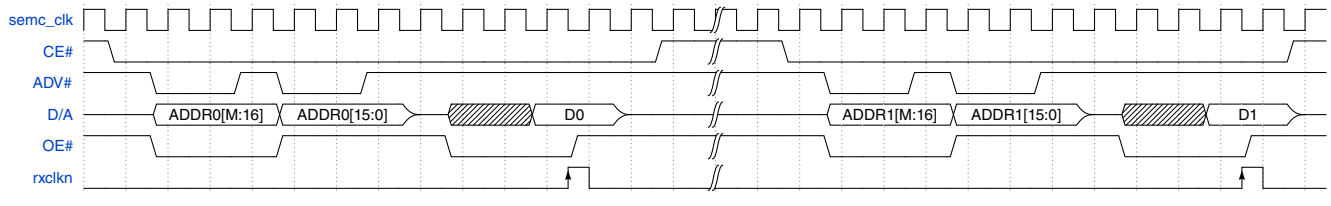

Figure 156. ASYNC NOR Flash Read in AADM Address Mode

29.3.1.6.3 NOR Flash Write Operation in ASYNC Mode

Figure 157 shows the ASYNC NOR Flash write in Non-ADMUX address mode.

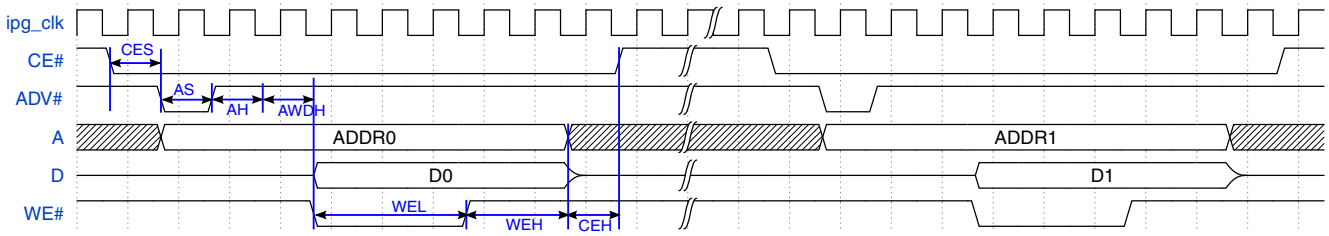

Figure 157. ASYNC NOR Flash Write in Non-ADMUX Address Mode

NOTE

- semc_clk is the SEMC functional clock.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 1 clock cycle (NORCR1[AS]=0)
  - Address hold time is 1 clock cycle (NORCR1[AH]=0)
  - Address to write data hold time is 1 clock cycle (NORCR2[AWDH]=1)
  - WE# low time is 3 clock cycles (NORCR1[WEL]=2)
  - WE# high time is 2 clock cycles (NORCR1[WEH]=1)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 158 shows the ASYNC NOR Flash write in ADMUX address mode.

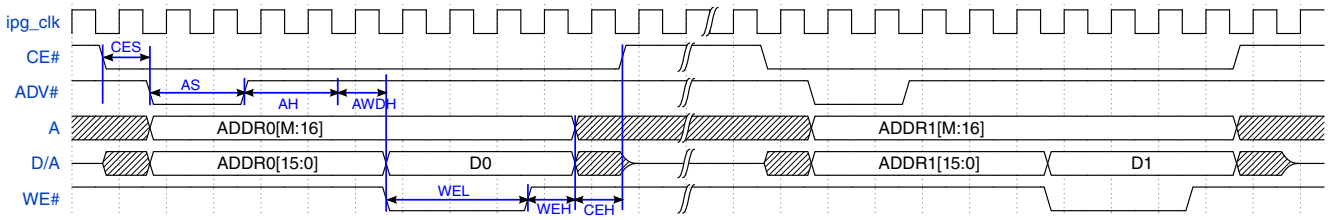

Figure 158. ASYNC NOR Flash Write in ADMUX Address Mode

NOTE

- semc_clk is the SEMC functional clock.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 2 clock cycles (NORCR1[AS]=1)
  - Address hold time is 2 clock cycles (NORCR1[AH]=1)
  - Address to write data hold time is 1 clock cycle (NORCR2[AWDH]=1)
  - WE# low time is 3 clock cycles (NORCR1[WEL]=2)
  - WE# high time is 1 clock cycle (NORCR1[WEH]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 159 shows the ASYNC NOR Flash write in AADM address mode.

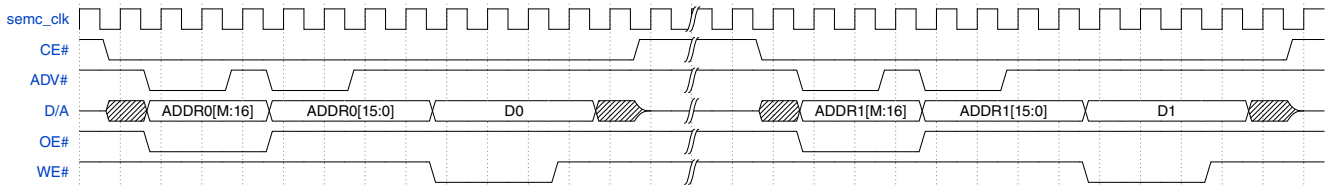

Figure 159. ASYNC NOR Flash Write in AADM Address Mode

29.3.1.6.4 NOR Flash Read Operation in SYNC Mode

Figure 160 shows the SYNC NOR Flash read in Non-ADMUX address mode.

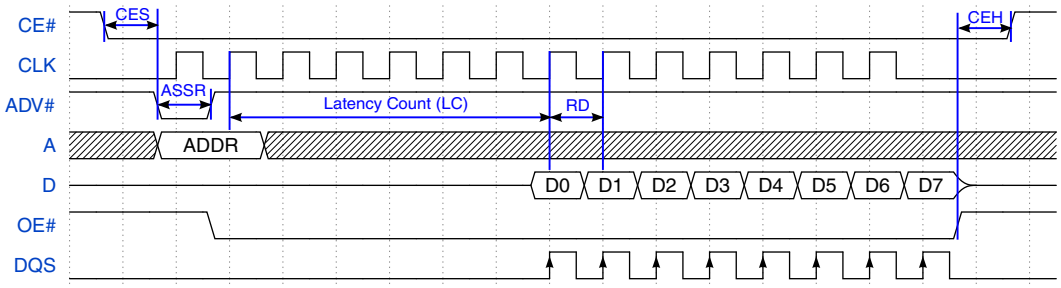

Figure 160. SYNC Flash Read in Non-ADMUX Address Mode

NOTE

- DQS is the clock to sample data from NOR Flash. It generally loops back from DQS pad.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 1 clock cycle (NORCR3[ASSR]=0)
  - Latency count is 6 clock cycles (NORCR2[LC]=6)
  - Read time is 1 clock cycle (NORCR2[RD]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 161 shows the SYNC NOR Flash read in ADMUX address mode.

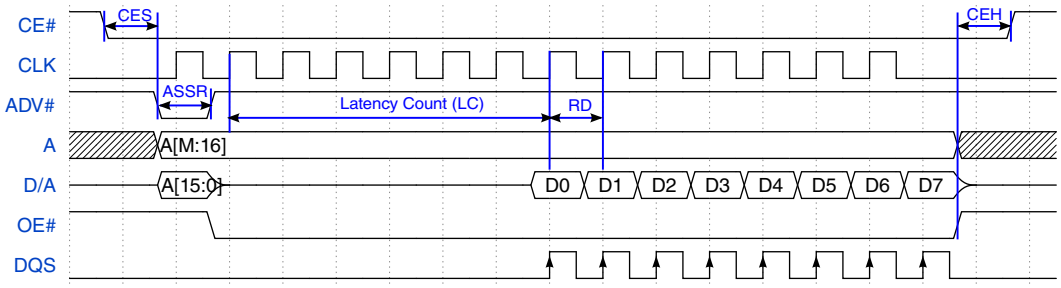

Figure 161. SYNC Flash Read in ADMUX Address Mode

NOTE

- DQS is the clock to sample data from NOR Flash. It generally loops back from DQS pad.
- For this example:
  - CE# setup time is 1 clock cycle (NORCR1[CES]=0)
  - Address setup time is 1 clock cycle (NORCR3[ASSR]=0)
  - Latency count is 6 clock cycles (NORCR2[LC]=6)
  - Read time is 1 clock cycle (NORCR2[RD]=0)
  - CE# hold time is 1 clock cycle (NORCR1[CEH]=0)

Figure 162 shows the SYNC NOR Flash read in AADM address mode.

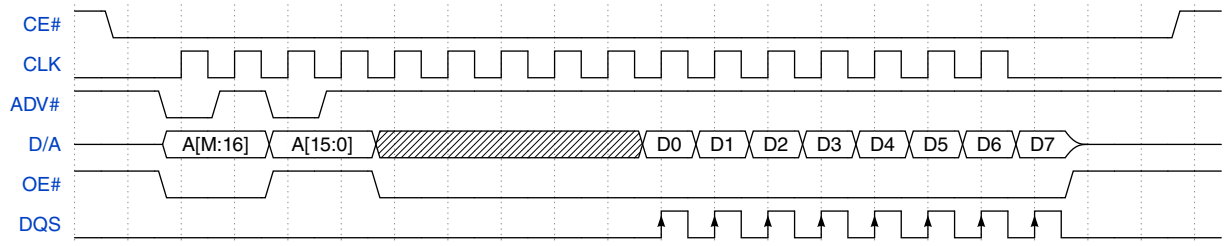

Figure 162. SYNC Flash Read in AADM Address Mode

29.3.1.6.5 NOR Flash Write Operation in SYNC Mode

Flash write operation in SYNC mode is same as asynchronous.

29.3.1.7 SRAM Controller Operations

This section describes the operations of SRAM controller.

29.3.1.7.1 SRAM Address Multiplexing

SRAM use a multiplexed address split into rows and columns. Figure 163 shows how the bits of the linear address sent to the SEMC are split up into the row and column addresses sent to the SRAM memory device.

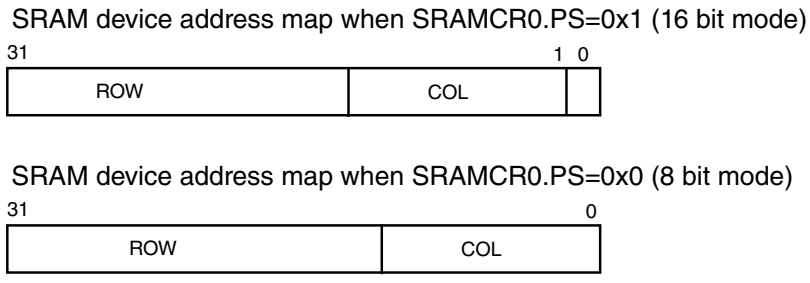

Figure 163. SRAM Address Multiplexing

NOTE

- SRAM address bits consist of row and column address bits.
- Column address bits offset is bit 0 if SRAMCR0[PS]=0, offset is bit 1 if SRAMCR0[PS]=1. Column address bit width is determined by SRAMCR0[COL].
- Row address bits offset is determined by SRAMCR0[PS] and SRAMCR0[COL].
- SRAM device base address on SoC is configured by BR6, BR9, BR10 and BR11 registers.

29.3.1.7.2 SRAM Read Operation in ASYNC Mode

Figure 164 shows the ASYNC SRAM read in Non-ADMUX address mode.

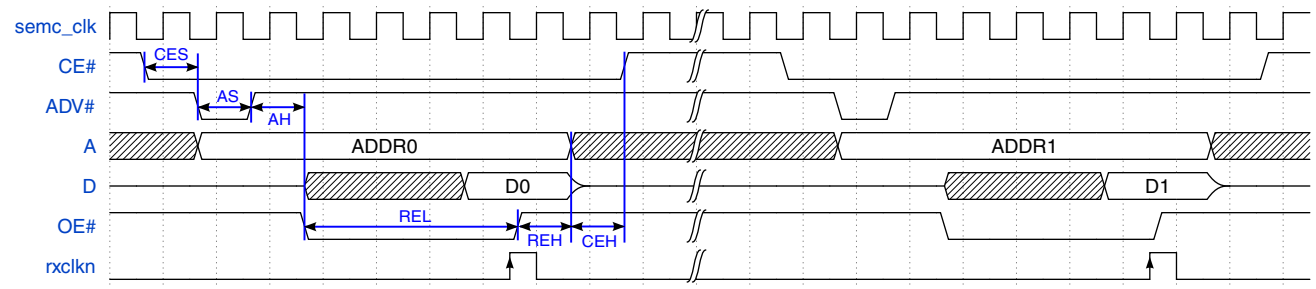

Figure 164. ASYNC SRAM Read in Non-ADMUX Address Mode

NOTE

- semc_clk and rxclkn are the internal signals. semc_clk is the SEMC functional clock. rxclkn is the clock to sample data from SRAM.
- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Address hold time is 1 clock cycle (SRAMCR1[AH]=0)
  - OE# low time is 4 clock cycles (SRAMCR1[REL]=3)
  - OE# high time is 1 clock cycle (SRAMCR1[REH]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 165 shows the ASYNC SRAM read in ADMUX address mode.

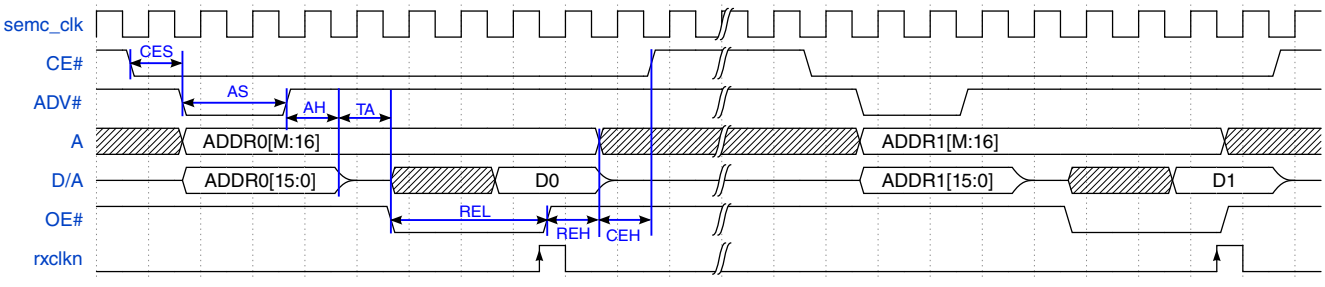

Figure 165. ASYNC SRAM Read in ADMUX Address Mode

NOTE

- semc_clk and rxclkn are the internal signals. semc_clk is the SEMC functional clock. rxclkn is the clock to sample data from SRAM.
- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 2 clock cycles (SRAMCR1[AS]=1)
  - Address hold time is 1 clock cycle (SRAMCR1[AH]=0)
  - Turnaround time is 1 clock cycle (SRAMCR2[TA]=0)
  - OE# low time is 3 clock cycles (SRAMCR1[REL]=2)
  - OE# high time is 1 clock cycle (SRAMCR1[REH]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 166 shows the ASYNC SRAM read in AADM address mode.

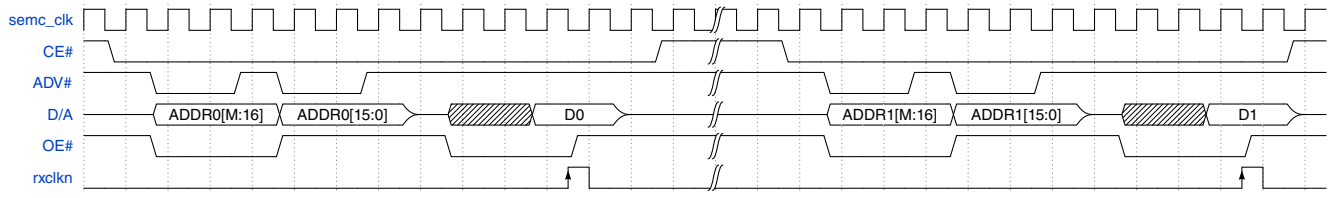

Figure 166. ASYNC SRAM Read in AADM Address Mode

29.3.1.7.3 SRAM Write Operation in ASYNC Mode

Figure 167 shows the ASYNC SRAM write in Non-ADMUX address mode.

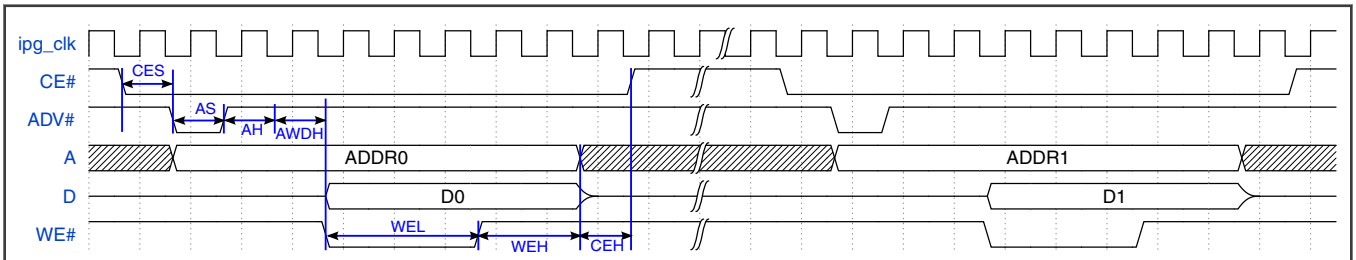

Figure 167. ASYNC SRAM Write in Non-ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Address hold time is 1 clock cycle (SRAMCR1[AH]=0)
  - Address to write data hold time is 1 clock cycle (SRAMCR2[AWDH]=1)
  - WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
  - WE# high time is 2 clock cycles (SRAMCR1[WEH]=1)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 168 shows the ASYNC SRAM write in ADMUX address mode.

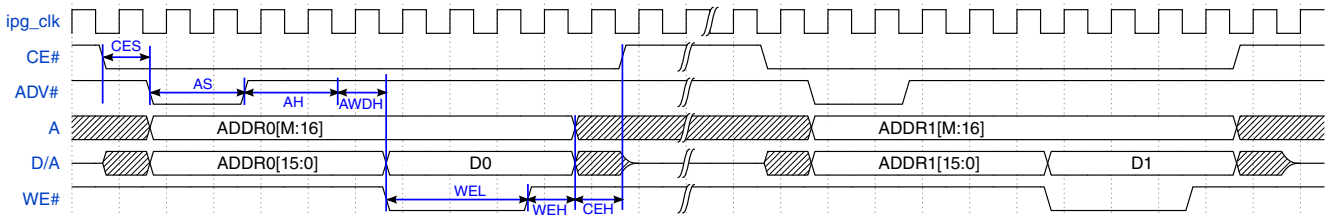

Figure 168. ASYNC SRAM Write in ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 2 clock cycles (SRAMCR1[AS]=1)
  - Address hold time is 2 clock cycles (SRAMCR1[AH]=1)
  - Address to write data hold time is 1 clock cycle (SRAMCR2[AWDH]=1)
  - WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
  - WE# high time is 1 clock cycle (SRAMCR1[WEH]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 169 shows the ASYNC SRAM write in AADM address mode.

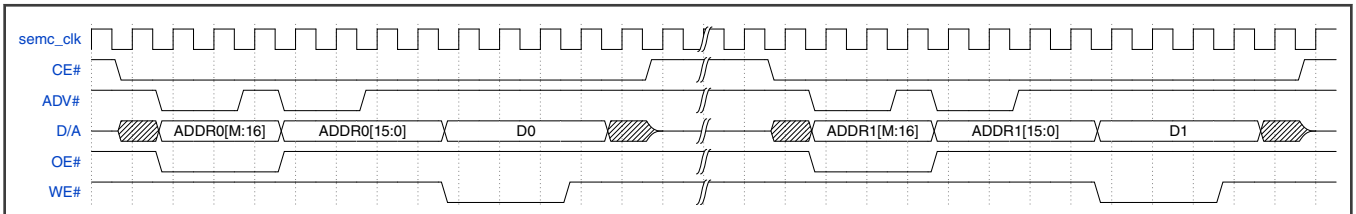

Figure 169. ASYNC SRAM Write in AADM Address Mode

29.3.1.7.4 SRAM Register Operation in ASYNC Mode

Figure 170 shows the ASYNC SRAM register access in ADMUX address mode.

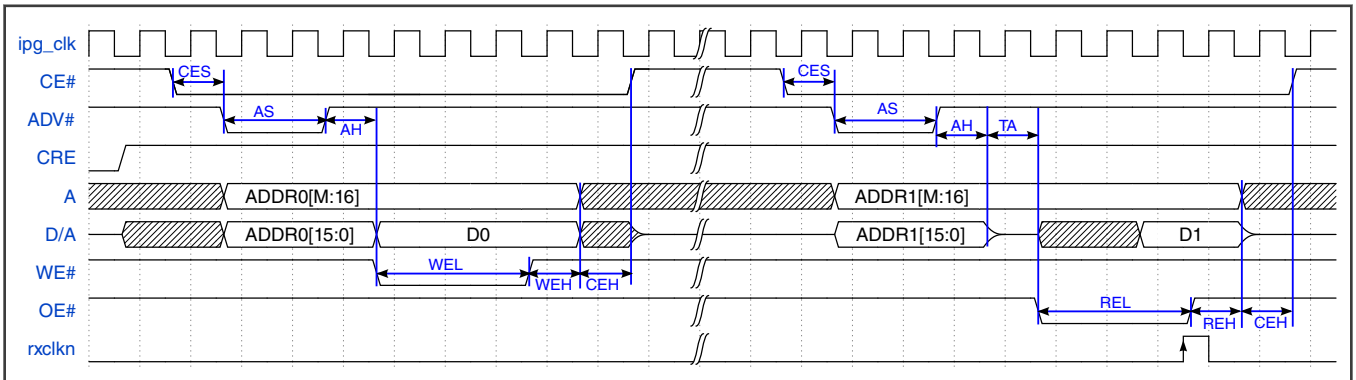

Figure 170. ASYNC SRAM Register Access in ADMUX Address Mode

NOTE

- For this example:
  - First operation is SRAM register write access. ADDR0[M:0] contains the value for writing to SRAM register. The value of D0 can be ignored.
  - Second operation is SRAM register read access. ADDR1[M:0] contains the value for choosing of SRAM register. D1 is the value that read from SRAM register.
  - The value of ADDR0/1 comes from IPCR0 register.
    - If BR6[BA]=0x98000 and IPCR0=0x9810883E, ADDR0/1 is 0x8441F when port size is 16bit mode. The address is divided by 2 in 16bit mode.
    - If BR6[BA]=0x98000 and IPCR0=0x9810883E, ADDR0/1 is 0x10883E when port size is 8bit mode.
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 2 clock cycles (SRAMCR1[AS]=1)
  - Address hold time is 1 clock cycle (SRAMCR1[AH]=0)
  - WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
  - WE# high time is 1 clock cycle (SRAMCR1[WEH]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)
  - Turnaround time is 1 clock cycle (SRAMCR2[TA]=0)
  - OE# low time is 3 clock cycles (SRAMCR1[REL]=2)
  - OE# high time is 1 clock cycle (SRAMCR1[REH]=0)

29.3.1.7.5 SRAM Read Operation in ASYNC Mode with Wait Pin

SRAM read operation in ASYNC mode with wait pin is indicated in following diagrams:

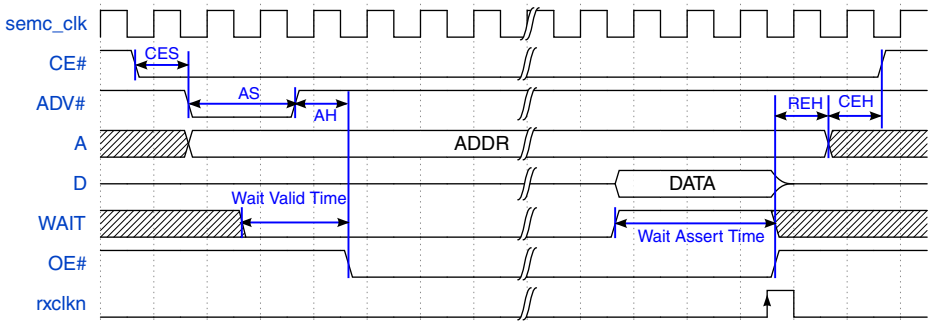

Figure 171. SRAM Read in ASYNC Mode (Non-ADMUX) with Wait Pin

NOTE

1. Wait Valid Time must be no less than 2 semc_clk cycles.
2. Wait and DATA must be valid till OE# high.
3. For this example:
   - SRAMCR0[WAITEN]=1
   - SRAMCR0[WAITSP]=1
   - MCR[WPOL0]=0

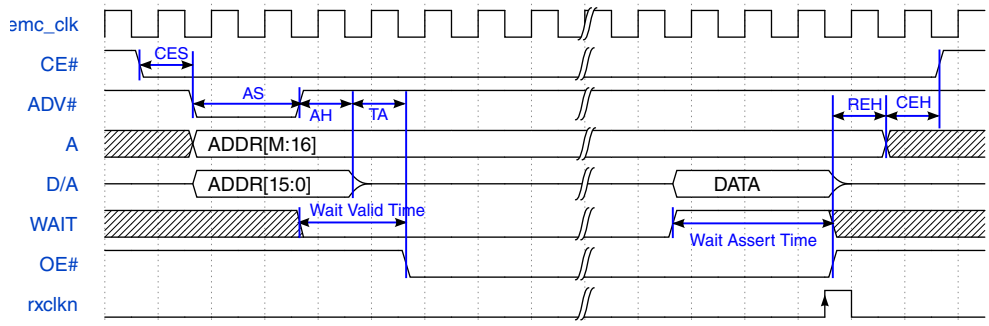

Figure 172. SRAM Read in ASYNC Mode (ADMUX) with Wait Pin

NOTE

1. Wait Valid Time must be no less than 2 semc_clk cycles.
2. Wait and DATA must be valid till OE# high.
3. For this example:
   - SRAMCR0[WAITEN]=1
   - SRAMCR0[WAITSP]=1
   - MCR[WPOL0]=0

29.3.1.7.6 SRAM Write Operation in ASYNC Mode with Wait Pin

SRAM write operation in ASYNC mode is indicated in following diagrams:

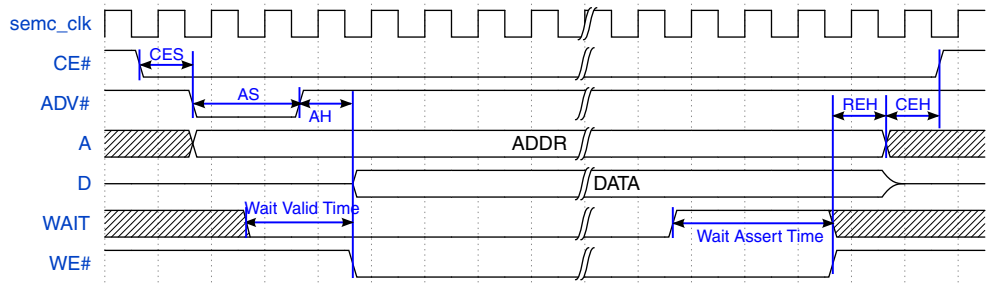

Figure 173. SRAM Write in ASYNC Mode (Non-ADMUX) with Wait Pin

NOTE

1. Wait Valid Time must be no less than 2 semc_clk cycles.
2. Wait must be valid till WE# high.
3. For this example:
   - SRAMCR0[WAITEN]=1
   - SRAMCR0[WAITSP]=1
   - MCR[WPOL0]=0

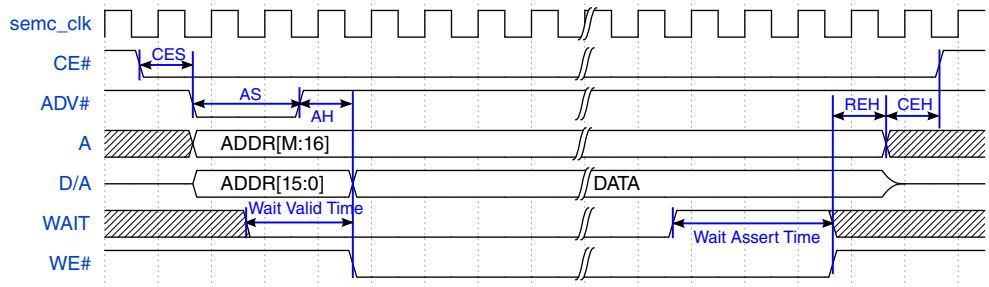

Figure 174. SRAM Write in ASYNC Mode (ADMUX) with Wait Pin

NOTE

1. Wait Valid Time must be no less than 2 semc_clk cycles.
2. Wait must be valid till WE# high.
3. For this example:
   - SRAMCR0[WAITEN]=1
   - SRAMCR0[WAITSP]=1
   - MCR[WPOL0]=0

29.3.1.7.7 SRAM Read Operation in SYNC Mode

Figure 175 shows the SYNC SRAM read in Non-ADMUX address mode.

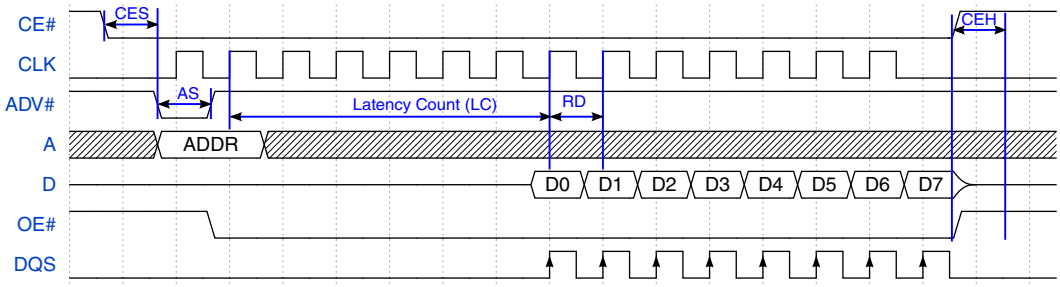

Figure 175. SYNC SRAM Read in Non-ADMUX Address Mode

NOTE

- DQS is the clock to sample data from SRAM. It generally loops back from DQS pad.
- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Latency count is 6 clock cycles (SRAMCR2[LC]=6)
  - Read time is 1 clock cycle (SRAMCR2[RD]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 176 shows the SYNC SRAM read in ADMUX address mode.

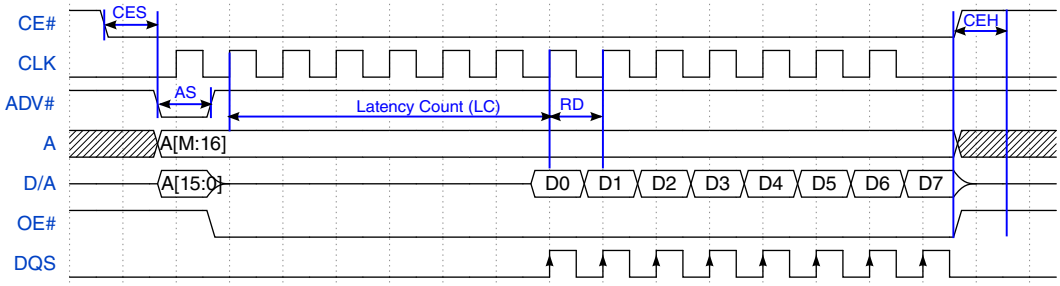

Figure 176. SYNC SRAM Read in ADMUX Address Mode

NOTE

- DQS is the clock to sample data from SRAM. It generally loops back from DQS pad.
- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Latency count is 6 clock cycles (SRAMCR2[LC]=6)
  - Read time is 1 clock cycle (SRAMCR2[RD]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

29.3.1.7.8 SRAM Write Operation in SYNC Mode

Figure 177 shows the SYNC SRAM write in Non-ADMUX address mode.

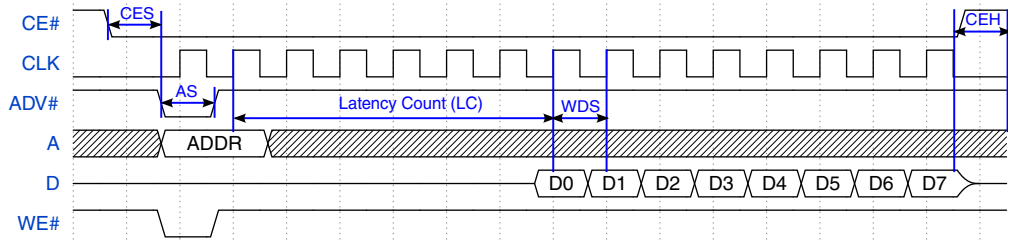

Figure 177. SRAM Write in SYNC Mode (Non-ADMUX)

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Latency count is 6 clock cycles (SRAMCR2[LC]=6)
  - Write data setup time is 1 clock cycle (SRAMCR2[WDS]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

Figure 178 shows the SYNC SRAM write in ADMUX address mode.

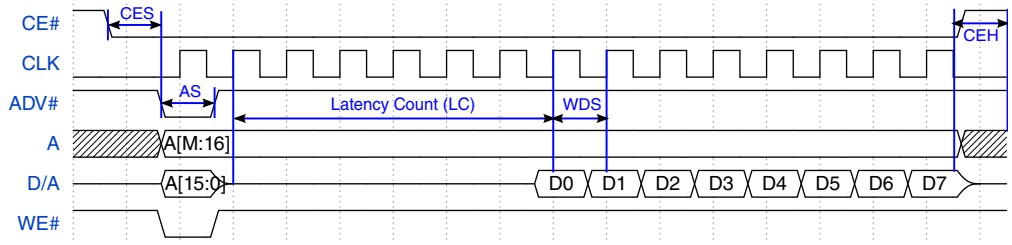

Figure 178. SRAM Write in SYNC Mode (ADMUX)

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR1[CES]=0)
  - Address setup time is 1 clock cycle (SRAMCR1[AS]=0)
  - Latency count is 6 clock cycles (SRAMCR2[LC]=6)
  - Write data setup time is 1 clock cycle (SRAMCR2[WDS]=0)
  - CE# hold time is 1 clock cycle (SRAMCR1[CEH]=0)

29.3.1.8 Display Bus Interface Controller Operations

This section describes the operations of DBI controller.

DCX signal is controlled by write address. Write access to DBI is handled as DBI COMMAND WRITE transaction if address is higher than 0x10000 (DCX low). Otherwise, it is handled as DBI DATA WRITE transaction (DCX high).

For example, if BR7[BA]=0x9C000:

- An AXI write to address 0x9C010000 is treated as DBI COMMAND WRITE transaction.
- An AXI write to address 0x9C000000 is treated as DBI DATA WRITE transaction.

Figure 179 shows DBI write operation.

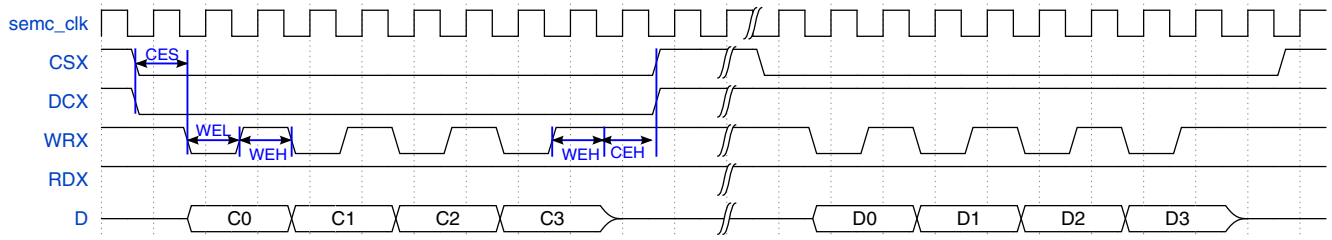

Figure 179. DBI Write Operation

NOTE

- DBI address is used to determine DBI COMMAND or DATA WRITE.
- DBI bus never send out address information for COMMAND and DATA WRITE.
- AXI WRAP write access to DBI is supported.
- DBI bus interface does not support WRITE mask feature.
- All write strobe in AXI write access to DBI must be valid. If AXI write strobe is invalid, the SEMC sends write data 0x00 instead of original write data.
- When DBI bus is 16 bit (DBICR0[PS]=1), AXI or IP command access start address to DBI bus must be 16 bit aligned. Otherwise the write data to DBI may be wrong. There is no bus error response or internal error status generated for this case.
- For this example:
  - CSX setup time is 1 clock cycle (DBICR1[CES]=0)
  - WRX low time is 1 clock cycle (DBICR1[WEL]=0)
  - WRX high time is 1 clock cycle (DBICR1[WEH]=0)
  - CSX hold time is 1 clock cycle (DBICR1[CEH]=0)

Figure 180 shows DBI read operation.

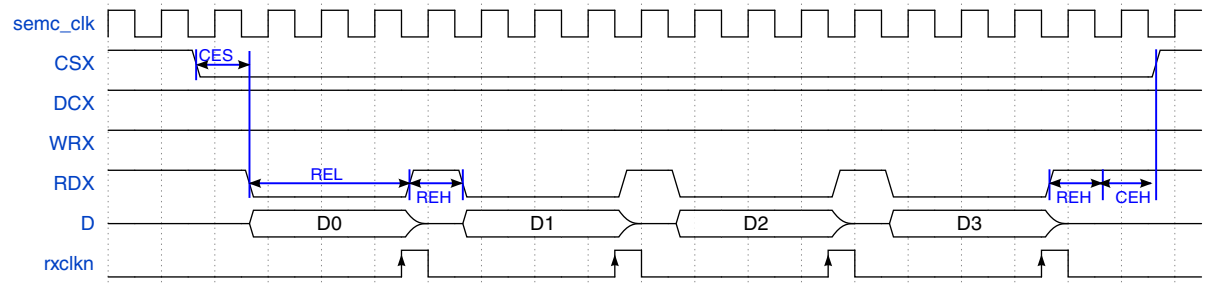

Figure 180. DBI Read Operation

NOTE

- Read access to DBI is always handled as DBI DATA READ transaction.
- DBI bus never sent out address information for DATA READ command.
- AXI WRAP read access to DBI is not supported except when the first beat address offset is zero in the burst.
- When DBI bus is 16 bit (DBICR0[PS]=1), AXI command or IP command access start address to DBI bus must be 16 bit aligned. Otherwise the read data is unknown. There is no bus error response or internal error status generated for this case.
- For this example:
  - CSX setup time is 1 clock cycle (DBICR1[CES]=0)
  - RDX low time is 3 clock cycles (DBICR1[REL]=2)
  - RDX high time is 1 clock cycle (DBICR1[REH]=0)
  - CSX hold time is 1 clock cycle (DBICR1[CEH]=0)

29.3.2 Clocks

There is one clock used for the SEMC AXI bus, IP bus, internal logic and external interface. It is shown as semc_clk in SEMC timing figures.

29.3.3 Reset

There is a hardware reset for the SEMC, which reset all the logic inside it. When set MCR[SWRST], there will be a software reset to reset all logic in the SEMC except configuration registers.

29.3.4 Interrupts

There is an interrupt output from the SEMC. It indicates the interrupt source that defined in INTR register. The interrupt source is enabled by INTEN register.

29.4 External Signals

Table 188 lists the SEMC module signals.

Table 188. SEMC Signals

Signal	Direction	Description
SEMC_DATA[31-00]	I/O	Data/Address Bits The SEMC has several controllers, and they share pins. SEMC_DATA works as data signal in SDRAM/NAND/8080 applications and works as data or address signal in NOR/SRAM applications. For detail pin mux information, refer to Pin Mux.
SEMC_DM[3-0]	O	Write Data Mask Bits
SEMC_ADDR[12-00]	O	Address Bits SEMC_ADDR08 can work as chip select pin in NAND/NOR/SRAM/ 8080 applications.
SEMC_BA[1-0]	O	Bank Address Bits SEMC_BA0 can work as WAIT in SRAM application. SEMC_BA1 can work as ALE/ADV#/DCX in NAND/NOR/SRAM/8080 applications.
SEMC_CAS	O	SDRAM Column Address Strobe
SEMC_RAS	O	SDRAM Row Address Strobe
SEMC_WE	O	SDRAM Write Enable
SEMC_CKE	O	SDRAM Clock enable
SEMC_CLK	O	SDRAM Clock
SEMC_CS0	O	SDRAM Chip Select 0
SEMC_CSX[3-0]	O	Configurable Chip Select bits
SEMC_RDY	I/O	Ready input pin for NAND It can also work as chip select pin in SDRAM/NOR/SRAM/ 8080 applications.
SEMC_DQS	I/O	DQS SEMC controller provides internal dummy read strobe for read data from SDRAM/NOR/SRAM. Higher read frequency can be achieved by looping back this dummy read strobe from pad. This pin can be floated

Table continues on the next page...

Table 188. SEMC Signals (continued)

Signal	Direction	Description
		or put some cap loads on board level to compensate DATA/CLK pins load. DCCR register can also be configured to compensate DATA/CLK timing delays.
SEMC_DQS4	I/O	DQS Data read strobe for NAND Flash.
SEMC_CLKX0	O	Configurable clock 0 for NOR/SRAM
SEMC_CLKX1	O	Configurable clock 1 for NOR/SRAM

29.4.1 Pin Mux

Table 189 lists the pin mux of the SEMC module.

Table 189. SEMC Pin Mux Overview

Signal	SDRAM	NAND	NOR (ADMUX 16bit)	SRAM (ADMUX 16bit)	DBI	Comment
SEMC_DATA00	D0	D0	D0/A0	D0/A0	D0	Hardware MUX The SEMC determines the pin function according to its internal state

SEMC_CLKX1	-	-	CLK	CLK	-	Configured by IOCR[MUX_CLKX1]

NOTE

- IOCR configuration should be static. Dynamic remapping of pin muxing controlled by IOCR is not supported.
- NOR and SRAM pins are configured as 16 bit ADMUX mode in above table. It is the recommended configuration.

Table 190 lists the different configurations for NOR and SRAM pin mux of the SEMC module.

Table 190. SEMC Pin Mux for NOR and SRAM

Signal	NOR (Non-ADMUX)	NOR (ADMUX 8bit)	NOR (ADMUX 16bit)	NOR (AADM 16bit)	SRAM (Non-ADMUX)	SRAM (ADMUX 8bit)	SRAM (ADMUX 16bit)	SRAM (AADM 16bit)

SEMC_CLKX1	CLK	CLK	CLK	CLK	CLK	CLK	CLK	CLK

29.5 Initialization

To initialize the block:

- Ensure the clock for the SEMC is enabled.
- Configure corresponding pin MUX for the SEMC external signals.
- Configure registers of the SEMC properly, according to the applications.
- Configure the Module Control Register and clear MCR[MDIS] bit to enable the SEMC module.
- Reset SEMC optionally by setting the MCR[SWRST] bit.

29.6 Application Information

This section describes applications supported by the SEMC module.

29.6.1 SDRAM Application

This section provides the example sequences for SDRAM device.

- Configure MCR[DQSMD] bit to select the read clock source. Suggest to set it with 0x1 to reach high clock frequency.
- Configure IOCR register to choose chip select pins.
- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.
- Configure Base Register 0/1/2/3 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure SDRAM Control Registers with valid settings that matches SDRAM device.
- Initialize SDRAM device by IP command registers (IPCR0/1/2, IPCMD and IPTXDAT).
- Write and read operations can be triggered by AXI or IP command. However, AXI command is suggested.

29.6.2 NAND Application

This section provides the example sequences for NAND device.

- Configure IOCR register to choose chip select pins.
- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.
- Configure Base Register 4/8 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure NAND Control Registers with valid settings that matches NAND device.
- Configure DLL Control Register for synchronous mode.
- Initialize NAND device by IP command registers (IPCR0/1/2, IPCMD and IPTXDAT).
- For programming operation, need to open page by IP command. Then you can write data to the NAND buffer by IP or AXI bus.
- For read operation, need to open page by IP command. Then you can read data from the NAND buffer by IP or AXI bus.
- For erase operation, you should do it by IP command.

29.6.3 NOR Application

This section provides the example sequences for NOR device.

- Configure MCR[DQSMD] bit to select the read clock source for synchronous mode. Suggest to set it with 0x1 to reach high clock frequency.
- Configure IOCR register to choose chip select pins.

- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.
- Configure Base Register 5 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure NOR Control Registers with valid settings that matches NOR device.
- Initialize NOR device by IP command registers (IPCR0/1/2, IPCMD and IPTXDAT) if needed.
- Programming operation can be triggered by IP command only.
- Read operation can be triggered by AXI or IP command.

29.6.4 SRAM Application

This section provides the example sequences for SRAM device.

- Configure MCR[DQSMD] bit to select the read clock source for synchronous mode. Suggest to set it with 0x1 to reach high clock frequency.
- Configure IOCR register to choose chip select pins.
- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.
- Configure Base Register 6/9/10/11 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure SRAM Control Registers with valid settings that matches SRAM device.
- Initialize SRAM device by IP command registers (IPCR0/1/2, IPCMD and IPTXDAT) if needed.
- Write and read operations can be triggered by AXI or IP command.

29.6.5 DBI Application

This section provides the example sequences for Display Bus Interface.

- Configure IOCR register to choose chip select pins.
- Configure BMCR0/1 registers to adjust AXI bus access efficiency scheme.
- Configure Base Register 7 with base address, memory size and valid information.
- Configure INTEN and INTR registers if need to generate interrupt.
- Configure DBI Control Registers with valid settings that matches DBI device.
- Write and read operations can be triggered by AXI or IP command.

29.7 Memory Map and Register Definition

This section includes the SEMC module memory map and detailed descriptions of all registers.

29.7.1 SEMC register descriptions

29.7.1.1 SEMC memory map

SEMC base address: 4291_0000h

Offset	Register	Width (In bits)	Access	Reset value

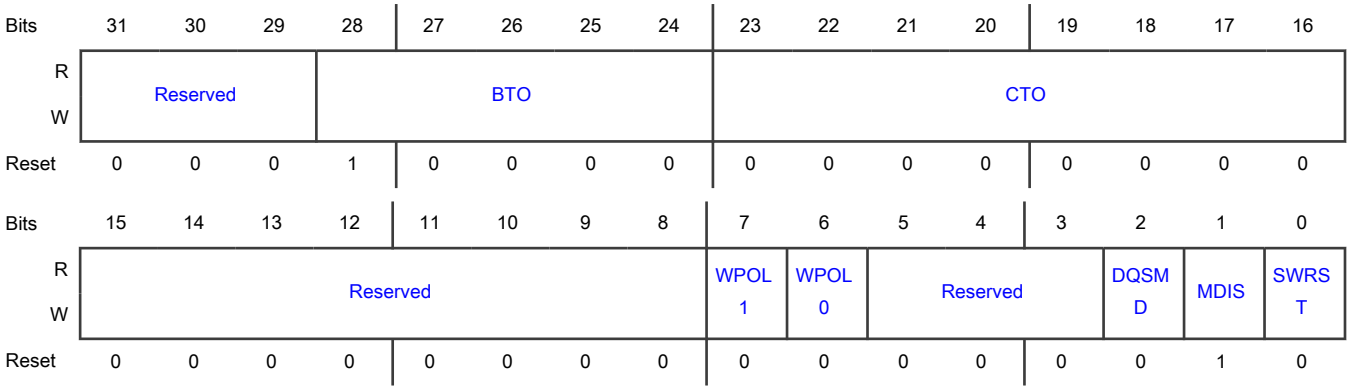
29.7.1.2 Module Control Register (MCR)

Offset

Register	Offset
MCR	0h

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 BTO	Bus timeout cycles The SEMC monitors AXI transactions in the queue. When it exceeds the timeout cycles, an AXIBUSERR interrupt is generated. The AXI Bus timeout is $255*2^{BTO}$ clock cycles. 0_0000b - 255*1 0_0001b - 255*2 1_1111b - 255*2^31
23-16 CTO	Command Execution timeout cycles When Command Execution time exceeds the timeout cycles, an IPCMDERR or AXICMDERR interrupt is generated. When CTO is set to zero, timeout cycles is 256*1024 cycle. Otherwise timeout cycles is CTO*1024 cycle.
15-8 —	Reserved
7 WPOL1	R/B# polarity for NAND device This bit configures the expected polarity of R/B# signal from NAND device.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - R/B# polarity is not changed. 1b - R/B# polarity is inverted.
6 WPOL0	WAIT/RDY polarity for SRAM/NOR This bit configures the expected polarity of WAIT/RDY signal from SRAM and NOR devices. 0b - WAIT/RDY polarity is not changed. 1b - WAIT/RDY polarity is inverted.
5-3 —	Reserved
2 DQSMD	DQS (read strobe) mode DQSMD controls the read clock source of SDRAM, NOR and SRAM in synchronous mode. When it set, the read clock is loopbacked from DQS pad, it benefits the read path timing, and can get high read clock frequency. Delay Chain Control Register (DCCR) register can slightly adjust the DQS timing if DQS is faster than read data in sample phase. 0b - Dummy read strobe loopbacked internally 1b - Dummy read strobe loopbacked from DQS pad
1 MDIS	Module Disable When this bit set, the SEMC internal clock is stopped, and no function is available except register access. 0b - Module enabled 1b - Module disabled
0 SWRST	Software Reset Reset all internal logic in the SEMC except configuration registers. It is an auto clear bit. 0b - No reset 1b - Reset

29.7.1.3 IO MUX Control Register (IOCR)

Offset

Register	Offset
IOCR	4h

3-0 MUX_A8	SEMC_ADDR08 output selection This field controls the function of SEMC_ADDR08 signal. 0000b-0011b - SDRAM Address bit 8 (A8) or NOR/SRAM Address bit 24 (A24) in ADMUX 16bit mode 0100b - NAND CE# 0101b - NOR CE# 0110b - SRAM CE# 0 0111b - DBI CSX 1000b - SRAM CE# 1 1001b - SRAM CE# 2 1010b - SRAM CE# 3 1011b-1111b - SDRAM Address bit 8 (A8) or NOR/SRAM Address bit 24 (A24) in ADMUX 16bit mode

29.7.1.4 Bus (AXI) Master Control Register 0 (BMCR0)

Offset

Register	Offset
BMCR0	8h

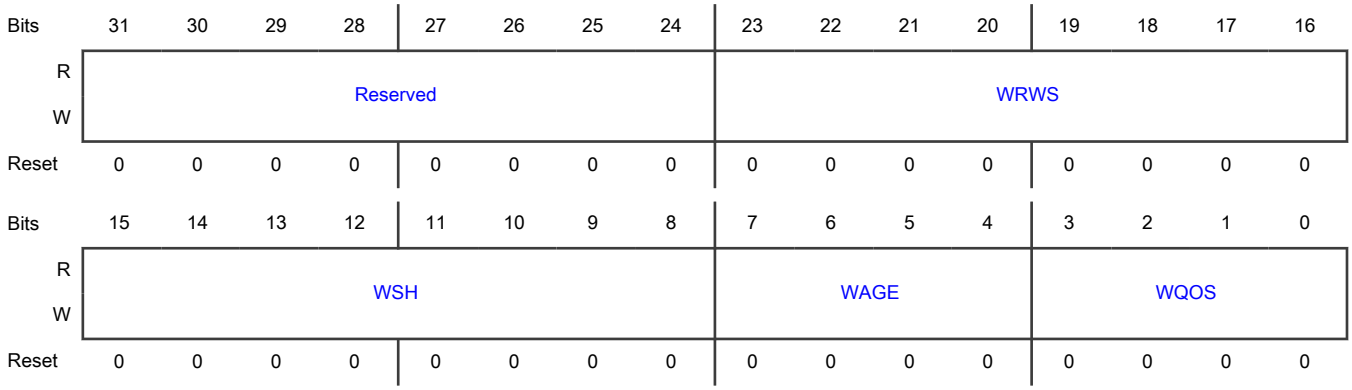
Function

Queue A weight settings for AXI bus access to SDRAM, NAND, NOR, SRAM and DBI slaves.

NOTE

Please refer to BMCR0 Register Configuration

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 WRWS	Weight of slave hit with Read/Write Switch This weight score is valid when the queue command's slave is same as current executing command with read/write operation switch.
15-8 WSH	Weight of Slave Hit without read/write switch This weight score is valid when queue command's slave is the same as current executing command without read/write operation switch.
7-4 WAGE	Weight of AGE Each command in queue has an age score to indicate its wait period. The age score is multiplied by WAGE to get the weight score. Recommend to use non-zero value.
3-0 WQOS	Weight of QOS AXI bus access has AxQOS signal set, which is used as a priority indicator for the associated write or read transaction. A higher value indicates a higher priority transaction. AxQOS is multiplied by WQOS to get the weight score.

29.7.1.5 Bus (AXI) Master Control Register 1 (BMCR1)

Offset

Register	Offset
BMCR1	Ch

Function

Queue B weight settings for AXI bus access to SDRAM slave.

NOTE

Please refer to BMCR1 Register Configuration

Field	Function
31-24 WBR	Weight of Bank Rotation This weight score is valid when queue command's bank is not same as current executing command.
23-16 WRWS	Weight of slave hit without Read/Write Switch This weight score is valid when queue command's read/write operation is same as current executing command.
15-8 WPH	Weight of Page Hit This weight score is valid when queue command's page hits current executing command.
7-4 WAGE	Weight of AGE Each command in queue has an age signal to indicate its wait period. It is multiplied by WAGE to get the weight score. Recommend to use non-zero value.
3-0 WQOS	Weight of QOS AXI bus access has AxQOS signal set, which is used as a priority indicator for the associated write or read transaction. A higher value indicates a higher priority transaction. AxQOS is multiplied by WQOS to get the weight score.

29.7.1.6 Base Register n (BR0 - BR8)

Offset

For n = 0 to 8:

Register	Offset
BRn	10h + (n × 4h)

Function

Table 191 shows the detail information about the Base Registers.

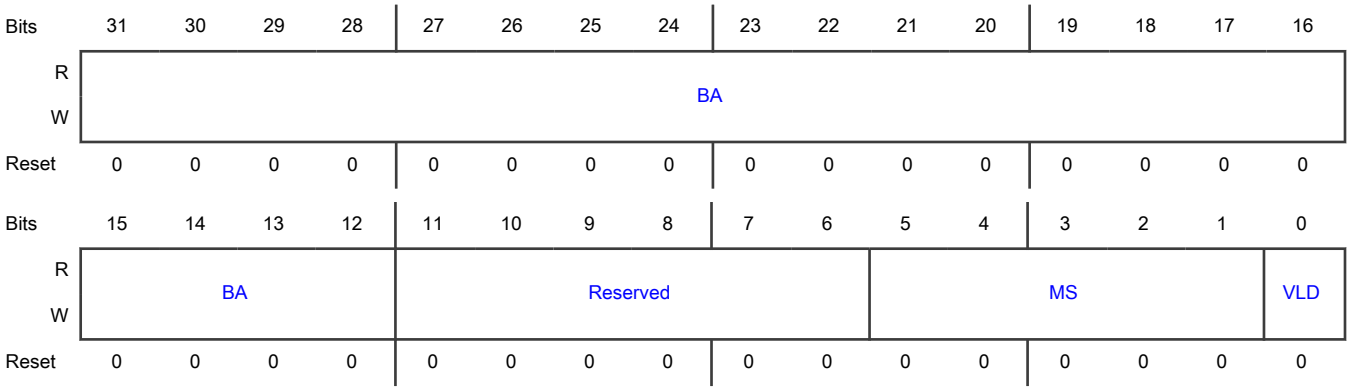
Table 191. Base Register Information

Register	Reset Value	Purpose	Comments
BR0	0x8000001D	For SDRAM CS0	For AXI and IP commands
BR1	0x8400001C	For SDRAM CS1	For AXI and IP commands
BR2	0x8800001C	For SDRAM CS2	For AXI and IP commands
BR3	0x8C00001C	For SDRAM CS3	For AXI and IP commands
BR4	0x9E00001A	For NAND	For AXI command only
BR5	0x90000018	For NOR	For AXI and IP commands
BR6	0x98000018	For SRAM CS0	For AXI and IP commands
BR7	0x9C00001A	For DBI-B	For AXI and IP commands
BR8	0x00000026	For NAND	For IP command only

NOTE

Base Register 9 (BR9), Base Register 10 (BR10) and Base Register 11 (BR11) show Base Registers for other SRAM devices.

Diagram



Fields

Field	Function
31-12 BA	Base Address This field determines high position 20 bits of SoC level base address. The low position 12 bits of the address are all zero. The base address must be within the SEMC range defined for the device memory map.
11-6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-1 MS	Memory size It defines the size of the memory. Memory size must be aligned with base address. Memory regions should be configured to avoid overlapping areas. Overlapping regions will cause bus errors. 0_0000b - 4KB 0_0001b - 8KB 0_0010b - 16KB 0_0011b - 32KB 0_0100b - 64KB 0_0101b - 128KB 0_0110b - 256KB 0_0111b - 512KB 0_1000b - 1MB 0_1001b - 2MB 0_1010b - 4MB 0_1011b - 8MB 0_1100b - 16MB 0_1101b - 32MB 0_1110b - 64MB 0_1111b - 128MB 1_0000b - 256MB 1_0001b - 512MB 1_0010b - 1GB 1_0011b - 2GB 1_0100b-1_1111b - 4GB
0 VLD	Valid This bit controls whether the memory is valid or not. 0b - The memory is invalid, can not be accessed. 1b - The memory is valid, can be accessed.

29.7.1.7 DLL Control Register (DLLCR)

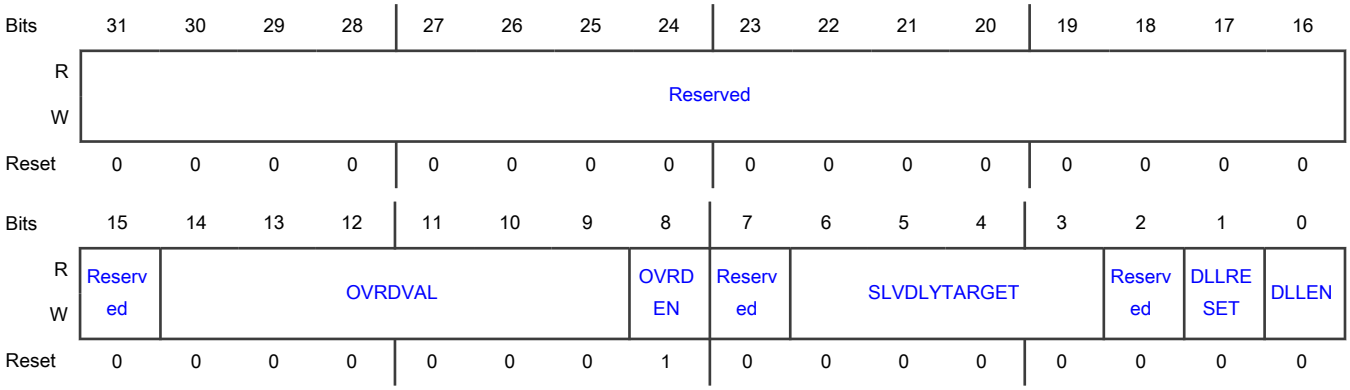
Offset

Register	Offset
DLLCR	34h

Function

This register provides the configuration fields for sample clock from DLL. It is for NAND only.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-9 OVRDVAL	Override Value When OVRDEN is set, the delay cell number is OVRDVAL+1 for slave clock delay line.
8 OVRDEN	Override Enable Slave clock delay line delay cell number selection override enable. 0b - The delay cell number is not overridden. 1b - The delay cell number is overridden.
7 —	Reserved
6-3 SLVDLYTARGET	Delay Target for Slave The delay target for slave delay line is: ((SLVDLYTARGET+1) * 1/32 * clock cycle of reference clock (ipgclock).
2 —	Reserved
1 DLLRESET	DLL Reset Software can force a reset on DLL by setting this field to 0x1. This causes the DLL to lose lock and re-calibrate to detect an ref_clock half period phase shift. The reset action is edge triggered, so software need to clear this bit after setting this bit (no delay limitation). 0b - DLL is not reset.

Table continues on the next page...

Table continued from the previous page...

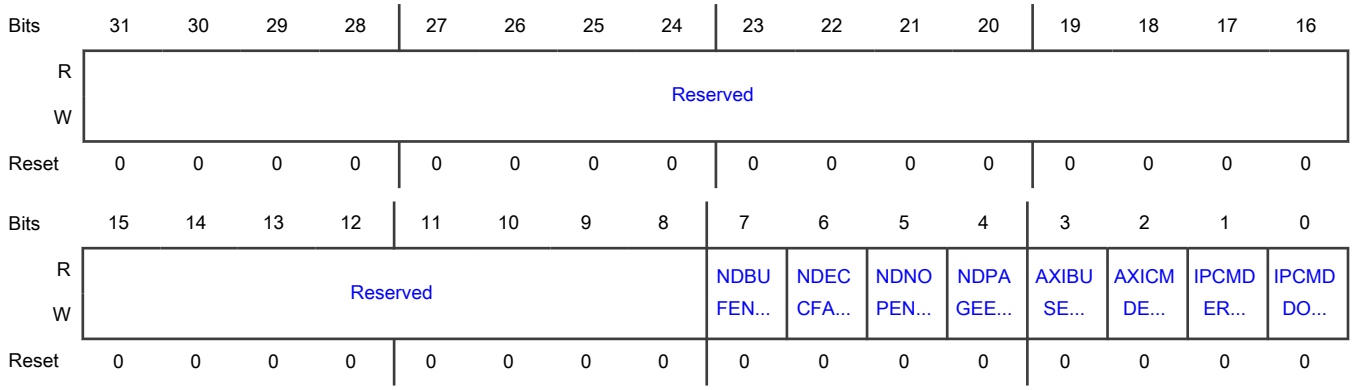
Field	Function
	1b - DLL is reset.
0 DLLEN	DLL calibration enable When this bit is cleared, DLL calibration is disabled and the delay cell number in slave delay line is always 1. Please note that SLV delay line is overridden when OVRDEN bit is set and this bit field setting is ignored. 0b - DLL calibration is disabled. 1b - DLL calibration is enabled.

29.7.1.8 Interrupt Enable Register (INTEN)

Offset

Register	Offset
INTEN	38h

Diagram



Fields

Field	Function
31-8 —	Reserved
7 NDBUFENDEN	NAND buffer end interrupt enable This bit enable/disable the NDBUFEND interrupt generation. 0b - Interrupt is disabled 1b - Interrupt is enabled

Table continues on the next page...

Table continued from the previous page...

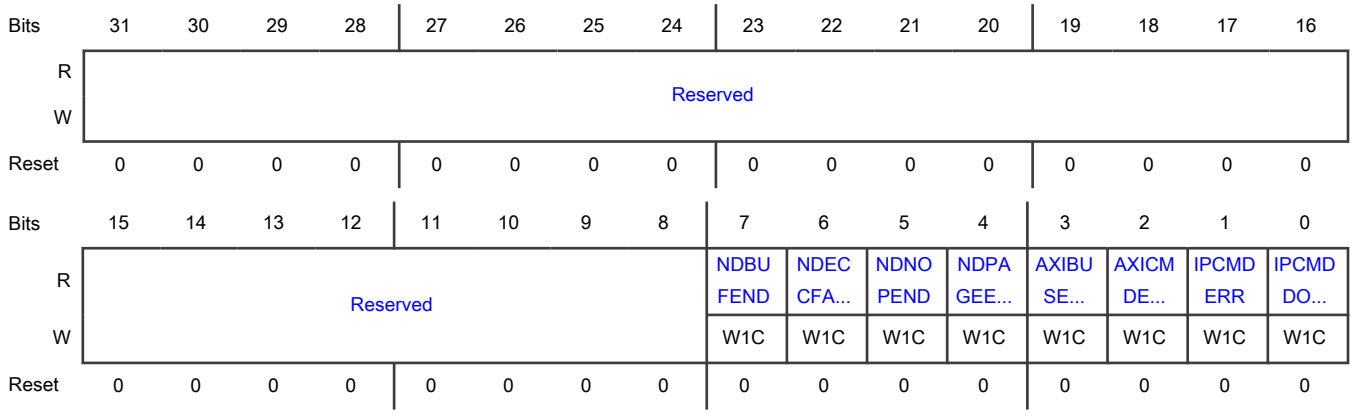
Field	Function
6 NDECCFAILEN	NAND ECC fail interrupt enable This bit enable/disable the NDECCFAIL interrupt generation. 0b - Interrupt is disabled 1b - Interrupt is enabled
5 NDNOPENDEN	NAND no pending AXI access interrupt enable This bit enable/disable the NDNOPEND interrupt generation. 0b - Interrupt is disabled 1b - Interrupt is enabled
4 NDPAGEENDEN	NAND page end interrupt enable This bit enable/disable the NDPAGEEND interrupt generation. 0b - Interrupt is disabled 1b - Interrupt is enabled
3 AXIBUSERREN	AXI bus error interrupt enable 0b - Interrupt is disabled 1b - Interrupt is enabled
2 AXICMDERREN	AXI command error interrupt enable 0b - Interrupt is disabled 1b - Interrupt is enabled
1 IPCMDERREN	IP command error interrupt enable 0b - Interrupt is disabled 1b - Interrupt is enabled
0 IPCMDDONEEN	IP command done interrupt enable 0b - Interrupt is disabled 1b - Interrupt is enabled

29.7.1.9 Interrupt Register (INTR)

Offset

Register	Offset
INTR	3Ch

Diagram



Fields

Field	Function
31-8 —	Reserved
7 NDBUFEND	NAND buffer end interrupt This interrupt is generated when the last valid address of NAND buffer is written by AXI command. The last valid address is related with NAND Control register's SECTOR_SIZE and SECTOR_NUM settings. The trigger address is SECTOR_SIZE*(sector numbers)-1. 0b - Last valid address of NAND buffer is not written by AXI command. 1b - Last valid address of NAND buffer is written by AXI command.
6 NDECCFAIL	NAND ECC fail interrupt This interrupt is generated when NAND ECC data correction failed. 0b - NAND ECC data correction pass. 1b - NAND ECC data correction fail.
5 NDNOPEND	NAND no pending AXI write transaction interrupt This interrupt is generated when all pending AXI write transactions to NAND are finished. 0b - At least one NAND AXI write transaction is pending or no NAND write transaction is sent to the queue. 1b - All NAND AXI write pending transactions are finished.
4 NDPAGEEND	NAND page end interrupt This interrupt is generated when the last address of one page in NAND device is written by AXI command. 0b - The last address of main space in the NAND is not written by AXI command. 1b - The last address of main space in the NAND is written by AXI command.
3	AXI bus error interrupt

Table continues on the next page...

Table continued from the previous page...

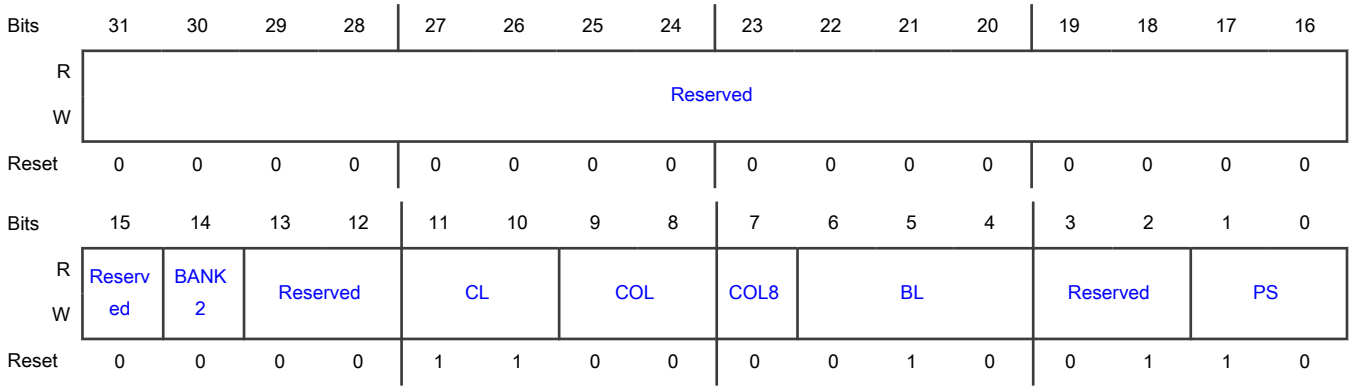
Field	Function
AXIBUSERR	AXI Bus error interrupt is generated in following cases: • AXI address is invalid • AXI write to NOR Flash • AXI 8-bit write to 16-bit NAND Flash • AXI 8-bit or 16-bit WRAP write/read 0b - No AXI bus error. 1b - AXI bus error occurs.
2 AXICMDERR	AXI command error interrupt AXI command error interrupt is generated when AXI command execution times out. 0b - No AXI command error. 1b - AXI command error occurs.
1 IPCMDERR	IP command error done interrupt IP command error interrupt is generated in following cases: • IP Command Address target invalid device space • IP Command Code unsupported • IP Command triggered when previous command not finished yet • IP Command Execution timeout 0b - No IP command error. 1b - IP command error occurs.
0 IPCMDDONE	IP command normal done interrupt It monitors whether IP command is done or not. 0b - IP command is not done. 1b - IP command is done.

29.7.1.10 SDRAM Control Register 0 (SDRAMCR0)

Offset

Register	Offset
SDRAMCR0	40h

Diagram



Fields

Field	Function
31-15 —	Reserved
14 BANK2	2 Bank selection bit This bit configures the bank numbers. 0b - SDRAM device has 4 banks. 1b - SDRAM device has 2 banks.
13-12 —	Reserved
11-10 CL	CAS Latency The CAS latency (CL) is the delay, in clock cycles, between the registration of a READ command and the availability of the output data. 00b - 1 01b - 1 10b - 2 11b - 3
9-8 COL	Column address bit number 00b - 12 01b - 11 10b - 10 11b - 9
7 COL8	Column 8 selection This bit works with COL field to determine the column address bit number.

Table continues on the next page...

Table continued from the previous page...

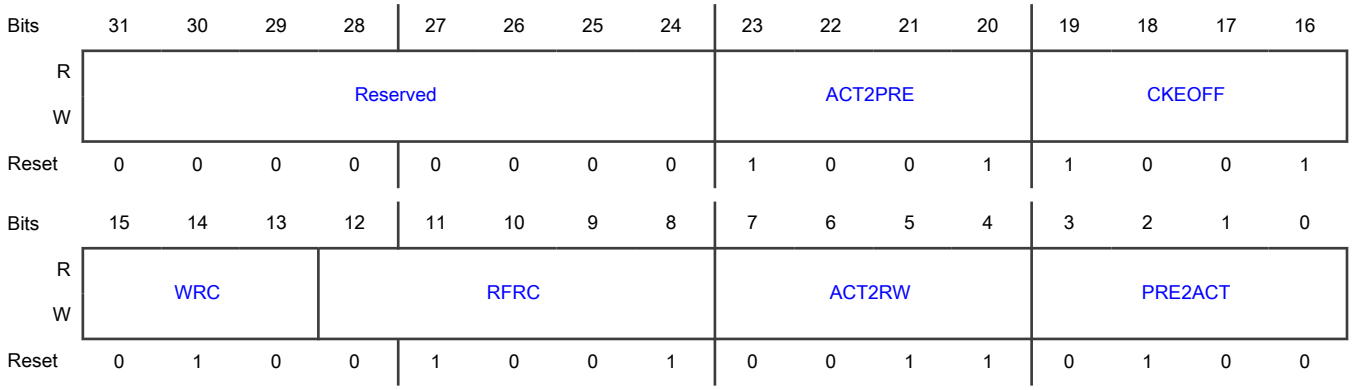
Field	Function
	0b - Column address bit number is decided by COL field. 1b - Column address bit number is 8. COL field is ignored.
6-4 BL	Burst Length The burst length determines the number of column locations that can be accessed for a given READ or WRITE command. 000b - 1 001b - 2 010b - 4 011b - 8 100b - 8 101b - 8 110b - 8 111b - 8
3-2 —	Reserved
1-0 PS	Port Size The port size must be aligned with SDRAM data width. 00b - 8bit 01b - 16bit 10b - 32bit 11b - Reserved

29.7.1.11 SDRAM Control Register 1 (SDRAMCR1)

Offset

Register	Offset
SDRAMCR1	44h

Diagram



Fields

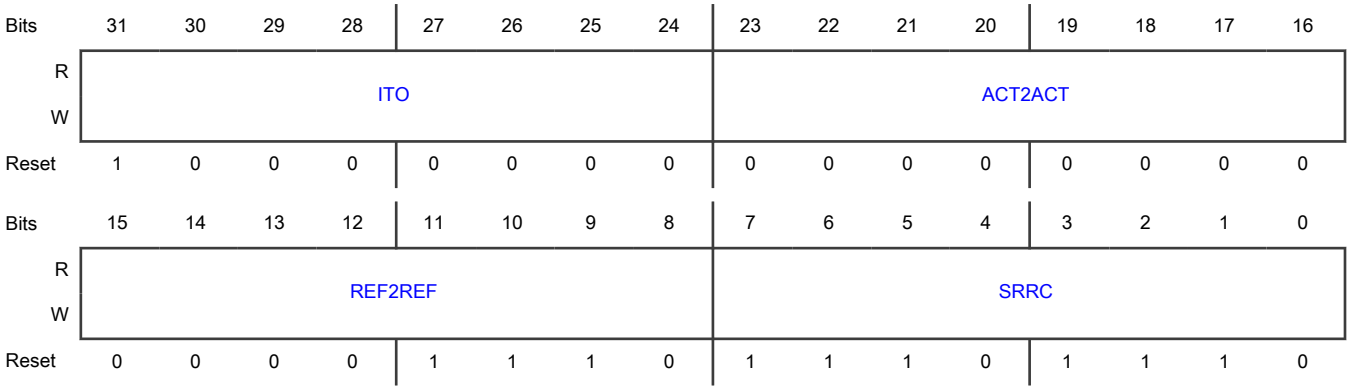
Field	Function
31-24 —	Reserved
23-20 ACT2PRE	ACTIVE to PRECHARGE minimum time The SEMC promises ACT2PRE+1 clock cycles delay between ACTIVE command to PRECHARGE/ PRECHARGE ALL command. It helps to meet tRAS timing requirement by SDRAM device.
19-16 CKEOFF	CKE off minimum time The SEMC promises at least CKEOFF+1 clock cycles in self refresh mode. It helps to meet the minimum period request to remain in self refresh mode.
15-13 WRC	WRITE recovery time The SEMC promises WRC+1 clock cycles delay between WRITE command to PRECHARGE/ PRECHARGE ALL command. It helps to meet tWR timing requirement by SDRAM device.
12-8 RFRC	REFRESH recovery time The SEMC promises RFRC+1 clock cycles delay between AUTO REFRESH command to ACTIVE command. It helps to meet tRFC timing requirement by SDRAM device.
7-4 ACT2RW	ACTIVE to READ/WRITE delay The SEMC promises ACT2RW+1 clock cycles delay between ACTIVE command to READ/WRITE command. It helps to meet tRCD timing requirement by SDRAM device.
3-0 PRE2ACT	PRECHARGE to ACTIVE/REFRESH command wait time The SEMC promises PRE2ACT+1 clock cycles delay between PRECHARGE/PRECHARGE ALL command to ACTIVE/REFRESH command. It helps to meet tRP timing requirement by SDRAM device.

29.7.1.12 SDRAM Control Register 2 (SDRAMCR2)

Offset

Register	Offset
SDRAMCR2	48h

Diagram



Fields

Field	Function
31-24 ITO	SDRAM idle timeout The SEMC closes all opened pages if the SDRAM idle time lasts more than idle timeout period. SDRAM is considered idle when there is no AXI Bus transfer and no SDRAM command pending. 0000_0000b - IDLE timeout period is 256*Prescale period. 0000_0001b-1111_1111b - IDLE timeout period is ITO*Prescale period.
23-16 ACT2ACT	ACTIVE to ACTIVE delay The SEMC promises ACT2ACT+1 clock cycles delay between ACTIVE command to ACTIVE command. It helps to meet tRRD timing requirement by SDRAM device.
15-8 REF2REF	REFRESH to REFRESH delay The SEMC promises REF2REF+1 clock cycles delay between REFRESH command to REFRESH command. It helps to meet tRFC timing requirement by SDRAM device.
7-0 SRRC	SELF REFRESH recovery time The SEMC promises SRRC+1 clock cycles delay between SELF REFRESH command to any subsequent command. SDRAM device may have limitation on self refresh recovery time. It help to meet the wait time from exiting self refresh mode to sending new command to device.

29.7.1.13 SDRAM Control Register 3 (SDRAMCR3)

Offset

Register	Offset
SDRAMCR3	4Ch

Diagram

W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 UT	Urgent refresh threshold Urgent refresh threshold is used to handle urgent refresh request. Urgent refresh timer starts to count when normal refresh request is asserted but not handled by the controller yet. When the urgent refresh timer count up to the threshold, urgent refresh request is sent to the controller. The priority of urgent refresh is higher than any pending AXI or IP command to SDRAM, so it can be handled by the controller at the first time. **NOTE** Refresh request is considered as urgent refresh request when urgent threshold is no less than refresh period. 0000_0000b - 256*(Prescaler period) 0000_0001b-1111_1111b - UT*(Prescaler period)
23-16 RT	Refresh timer period Refresh timer period is the threshold for SDRAM normal refresh request. The normal refresh request is sent to the controller when the refresh timer count up to it. The priority of normal refresh request is lower than any pending AXI or IP command to SDRAM. 0000_0000b - (256+1)*(Prescaler period) 0000_0001b-1111_1111b - (RT+1)*(Prescaler period)
15-8 PRESCALE	Prescaler period Prescaler period is used as a clock cycle count unit for refresh and bus idle timer period.

Table continues on the next page...

Table continued from the previous page...

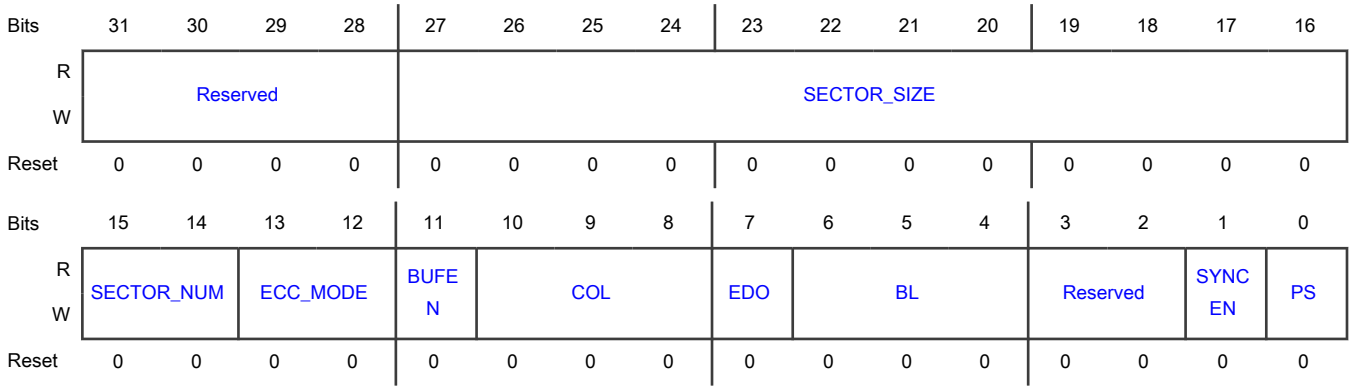
Field	Function
	0000_0000b - (256*16+1) clock cycles 0000_0001b-1111_1111b - (PRESCALE*16+1) clock cycles
7-4 —	Reserved
3-1 REBL	Refresh burst length The SEMC can send multiple AUTO REFRESH commands in one burst when REBL is set to non-zero. The number of AUTO REFRESH command in one burst is listed below. 000b - 1 001b - 2 010b - 3 011b - 4 100b - 5 101b - 6 110b - 7 111b - 8
0 REN	Refresh enable The SEMC sends AUTO REFRESH command automatically when REN bit is set. The AUTO REFRESH command interval is decided by UT, RT and PRESCALE bits. 0b - The SEMC does not send AUTO REFRESH command automatically 1b - The SEMC sends AUTO REFRESH command automatically

29.7.1.14 NAND Control Register 0 (NANDCR0)

Offset

Register	Offset
NANDCR0	50h

Diagram



Fields

Field	Function
31-28 —	Reserved
27-16 SECTOR_SIZE	Size in bytes of one elementary unit of ECC correction. Sector size includes data bits only. Sector size can not greater than (buffer size)/SECTOR_NUM, and it should be 4 bytes aligned. NAND buffer size is 2112 bytes. **NOTE** It refer to "Sector Size in Buffer" of NAND Flash Data Map
15-14 SECTOR_NUM	Sector numbers in NAND buffer 00b - There is 1 sector in buffer 01b - There are 2 sectors in buffer 10b - There are 4 sectors in buffer 11b - Reserved
13-12 ECC_MODE	ECC mode selection 00b - No correction, ECC bypass 01b - 4-error correction (8 ECC bytes) 10b - 8-error correction (16 ECC bytes) 11b - Reserved
11 BUFEN	NAND buffer enable for AXI access 0b - AXI access to NAND device directly 1b - AXI access through NAND buffer. It must be enabled for error correction schemes.
10-8 COL	Column address bit number 000b - 16

Table continues on the next page...

Table continued from the previous page...

Field	Function
	001b - 15 010b - 14 011b - 13 100b - 12 101b - 11 110b - 10 111b - 9
7 EDO	EDO mode enabled It defines the read access timing in asynchronous mode. 0b - EDO mode disabled 1b - EDO mode enabled
6-4 BL	Burst Length The burst length determines the number of column locations that can be accessed for a given READ or WRITE command. 000b - 1 001b - 2 010b - 4 011b - 8 100b - 16 101b - 32 110b - 64 111b - 64
3-2 —	Reserved
1 SYNCEN	Synchronous Mode Enable It defines the access mode. 0b - Asynchronous mode is enabled. 1b - Synchronous mode is enabled.
0 PS	Port Size The port size must be aligned with NAND Flash data width. 0b - 8bit 1b - 16bit

Fields

Field	Function
31-28 REH	RE high time RE high time is REH+1 clock cycles. This field applied to ASYNC mode only.
27-24 REL	RE low time RE low time is REL+1 clock cycles. This field applied to ASYNC mode only.
23-20 WEH	WE high time WE high time is WEH+1 clock cycles. This field applied to ASYNC mode only.
19-16 WEL	WE low time WE low time is WEL+1 clock cycles. This field applied to ASYNC mode only.
15-12 AH	Address hold time Address hold time is AH+1 clock cycles for ASYNC mode. Address hold time is AH clock cycles for SYNC mode.
11-8 AS	Address setup time Address setup time is AS+1 clock cycles
7-4 CEH	CE hold time CE Hold time is CEH+1 clock cycles This field determines the minimum hold time. Actual hold time may be larger in order to wait all read data sampled.
3-0 CES	CE setup time CE setup time is CES+1 clock cycles.

29.7.1.24 SRAM Control Register 2 (SRAMCR2)

Offset

Register	Offset
SRAMCR2	78h

Function
This register configures SRAM device 0

Diagram

Fields

Field	Function
31-12 BA	Base Address This field determines high position 20 bits of SoC level Base Address. The low position 12 bits of the address are all zero. The base address must be within the SEMC range defined for the device memory map.
11-6 —	Reserved
5-1 MS	Memory size It defines the size of the memory. Memory size must be aligned with base address. Memory regions should be configured to avoid overlapping areas. Overlapping regions will cause bus errors. 0_0000b - 4KB 0_0001b - 8KB 0_0010b - 16KB 0_0011b - 32KB 0_0100b - 64KB 0_0101b - 128KB 0_0110b - 256KB 0_0111b - 512KB 0_1000b - 1MB 0_1001b - 2MB 0_1010b - 4MB 0_1011b - 8MB 0_1100b - 16MB 0_1101b - 32MB 0_1110b - 64MB 0_1111b - 128MB 1_0000b - 256MB 1_0001b - 512MB 1_0010b - 1GB 1_0011b - 2GB 1_0100b-1_1111b - 4GB
0 VLD	Valid This bit controls whether the memory is valid or not. 0b - The memory is invalid, can not be accessed. 1b - The memory is valid, can be accessed.

29.7.1.52 Base Register 10 (BR10)

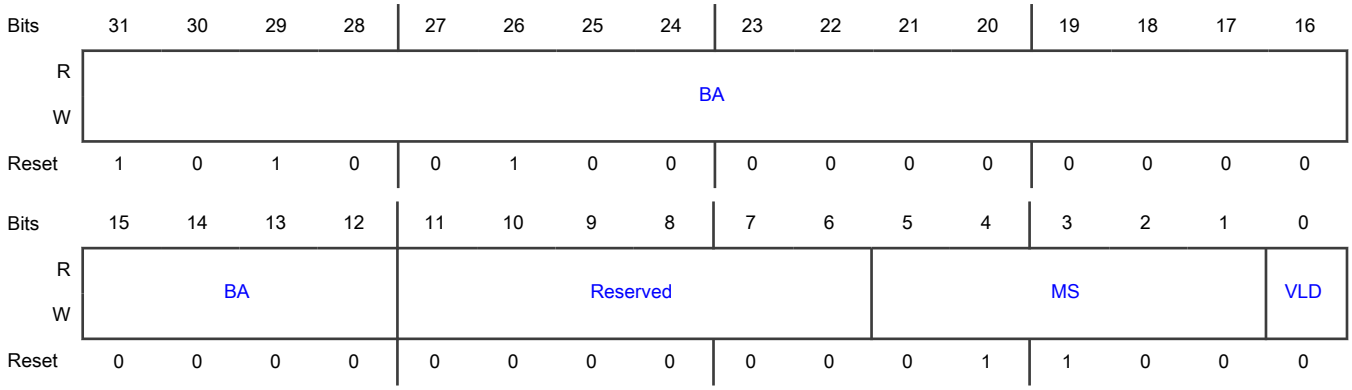
Offset

Register	Offset
BR10	104h

Function

This is the address base register for SRAM device 2. It is applied to both AXI and IP commands.

Diagram



Fields

Field	Function
31-12 BA	Base Address This field determines high position 20 bits of SoC level Base Address. The low position 12 bits of the address are all zero. The base address must be within the SEMC range defined for the device memory map.
11-6 —	Reserved
5-1 MS	Memory size It defines the size of the memory. Memory size must be aligned with base address. Memory regions should be configured to avoid overlapping areas. Overlapping regions will cause bus errors. 0_0000b - 4KB 0_0001b - 8KB 0_0010b - 16KB 0_0011b - 32KB 0_0100b - 64KB 0_0101b - 128KB

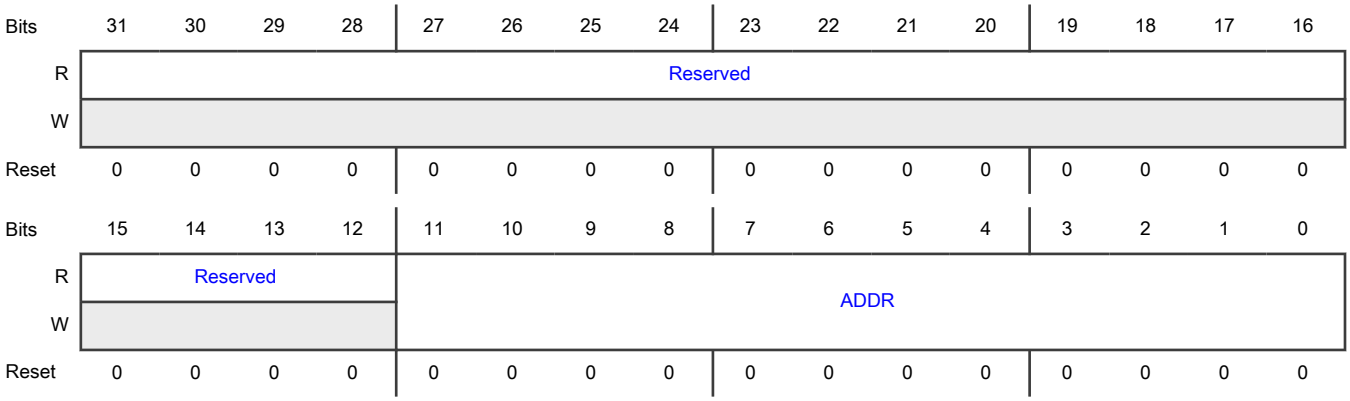
31-0 DAT	NAND Buffer data. It is used for program or read operation from IPS bus.

29.7.1.58 NAND Buffer Address Register (NDBA)

Offset

Register	Offset
NDBA	144h

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 ADDR	NAND Buffer address. It is used for program or read operation from IPS bus. It should be configured to proper value before access to NDBD register.

29.7.1.59 Delay Chain Control Register (DCCR)

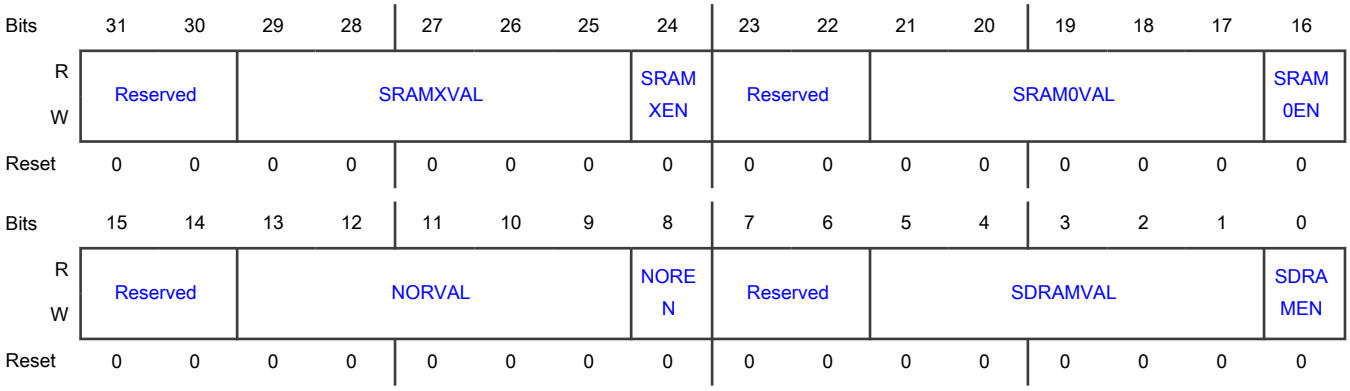
Offset

Register	Offset
DCCR	150h

Function

This register provides the configuration fields for sample clock DQS in synchronous mode. It adds delays on DQS clock to compensate timings while DQS is faster than read data. It is for synchronous SDRAM, SRAM and NOR read access.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-25 SRAMXVAL	Clock delay line delay cell number selection value for SRAM device 1-3. When SRAMXEN is set, the delay cell number in delay chain is SRAMXVAL+1.
24 SRAMXEN	Delay chain insertion enable for SRAM device 1-3. 0b - Delay chain is not inserted. 1b - Delay chain is inserted.
23-22 —	Reserved
21-17 SRAM0VAL	Clock delay line delay cell number selection value for SRAM device 0. When SRAM0EN is set, the delay cell number in delay chain is SRAM0VAL+1.
16 SRAM0EN	Delay chain insertion enable for SRAM device 0. 0b - Delay chain is not inserted. 1b - Delay chain is inserted.
15-14 —	Reserved
13-9 NORVAL	Clock delay line delay cell number selection value for NOR device. When NOREN is set, the delay cell number in delay chain is NORVAL+1.

Table continues on the next page...

Table continued from the previous page...

Field	Function

30.1.1 Address space for SRAMC CS0-CS3

The following memory address spaces are used for SRAMC CS0-CS3:

- Region from 4388_0000 (NS) to 4389_FFFF (NS) for SRAMC CS0
- Region from 438A_0000 (NS) to 438B_FFFF (NS) for SRAMC CS1 device
- Region from 438C_0000 (NS) to 438D_FFFF (NS) for SRAMC CS2 device
- Region from 438E_0000 (NS) to 438F_FFFF (NS) for SRAMC CS3 device

30.2 Overview

The AHB SRAM Controller is a memory controller for asynchronous SRAM or SRAM like FPGA.

30.2.1 Block diagram

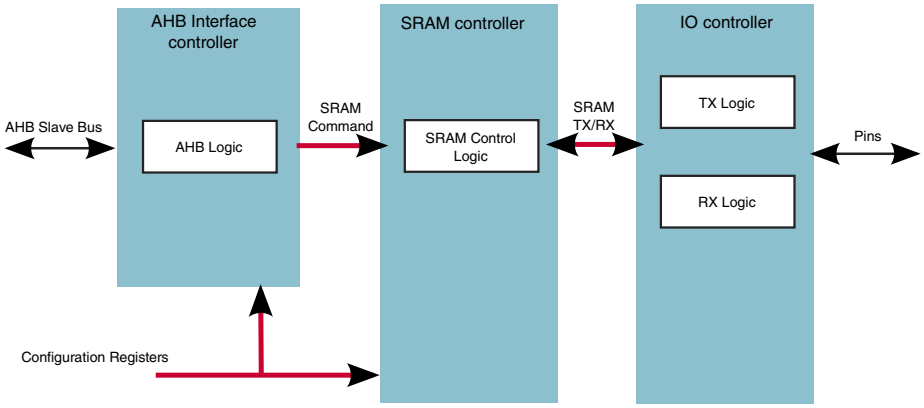

Figure 181. AHB SRAM Controller block diagram

30.2.2 Features

The AHB SRAM Controller includes the following features:

- Supports Asynchronous SRAM
- Supports 8/16 bit modes
- Supports ADMUX and Non-ADMUX modes
- Up to 4 Chip Select (CS)
- Up to 128 KB memory size each CS

30.3 Functional description

The following sections describe functional details of the AHB SRAM Controller module.

It support two address mux modes:

- ADMUX mode: Address/Data Multiplex mode
- Non-ADMUX mode: Address/Data Non-Multiplex mode

30.3.1 Operations

The following sections describe operations of the AHB SRAM Controller module.

30.3.1.1 SRAM Read Operation in ASYNC Mode

Figure 182, Figure 183 and Figure 184 show the ASYNC SRAM read in Non-ADMUX address mode.

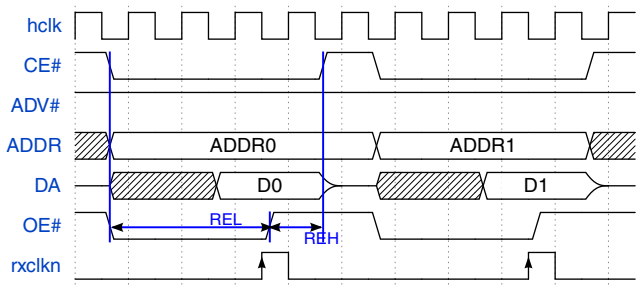

Figure 182. ASYNC SRAM Read in Non-ADMUX Address Mode

NOTE

- hclk is the AHB SRAM Controller functional clock. rxclk is the clock to sample data from SRAM.
- For this example:
  - CE# setup time is 0 clock cycle (SRAMCR0[CES]=0)
  - CE# hold time is 0 clock cycle (SRAMCR0[CEH]=0)
  - Address setup time is 0 clock cycle (SRAMCR0[AS]=0)
  - Address hold time is 0 clock cycle (SRAMCR0[AH]=0)
  - OE# low time is 3 clock cycles (SRAMCR1[REL]=2)
  - OE# high time is 1 clock cycle (SRAMCR1[REH]=0)
  - Prescaler timer's time granularity is 1 clock cycle (SRAMCR1[PRE]=0)

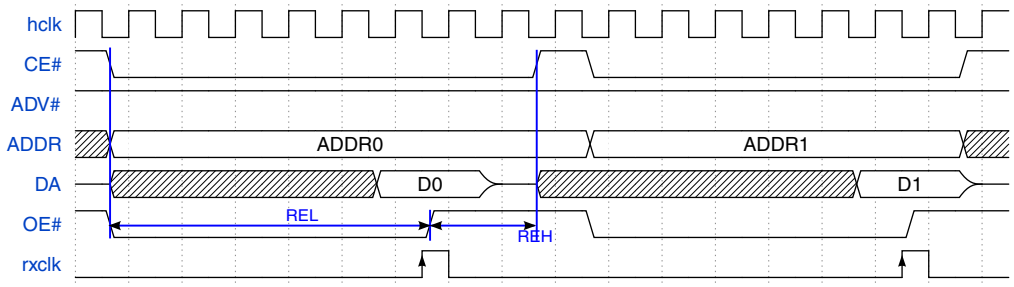

Figure 183. ASYNC SRAM Read in Non-ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 0 clock cycle (SRAMCR0[CES]=0)
  - CE# hold time is 0 clock cycle (SRAMCR0[CEH]=0)
  - Address setup time is 0 clock cycle (SRAMCR0[AS]=0)
  - Address hold time is 0 clock cycle (SRAMCR0[AH]=0)
  - OE# low time is 6 clock cycles (SRAMCR1[REL]=2)
  - OE# high time is 2 clock cycle (SRAMCR1[REH]=0)
  - Prescaler timer's time granularity is 2 clock cycles (SRAMCR1[PRE]=1)

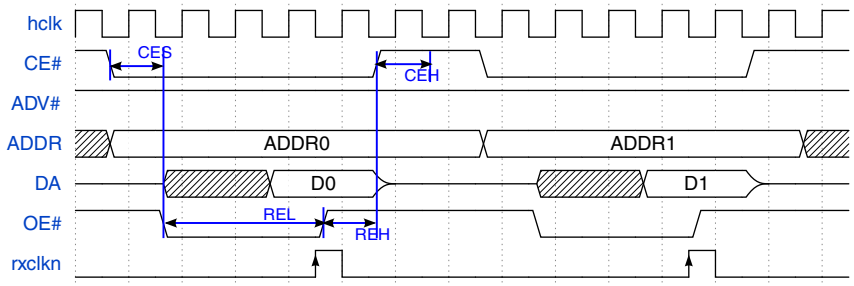

Figure 184. ASYNC SRAM Read in Non-ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR0[CES]=1)
  - CE# hold time is 1 clock cycle (SRAMCR0[CEH]=1)
  - Address setup time is 0 clock cycle (SRAMCR0[AS]=0)
  - Address hold time is 0 clock cycle (SRAMCR0[AH]=0)
  - OE# low time is 3 clock cycles (SRAMCR1[REL]=2)
  - OE# high time is 1 clock cycle (SRAMCR1[REH]=0)
  - Prescaler timer's time granularity is 1 clock cycle (SRAMCR1[PRE]=0)

Figure 185 and Figure 186 show the ASYNC SRAM read in ADMUX address mode.

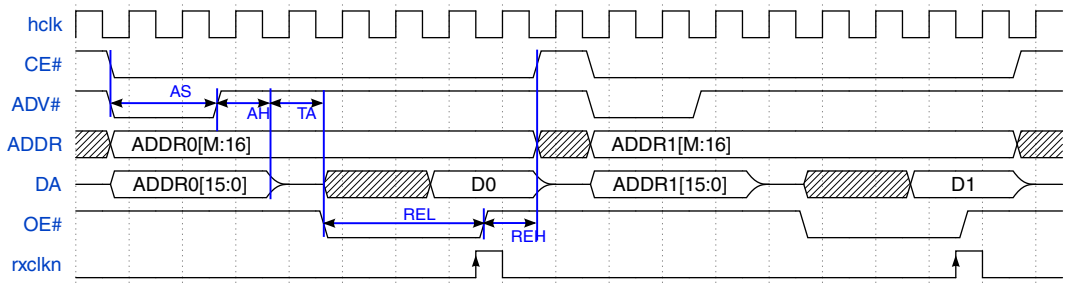

Figure 185. ASYNC SRAM Read in ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 0 clock cycle (SRAMCR0[CES]=0)
  - CE# hold time is 0 clock cycle (SRAMCR0[CEH]=0)
  - Address setup time is 2 clock cycles (SRAMCR0[AS]=2)
  - Address hold time is 1 clock cycle (SRAMCR0[AH]=0)
  - Turnaround time is 1 clock cycle (SRAMCR0[TA]=0)
  - OE# low time is 3 clock cycles (SRAMCR1[REL]=2)
  - OE# high time is 1 clock cycle (SRAMCR1[REH]=0)
  - Prescaler timer's time granularity is 1 clock cycle (SRAMCR1[PRE]=0)

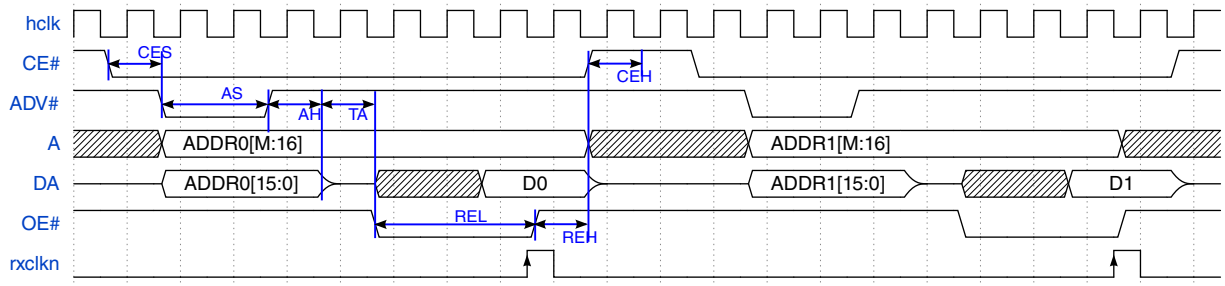

Figure 186. ASYNC SRAM Read in ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR0[CES]=1)
  - CE# hold time is 1 clock cycle (SRAMCR0[CEH]=1)
  - Address setup time is 2 clock cycles (SRAMCR0[AS]=2)
  - Address hold time is 1 clock cycle (SRAMCR0[AH]=0)
  - Turnaround time is 1 clock cycle (SRAMCR0[TA]=0)
  - OE# low time is 3 clock cycles (SRAMCR1[REL]=2)
  - OE# high time is 1 clock cycle (SRAMCR1[REH]=0)
  - Prescaler timer's time granularity is 1 clock cycle (SRAMCR1[PRE]=0)

30.3.1.2 SRAM Write Operation in ASYNC Mode

Figure 187, Figure 188 and Figure 189 show the ASYNC SRAM write in Non-ADMUX address mode.

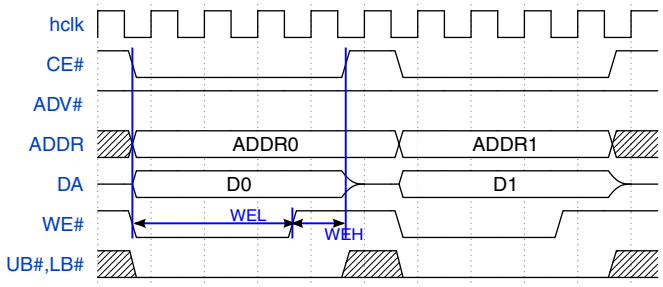

Figure 187. ASYNC SRAM Write in Non-ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 0 clock cycle (SRAMCR0[CES]=0)
  - CE# hold time is 0 clock cycle (SRAMCR0[CEH]=0)
  - Address setup time is 0 clock cycle (SRAMCR0[AS]=0)
  - Address hold time is 0 clock cycle (SRAMCR0[AH]=0)
  - WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
  - WE# high time is 1 clock cycles (SRAMCR1[WEH]=0)
  - Prescaler timer's time granularity is 1 clock cycle (SRAMCR1[PRE]=0)

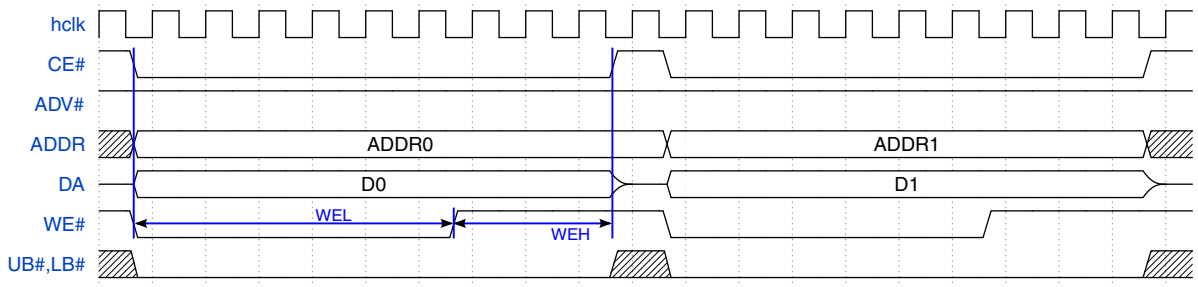

Figure 188. ASYNC SRAM Write in Non-ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 0 clock cycle (SRAMCR0[CES]=0)
  - CE# hold time is 0 clock cycle (SRAMCR0[CEH]=0)
  - Address setup time is 0 clock cycle (SRAMCR0[AS]=0)
  - Address hold time is 0 clock cycle (SRAMCR0[AH]=0)
  - WE# low time is 6 clock cycles (SRAMCR1[WEL]=1)
  - WE# high time is 3 clock cycles (SRAMCR1[WEH]=0)
  - Prescaler timer's time granularity is 3 clock cycles (SRAMCR1[PRE]=2)

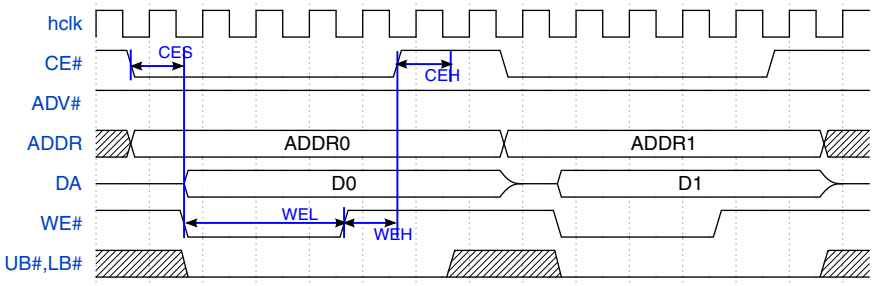

Figure 189. ASYNC SRAM Write in Non-ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR0[CES]=1)
  - CE# hold time is 1 clock cycle (SRAMCR0[CEH]=1)
  - Address setup time is 0 clock cycle (SRAMCR0[AS]=0)
  - Address hold time is 0 clock cycle (SRAMCR0[AH]=0)
  - WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
  - WE# high time is 1 clock cycles (SRAMCR1[WEH]=0)
  - Prescaler timer's time granularity is 1 clock cycle (SRAMCR1[PRE]=0)

Figure 190 and Figure 191 show the ASYNC SRAM write in ADMUX address mode.

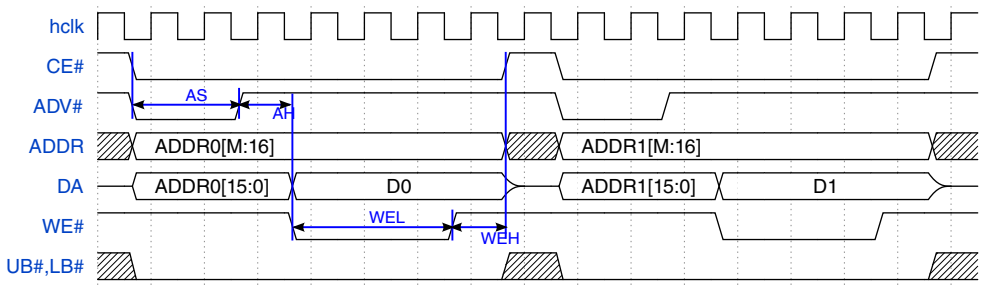

Figure 190. ASYNC SRAM Write in ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 0 clock cycle (SRAMCR0[CES]=0)
  - CE# hold time is 0 clock cycle (SRAMCR0[CEH]=0)
  - Address setup time is 2 clock cycles (SRAMCR0[AS]=2)
  - Address hold time is 1 clock cycles (SRAMCR0[AH]=0)
  - WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
  - WE# high time is 1 clock cycle (SRAMCR1[WEH]=0)
  - Prescaler timer's time granularity is 1 clock cycle (SRAMCR1[PRE]=0)

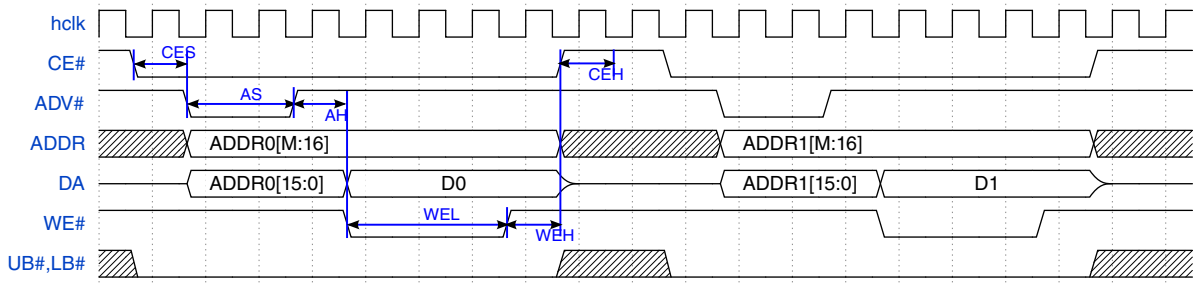

Figure 191. ASYNC SRAM Write in ADMUX Address Mode

NOTE

- For this example:
  - CE# setup time is 1 clock cycle (SRAMCR0[CES]=1)
  - CE# hold time is 1 clock cycle (SRAMCR0[CEH]=1)
  - Address setup time is 2 clock cycles (SRAMCR0[AS]=2)
  - Address hold time is 1 clock cycles (SRAMCR0[AH]=0)
  - WE# low time is 3 clock cycles (SRAMCR1[WEL]=2)
  - WE# high time is 1 clock cycle (SRAMCR1[WEH]=0)
  - Prescaler timer's time granularity is 1 clock cycle (SRAMCR1[PRE]=0)

30.3.2 Clocks

hclk is used for the functional clock for AHB SRAM Controller's AXI bus, internal logic and external interface. rxclkn is used to sample data from external SRAM device, which is generated from hclk.

30.3.3 Reset

There is a hardware reset for the AHB SRAM Controller, which reset all the logic inside it.

30.3.4 Interrupts

There is no interrupt output from the AHB SRAM Controller.

30.4 External signals

Table 193 lists the AHB SRAM Controller module signals.

Table 193. AHB SRAM Controller signals

Signal	Direction	Description
SRAMC_DA[15-00]	I/O	Data/Address Bits SRAMC_DATA works as data or address signal in applications..
SRAMC_ADDR[16-00]	O	Address Bits
SRAMC_CEB[3-0]	O	Chip Enable bits
SRAMC_OEB	O	Read Enable
SRAMC_WEB	O	Write Enable
SRAMC_ADVB	O	Address Enable
SRAMC_UBB	O	Upper Byte Control
SRAMC_LBB	O	Lower Byte Control

30.5 Initialization

To initialize the block:

- Ensure the clock for the AHB SRAM Controller is enabled.
- Configure corresponding pin MUX for the AHB SRAM Controller external signals.

- Configure registers of the AHB SRAM Controller properly, according to the applications.

30.6 Application information

This section describes applications supported by the AHB SRAM Controller module.

30.6.1 SRAM Application

This section provides the example sequences for SRAM device.

- Configure SRAM Control Registers with valid settings that matches SRAM device.
- Write and read operations can be triggered by AXI access.

30.7 Memory map and register definition

The AHB SRAM Controller registers are defined in chapter "Block Control - Wake-up Domain(BLK_CTRL_WAKEUP)" memory map, as registers SRAMCR0 and SRAMCR1.

Chapter 31
Flexible Serial Peripheral Interface (FlexSPI)

31.1 Chip-specific FlexSPI information

31.1.1 AHB Memory Map Address Ranges

The table below shows the address range calculations for the various instances of FlexSPI:

Table 196. Memory Map Address Ranges

Description	FlexSPI1	FlexSPI2
Address range is mapped for AHB read access to IP RX FIFO	0x4742_0000 – 0x4742_00FF	0x4DE0_0000 – 0x4DE0_00FF
Address range is mapped for AHB write access to IP TX FIFO	0x4743_0000 – 0x4743_03FF	0x4DE1_0000 – 0x4DE1_03FF

Table continues on the next page...

Table 196. Memory Map Address Ranges (continued)

Description	FlexSPI1	FlexSPI2
AHB Memory Map for Serial Flash memory access	0x2800_0000	0x0400_0000
Total AHB RX Buffer size	4 KBytes	4 KBytes
AHB TX Buffer size	64 Bytes	64 Bytes
IP Bus memory space access	0x4742_0000 – 0x4742_00FF	0x4DE0_0000 – 0x4DE0_00FF
AHB bus memory space access	0x2800_0000 – 0x2FFF_FFFF	0x0400_0000 – 0x07FF_FFFF

31.1.2 Controller ID allocation

Table 197. Controller IDs

Module	Controller ID
NETC	0000
USB1, USB2	0001
FlexSPI Follower	0010
Cortex-M33	1000
Cortex-M7	1001
Edgelock	1010
eDMA3(AHB)	1011
eDMA4(AXI)	1100
uSDHC1, uSDHC2, and others	1111

31.1.3 FlexSPI connection modes

The table below shows details about the Parallel, Individual, and Combination modes for Flash memory.

Table 198. Relation between Modes and Bus size for FlexSPI instances

Mode	Instance	Effective Bus Size	Data Signals	Function	Devices Attached to Bus	Chip Selects
INDIVIDUAL	FLEXSPI1	4bit	A_DATA0- A_DATA3	Single QSPI chip support(1b,2b,4b)	Up to 2	A_SS0_B, A_SS1_B
INDIVIDUAL	FLEXSPI1	4bit	B_DATA0- B_DATA3	Single QSPI chip support(1b,2b,4b)	Up to 2	B_SS0_B, B_SS1_B
INDIVIDUAL	FLEXSPI1	8bit	A_DATA0- A_DATA7	Single Octal/	Up to 2	A_SS0_B, A_SS1_B

Table continues on the next page...

Table 198. Relation between Modes and Bus size for FlexSPI instances (continued)

Mode	Instance	Effective Bus Size	Data Signals	Function	Devices Attached to Bus	Chip Selects
				Hyperbus/ Xccela chip support(1x8b)		
INDIVIDUAL	FLEXSPI1	8bit	B_DATA0- B_DATA7	Single Octal/ Hyperbus/ Xccela chip support(1x8b)	Up to 2	B_SS0_B, B_SS1_B
PARALLEL	FLEXSPI1	8bit	A_DATA0- A_DATA3 | B_DATA0- B_DATA3	Two QSPI chips in parallel(2x4b)	2 parallel chips x2 = up to 4	(A_SS0_B | B_SS0_B), (A_SS1_B | B_SS1_B)
PARALLEL	FLEXSPI1	16bit	A_DATA0- A_DATA7 | B_DATA0- B_DATA7	Two Octal/ Hyperbus/ Xccela chips in parallel(2x8b)	2 parallel chips x2 = up to 4	(A_SS0_B | B_SS0_B), (A_SS1_B | B_SS1_B)
INDIVIDUAL	FLEXSPI2	4bit	A_DATA0- A_DATA3	Single QSPI chip support(1b,2b,4b)	Up to 2	A_SS0_B, A_SS1_B
INDIVIDUAL	FLEXSPI2	4bit	B_DATA0- B_DATA3	Single QSPI chip support(1b,2b,4b)	Up to 2	B_SS0_B, B_SS1_B
COMBINE	FLEXSPI2	8bit	A_DATA0- A_DATA3 | B_DATA0- B_DATA3	Single Octal/ Hyperbus/ Xccela chip support(1x8b)	Up to 2	A_SS0_B, A_SS1_B
PARALLEL	FLEXSPI2	8bit	A_DATA0- A_DATA3 | B_DATA0- B_DATA3	Two QSPI chips in parallel(2x4b)	2 parallel chips x2 = up to 4	(A_SS0_B | B_SS0_B), (A_SS1_B | B_SS1_B)

31.2 Overview

FlexSPI supports two SPI channels and up to four external devices. Each channel supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines).

The FlexSPI configuration depends on the chip configuration. See the system-level section for boot information and pinmux for chip-specific information regarding the modes and number of devices supported.

FlexSPI supports communication with both serial flash memory and serial RAM devices. While many of the descriptions, registers, and fields specifically reference flash memory, almost all information can also be applied to serial RAM. Flash memory is used as an example in the tables and figures in this chapter.

NOTE

Terminology in this chapter has been updated to align with JEDEC standard *Expanded Serial Peripheral Interface (xSPI) for Non Volatile Memory Devices, Version 1.0*.

Table 199. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

31.2.1 Block diagram

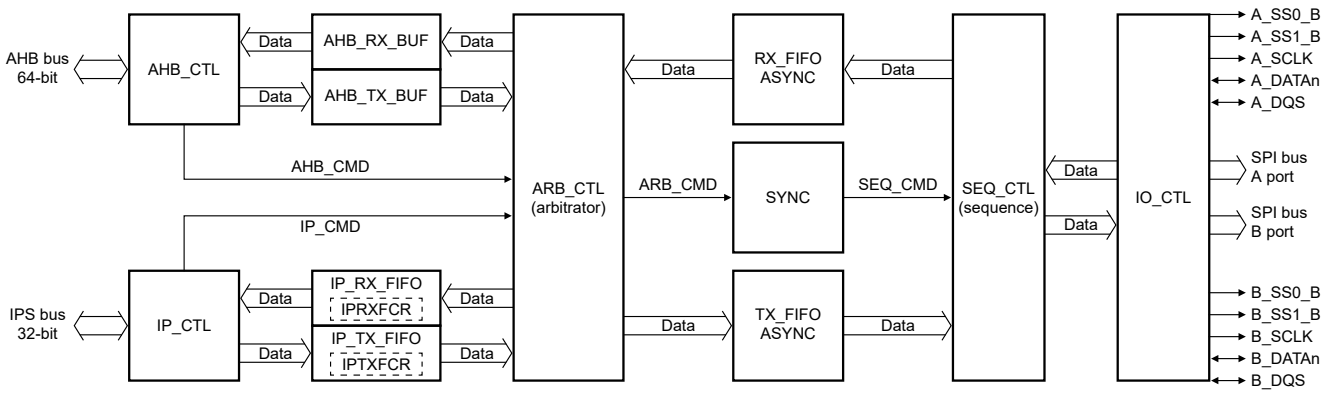

Figure 192. Block diagram

31.2.2 Features

FlexSPI supports:

- Flexible sequence engine (lookup table) to support various vendor devices
  - Serial NOR flash memory and other devices with SPI protocol similar to serial NOR flash memory
  - Serial NAND flash memory
  - HyperBus devices (HyperFlash/HyperRAM)
  - XCCELA devices
  - FPGA devices
- Flash memory access modes
  - Single, Dual, Quad, Octal mode
  - Single Data Transfer Rate (SDR) and Double Data Transfer Rate (DDR) mode
  - Individual/Parallel mode
- Sampling clock mode
  - Internal dummy read strobe looped back internally
  - Internal dummy read strobe looped back from pad

- Flash-memory-provided read strobe

- Memory mapped read and write access by AHB bus
  - AHB receive buffer implemented to reduce read latency. See the chip-specific section for AHB buffer size.
  - 16 AHB controllers with programmable priority for read access from each
  - 8 flexible and configurable buffers in AHB receive buffer
  - AHB transmit buffer implemented to buffer all write data from one AHB burst. See the chip-specific section for AHB buffer size.

NOTE

All AHB controllers share this AHB transmit buffer. There is no AHB controller number limitation for write access.

- Software-triggered flash memory read and write access by IP bus
  - IP receive FIFO implemented to buffer all read data from external devices. FIFO size: 256 bytes
  - IP transmit FIFO implemented to buffer all write data to external devices. FIFO size: 1024 bytes
  - DMA support to read IP receive FIFO
  - DMA support to fill IP transmit FIFO
  - SCLK stops when IP receive FIFO is full during reading flash memory data
  - SCLK stops when IP transmit FIFO is empty during writing flash memory data

31.3 Functional description

31.3.1 Flash connection

There are two FlexSPI interface ports (port A and port B). Each port supports up to two flash devices by providing two chip select outputs.

NOTE

FlexSPI configuration depends on the chip configuration. See the chip-specific FlexSPI information regarding the number of devices supported.

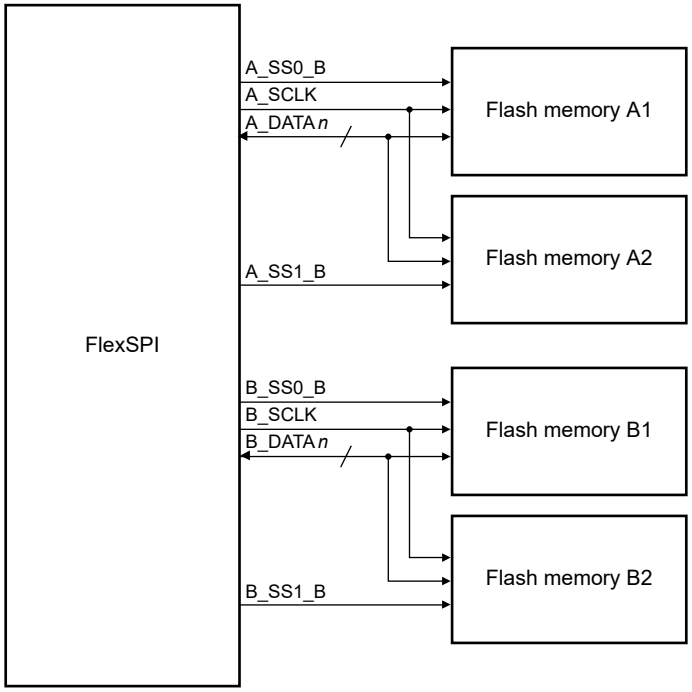

Figure 193. FlexSPI connection diagram with four devices.

NOTE

- Flash A1 and Flash A2 can be two flash chip packages or two flash dies in the same package. There is no difference to FlexSPI. This statement is also true for Flash B1 and Flash B2.
- Flash A1 and Flash B1 can be accessed in parallel, using parallel mode. FlexSPI merges or splits the flash read and program data automatically. This statement is also true for Flash A2 and Flash B2.
- In parallel mode, Flash A1 and Flash A2 cannot be accessed at the same time. This statement is also true for Flash B1 and Flash B2.
- In individual mode, flash devices cannot be accessed at the same time. But these four devices can be accessed separately.

There is a combination mode (MCR0[COMBINATIONEN] = 1) used to provide octal flash memory support by combining Port A (A_DATA[3:0]) and Port B (B_DATA[3:0]) together. Normal mode can also support Octal mode by using all eight data lines from Port A or Port B. Figure 194 shows the connection diagram for combination mode.

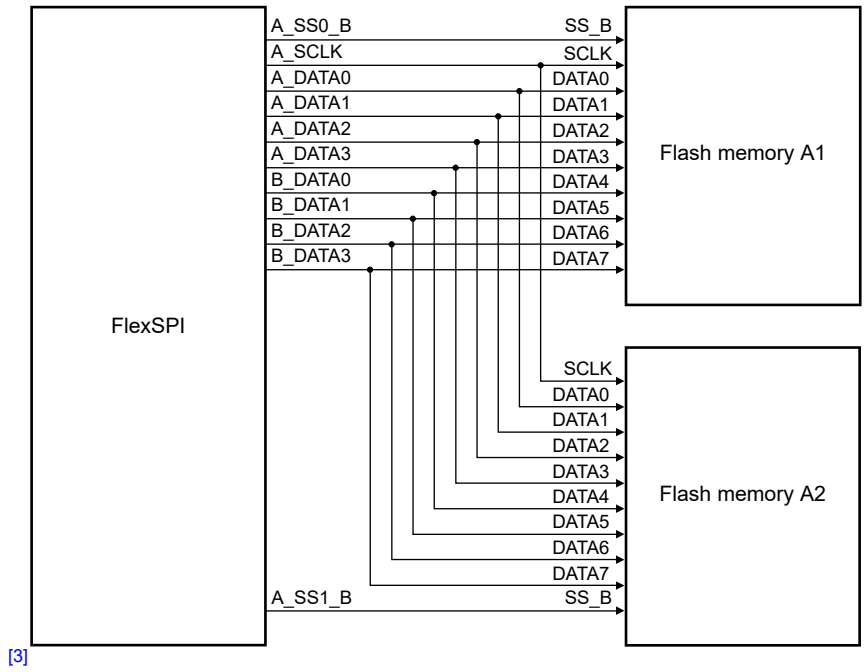

Figure 194. FlexSPI connection diagram for combination mode

31.3.2 Flash memory access mode

31.3.2.1 SPI clock mode

FlexSPI only supports SPI clock mode 0: clock polarity (CPOL) = 0 and clock phase (CPHA) = 0. When the SPI bus is idle, SCLK stays at a logic low state.

31.3.2.2 Individual mode and Parallel mode

In individual mode, read and write data are received and transmitted on port A or port B.

In parallel mode, read and write data are received and transmitted on port A and port B in parallel. FlexSPI merges or splits the read and program data automatically (READ/WRITE instruction). Only read and program data is merged or split (READ/WRITE instruction). For other instructions (such as Command, Address, Mode, and Data size), the same associated information is transmitted to the devices connected to port A and port B. For more details, see Executing instructions on SPI interface.

IPCR1[IPAREN] (for IP command) or AHBCR[APAREN] (for AHB command) statistically determines Individual and Parallel mode.

NOTE

FlexSPI does not support 16-bit read and write for the SPI interface.

31.3.2.3 SDR mode and DDR mode

In SDR mode, flash memory receives data on the rising edge of SCLK and transmits data on the falling edge of SCLK.

In DDR mode, flash memory receives and transmits data on both the rising and falling edges of SCLK.

[3] Parallel mode access is not available in combination mode.

The instruction (opcode) in the LUT sequence dynamically determines SDR and DDR modes. There is no static configuration register field setting for SDR and DDR modes. See FlexSPI input timing and FlexSPI output timing for details about input and output timing.

31.3.2.4 Single, Dual, Quad, and Octal mode

In Single mode, FlexSPI transmits and receives data on one data pin (DATA0 for transmitting, DATA1 for receiving).

In Dual mode, FlexSPI transmits and receives data on two data pins (DATA0–DATA1 for both transmitting and receiving).

In Quad mode, FlexSPI transmits and receives data on four data pins (DATA0–DATA3 for both transmitting and receiving).

In Octal mode, FlexSPI transmits and receives data on eight data pins (DATA0–DATA7 for both transmitting and receiving).

Instruction (num_pads) in the LUT sequence dynamically determine Single, Dual, Quad, and Octal modes. There is no static configuration register field setting for Single, Dual, Quad, and Octal modes.

31.3.3 Modes of operation

FlexSPI operates with these modes.

Table 200. Operating modes

Mode	Description
Module Disable	This mode is a low-power mode for FlexSPI. In Module Disable mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock domain is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, and IP transmit FIFO cannot be accessed. Serial memory access is also not available. Write 1 to MCR0[MDIS] to enter this mode. Write 0 to MCR0[MDIS] to exit this mode.
Doze	This mode is a low-power mode for the chip. When the chip requires FlexSPI to enter Doze mode and MCR0[DOZEEN] = 1, FlexSPI enters Doze mode after all transactions are completed (STS0[ARBIDLE] = 1). In Doze mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, the IP transmit FIFO cannot be accessed. Serial memory access is also not available. This mode is entered via system request, and exited by deasserting this system request.
Stop	This mode is a low-power mode for the chip. When the chip requires the FlexSPI to enter Stop mode, FlexSPI waits for all transactions to complete (STS0[ARBIDLE] = 1) and return ACK handshake to the system. After the ACK handshake is returned, FlexSPI gates off the AHB clock and serial clock domains internally. The system can gate off the AHB bus clock, IPS bus clock, and serial clock at the system level. This mode is entered via system request. This mode is exited by deasserting this system request, and the ACK handshake message is also deasserted immediately.
Normal	No clock is gated off internally. Normal register access and serial memory access are available.

31.3.4 AHB access memory map

FlexSPI allocates AHB memory space for each memory device starting from the FlexSPI region base address of the system memory map. The FLSHxCR0[FLSHSZ] field determines the amount of memory allocated for each memory device in KB, Fx_SIZE. The memory is then allocated sequentially and contiguously.

NOTE

See the chip-specific section for the maximum flash size supported.

When MCR2[SAMEDEVICEEN] = 1:

- FA1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FA2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB

When MCR2[SAMEDEVICEEN] = 0:

- FA1_SIZE = FLSHSZ × 1 KB
- FA2_SIZE = FLSHA2CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHB1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHB2CR0[FLSHSZ] × 1 KB

Flash B1 and Flash B2 size settings are ignored in parallel mode (FLSHB1CR0[FLSHSZ], FLSHB2CR0[FLSHSZ]). To execute in parallel mode, Flash B1 should be the same device as Flash A1, and Flash B2 should be the same device as Flash A2.

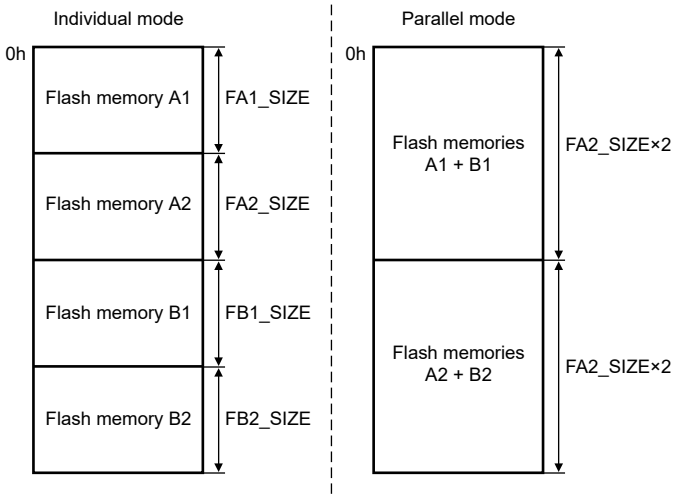

Figure 195. AHB access memory map in individual and parallel mode

AHB access memory map in individual mode:

- Flash A1 address range: 0000_0000h to FA1_SIZE
- Flash A2 address range: FA1_SIZE to (FA1_SIZE + FA2_SIZE)
- Flash B1 address range: (FA1_SIZE + FA2_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE)
- Flash B2 address range: (FA1_SIZE + FA2_SIZE + FB1_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE + FB2_SIZE)

AHB access memory map in parallel mode:

- Flash A1+B1 address range: 0000_0000h to FA1_SIZE × 2
- Flash A2+B2 address range: FA1_SIZE × 2 to (FA1_SIZE × 2 + FA2_SIZE × 2)

NOTE

The address used in Figure 195 and equations in this topic is the address presented to the memory. The base address for FlexSPI in the system memory map has already been removed, so it not used or shown here.

31.3.4.1 Flash address sent to flash memory devices

The AHB address (AHB command) or IPCR0[SFAR] (IP command) determines the flash memory access start address. See Flash memory access via AHB command and Flash memory access via IP command for more details.

For AHB commands, the FlexSPI controller removes the flash memory base address automatically when sending flash addresses to flash devices. The flash address is sent to devices in two parts: row address and column address. For flash devices that do not support the column address, set FLSHxCR1[CAS] to 0. This setting causes all flash address bits to be sent to flash devices as row addresses.

For word-addressable flash devices, the last bit of the address is not needed, because flash memory is read and programmed in terms of two bytes. For parallel mode, Flash A1 and Flash B1 (or Flash A2 and Flash B2) are accessed in parallel. As a result, the flash memory address sent to flash devices should be divided by 2. Table 201 indicates the relationship of row address, column address, and flash address (FA).

Table 201. Flash address, row address, and column address

Parallel mode	Word-addressable	Row address	Column address	Comment
0	0	FA[31:CAS]	FA[CAS-1:0]	There is no limitation on FA and data size alignment.
0	1	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be two-byte aligned.
1	0	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be two-byte aligned.
1	1	FA[31:CAS+2]	FA[CAS+1:2]	FA and data size should be four-byte aligned.

NOTE

- FA is the flash address without base address.
- If the bit number of the row or column flash address is more than the valid value, the high position bits are supplemented with zero. See Programmable sequence engine for details about row or column address instructions.

When parallel mode is enabled or word-addressable flash memory is used, there are limitations on the flash memory start address and data size. You can address this requirement by aligning the AHB bus access address (for AHB command) or IP command address IPCR0[SFAR] (for IP command) in software. There are two ways to avoid these limitations in the specified case.

1. For AHB Read Command only:

   When AHBCR[READADDROPT] and AHBCR[PREFETCHEN] are both 1, or OTFAD is enabled, FlexSPI guarantees the start address and data size for the flash memory access are eight-byte aligned by hardware.

   When AHBCR[READADDROPT] is 1, or OTFAD is enabled, FlexSPI fetches redundant data to guarantee the flash memory start address is eight-byte aligned. When prefetch is enabled (AHBCR[PREFETCHEN] is 1), the size of the eight-byte-aligned AHB receive buffer determines the flash memory read data size.

2. For AHB Write Command and Individual Mode only:

   By default, FlexSPI guarantees the flash memory write access start address and data size are two-byte aligned when using DQS as write mask (FLSHCR4[WMENB or WMENA] = 1).

   This feature is not applied in parallel mode and must be used if the external device supports write mask feature.

   For example, for odd start address:

- To write 6 bytes, FlexSPI sends 8 bytes, the first and last byte are both masked.
- To write 7 bytes, FlexSPI sends 8 bytes, only the first byte is masked.
- To write 8 bytes, FlexSPI sends 10 bytes, the first and last byte are both masked.

For even start address:

- To write 6 bytes, FlexSPI sends 6 bytes, no bytes are masked.
- To write 7 bytes, FlexSPI sends 8 bytes, last byte is masked.
- To write 8 bytes, FlexSPI sends 8 bytes, no bytes are masked.

31.3.5 Lookup table (LUT)

The LUT is an internal memory that preserves a number of preprogrammed sequences. Each sequence consists of up to eight instructions which are executed sequentially. When an IP command or an AHB command triggers a flash memory access, the FlexSPI controller:

1. Fetches the sequence from LUT (sequence index or number).
2. Executes the flash memory access to generate a valid flash transaction on the SPI interface.

Figure 196 shows the LUT structures, sequences, and instructions.

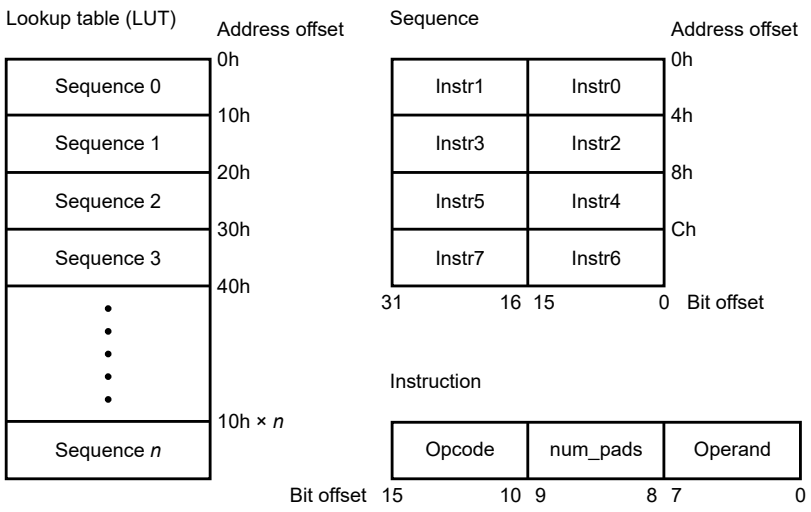

Figure 196. LUT structure, sequences, and instructions

NOTE

If the number of instructions needed for a flash transaction is less than eight, the STOP instruction (code 0000_0000h) must be programmed for unneeded instructions.

For IP and AHB write commands, the FlexSPI controller always executes from instruction pointer 0. For AHB read commands, the FlexSPI controller executes from a saved instruction start pointer. The FlexSPI controller saves the instruction start pointers separately for each flash device. All these saved instruction pointers are zero before the JMP_ON_CS instruction is executed. When the JMP_ON_CS instruction is executed, the operand in the JMP_ON_CS instruction is saved as instruction start pointer. See Execute-In-Place (XIP) enhanced mode.

The reset value of the LUT is unknown because it is implemented as internal memory. The LUT must be programmed according to the connected device. To protect its contents during a code runover, the LUT can be locked or unlocked to prevent unwanted changes after the LUT has been configured. The key to lock or unlock the LUT is **5AF05AF0h**.

To lock the LUT:

1. Write the key (5AF05AF0h) to LUT Key (LUTKEY).
2. Write 1 to LUTCR[LOCK] and write 0 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

To unlock the LUT:

1. Write the key (5AF05AF0h) to the LUT Key Register LUT Key (LUTKEY).
2. Write 0 to LUTCR[LOCK] and write 1 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

The lock status of the LUT can be read from LUTCR[LOCK] and LUTCR[UNLOCK].

31.3.6 Programmable sequence engine

The FlexSPI controller implements a programmable sequence engine that executes the sequence from the LUT. The FlexSPI controller executes the instructions sequentially, and generates flash transactions on the SPI interface accordingly. Table 202 is a complete list of the supported instructions.

Table 202. Instruction set

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
CMD_SDR	00_0001h	00h - one pad (Single mode) 01h - two pads (Dual mode) 02h - four pads (Quad mode) 03h - eight pads (Octal mode)	Transmit command code to flash memory	Command code: Operand[7:0]	Bit number: 8
CMD_DDR	00_0021h				
RADDR_SDR	00_0002h		Transmit row address to flash memory See Flash address sent to flash memory devices	Row_Address[31:0] Row_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Row_Address.
RADDR_DDR	00_0022h				
CADDR_SDR	00_0003h		Transmit column address to flash memory. See Flash address sent to flash memory devices.	Column_Address[31:0] Column_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Column_Address.
CADDR_DDR	00_0023h				
MODE1_SDR	00_0004h		Transmit mode bits to flash memory	Mode bits: Operand[0]	Bit number: 1
MODE1_DDR	00_0024h				
MODE2_SDR	00_0005h			Mode bits: Operand[1:0]	Bit number: 2
MODE2_DDR	00_0025h				
MODE4_SDR	00_0006h			Mode bits: Operand[3:0]	Bit number: 4
MODE4_DDR	00_0026h				

Table continues on the next page...

Table 202. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
MODE8_SDR	00_0007h			Mode bits: Operand[7:0]	Bit number: 8
MODE8_DDR	00_0027h				
WRITE_SDR	00_0008h		Transmit program data to flash device	Program data in IP_TX_FIFO or AHB_TX_BUF	AHB burst size and burst type (AHB command) or IPCR1[IDATSZ] (IP command) determines byte number (data size). For details about flash read or program data size, see Flash memory access via AHB command and Flash memory access via IP command.
WRITE_DDR	00_0028h				
READ_SDR	00_0009h		Receive read data from flash device Read data is put into AHB_RX_BUF or IP_RX_FIFO.	-	
READ_DDR	00_0029h				
DATSZ_SDR	00_000Bh		Transmit read or program data size (byte number) to flash device	Internal logic Read or program data size for current command sequence	Bit number: operand[7:0] Never set operand to zero or greater than 64 for DATSZ instruction.
DATSZ_DDR	00_002Bh				
DUMMY_SDR	00_000Ch		Leave data lines undriven by FlexSPI controller. Turnaround cycles are provided from host driving to device driving. num_pads determines number of pads in input mode.	-	Dummy cycle number (in serial root clock): Operand[7:0] Dummy cycle (N), described in data sheet of flash device, is in number of SCLK cycles. This number may be configurable. In SDR mode, SCLK cycle is same as serial root clock. Operand value must be set to N. In DDR mode, SCLK cycle is double serial root clock cycle. Operand value must be set to 2N, 2N-1 or 2N+1 depending on definition of dummy in data sheet of flash device. See Flash memory access sequence examples and dummy cycle definition in data sheet of external memory.
DUMMY_DDR	00_002Ch				
DUMMY_RWDS_SDR	00_000Dh		Similar to DUMMY_SDR/ DUMMY_DDR instruction.	-	For read command, dummy cycle number (in serial root clock):
DUMMY_RWDS_DDR	00_002Dh				

Table continues on the next page...

Table 202. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
			Difference is in dummy cycle number. DQS pin is called RWDS in HyperBus specification. See Dummy instruction for details. **Set operand to "Latency count" for HyperBus devices.**		(operand[7:0] × 4 - 1) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 1) if RWDS (DQS pin) is low; For write command, dummy cycle number (in serial root clock): (operand[7:0] × 4 - 2) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 2) if RWDS (DQS pin) is low;
JMP_ON_CS	00_001Fh	Num_pads setting ignored.	Stop execution, deassert CS and save operand[7:0] as instruction start pointer for next sequence. Normally this instruction is used to support Execute-In-Place enhanced mode. See Execute-In-Place (XIP) enhanced mode. This instruction is only allowed for AHB read commands. When using this instruction in IP command or AHB write command, interrupt status flag set (INTR[IPCMDERR] or INTR[AHBCMDERR]).	-	No transaction on SPI interface.
STOP	00_0000h		Stop execution and deassert CS. Next command sequence (to same	-	

Table continues on the next page...

Table 202. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
			flash device) starts from instruction pointer 0.		

The programmable sequence engine allows configuration of the LUT according to the connected external serial device. The flexible LUT structure easily adapts to new command or protocol changes from different vendors.

The DDR sequence is a flash memory access sequence that contains DDR instructions other than DUMMY_DDR, and may contain SDR instructions. The output and input timing on FlexSPI differs for SDR and DDR sequences. When included as part of a DDR sequence, SDR instructions execute differently from SDR instructions in an SDR sequence. See FlexSPI input timing and FlexSPI output timing.

31.3.6.1 Executing instructions on SPI interface

This section describes the execution of instructions on the SPI interface. For all instructions that receive bits from or transmit bits to flash devices:

- The bit order in one byte is higher on DATA7 than DATA0.
- The bit order is higher on port B than port A.

This order is shown in Figure 197.

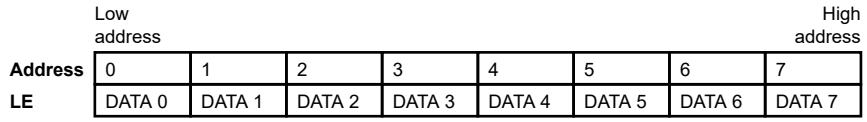

Figure 197. Bus bit order

Table 203. SPI instructions

Instructions	Description
Command (CMD_SDR, CMD_DDR)	Normally used to transmit a command code to the external device. The command code is the 8-bit operand in the instructions. Command code is sent to both port A and port B in parallel mode. See Flash memory access sequence examples.
Address (RADDR_SDR, RADDR_DDR, CADDR_SDR, CADDR_DDR)	Normally used to send the flash memory access start address (row address or column address) to an external device. FlexSPI determines the bits of the row address or column address according to the AHB access address or IP command address. See Flash address sent to flash memory devices. The operand value in the instruction code represents the number of address bits to send. The bits in the row address or column address are sent to both port A and port B in parallel mode. For example, when NUM_PADSn = 8, a memory reading the flash memory address on four SCK edges requires the sum of bits in CADDR and RADDR instructions to be 32. Otherwise, FlexSPI does not generate four SCK edges of address phase. See Flash memory access sequence examples.
Mode	Normally used to send mode bits to external devices. Mode bits are the lower bits of an operand. For example, the bit number is 1 for MODE1_SDR and MODE1_DDR, 2 for MODE2_SDR

Table continues on the next page...

Table 203. SPI instructions (continued)

Instructions	Description
(MODEx_SDR, MODEx_DDR)	and MODE2_DDR, 4 for MODE4_SDR and MODE4_DDR, and 8 for MODE8_SDR and MODE8_DDR. The pad number should not be greater than the mode bit number. For example, you cannot set NUM_PADSn to 11b (Octal mode) for MODE4_* instructions. Mode bits are sent to both port A and port B in parallel mode. See Flash memory access sequence examples for more details.
Data Size (DATSZ_SDR, DATSZ_DDR)	Used to send the size of program data or read data (byte number) to external devices. This instruction is normally used in FPGA applications where the memory space in external device acts like a FIFO. The external device requires data size information to determine how much data are popped from or pushed into the internal FIFO. The operation value in the data size instructions is the bit number. Data size is sent to both port A and port B in parallel mode. See Flash memory access sequence examples.
Write (WRITE_SDR, WRITE_DDR)	Normally used to send program data to external device. Programming data is fetched from IP_TX_FIFO (IP Command) or AHB_TX_Buffer (AHB command). For details about flash program data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for program data is always from low to high. Odd bytes are sent on port A and even bytes are sent on port B in parallel mode. See Flash memory access sequence examples for more details.
Read (READ_SDR, READ_DDR)	Normally used to receive flash memory data from external devices. Received data is put into IP_RX_FIFO (IP Command) or AHB_RX_Buffer (AHB command). For information about flash memory read data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for reading data is always from low to high. Odd bytes are received from port A and even bytes are received from port B in parallel mode. See Flash memory access sequence examples.
Dummy (DUMMY_SDR, DUMMY_DDR, DUMMY_RWDS_SDR, DUMMY_RWDS_DDR)	Used to provide turnaround cycles on the SPI interface. During dummy instruction, the FlexSPI controller and external devices do not drive the SPI interface. See Programmable sequence engine for details about dummy cycle number. DUMMY_RWDS_DDR can be used for a HyperBus device that uses RWDS pin to indicate whether extra latency is needed. DUMMY_RWDS_SDR is reserved. The FlexSPI controller checks the DQS pin input level at the fourth cycle after SCLK output toggling is enabled. The DQS pin is called RWDS in HyperBus specification. See Flash memory access sequence examples. **NOTE** FlexSPI releases the bus after at least one cycle. To avoid data contention, the NUM_PADSn value for the dummy commands should be configured to match the number of data lines used for the external memory.

31.3.6.2 Flash memory access sequence examples

Diagrams below all assume MCR0[SERCLKDIV] = 0.

Figure 198 shows an example SDR single I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

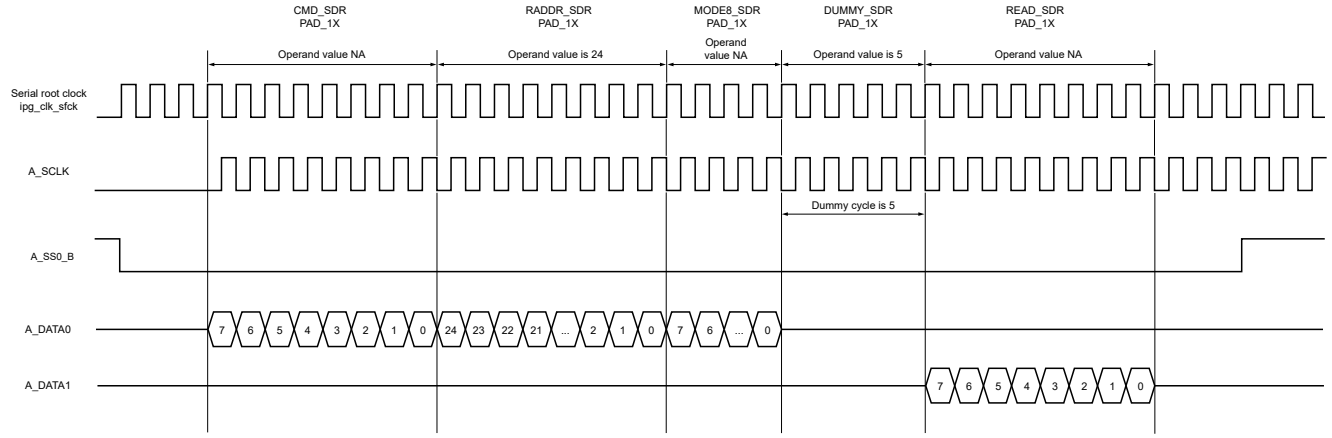

Figure 198. Flash memory access sequence example (SDR single I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 199 shows an example SDR quad I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

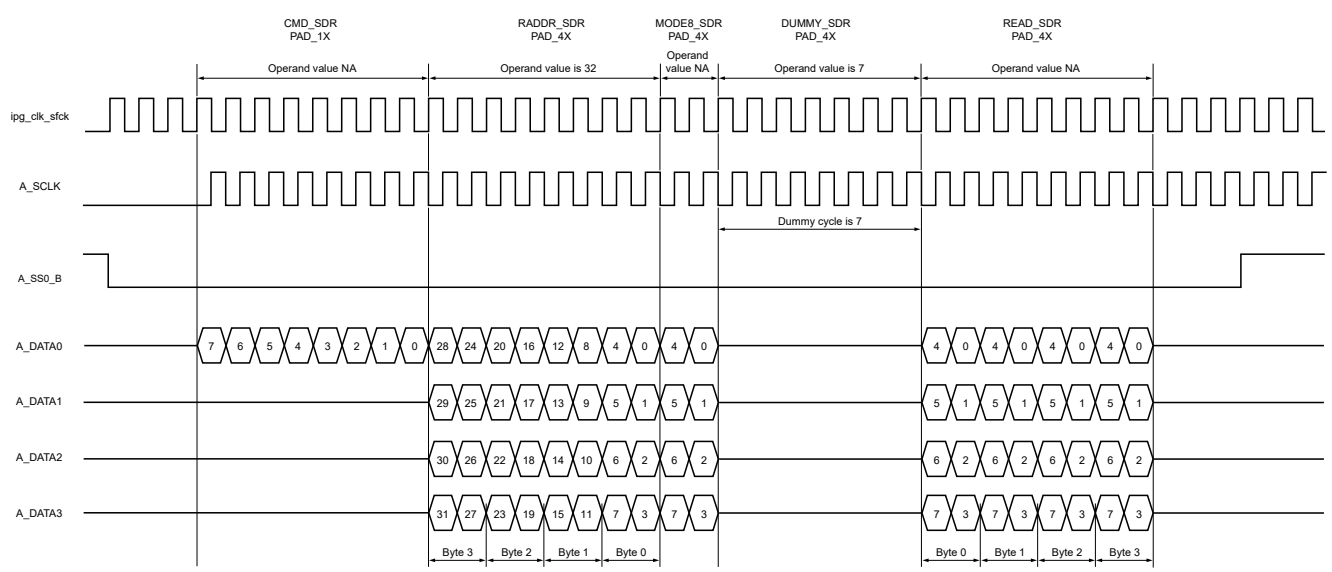

Figure 199. Flash memory access sequence example (SDR quad I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 200 shows an example DDR quad I/O read sequence (Cypress Serial Nor Flash S25FS512S) in parallel mode.

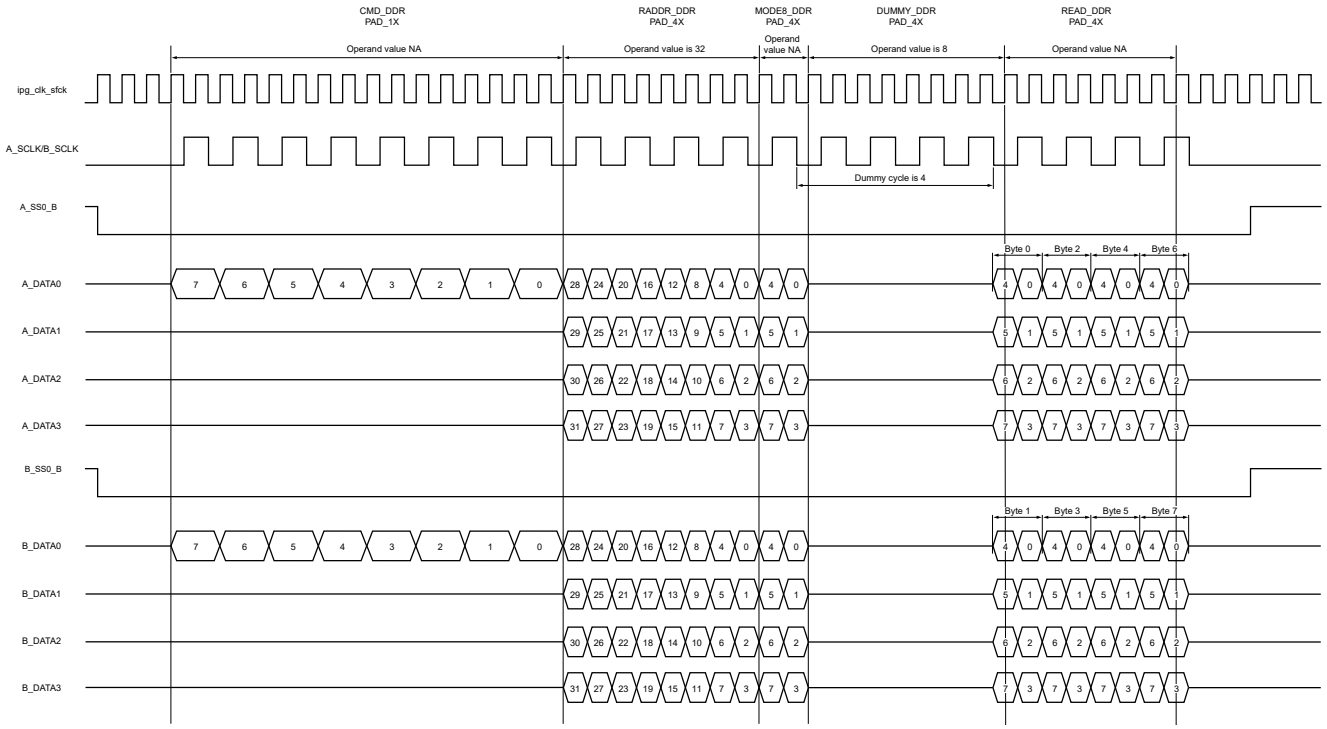

Figure 200. Flash memory access sequence example (DDR quad I/O read sequence)

Figure 201 shows an example HyperBus device read transaction (single latency count) in individual mode.

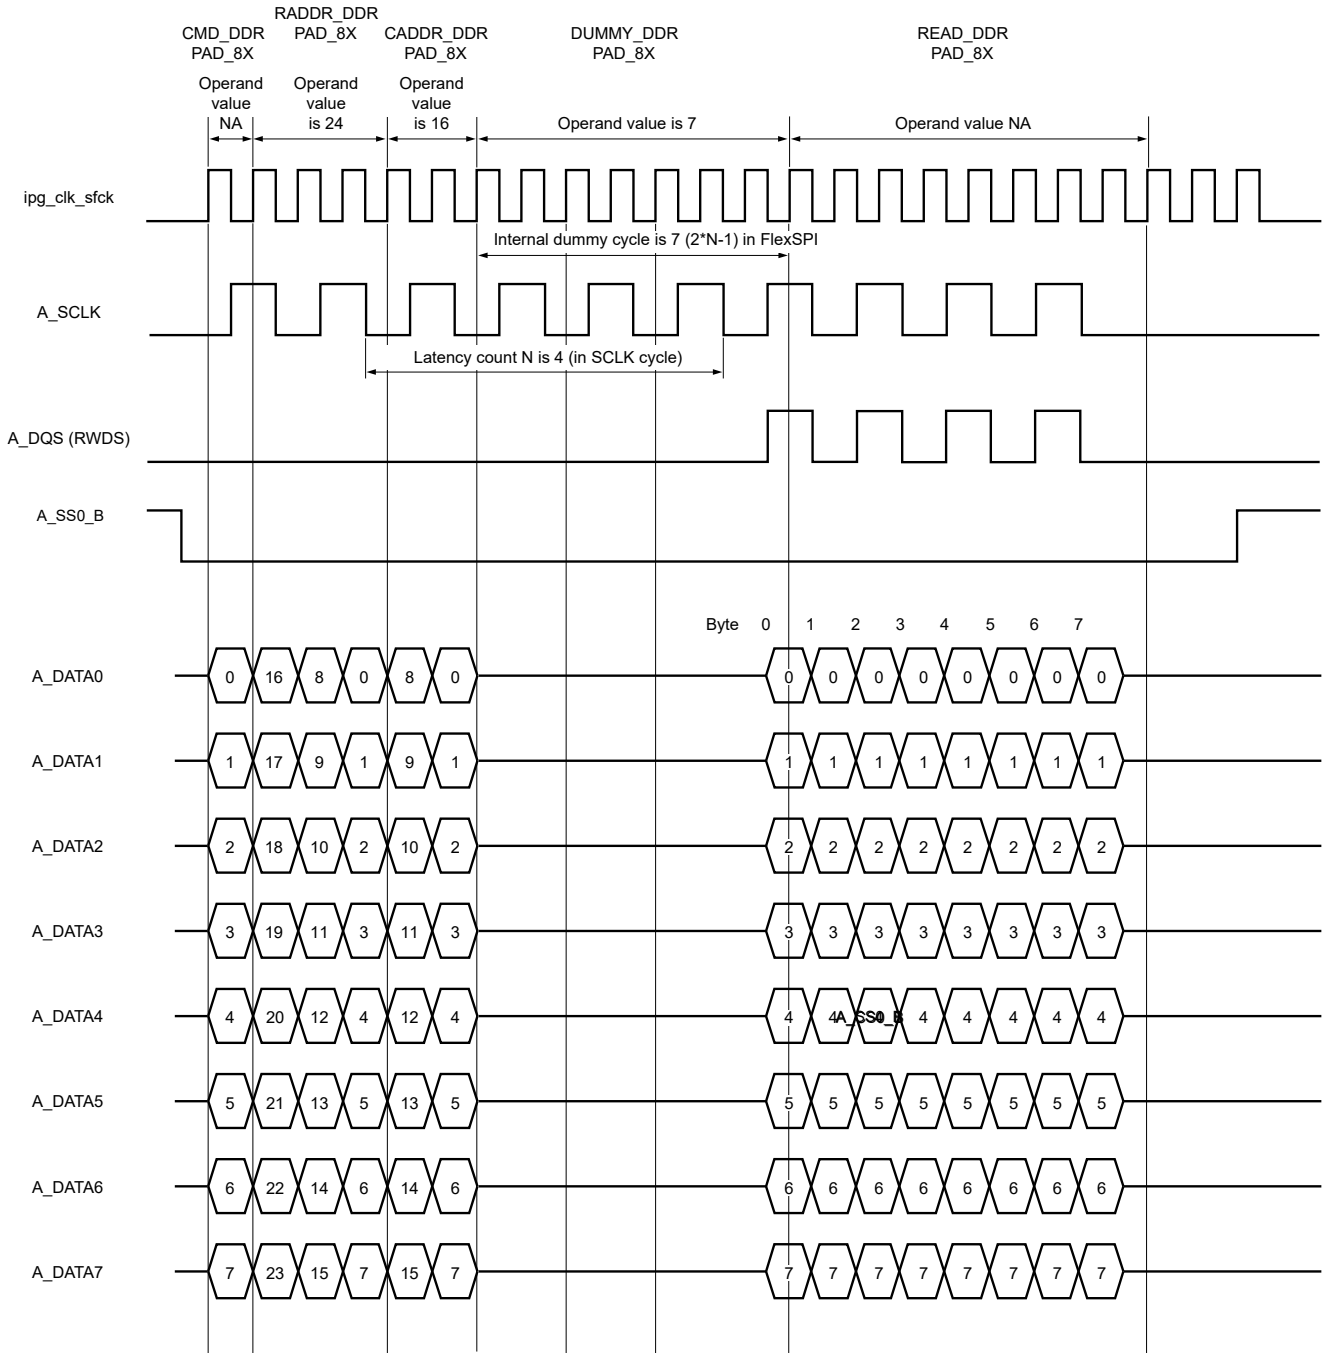

Figure 201. HyperBus device read transaction with single latency count

NOTE

FlexSPI continues to drive the clock until it has latched all of the read data it is expecting. On-chip delay for the data to reach FlexSPI can increase the number of SCK clock pulses.

Figure 202 shows an example HyperBus device read transaction (additional latency count) in individual mode.

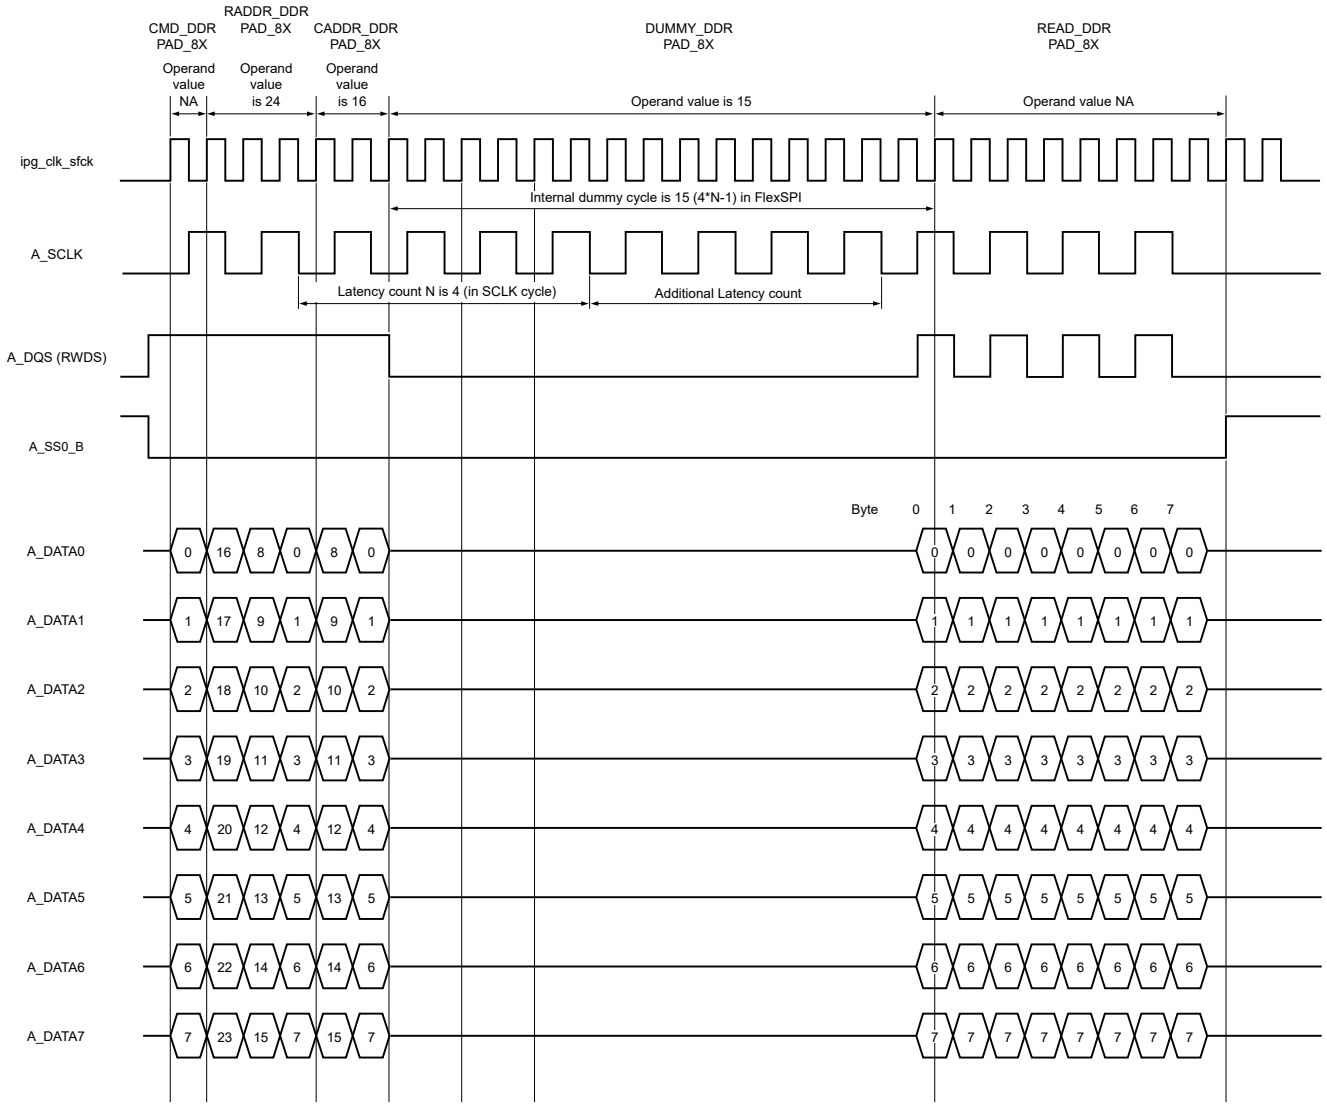

Figure 202. HyperBus device read transaction with additional latency count

Figure 203 shows an example HyperBus device write transaction (single latency count) in individual mode.

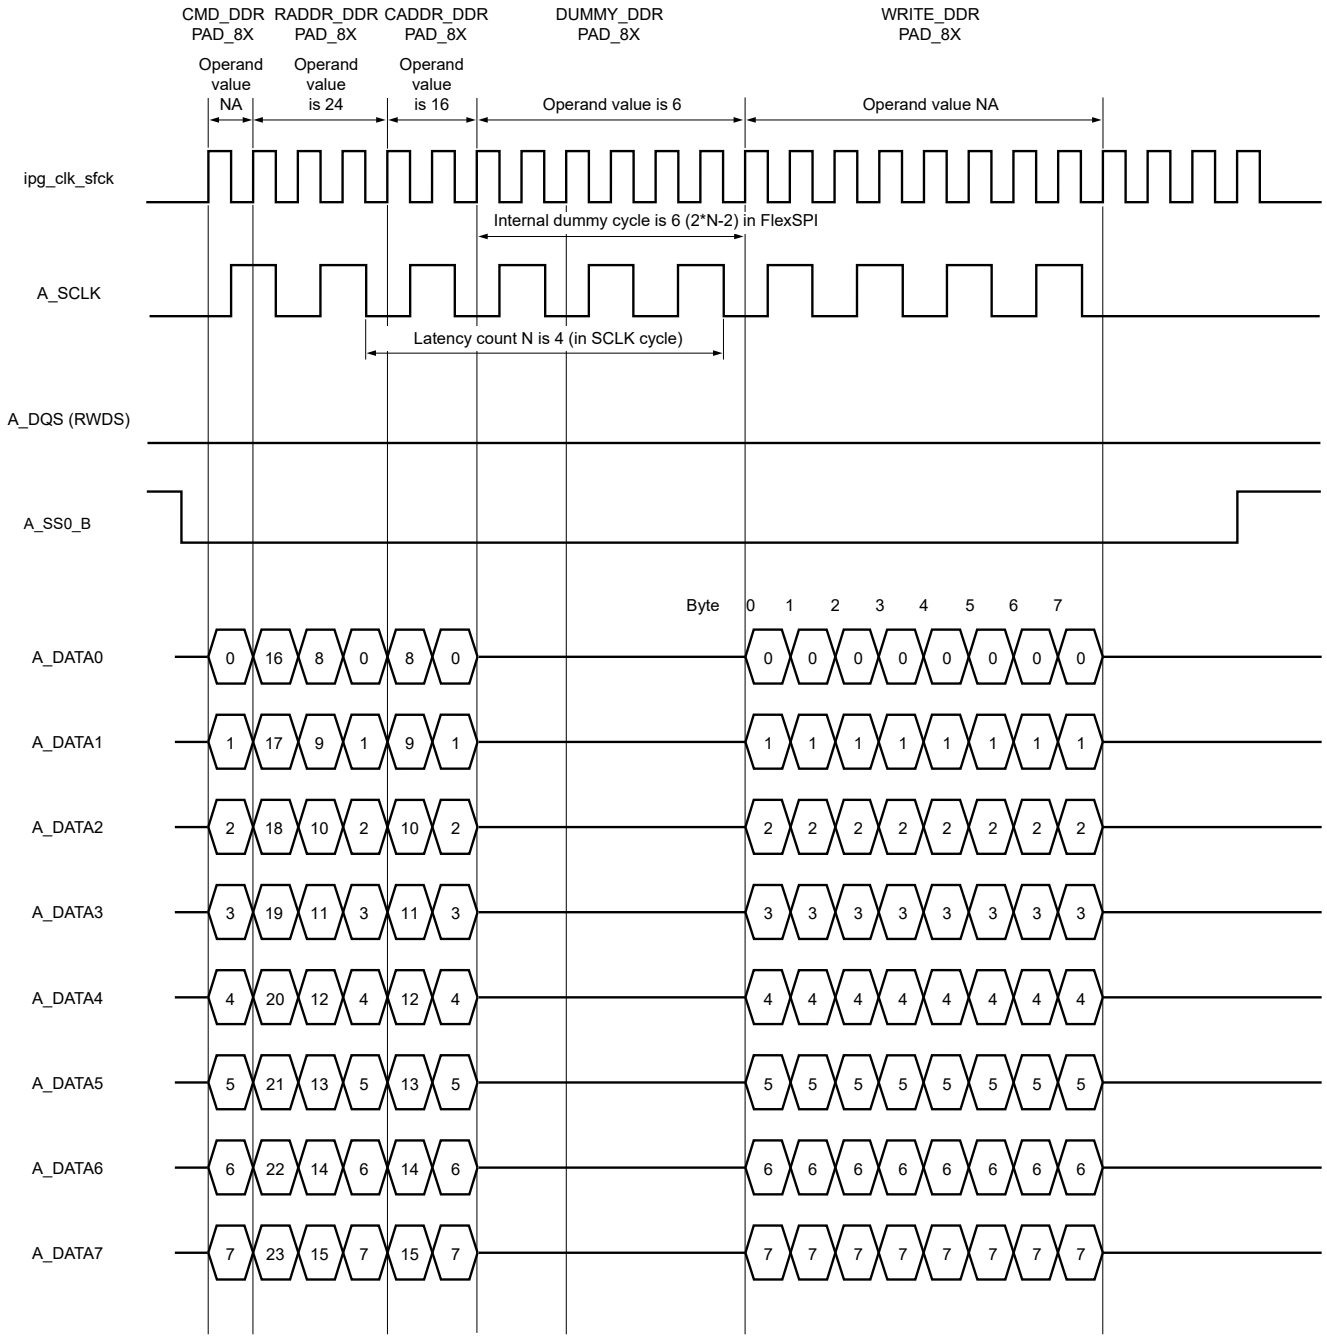

Figure 203. HyperBus device write transaction with single latency count

Figure 204 shows an example HyperBus device write transaction (additional latency count) in individual mode.

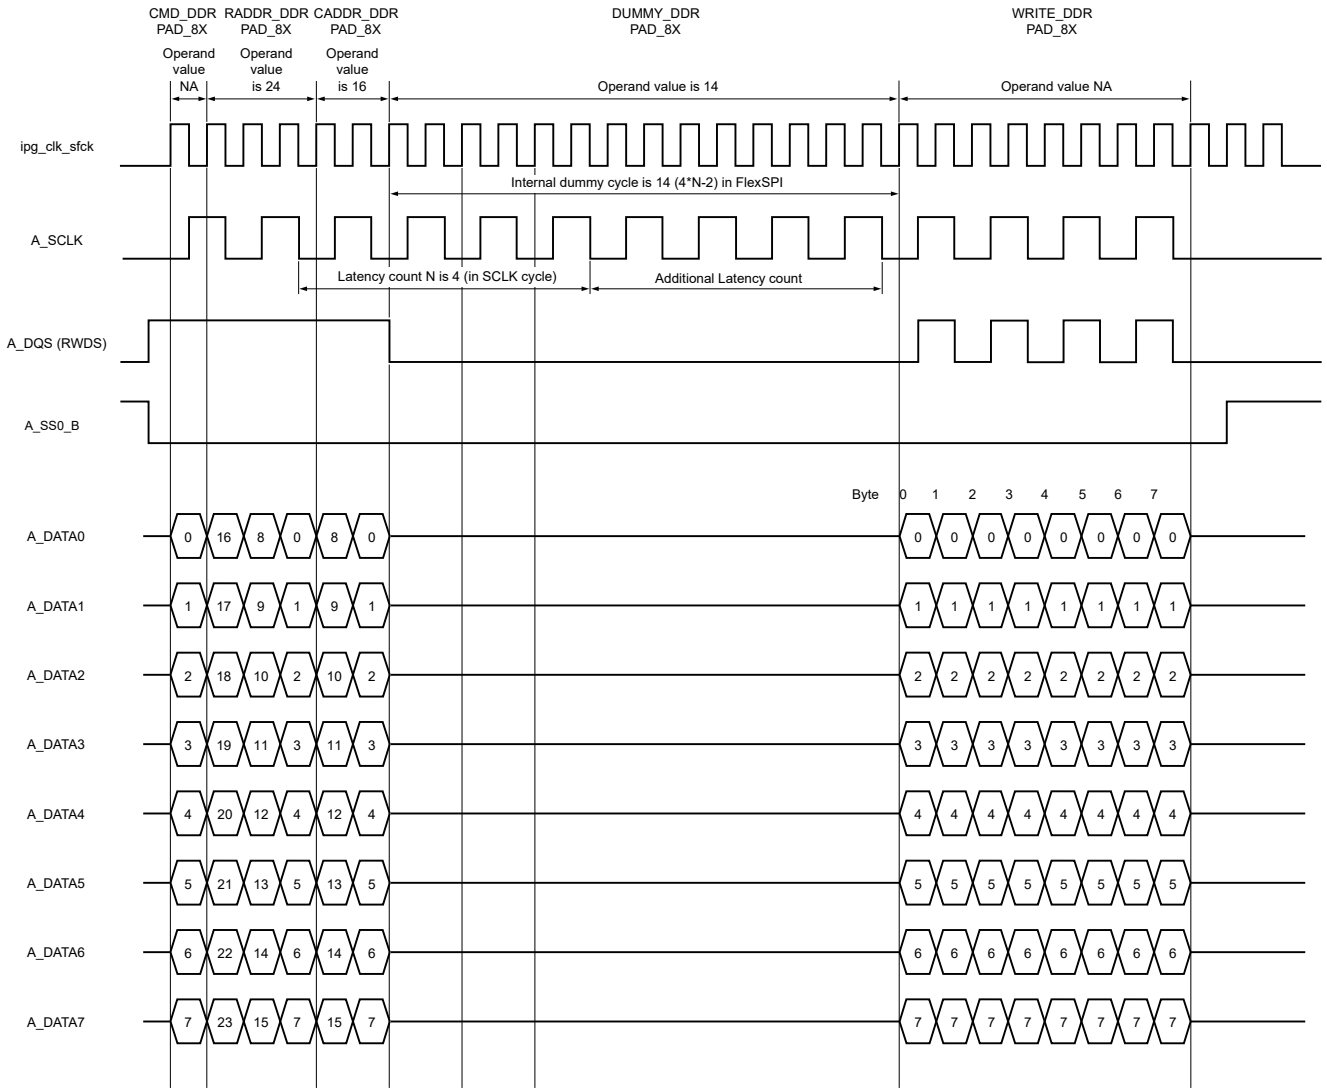

Figure 204. HyperBus device write transaction with additional latency count

31.3.7 Clocking

This section describes FlexSPI clocks and special clocking requirements.

Table 204. Clock usage

Clock name	Description	Comment
serial clock root (ipg_clk_sfck)	Root clock for Serial domain	FlexSPI core clock, used to generate the serial clock output. The clock is optionally divided using MCR0[SERCLKDIV] to obtain the SCLK.

Table continues on the next page...

Table 204. Clock usage (continued)

Clock name	Description	Comment
		Its frequency is same as SPI SCK frequency in SDR mode if MCR0[SERCLKDIV] = 0.
ahb clock (hclk)	AHB bus clock	hclk frequency is higher than 1/4 of serial root clock, so internal async FIFO is never full. This clock is used for internal logic in FlexSPI.
ipg clock (ipg_clk)	IPS bus clock	Register access clock. ipg_clk must be equal to hclk or an integer division of hclk. For example, ipg_clk = hclk/2.
SCLK	FlexSPI serial clock. Output clock on SCLK pin	Half clock frequency of serial clock root in DDR mode, and same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
DQS_OUT	Dummy Read Strobe output	Same frequency as SCLK. Clock output toggles during READ and LEARN instructions. The DQS ensures that the data can be strobed correctly. It is only used for data strobe, instead of command or address strobe. The data includes useful read data and data learning patterns.
DQS_IN	Sample clock for receive data	Same frequency as SCLK. Sample clock comes from looped-back dummy read strobe, looped-back SCLK, or flash-memory-provided read strobe.

31.3.8 Interrupts

Table 205 describes all interrupts that FlexSPI generates.

Table 205. Flash memory address, row address, and column address

Interrupt	Enable	Condition
IP command done	INTEN[IPCMDDONEEN]	An IP command is finished.
IP command grant error	INTEN[IPCMDGEEN]	An IP command grant timeout occurs (bus not granted after MCR0[IPGRANTWAIT] × 1024 AHB clock cycles). See Overview of error categories, flags, and triggered sources.
AHB command grant error	INTEN[AHBCMDGEEN]	An AHB command grant timeout occurs (bus not granted after MCR0[AHBGRANTWAIT] × 1024 AHB

Table continues on the next page...

Table 205. Flash memory address, row address, and column address (continued)

		clock cycles). See Overview of error categories, flags, and triggered sources.
IP command error	INTEN[IPCMDERREN]	A command check error or a command execution error for an IP command occurs. See Overview of error categories, flags, and triggered sources.
AHB command error	INTEN[AHBCMDERREN]	A command check error or a command execution error for AHB command occurs. See Overview of error categories, flags, and triggered sources.
IP_RX_FIFO watermark available	INTEN[IPRXWAEN]	The fill level of IP_RX_FIFO reaches the watermark level (IPRXFCR[RXWMRK]).
IP_TX_FIFO watermark empty	INTEN[IPTXWEEN]	The empty level of IP_TX_FIFO reaches the watermark level (IPTXFCR[TXWMRK]).
Sequence execution timeout	INTEN[SEQTIMEOUTEN]	A sequence execution time exceeds the timeout wait time (MCR1[SEQWAIT]). For example, the following flash memory read command sequence lasts about 800_0000h cycles (ipg_clk_sfck). If SEQWAIT is set to FFFFh, a sequence timeout interrupt is generated. • IP command triggers timeout. • Flash memory read data size is 100_0000h bytes. • Flash memory accesses in single mode and SDR mode.
AHB bus error	INTEN[AHBBUSERROREN]	AHB bus response timeout occurs, or AHB read access occurs while OTFAD is enabled and FlexSPI is still fetching the key blob. For example, AHB read sequence is not configured properly in LUT (such as without a READ instruction). No data is read from the external device. As a result, FlexSPI cannot reach the read data in AHB_RX_Buffers for the AHB read command.
Write command stops SCLK	INTEN[SCKSTOPBYWREN]	IP_TX_FIFO is empty while executing a write command sequence. FlexSPI stops SCLK output clock toggling and waits for write data filling.
Read command stops SCLK	INTEN[SCKSTOPBYRDEN]	IP_RX_FIFO is full while executing a read command sequence. FlexSPI stops SCLK output clock toggling

Table continues on the next page...

Table 205. Flash memory address, row address, and column address (continued)

		and waits to read the data from IP_RX_FIFO.
Key done	INTEN[KEYDONEEN]	OTFAD is enabled and key blob processing is enabled, key blob processing is done, and no error is detected.
Key error	INTEN[KEYERROREN]	OTFAD is enabled and key blob processing is enabled, and an error occurs during key blob processing. Once this interrupt is set, only reset can clear it.

31.3.9 On-The-Fly AES Decryption (OTFAD) support

After power-up, if OTFAD and key fetches are enabled in the system, FlexSPI automatically starts fetching the key blobs from location 0 of flash A1. The key fetches continue until OTFAD receives and processes all key blobs. During the fetch operation, any AHB access causes an error response, and INTR[AHBBUSERROR] is set. No IPS access is allowed during the fetching of key blobs. INTR[KEYDONE] or INTR[KEYERROR] represents the key blob processing result.

After OTFAD processes all key blobs, the OTFAD engine decrypts any reads from FlexSPI and returns them on the AHB bus. When OTFAD is enabled, FlexSPI always enables prefetch; only AHBCR[READSZALIGN] can disable the prefetch. The Read Resume function is also disabled. All read access addresses are eight-byte-aligned automatically, regardless the setting of AHBCR[READADDROPT]. If OTFAD is enabled, the prefetch never crosses the 1 KB boundary.

31.3.10 Flash memory access via IP command

Follow these steps to trigger a flash memory access via IP command.

1. If this command is a programing command, fill the IP transmit FIFO with programming data (for instance, programming flash data and flash memory status registers.)
2. Write the flash memory access start address to IPCR0[SFAR].
3. Write the read or program data size to IPCR1[IDATSZ]. Write the sequence index to IPCR1[ISEQID]. Write the sequence number to IPCR1[ISEQNUM].
4. Write 1 to IPCMD[TRG] to trigger a flash memory access command.
5. Wait for the INTR[IPCMDDONE] flag to set or for the IP command done interrupt to fire, indicating the command has completed on the FlexSPI interface.

NOTE

- The IP transmit FIFO can be filled before or after writing the IPCR0, IPCR1, and IPCMD registers. If the SFM command starts with the IP transmit FIFO empty, FlexSPI stops SCLK toggling to wait for transmit data ready automatically.
- The IPCMD register must be written after writing the IPCR0 and IPCR1 registers.
- One IP command can issue up to eight command sequences.
- You cannot issue another IP command before the previous IP command is finished. Performing this action results in unknown behavior.

If this command is a read command, all read data from flash memory is put into the IP receive FIFO. Software must read data from the IP receive FIFO via AHB bus or IP bus. When the IP receive FIFO is full and the flash device still contains data to read, FlexSPI stops SCLK toggling until the FIFO has free space. See SCLK stop.

A triggered serial flash command contains:

- A flash memory access start address. IPCR0[SFAR] determines this address.
- A flash chip select. The flash memory access address and flash memory size setting (FLSHxCR0[FLSHSZ]) determine the chip select.
- A flash command sequence index and sequence number. FlexSPI sequentially executes the sequences indexed from IPCR1[ISEQID] to (IPCR1[ISEQID] + IPCR1[ISEQNUM]) in LUT.
- Flash individual/parallel memory access mode:

  Determined by IPCR1[IPAREN].
- The flash memory read or program data size, in bytes.
  - If the value of IPCR1[IDATSZ] is nonzero, the data size is IPCR1[IDATSZ].
  - If the value of IPCR1[IDATSZ] is zero, the operand value in the read or write instruction determines the data size.

NOTE

- Software must ensure that the last sequence index never exceeds the LUT sequence number. That is, IPCR1[ISEQID] + IPCR1[ISEQNUM] must be less than 32.
- For sequence numbers greater than one, the data size is applied to every command sequence.
- If there is no write or read instruction in the command sequence, the data size is ignored.

The IP command request is sent to the arbitrator after software triggers it. It is not executed on the FlexSPI interface until the arbitrator grants it. See Command arbitration.

31.3.10.1 Reading data from IP receive FIFO

FlexSPI puts read data from the external device into the IP receive FIFO for IP commands.

The data stored in the IP receive FIFO can be read using IPS and register or system and AHB bus transactions:

- Via IP bus
- Via AHB bus

If MCR0[ARDFEN] = 1, only the AHB bus can read the read data in the IP receive FIFO. Read access to the IP receive FIFO using IP bus always returns with data zero, and no bus error occurs.

If MCR0[ARDFEN] = 0, only the IPS bus can read the read data in the IP receive FIFO. Read access to the IP receive FIFO using the AHB bus triggers a bus error.

FlexSPI pushes read data into the IP receive FIFO in sets of 64 bits each time it receives 64 bits of data from an external device. When the number of read data bits is not 64-bit-aligned, FlexSPI pushes additional zero bits into the IP receive FIFO for the last push.

The processor or DMA can read the IP receive FIFO.

31.3.10.1.1 Reading via processor

To read data from the IP receive FIFO via processor, configure the items below.

- Write 0 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPRXWAEN] to enable the IP receive FIFO watermark available interrupt (optional).

The processor must poll INTR[IPRXWA] or wait for the IP receive FIFO watermark available interrupt before reading data from the FIFO. Waiting ensures that a watermark level amount of data is filled in the IP receive FIFO before reading.

After reading a watermark level amount of data from the FIFO, software must set the INTR[IPRXWA] flag to pop that data from the FIFO.

Figure 205 shows the reading flow from the IP receive FIFO via processor.

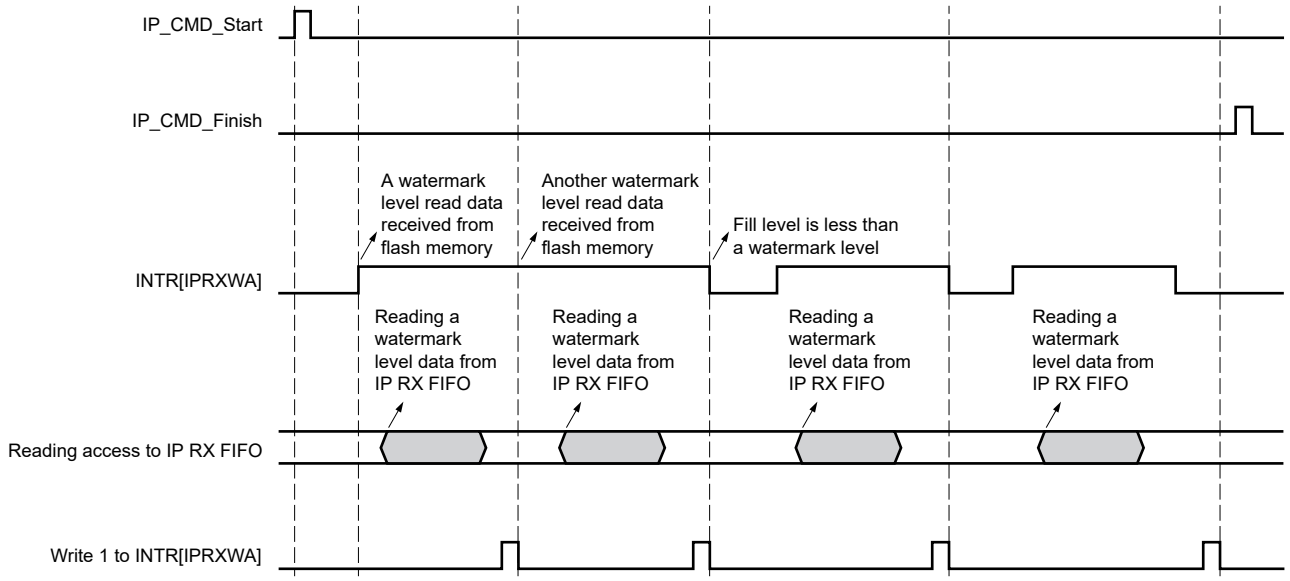

Figure 205. Reading IP receive FIFO via processor

NOTE

- The processor must read a watermark level of data from the IP receive FIFO before setting the INTR[IPRXWA] flag.
- The total flash read or program data size is not required to be a multiple of the watermark level. When the reading data size from the FIFO is less than a watermark level for the last time, software polls IPRXFSTS[FILL], not INTR[IPRXWA]. After all data from the FIFO are copied and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), software sets IPRXFCR[CLRIPRXF] to clear the FIFO. If the FIFO is not cleared, the reading data will be incorrect for the next reading command to flash memory.
- Setting the INTR[IPRXWA] flag pops the IP receive FIFO data. Each read access to the FIFO does not pop the data.

31.3.10.1.2 Reading via DMA

To read data from the IP receive FIFO via DMA, configure the items below.

- Write 1 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.
- Configure the DMA transfer minor loop size to match the watermark level.

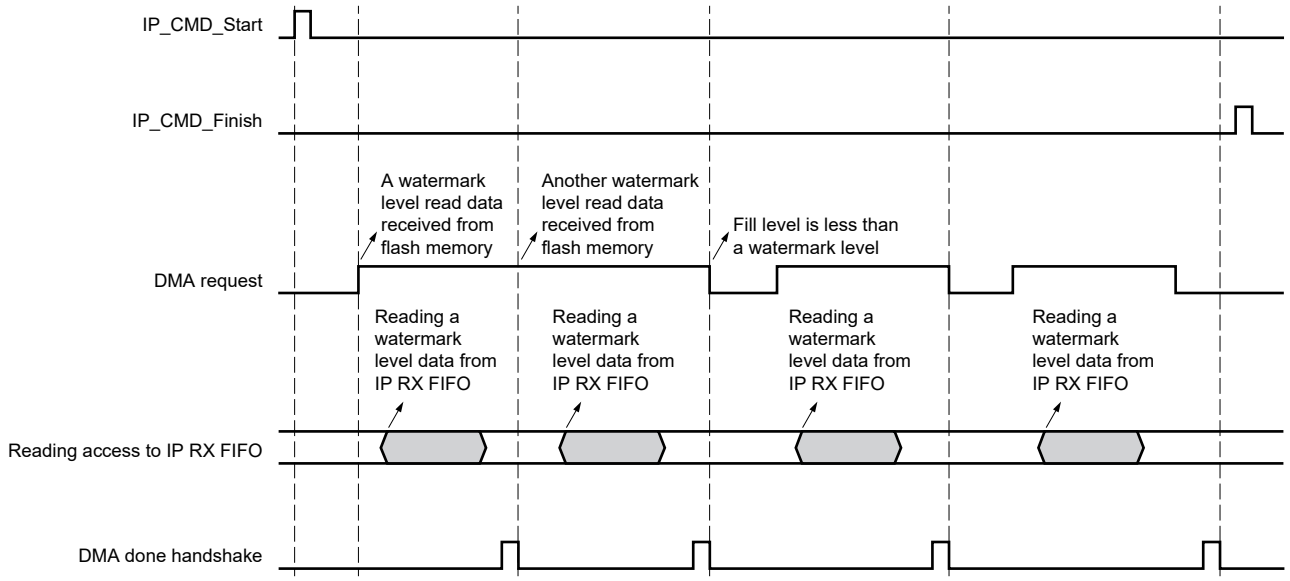

Figure 206. Reading from IP receive FIFO via DMA

NOTE

- When the fill level of the FIFO meets or exceeds the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA reads a watermark level amount of data from the IP receive FIFO each time. (Configure the minor loop size to match the watermark level).
- DMA must return a done handshake (pulse valid) to FlexSPI each time it finishes reading a watermark level amount of data.
- The DMA done handshake (not each read access) pops the IP receive FIFO data.
- The total read and write data size (major loop size) must be a multiple of the watermark level. The DMA does not know when the data is ready for the last reading. When the data size is not a multiple of the watermark level, it is too complex for the DMA driver to poll IPRXFSTS[FILL].

31.3.10.2 Writing data to IP transmit FIFO

The programming data is put into the IP transmit FIFO, then FlexSPI transmits it to the flash memory. IPS or AHB access can write it:

- Via IP bus
- Via AHB bus

To write the programming data into the IP transmit FIFO via AHB bus, write 1 to MCR0[ATDFEN]. The IP bus write access to the FIFO is ignored, but no bus error occurs.

To write the programming data into the IP transmit FIFO via IP bus, write 0 to MCR0[ATDFEN]. The AHB bus write access to the FIFO returns a bus error.

When FlexSPI fetches data to transmit, 64 bits of data from the IP transmit FIFO are popped. If the programming data size is not a multiple of 64 bits, the number of last popped valid bits is less than 64 bits. No error occurs; these invalid bits are not transmitted to the flash memory.

The processor or DMA can fill the IP transmit FIFO with programming data.

31.3.10.2.1 Writing via processor

To write data into the IP transmit FIFO via processor, configure the items below.

- Write 0 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPTXWEEN] to enable the IP transmit FIFO watermark available interrupt (optional).

The processor must poll INTR[IPTXWE] or wait for the IP transmit FIFO watermark empty interrupt before writing data to the FIFO. Waiting ensures that a watermark level amount of data is available in the IP transmit FIFO before writing.

After writing a watermark level amount of data to the FIFO, software must set the INTR[IPTXWE] flag to push that data into the FIFO. (The write pointer is incremented.)

NOTE

Setting the INTR[IPTXWE] flag pushes the IP transmit FIFO data. Each write access to the FIFO does not push the data.

Figure 207 shows the writing flow to the IP transmit FIFO via processor.

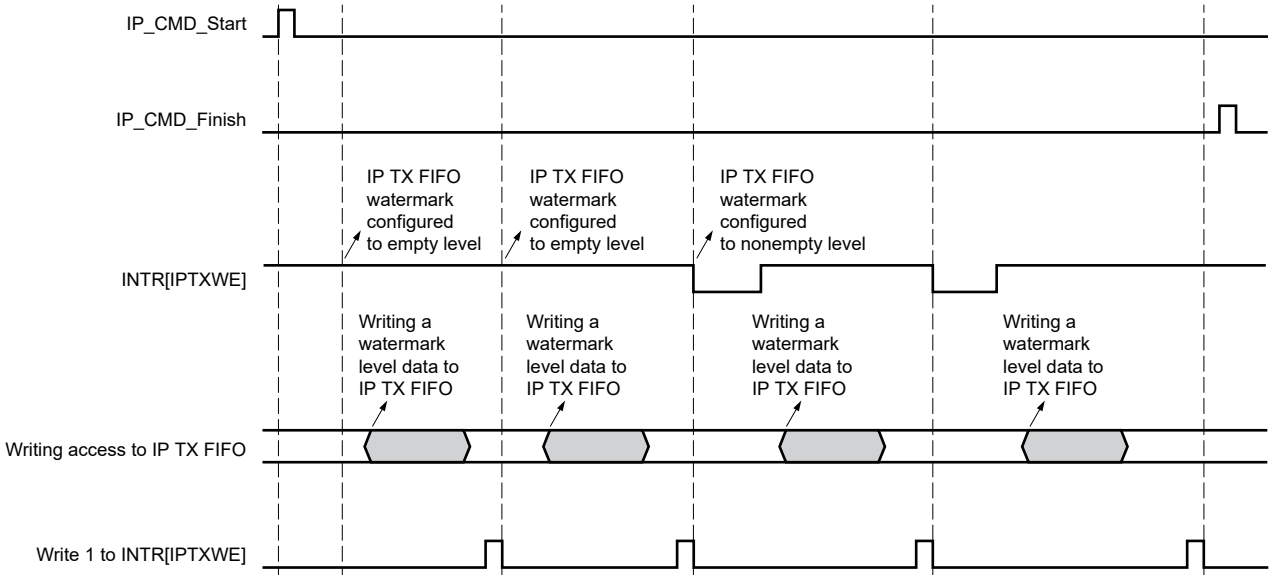

Figure 207. Writing to IP transmit FIFO via processor

NOTE

- The processor must write a watermark level amount of data into the IP transmit FIFO each time.
- The total flash write data size is not required to be a multiple of the watermark level. In this case, the writing data size to the FIFO is less than a watermark level for the last time. After all data to the FIFO are written and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), the processor sets IPTXFCR[CLRIPTXF] to clear the FIFO. If the FIFO is not cleared, the programming data will be incorrect for the next programming command to flash memory.

31.3.10.2.2 Writing via DMA

To write data into the IP transmit FIFO via DMA, configure the items below.

- Write 1 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.

- Configure the DMA transfer minor loop size to match the watermark level.

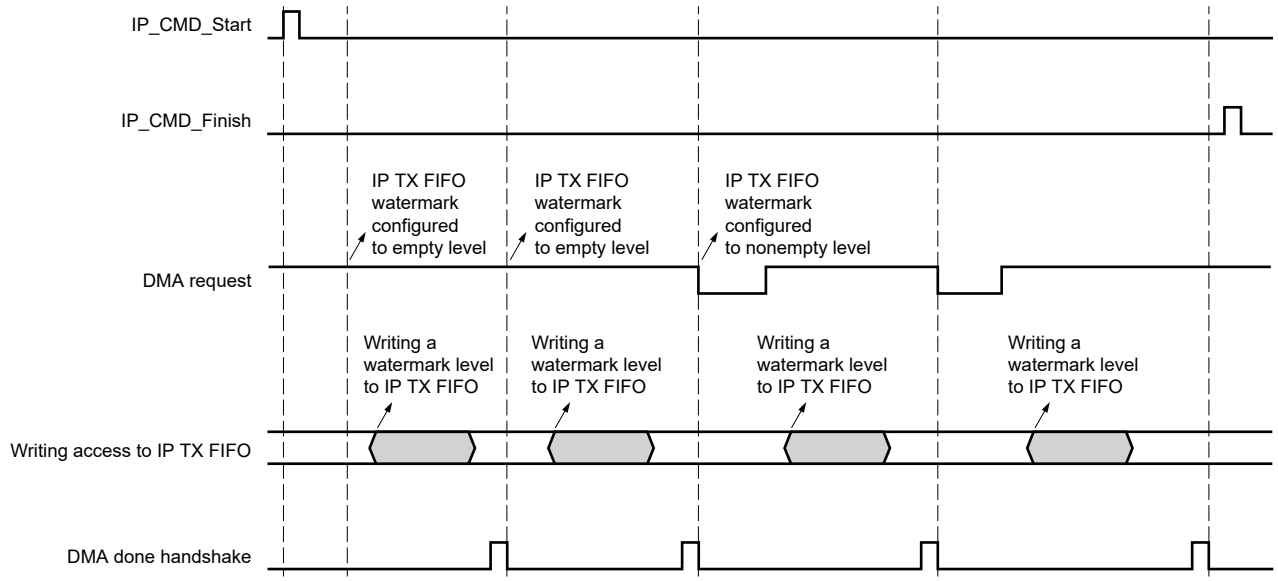

Figure 208. Writing into IP transfer FIFO via DMA

NOTE

- When there is empty space in the IP transmit FIFO greater than the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA writes a watermark level amount of data into the FIFO each time. (Configure the minor loop size to match the watermark level.
- DMA returns a done handshake (pulse valid) to FlexSPI each time it finishes writing a watermark level amount of data.
- The DMA done handshake (not each write access) pushes the IP transmit FIFO data.
- The total program data size (major loop size) is not required to be a multiple of the watermark level. After writing all data into the IP transmit FIFO and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), write 1 to IPTXFCR[CLRIPTXF] to clear the FIFO. Failure to clear the FIFO results in incorrect programming data for the next programming command to flash memory.

31.3.11 Flash memory access via AHB command

Flash memory can be accessed via AHB bus directly on the AHB address space. This address space is mapped to serial flash memory in FlexSPI. AHB bus accesses to this address space trigger flash memory access command sequences as needed.

For AHB read access to serial flash memory, FlexSPI fetches data from flash memory into the AHB receive buffer, then returns the data on the AHB bus. For AHB write access to serial flash memory, FlexSPI buffers AHB bus write data into the AHB transmit buffer, then transmits the data to serial flash memory.

No software configuration or polling is needed for AHB commands, except for FlexSPI initialization. As with a normal AHB target, the AHB controller accesses the external flash device transparently.

AHB commands are normally used to access serial flash memory space. IP commands must be used to access the control and status registers or other spaces, such as a one-time programmable (OTP) space in an external flash device.

The AHB commands for read and write access are discussed in detail below.

31.3.11.1 AHB write access to flash memory

For AHB write access to flash memory, FlexSPI buffers the write data from the AHB bus into the internal AHB transmit buffer. FlexSPI then transmits the data to flash memory. FlexSPI only buffers write data for one AHB burst. Figure 209 shows the hardware operation in response to an AHB write access to flash memory.

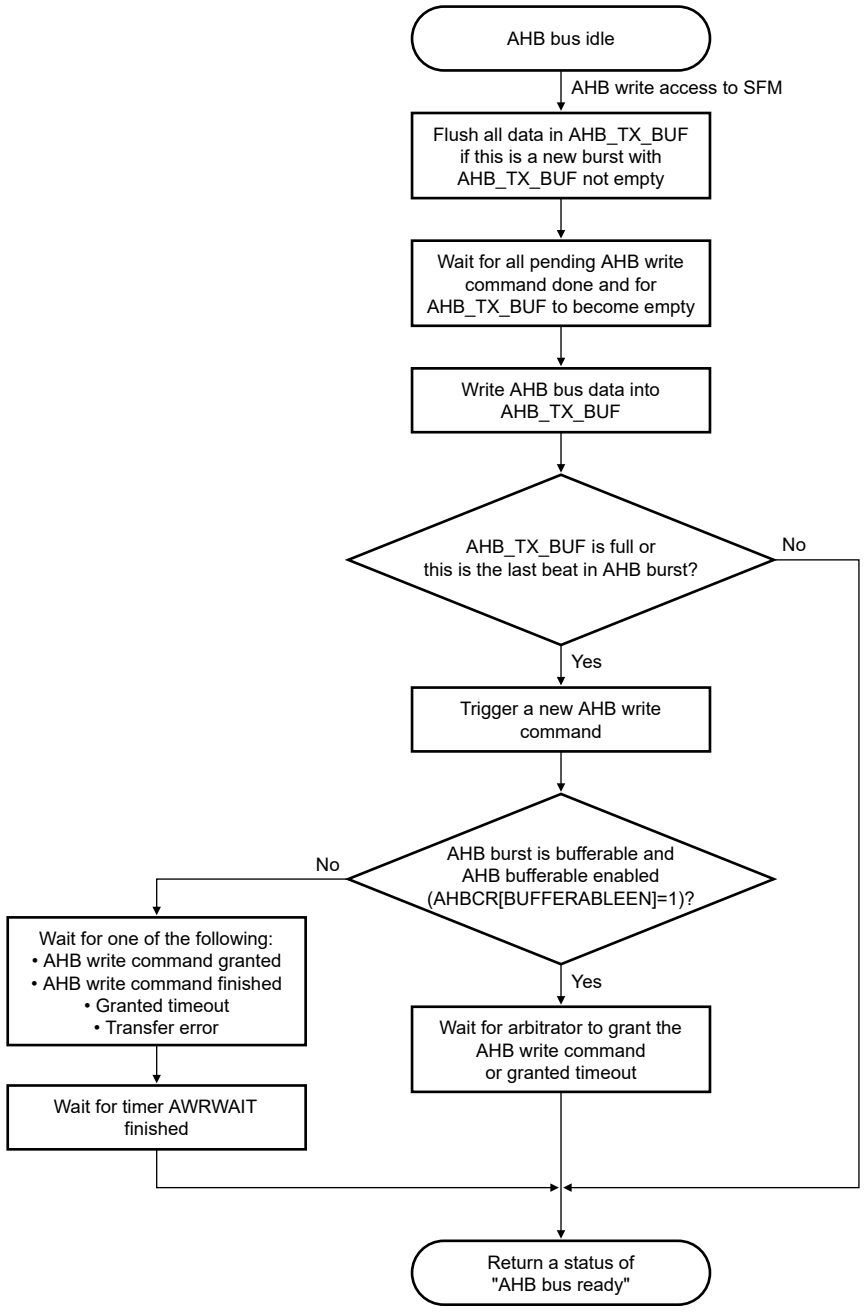

Figure 209. Hardware operation in response to AHB write access to flash memory

NOTE

1. If previous AHB burst is INCR write burst, AHB transmit buffer may not be empty when AHB bus is idle or new burst arrives. A new AHB write command is triggered to flush all data in AHB transmit buffer to external flash device. The new burst is held until this AHB write command finishes.
2. If the current access is bufferable, when the AHB write command is triggered, AHB ready is returned after the write command is granted. If the current access is non-bufferable, AHB ready is returned after the write command finishes.

FlexSPI triggers a new AHB write command in these cases:

- This beat is the last one in the current AHB burst, for any burst type except INCR.
- AHB transmit buffer is full after the current beat data is buffered.
- AHB bus becomes idle or a new burst arrives with the AHB transmit buffer not empty.

Table 206 describes the details of a triggered AHB write command.

Table 206. Triggered AHB write command

Item	Description
Flash memory access start address	Determined by AHB burst address. FlexSPI records the start address for the data in AHB transmit buffer, which is used as flash memory access start address.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip selection.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB write command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual/ Parallel)	Determined by AHBCR[APAREN].
Flash memory data size	Determined by byte number of buffered data in AHB transmit buffer.

The following examples indicate internal logic for AHB write access to flash memory, where AHB_TX_BUF is 64 bytes :

- AHB INCR 64-bit bufferable burst with address sequence 8h, 10h, 18h, 20h, ..., 50h (10 beats total).

  Two AHB write commands are triggered: the first command with flash memory start address 8h and data size 40h; the second command with flash memory start address 48h and data size 10h. See Figure 210.

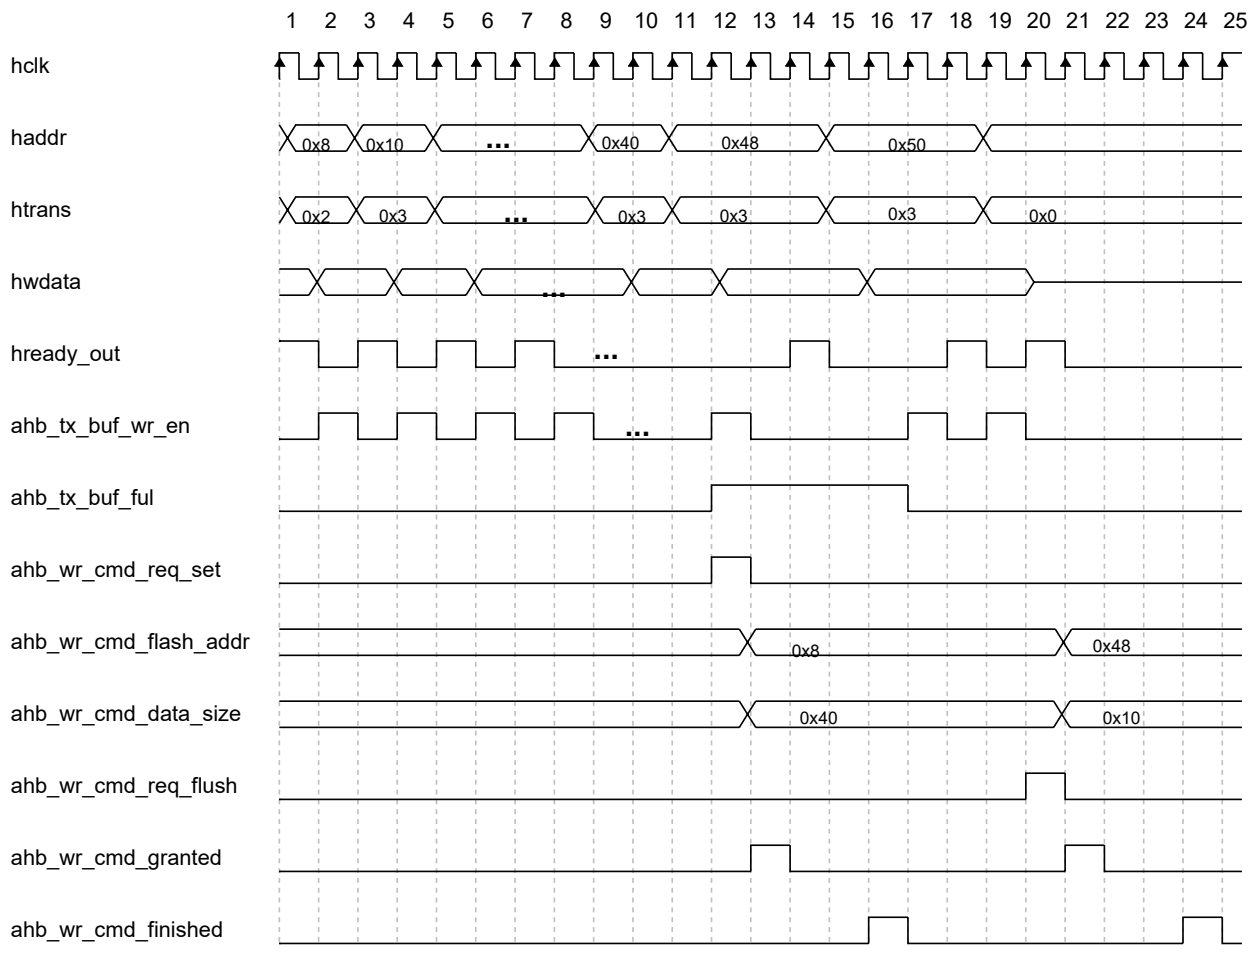

Figure 210. AHB write access (INCR, 64-bit, bufferable)

- AHB WRAP8 64-bit bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h. See Figure 211.

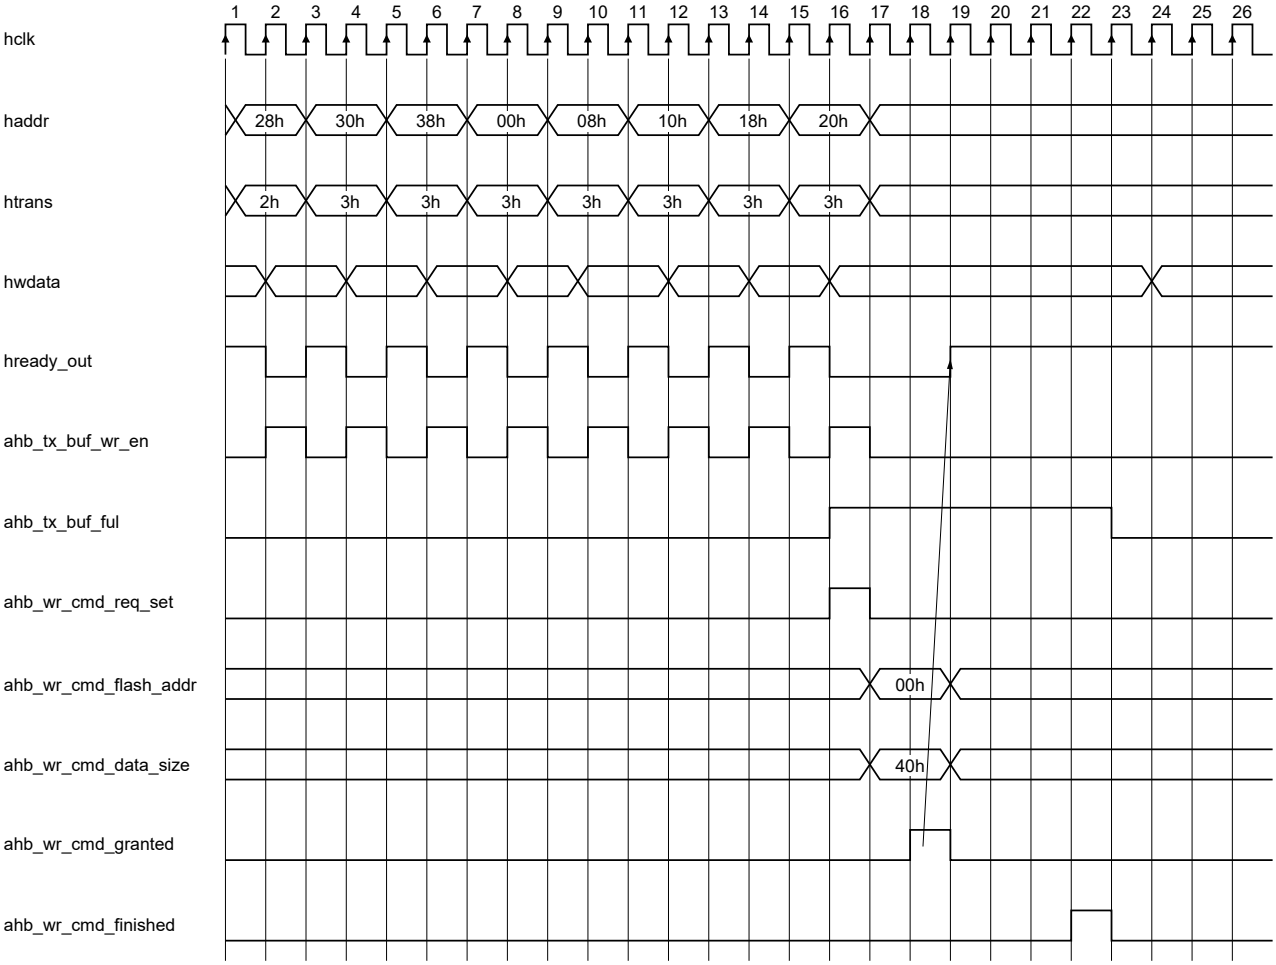

Figure 211. AHB write access (WRAP8, 64-bit, bufferable)

- AHB WRAP8 64-bit non-bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h.

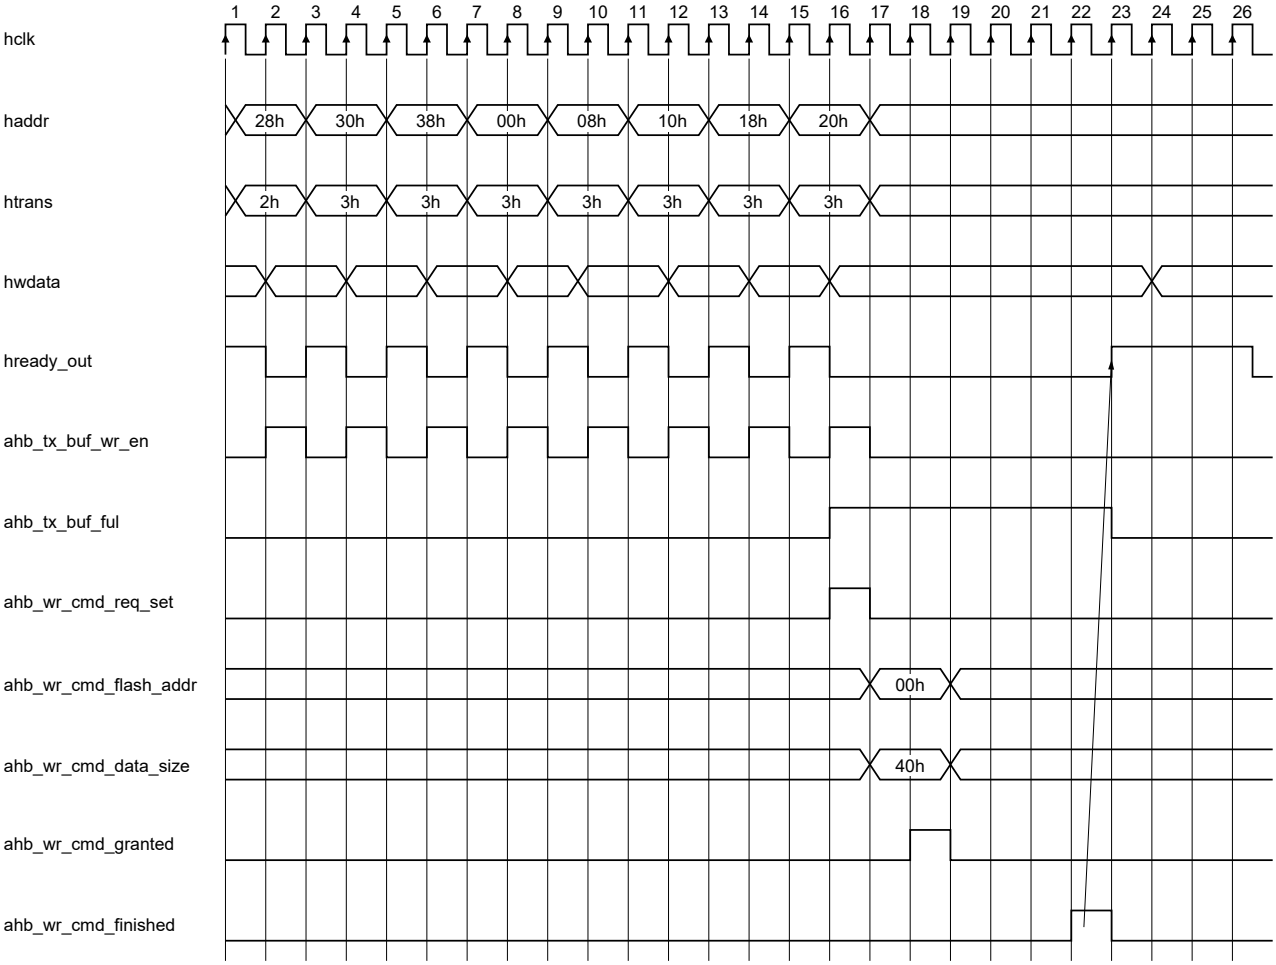

Figure 212. AHB write access (WRAP8, 64-bit, non-bufferable)

NOTE

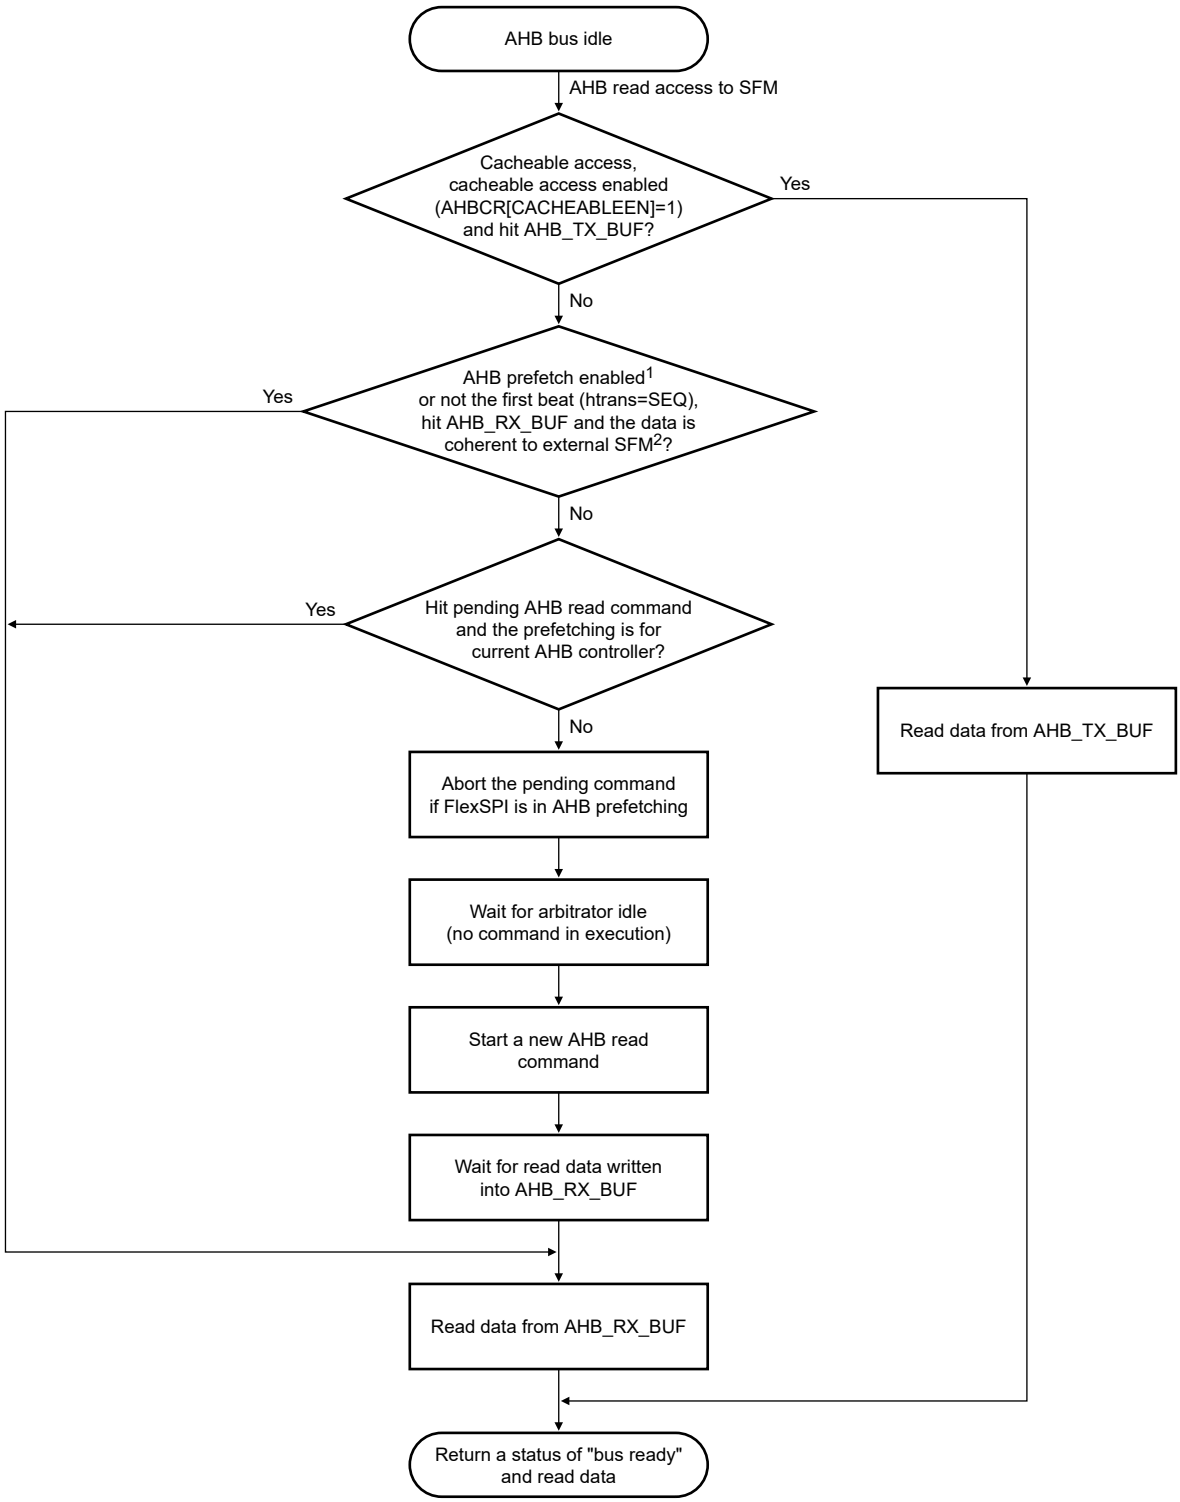
If the burst data size (in bytes) is greater than the AHB transmit buffer size, wrapper burst is not supported. For example, if AHB_TX_BUF is 64 bytes, AHB WRAP16 (16 × 64 bits = 128 bytes) write burst access is not supported.

31.3.11.2 AHB read access to flash memory

For AHB read access to flash memory, FlexSPI checks the burst access type and register setting to determine whether to access these locations:

- The AHB transmit buffer
- The AHB receive buffer
- A pending AHB read command

If all of these options are missed, FlexSPI triggers a new AHB read command to fetch data from flash memory. Figure 213 shows the hardware operation in response to AHB read access to flash memory.



Notes:
1) AHB prefetch is enabled when both AHBCR[PREFETCHEN]=1 and AHBRXBUFxCR0[PREFETCHEN]=1 (x is the AHB RX buffer ID for the current AHB controller) or OTFAD is enabled.
2) The AHB RX buffer holds the data read from flash memory. This data may become incoherent if AHB writes to the same flash-memory address.

Figure 213. Hardware operation in response to AHB read access to flash memory

Table 207 describes the details of a triggered AHB read command.

Table 207. Triggered AHB read command

Item	Description
Flash memory access start address and data size	Determined by AHB address, burst type, and burst size. FlexSPI fetches read data from the start address for the current burst or beat. See Table 208 for details.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip select.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB read command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual/ Parallel)	Determined by AHBCR[APAREN].

NOTE

- FlexSPI automatically determines which ARDSEQNUM and ARDSEQID fields that the flash device uses as sequence ID for chip selection. See MCR2[SAMEDEVICEEN].
- FlexSPI determines which AHB receive buffer to use for the current AHB read access by controller ID. For details about the AHB receive buffer ID and AHB controller ID mapping, see AHB receive buffer management.
- You cannot allocate the size of the AHB receive buffer to be less than the AHB Burst size. This allocation results in unknown behavior.

Table 208. AHB read command flash memory start address and data size

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [26:0]	Data size
0	Never cross flash boundary, because AHB burst never crosses 1 KB boundary.	SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(hburst_end_address-hbeat_start_address)
		INCR	hbeat_start_address	byte size of current beat For INCR burst with prefetch disabled, each beat is handled same as SINGLE burst.
		WRAP4, WRAP8, WRAP16	hburst_start_address	(hburst_end_address-hburst_start_address)
1	No	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	ahb_rx_buf_sz
	No	WRAP4, WRAP8, WRAP16	hburst_start_address	ahb_rx_buf_sz

Table continues on the next page...

Table 208. AHB read command flash memory start address and data size (continued)

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [26:0]	Data size
	Yes	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(flash_top_address-hbeat_start_address)
	Yes	WRAP4, WRAP8, WRAP16	hburst_start_address	(flash_top_address-hburst_start_address)

NOTE

- hbeat_start_address is HADDR input from the AHB controller for current beat.
- hburst_start_address (for example 00h) is the lowest address for current burst. hburst_end_address (for example 10h) is the highest address in current burst plus 1. For example, WRAP4 burst with HADDR 8h, Ch, 0h, 4h.
- ahb_rx_buf_sz is the buffer size in bytes of AHB receive buffer that the current AHB controller uses.
- flash_top_address is the top address of currently accessed flash memory.

31.3.11.3 AHB receive buffer management

There are 8 buffers (Buffer 0–7) in the AHB receive buffer. These buffers are transparent to AHB controllers. FlexSPI fetches flash memory data and returns it on the AHB bus automatically. No status register polling is needed for AHB read access to Serial Flash Memory (SFM).

See the chip-specific section for AHB buffer size.Use AHBRXBUF0CR0[BUFSZ]–AHBRXBUFCR7[BUFSZ] to configure the buffer size of each AHB receive buffer. The buffer size for Buffer 0 to Buffer 7 could be set to 0. If the buffer size is set to 0, FlexSPI ignores the related setting of AHBRXBUFxCR0[MSTRID]. Buffer 7 is used for all AHB controllers not assigned to Buffer 0–6. FlexSPI ignores the Buffer 7 size setting field (AHBRXBUF7CR0[BUFSZ]). Its buffer size is: (AHB receive buffer total size) - (the sum of the sizes of Buffer 0–6).

When an AHB read access to serial flash memory occurs, FlexSPI determines which buffer to use via this method:

1. If the controller ID equals AHBRXBUF0CR0[MSTRID] and AHBRXBUF0CR0[BUFSZ] is not zero, Buffer 0 is used.
2. If the controller ID equals AHBRXBUF1CR0[MSTRID] and AHBRXBUF1CR0[BUFSZ] is not zero, Buffer 1 is used.
3. If the controller ID equals AHBRXBUF2CR0[MSTRID] and AHBRXBUF2CR0[BUFSZ] is not zero, Buffer 2 is used.
4. If the controller ID equals AHBRXBUF3CR0[MSTRID] and AHBRXBUF3CR0[BUFSZ] is not zero, Buffer 3 is used.
5. If the controller ID equals AHBRXBUF4CR0[MSTRID] and AHBRXBUF4CR0[BUFSZ] is not zero, Buffer 4 is used.
6. If the controller ID equals AHBRXBUF5CR0[MSTRID] and AHBRXBUF5CR0[BUFSZ] is not zero, Buffer 5 is used.
7. If the controller ID equals AHBRXBUF6CR0[MSTRID] and AHBRXBUF6CR0[BUFSZ] is not zero, Buffer 6 is used.
8. If all the above cases are not met, Buffer 7 is used.

NOTE

- Software must ensure that the size of each buffer is not less than the maximum burst size of an AHB read access from the AHB controller using this buffer. Otherwise, the behavior is undefined. The minimum buffer size request depends on the chip implementation. For example, if the capability of the chip to send out a maximum burst is 64 bytes, the minimum AHB receive buffer is 64 bytes.
- Assigning multiple buffers to a single AHB controller is not supported, unless the prefetch buffer enhancement feature is being used.
- When AHB read prefetch is enabled (AHBCR[PREFETCHEN] = 1), the size of the buffer determines the prefetch data size. If it does not cross the flash boundary, FlexSPI fetches data from the external flash device with that buffer size.
- The priority setting of AHB controller (AHBRXBUFxCR0[PRIORITY] = 1) is used only for suspending control of AHB prefetching. See Command abort and suspend.

31.3.12 Command arbitration

There are four flash memory access command sources:

1. AHB command, that AHB write access to serial flash memory space triggers
2. AHB command, that AHB read access to serial flash memory space triggers
3. IP command, that writing IPCMD[TRG] triggers
4. Suspended command, an AHB read prefetch sequence which is suspended

An AHB bus access never triggers a write command and a read command at the same time.

The AHB prefetch sequence is an AHB command sequence triggered via AHB read access when AHB prefetch is enabled. After all read data is fetched for the current AHB read burst, FlexSPI prefetches more data to reduce read latency for the next AHB read access. An AHB command for a read operation is never aborted while fetching read data for the current AHB read burst. However, a new IP command or AHB command request while prefetching data (not for the current read burst) can abort an AHB read command.

When the arbitrator is idle (STS0[ARBIDLE] = 1), the granted priority of these command sources is:

1. AHB command (read or write)
2. IP command
3. Suspended command

NOTE

When the arbitrator is idle and there is no AHB or IP command request, a suspended command is not granted immediately. The arbitrator waits MCR2[RESUMEWAIT] AHB clock cycle idle states before resuming the suspended command to avoid AHB prefetch sequence being resumed and suspended frequently.

If the arbitrator is busy executing AHB or IP commands (not suspended commands), no new command requests are granted. If the grant times out, an AHB or IP command granted error occurs.

If a new AHB or IP command request comes while arbitrator is executing AHB read prefetch sequence, AHB read prefetch sequence is aborted (but not immediately). Arbitrator grants the AHB or IP command request after AHB read prefetch sequence is aborted on the FlexSPI interface and saved all internal data pointers.

31.3.12.1 Command abort and suspend

Table 209 describes the command abort and suspend mechanism.

Table 209. Command abort and suspend

Action	Description
Aborting a command	As mentioned above, if a new AHB or IP command request arrives, an AHB read prefetch sequence can be aborted.
Suspending a command	When an AHB read prefetch sequence is aborted on the FlexSPI interface, FlexSPI saves this suspended sequence in the cases listed below. FlexSPI resumes this sequence after the arbitrator has been idle for enough time. • There is no valid suspended command (AHBSPNDSTS[ACTIVE] = 0). This condition can occur when no command is suspended or when the suspended command is resumed. • The priority of aborted AHB read prefetch sequence is higher than the active suspend sequence. **NOTE** FlexSPI ignores and never resumes the original suspended sequence.
Activating a suspended command	The suspended command (internal status) becomes active when an AHB prefetch command is aborted and suspended. It becomes inactive in the following cases: • The arbitrator resumes the suspended command. • The AHB controller triggers a new AHB read command request using the same AHB receive buffer (buffer ID).

Figure 214 shows an example of the flow of command abort, suspend, or resume.

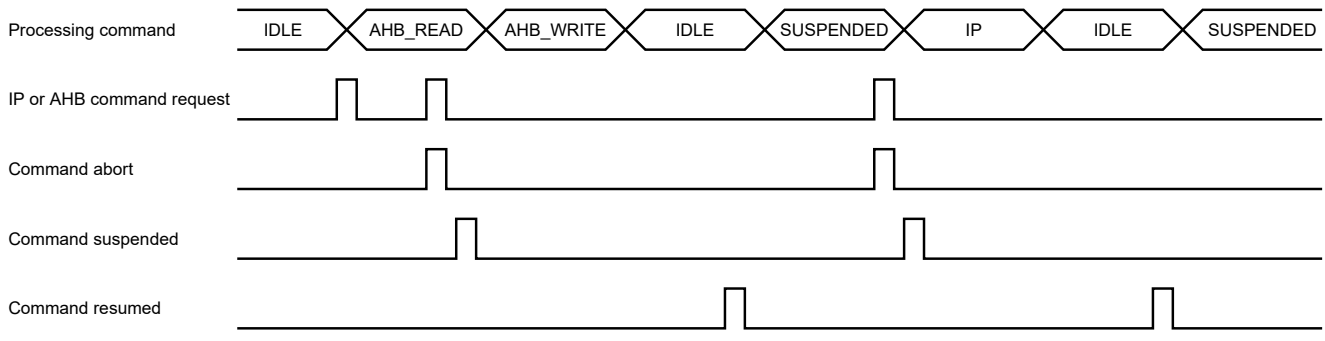


Figure 214. Command instruction execution on FlexSPI interface

NOTE

- The AHB prefetch sequence is aborted, suspended, or resumed twice in Figure 214. A new AHB write command request aborts the sequence the first time, and a new IP command request aborts the sequence the second time.
- The suspended sequence is resumed after a wait time of idle state. If there are frequent IP or AHB command requests and the wait time is not set reasonably, the suspend and resume activities may be triggered frequently.

31.3.13 SCLK stop

FlexSPI stops SCLK output toggling:

- When programming data is not ready for a programming command sequence.
- When an internal FIFO has no space to receive data for reading command sequence.

Certain devices may not support the stopping of SCLK during a command sequence (chip select is valid). SCLK stopping can be avoided via the methods described below.

- For flash memory reading that an IP command triggers:
  - Never trigger a read command with data size larger than IP receive FIFO size.
  - Internal asynchronous FIFO for flash memory reading should never be full.

    FlexSPI pops 64 bits of data per AHB clock cycle from this FIFO, and receives data from FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual or Parallel mode) determines the receiving speed. For example, in Octal mode and Parallel mode, FlexSPI receives 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never full.
- For flash memory programming that an IP command triggers:
  - Never trigger a program command with data size larger than the IP transmit FIFO size. Write all programming data into the IP transmit FIFO before triggering the IP command.
  - The internal asynchronous FIFO for flash memory programming must never be empty.

    FlexSPI fetches 64 bits of programming data per AHB clock cycle into this FIFO, and transmits data to the FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual or Parallel mode) determines the transmitting speed. For example, in Octal mode and Parallel mode, FlexSPI transmits 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never empty.
- For flash memory reading or programming that an AHB command triggers:
  - The internal asynchronous FIFO for flash memory reading and programming must never be full or empty. The frequency ratio limitation is same as it is for flash memory reading or flash memory programming that an IP command triggers.

NOTE

- FlexSPI never triggers an AHB read command with data size larger than the internal AHB receive buffer size.
- FlexSPI never triggers an AHB program command with data size larger than the internal AHB transmit buffer size.
- All programming data is buffered into the AHB transmit buffer before triggering an AHB program command in FlexSPI.

31.3.14 FlexSPI output timing

31.3.14.1 Output timing between data and SCLK

This section describes the output timing relationship of data (on A_DATA and B_DATA) and SCLK. There are three cases.

- **SDR instruction in SDR sequence**

  An SDR sequence contains only SDR instructions. In this case, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 215 shows the relationship between the serial root clock, data, and SCLK:

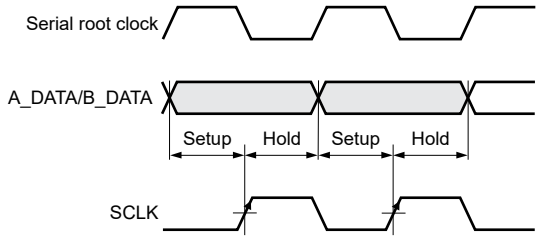

Figure 215. SDR instruction in SDR sequence

- **SDR instructions in a DDR sequence**

  A DDR sequence is a flash memory access command sequence that contains DDR instructions other than DUMMY_DDR. It may contain SDR instructions. If there are SDR instructions in a DDR sequence, all data bits last for two serial root clock cycles on the FlexSPI interface. Figure 216 shows the relationships between the serial root clock, data, and SCLK.

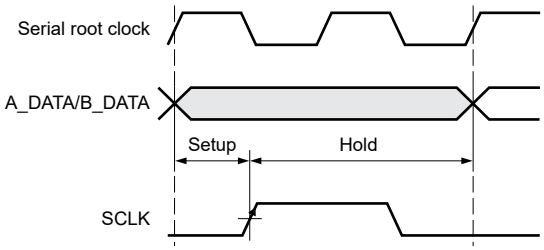

Figure 216. SDR instruction in DDR sequence

- **DDR instructions in a DDR sequence**

  For DDR instructions in a DDR sequence, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 217 shows the relationships between the serial root clock, data, and SCLK.

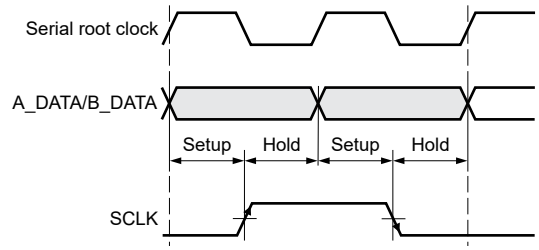

Figure 217. DDR instruction in DDR sequence

31.3.14.2 Output timing between chip select and SCLK

This section describes the output timing relationship between chip select (on A_SS0_B , A_SS1_B, B_SS0_B, and B_SS1_B) and SCLK. The timing relationship for the SDR sequence differs a little from the timing relationship for the DDR sequence.

- **Chip select timing in SDR sequence**

  For an SDR sequence, the delay from chip select assertion to the SCLK rising edge is (FLSHxCR1[TCSS] + 0.5) cycles of the serial root clock. The delay from SCLK falling edge to chip select deassertion is FLSHxCR1[TCSH] cycles of serial root clock. Figure 218 shows the timing relationship between the chip select and SCLK.

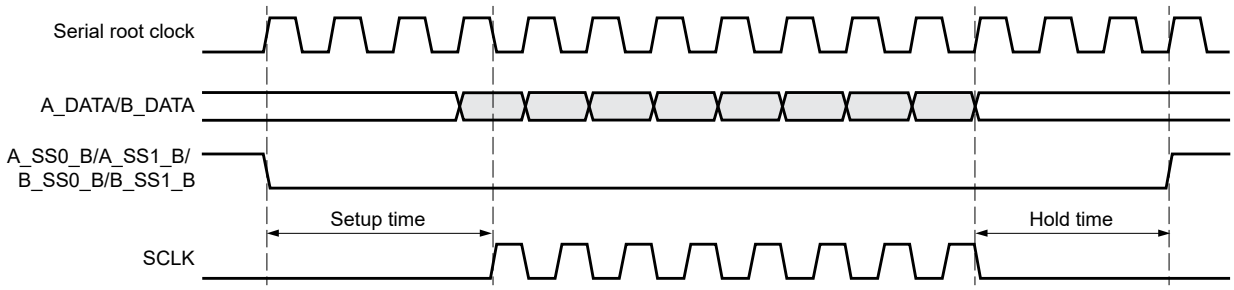

Figure 218. Chip select output timing for SDR sequence

- **Chip select timing in DDR sequence**

  For a DDR sequence, the delay from chip select assertion to the SCLK rising edge is **(FLSHxCR1[TCSS] + 0.5)** cycles of the serial root clock. The delay from the SCLK falling edge to chip select deassertion is **(FLSHxCR1[TCSH] + 0.5)** cycles of serial root clock.

  NOTE

  When AHB receive prefetch is enabled, and prefetch can be aborted, configure TCSH to 1 or greater. Configuring TCSH in this way guarantees a positive chip select hold time after the SCLK falling edge.

  Figure 219 shows the timing relationship between chip select and SCLK.

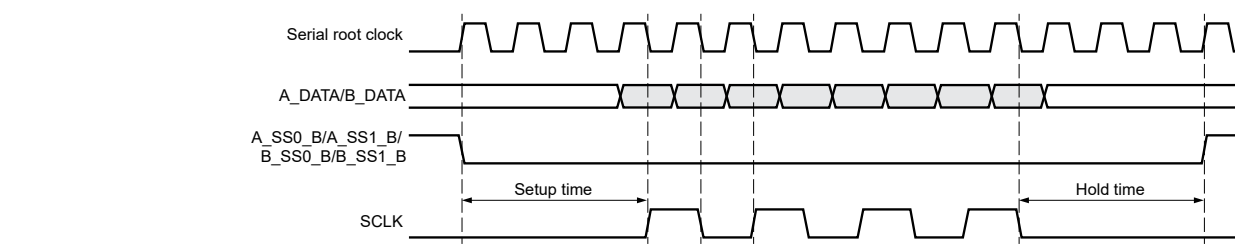

Figure 219. Chip select output timing for DDR sequence

For devices such as an FPGA device, a minimum chip select negation time (time between two chip select assertions) may be required. If the value of FLSHxCR1[CSINTERVAL] is nonzero, FlexSPI ensures a delay between chip select valid assertions. The delay time is CSINTERVAL × 256 cycles of serial root clock for an SDR or DDR sequence. If the external device has no limitation, configure the value of this field to zero. Figure 220 shows the timing of the chip select interval.

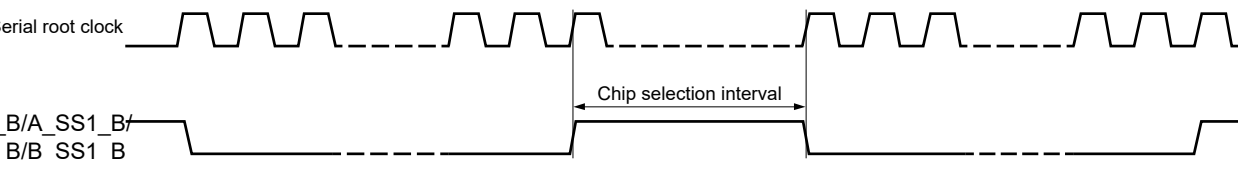

Figure 220. Chip select valid interval

31.3.15 FlexSPI input timing

This section describes the input timing of FlexSPI.

31.3.15.1 Receiving block

This section describes the receiving block in FlexSPI.

FlexSPI decodes instruction code to determine SDR mode or DDR mode. It also determines whether both the rising and falling edges are used for flash data sampling. FlexSPI samples the data line for learn instructions and read instructions.

MCR0[RXCLKSRC] selects the clock source from these four sources for the sampling clock:

- Internal dummy read strobe and looped back internally
- Internal dummy read strobe and looped back from DQS pad
- SCK output and looped back from SCK pad
- Flash-memory-provided read strobe

For details about DLL configuration, see DLL configuration for sampling.

Figure 221 shows the sampling block in FlexSPI.

FlexSPI uses both rising and falling edges to sample data from flash_A and flash_B. Two muxes with four clock source inputs generate the signals ipp_ind_io_fa, ipp_ind_io_fb. See Receive clock source features. ipp_ind_io_fa_int and ipp_ind_io_fb_int are reversed from ipp_ind_io_fa and ipp_ind_io_fb. Both sampling flip-flops are used when FlexSPI is in DDR mode. Only the falling edge sampling flip-flop is used in SDR mode.

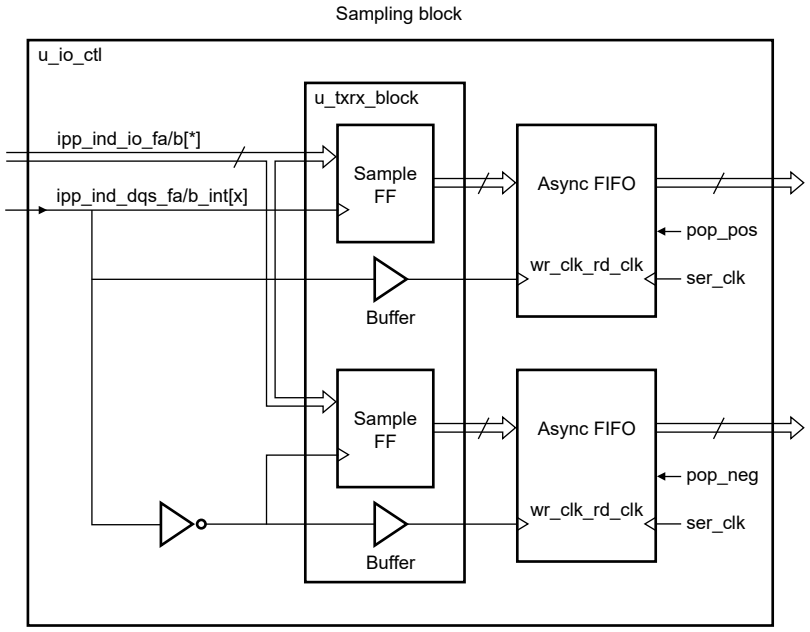

Figure 221. Sampling block in FlexSPI

There are 1 clock phases for sampling data. An internal delay chain delays the clock phases.

FlexSPI does not support read operations with a zero-turnaround cycle for direction switching on I/O pins. This read operation often occurs in QuadSPI configuration register reads. In Figure 222 and Figure 223, SIO[3:0] is an output from FlexSPI in the CMD phase, and is an input to FlexSPI in the DATA phase. No time remains for FlexSPI to switch the direction. This kind of read is not supported. FlexSPI and flash memory drive the I/O pins at the same time, which may cause a problem. To avoid this behavior on I/O pins, using SPI mode or reading with dummy cycles is required.

NOTE

The cycle numbers are not accurate in the examples below. See the device spec for accurate cycle numbers.

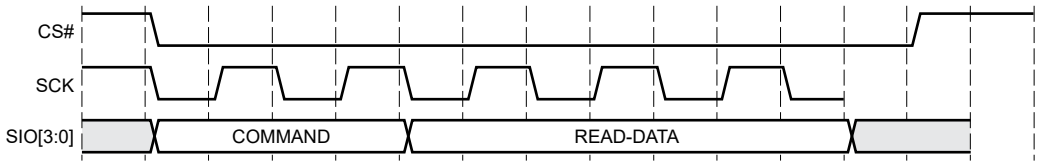

Figure 222. Unsupported read behavior

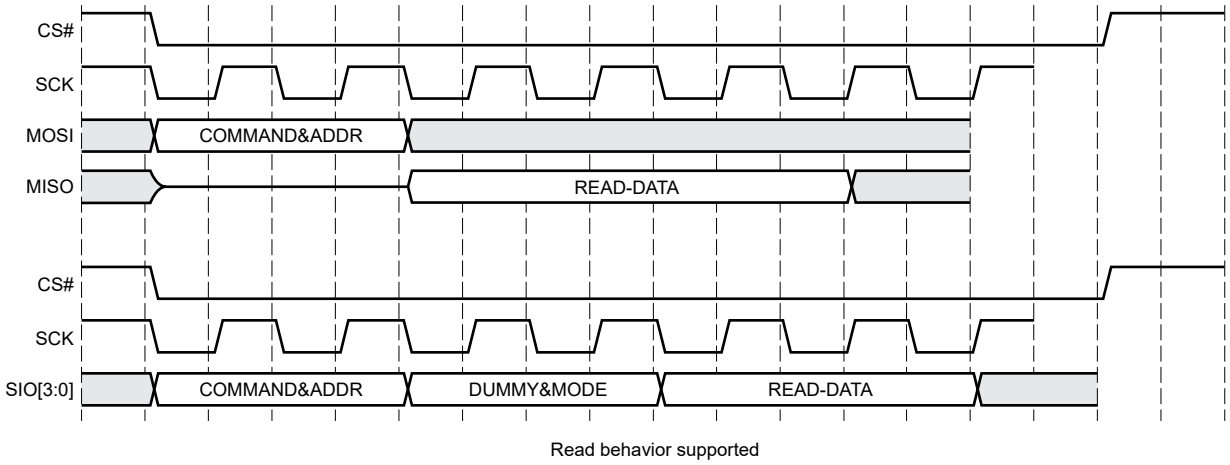

Figure 223. Supported read behavior

31.3.15.2 Receive clock source features

FlexSPI uses a read strobe to sample incoming data. There are several options for generating the read clock strobe that MCR0[RXCLKSRC] selects. Using the receive clock source method has implications for the board connections and can affect the maximum frequency that the interface supports. See the device data sheet for details on the maximum frequency supported for each RXCLKSRC option.

Table 210. RXCLKSRC options

MCR0[RXCLKSRC]	Description	Board connection	Max Frequency
0	Internal dummy read strobe and internal loopback	DQS pin is not used. The DQS pin can be configured for an alternate signal function.	Lowest
1	Internal dummy read strobe and loopback from DQS pad	FlexSPI uses the DQS pin, and it must be configured for its FlexSPI function. The internally generated read strobe is sent to the DQS pin and is sampled at the pin to match more closely the data pin timings. The DQS pin is typically left floating. External capacitance can be added to adjust timing.	Medium
3	Flash-memory-provided read strobe	DQS pin is connected to the DQS or RWDS signal that the memory provides.	Highest

31.3.15.3 Input timing for sampling with dummy read strobe

This section describes the input timing when sampling with the internal dummy read strobe (MCR0[RXCLKSRC] = 0 or 1). The timing for sampling with an internal dummy read strobe loopback is very similar to the timing for loopback from pad. Sampling with a dummy read strobe loopback from the DQS pad can achieve a higher read frequency. It compensates for the delay of the SCLK output path and data pin input path.

The input timing is different for SDR mode and DDR mode.

- **Input timing for sampling with dummy read strobe in SDR mode**

  For SDR read or learn instructions, FlexSPI samples input data pins with the falling edge of the dummy read strobe. Figure 224 shows the input timing for sampling with dummy read strobe in SDR mode.

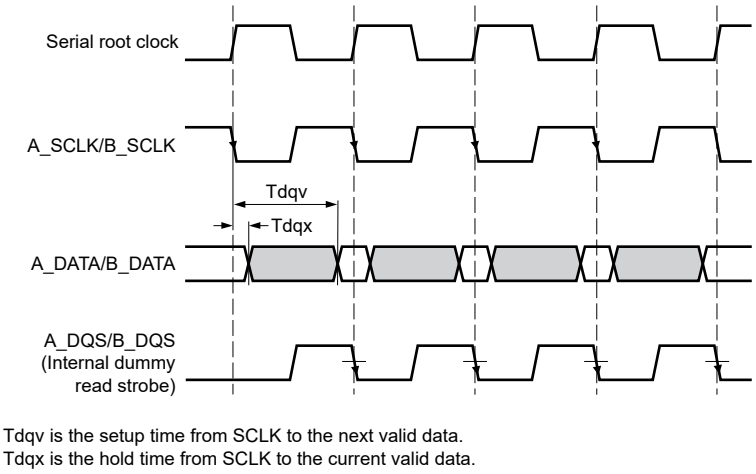

Figure 224. Input timing for sampling with dummy read strobe in SDR mode

- **Input timing for sampling with dummy read strobe in DDR mode**

  For DDR read or learn instructions, FlexSPI samples input data pins on rising and falling edges of the dummy read strobe. Figure 225 shows the input timing for sampling with dummy read strobe in DDR mode.

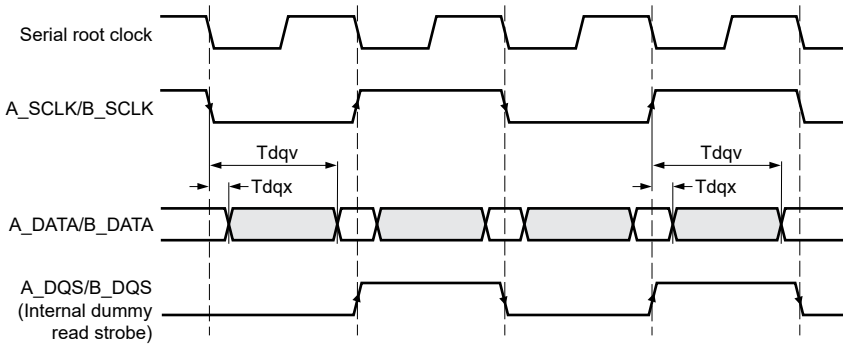

Figure 225. Input timing for sampling with dummy read strobe in DDR mode

31.3.15.4 Input timing for sampling with flash-memory-provided read strobe

This section describes the input timing when sampling with flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3). The input timing is different for SDR mode and DDR mode.

NOTE

There are no known devices that provide a read strobe and support SDR mode operation.

- **Flash-memory-provided read strobe with SCLK**

  Certain flash devices provide both read data and read strobes with SCLK. Then the read strobe edge is aligned with the read data change. The FlexSPI controller delays the read strobe for one half cycle of the serial root clock (with DLL), then samples read data with the delayed strobe. See DLL configuration for sampling. Figure 226 and Figure 227 show the input timing for sampling with flash memory read strobe in SDR mode and DDR mode.

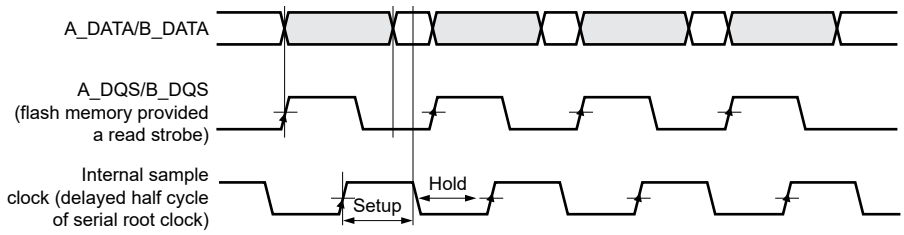

Figure 226. Input timing 2 for flash-memory-provided read strobe in SDR mode

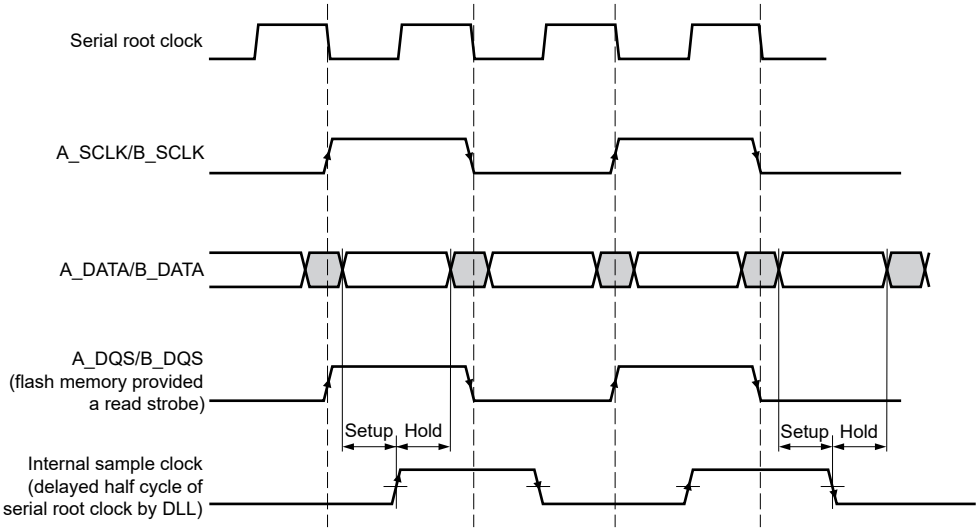

Figure 227. Input timing 2 for flash-memory-provided read strobe in DDR mode

31.3.15.5 DLL configuration for sampling

For the four sampling clock sources described previously, the input timing differs depending on the DLLxCR register configuration, according to the sampling clock source mode. The DLL is a delay-line chain that can be set to a fixed number of delay cells. It can also be auto-adjusted to lock on a certain phase delay to the reference clock.

- DLLxCR must be set to 0000_0100h (one fixed delay cell in DLL delay chain) in the following cases:
  - Sampling data with dummy read strobe looped back internally (MCR0[RXCLKSRC] = 0h)
  - Sampling data with dummy read strobe looped back from DQS pad (MCR0[RXCLKSRC] = 1h)
- When data is sampled with a flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3h) and flash memory provides the read strobe with SCLK, DLL must be configured as follows (when serial root clock is over 100 Mhz. These settings ensure a lock of the reference clock (serial root clock).
  - DLLxCR[SLVDLYTARGET] is up to flash parameters used.
  - DLLxCR[REFPHASEGAP] = 2h

- DLLxCR[DLLEN] = 1h
- DLLxCR[OVRDEN] = 0h
- Other fields in DLLxCR must be kept at their reset values (all zeroes).

After the register settings above are completed, set the DLL with following steps.

1. Reset the DLL(DLLxCR[DLLRESET] or MCR0[SWRESET]).
2. Wait for STS2[xREFLOCK] and STS2[xSLVLOCK] being asserted.
3. Wait for equal or more than 512 serial root clock cycles.
4. Start read or write operation.

NOTE

If the serial root clock is slower than 100 MHz, DLL cannot lock on a half cycle of serial root clock. The delay cell number is limited in the delay chain. DLL must be configured as follows instead:

- DLLxCR[OVRDEN] = 1
- DLLxCR[OVRDVAL] = N

  Each delay cell in DLL is about 75 ps to 225 ps. The delay of DLL delay chain is (N × Delay_cell_delay). N is set based on the maximum DDR frequency (N ≤ equation). This value is calculated based on the MAX_DDR_FREQ parameter. N = 21. This value is a recommended value. If a failure occurs, the value might require adjustment in a real application.

  You can calculate the delay of one delay cell and obtain the value of N. If the serial root clock is lower than 100 MHz, the delay chain can't lock with DLLxCR[SLVDLYTARGET] = 0xF (half cycle of root clock delay). You need to set DLLxCR[SLVDLYTARGET] as 0xE (15/32 cycle delay) or less. When DLL is locked (read STS2[AREFLOCK] and STS2[ASLVLOCK]), the delay cell number = STS2[ASLVSEL] +1 and the delay value (one delay cell) = (total delay)/(delay cell number). Based on delay value, the N can be easily calculated.
- Other fields in DLLxCR must be kept at their reset values (all zeroes).

31.3.16 Execute-In-Place (XIP) enhanced mode

FlexSPI always supports XIP, regardless of whether external devices provide XIP enhanced mode. To support XIP, put program codes on an external device, then read or execute these codes directly via AHB read access to serial flash memory space. There is no configuration or status polling needed during AHB read access to the memory of the external device. The AHB receive buffer is fully transparent to software.

Certain devices provide XIP enhanced mode to improve code execution. In this mode, the command code is only sent in the first read instruction. It saves many cycles for command instructions and improves code execution. Devices enter or exit XIP enhanced mode via a special sequence that external devices specify. See the external device data sheet for more details.

Normally, a device enters XIP enhanced mode via this sequence:

1. Enable XIP enhanced mode in external flash device via IP command.
2. Send the first read sequence to external flash device with correct mode bits. Command code is included in this read sequence.
3. Send the subsequent read sequences to external flash device with correct mode bits. Command code is not included in these read sequences. Mode bits must be sent according to the flash specified; otherwise, the flash exits XIP enhanced mode.

The instruction JMP_ON_CS in FlexSPI must be used to support XIP enhanced mode in external devices. This instruction is only allowed in the AHB read command; otherwise, the instruction generates an IPCMDERR or AHBCDMERR interrupt (when the interrupt is enabled). When external devices do not support XIP enhanced mode, JMP_ON_CS must never be used. To support XIP enhanced mode:

- The first instruction in the read sequence must be the command instruction.
- The last valid instruction must be JMP_ON_CS (with operand 1h).

For the first AHB read command triggered, FlexSPI executes the instructions from the instruction pointer 0 in the sequence (which is the command instruction). After this sequence is executed, FlexSPI saves the operand in the JMP_ON_CS instruction as the start pointer for the next command to current device internally. For the next AHB read command triggered, FlexSPI executes from the instruction pointer 1h, bypassing the command instruction.

After XIP enhanced mode is started, it is possible to access flash via other commands like program commands. You must, however, use a special sequence to exit enhanced XIP mode before you can run a different command. Figure 228 indicates XIP operation with Flash XIP enhanced mode.

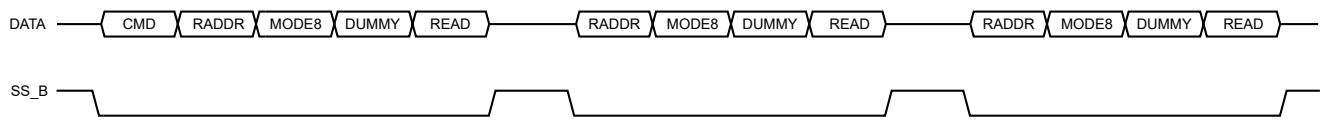

Figure 228. XIP Enhanced Mode Operation

31.4 External signals

This section provides the external signal information for the FlexSPI module.

Table 211. External Signal List

Signal name	Function	Direction	Description
A_SS0_B	Peripheral Chip Select Flash A1	O	Chip select for the serial flash device A1
A_SS1_B	Peripheral Chip Select Flash A2	O	Chip select for the serial flash device A2
B_SS0_B	Peripheral Chip Select Flash B1	O	Chip select for the serial flash device B1
B_SS1_B	Peripheral Chip Select Flash B2	O	Chip select for the serial flash device B2
A_SCLK	Serial Clock Flash A	O	Serial clock output to the serial flash device A. This clock runs at half the frequency of serial clock root in DDR mode, and at the same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
B_SCLK	Serial Clock Flash B	O	Serial clock output to the serial flash device B. This clock runs at half the frequency of serial clock root in DDR mode, and at the same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.

Table continues on the next page...

Table 211. External Signal List (continued)

Signal name	Function	Direction	Description
			NOTE B_SCLK may be used as the differential clock output of A_SCLK by writing 1 to MCR2[SCKBDIFFOPT].
A_DATAn	Serial I/O Flash A	I/O	Data I/O lines to and from the serial flash device A
B_DATAn	Serial I/O Flash B	I/O	Data I/O lines to and from the serial flash device B
A_DQS	Data Strobe Signal Flash A	I/O	Data strobe signal for port A. This signal has three functions: • Driven with read strobe by external device. Some flash devices provide the read strobe signal together with read data. In this case, if the external device drives this pad only when reading flash memory data, this pad may require a **pull-down** resistor. • Driven with latency information by external device. Some devices use this pin to indicate the dummy cycles needed (before program or read data transfer) such as HyperRAM or HyperFlash. • Loopback dummy read strobe. The FlexSPI controller provides internal dummy read strobe for flash memory read data. Higher read frequency can be achieved by looping back this dummy read strobe from the pad. This pin can be floated or have some capacitive load added at the board level to compensate for load on DATA or SCLK pins.
B_DQS	Data Strobe Signal Flash B	I/O	Similar to A_DQS

31.5 Initialization

The FlexSPI controller initialization sequence is:

1. Enable controller clocks (AHB clock, IP bus clock, or serial root clock) at system level.
2. To enter module stop mode, write 1 to MCR0[MDIS].
3. Configure module control registers: MCR0, MCR1, and MCR2. Do not change MCR0[MDIS].
4. When AHB commands are used, configure AHB Bus Control (AHBCR) and AHB Receive Buffer Control (AHBRXBUFxCR0) registers.
5. Configure flash control registers (FLSHxCR0, FLSHxCR1, or FLSHxCR2) according to external device type.
6. Configure DLL control register (DLLxCR) according to sample clock source selection.

7. To exit module stop mode, write 0 to MCR0[MDIS].
8. Configure LUT as needed for AHB command or IP command.
9. Optionally, to reset controller, write 1 to MCR0[SWRESET].

External devices must be configured via IP command normally after initialization. For example, the WRITE STATUS command performs device configuration for most serial NOR flash memory.

31.6 Application information

This section describes applications that FlexSPI supports.

31.6.1 Application on serial NOR flash device

This section provides the example LUT instruction sequences for serial NOR flash device (Cypress Flash S25FS128S).

31.6.1.1 Write enable command

Table 212 shows the WRITE ENABLE command sequence.

Table 212. WRITE ENABLE command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h	06h	Command name: WREN
1-7	STOP (00h)	0h	00h	

31.6.1.2 Write registers command

Table 213 shows the Write Registers command sequence.

Table 213. Write Registers command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	01h	Command name: WRR
1	WRITE_SDR	0h (Single)	1h or 2h	Data size is 1 byte or 2 bytes. Byte 0 is write data for Status Register 1; Byte 1 is write data for Configuration Register 1. IPCR1[IDATSZ] can override this value.
2-7	STOP (00h)	0h	00h	

31.6.1.3 Page Program command

Table 214 shows Page Program command sequence.

Table 214. PAGE PROGRAM command (Cypress serial NOR flash)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	02h or 12h	Command name: PP or 4PP

Table continues on the next page...

Table 214. PAGE PROGRAM command (Cypress serial NOR flash) (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
				PP is 3-byte address mode. 4PP is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	WRITE_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default programming data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

Table 215 shows Page Program command sequence (QPI mode).

Table 215. PAGE PROGRAM (QPI mode) command (Cypress serial NOR flash)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	2h (Quad)	02h or 12h	Command name: PP or 4PP PP is 3-byte address mode. 4PP is 4-byte address mode.
1	ADDR_SDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	WRITE_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default programming data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

31.6.1.4 Read Status 1 command

Table 216 shows READ STATUS 1 command sequence.

Table 216. READ STATUS 1 command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	05h	Command name: RDSR1
1	READ_SDR	0h (Single)	1h	1 byte for Status register 1
2-7	STOP (00h)	0h	00h	

31.6.1.5 Read command

Table 217 shows READ command sequence.

Table 217. READ command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	03h or 13h	Command name: READ or 4READ READ is 3-byte address mode. 4READ is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	READ_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

31.6.1.6 Fast Read command

Table 218 shows Fast Read command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h.

Table 218. FAST_READ command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	0Bh or 0Ch	Command name: FAST_READ or 4FAST_READ FAST_READ is 3-byte address mode. 4FAST_READ is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	DUMMY_SDR	0h (Single)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
3	READ_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
4-7	STOP (00h)	0h	00h	

31.6.1.7 Dual IO Fast Read command

Table 219 shows Dual IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h, Continuous Read mode.

Table 219. Dual IO FAST_READ command (Continuous Read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	BBh or BCh	Command name: DIOR or 4DIOR DIOR is 3-byte address mode. 4DIOR is 4-byte address mode.
1	ADDR_SDR	1h (Dual)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	1h (Dual)	Axh	Enter continuous read mode or remain in continuous read mode.
3	DUMMY_SDR	1h (Dual)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	1h (Dual)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
5	JMP_ON_CS	0h (or Don't care)	01h	CMD instruction is bypassed after the first read access.
6-7	STOP (00h)	0h	00h	

Table 220 shows Dual IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h, Noncontinuous Read mode.

Table 220. Dual IO FAST_READ command (Noncontinuous Read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	BBh or BCh	Command name: DIOR or 4DIOR DIOR is 3-byte address mode. 4DIOR is 4-byte address mode.
1	ADDR_SDR	1h (Dual)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	1h (Dual)	Any value other than Axh	Exit continuous read mode or remain in noncontinuous read mode.
3	DUMMY_SDR	1h (Dual)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	1h (Dual)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
5-7	STOP (00h)	0h	00h	

31.6.1.8 Quad IO Fast Read command

Table 221 shows Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[6] = 0, CR2V[3:0] = 8h, Non-QPI mode, Noncontinuous read mode.

Table 221. Quad IO FAST_READ command (Non-QPI mode, Noncontinuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	EBh or ECh	Command name: QIOR or 4QIOR QIOR is 3-byte address mode. 4QIOR is 4-byte address mode.
1	ADDR_SDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	2h (Quad)	Any value other than Axh	Exit continuous read mode or remain in noncontinuous read mode.
3	DUMMY_SDR	2h (Quad)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
5-7	STOP (00h)	0h	00h	

Table 222 shows Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[6] = 0, CR2V[3:0] = 8h, Non-QPI mode, Continuous read mode.

Table 222. Quad IO FAST_READ command (Non-QPI mode, Continuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	EBh or ECh	Command name: QIOR or 4QIOR QIOR is 3-byte address mode. 4QIOR is 4-byte address mode.
1	ADDR_SDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	2h (Quad)	A0h	Enter continuous read mode or remain in continuous read mode.
3	DUMMY_SDR	2h (Quad)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.

				data size. This value is ignored for AHB command.
5-7	STOP (00h)	0h	00h	

31.6.3 Application on Serial NAND flash device

This section provides example LUT instruction sequences for serial NAND flash device (Micron Flash MT29 series). The operation of serial NAND flash is similar to serial NOR flash.

The read operation sequence is:

- Page read. Transfer the data from the NAND flash array to the cache register.
- Get feature to read the status.
- Random data read

Table 232 shows the page read command sequence.

Table 232. Page Read command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	13h	Command code: 13h
1	RADDR_SDR	1h (Single)	18h	Row address: 24 bit
2-7	STOP (0h)	0h	00h	

Table 233 shows Get Feature command sequence.

Table 233. Get Feature command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	0Fh	Command code: 0Fh
1	CMD_SDR	1h (Single)	C0h	Status register address (C0h)
2	READ_SDR	0x1 (Single)	02h	2 bytes read data
3-7	STOP (0h)	0h	00h	

Table 234 shows Random Data Read command sequence.

Table 234. Read from Cache x4 command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	6Bh	Command code: 6Bh
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection

Table continues on the next page...

Table 234. Read from Cache x4 command (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
				is zero, software should write 0h to mode bits. Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	DUMMY_SDR	2h (Quad)	08h	Dummy cycle number: 8 (serial root clock)
4	READ_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size.
5-7	STOP (0x0)	0x0	0x00	

The program operation sequence is:

- Write enable
- Program Load. Transfer the write data to the cache register.
- Program Execute
- Get Feature to read the status.

Table 235 shows Program Load command sequence.

Table 235. Program Load command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	02h	Command code: 02h
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection is zero, software should write 0h to mode bits. Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	WRITE_SDR	1h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default writing data size.
4-7	STOP (0h)	0h	00h	

Table 236 shows Program Execute command sequence.

Table 236. Program Execute command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	10h	Command code: 10h
1	RADDR_SDR	1h (Single)	18h	Row Address: 24 bit
2-7	STOP (0h)	0h	00h	

31.6.4 Application on FPGA device

An FPGA device can be accessed via both AHB and IP commands. All AHB accesses to FPGA are transparent to the software driver (no software intervention). An FPGA device may have some special requirements.

Table 237. Special requirements for FPGA devices

Condition	How to manage the condition
Device type may be different on A1, A2, B1, or B2.	Write 0 to MCR2[SAMEDEVICEEN] and configure the FLSHxCR0 and FLSHxCR1 registers separately for up to four external devices.
Device requires different wait cycle for programming.	The AHB write wait cycle number can be set separately for these four external devices (via FLSHxCR2[AWRWAIT]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle). FlexSPI holds the AHB bus ready for this wait time; AHB bus performance may decrease when this wait time is very long.
Device requires different wait cycle for reading.	The AHB read sequence index and sequence number can be set separately for these four external devices (via FLSHxCR2[ARDSEQID] and FLSHxCR2[ARDSEQNUM]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle).
Device may be sensitive to read instruction clock cycle number.	If its internal memory is implemented similar to a FIFO, the device is sensitive to the read instruction clock cycle number. Software can send the data size information to the external device via DATSZ instruction. The FPGA device decodes the data size information and determines how many data bytes must be popped.
Device may require interval time between chip select valid.	This interval can be managed via FLSHxCR1[CSINTERVAL].
Device may use SCLK as reference clock for its internal PLL.	SCLK must be free-running and the clock frequency must be stable. To achieve this configuration, write 1 to MCR0[SCKFREERUNEN] and only use SDR sequences.

31.6.5 Overview of error categories, flags, and triggered sources

Table 238 provides an overview of the categories, flags, and triggered sources of errors in FlexSPI.

Table 238. Error category, triggered sources, and flags

Error Category	Triggered Sources	Description	Error Flags
Command grant error	AHB write command	Command grant timeout	INTR[AHBCMDGE] is set AHB bus error response

Table continues on the next page...

Table 238. Error category, triggered sources, and flags (continued)

Error Category	Triggered Sources	Description	Error Flags
	AHB read command		INTR[AHBCMDGE] is set AHB bus error response
	IP command		INTR[IPCMDGE] is set
Command check error	AHB write command	• AHB write command with JMP_ON_CS instruction used in the sequence • Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence	INTR[AHBCMDERR] is set Command is not executed when an error is detected in command check
	AHB read command	• Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence	INTR[AHBCMDERR] is set Command is not executed when an error is detected in command check
	IP command	• IP command with JMP_ON_CS instruction used in the sequence • Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence • Flash boundary across	INTR[IPCMDERR] is set Command is not executed when an error is detected in command check
Command execution error	AHB write command	Command timeout during execution	INTR[AHBCMDERR] is set INTR[SEQTIMEOUT] is set An AHB bus error response

Table continues on the next page...

Table 238. Error category, triggered sources, and flags (continued)

Error Category	Triggered Sources	Description	Error Flags
			occurs, except in following cases: • Flush triggers AHB write command (INCR burst ended with AHB_TX_BUF not empty) • AHB bufferable write access and bufferable enabled (AHBCR[BUFFERABLEEN] = 1)
	AHB read command		INTR[AHBCMDERR] is set INTR[SEQTIMEOUT] is set AHB bus error response
	IP command		INTR[IPCMDERR] is set INTR[SEQTIMEOUT] is set
AHB bus timeout	AHB write command	AHB bus timeout (no bus ready return)	AHB bus error response
	AHB read command		

31.7 Memory map and register definition

This section includes the FlexSPI module memory map and detailed descriptions of all registers.

31.7.1 Register access

All registers can be accessed with 8-bit, 16-bit, and 32-bit width operations. Never change the values of reserved fields in control registers. Changing the values of reserved fields may impact the normal functioning of the controller.

NOTE

When FlexSPI can access sensitive memory contents, the FlexSPI controller should protect those contents using resource isolation such as XRDC or TrustZone. Ensure that only trusted software is allowed to access the FlexSPI controller register interface.

31.7.2 FlexSPI register descriptions

31.7.2.1 FlexSPI memory map

FLEXSPI1 base address: 425E_0000h

Fields

Field	Function
31-24 AHBGRANTWAIT	Timeouts Wait Cycle for AHB command Grant Sets duration of timeout wait cycle for AHB commands. If the arbitrator does not grant the AHB-triggered command, it times out after (AHBGRANTTIMEOUT × 1024) AHB clock cycles. When the pending command sequence is IP-triggered and the read or write data size is too large, this grant timeout may occur. When an AHB command grant timeout occurs, an INTR[AHBCMDGE] interrupt is generated. When INTEN[AHBCMDGEEN] = 1, the arbitrator ignores AHB commands. **NOTE** This field is for debugging only. Do not change the value from its default.
23-16 IPGRANTWAIT	Timeout Wait Cycle for IP Command Grant Sets duration of timeout wait cycle for IP commands. If the arbitrator does not grant the IP-triggered command, it times out after (IPGRANTTIMEOUT × 1024) AHB clock cycles. When the pending command sequence is AHB-triggered and the read or write data size is too large, this grant timeout may occur. When IP command grant timeout occurs, an INTR[IPCMDGE] interrupt is generated. When INTEN[IPCMDGEEN] = 1, the arbitrator ignores IP commands. **NOTE** This field is for debugging only. Do not change the value from its default.
15 —	Reserved
14 SCKFREERUNEN	SCLK Free-running Enable Enables free-running SCLK output. For FPGA applications, the external device may use SCLK as a reference clock to its internal PLL. 0b - Disable 1b - Enable
13	Combination Mode Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
COMBINATIONEN	Enables combination mode, which supports flash Octal mode access. When Port A and Port B data are four bits wide, this mode combines Port A and B Data pins (A_DATA[3:0] and B_DATA[3:0]). When Port A and Port B data are eight bits wide, combination mode is not supported; write 0 to this field in this case. 0b - Disable 1b - Enable
12 DOZEEN	Doze Mode Enable Enables Doze mode. When enabled, AHB clock and serial clock are gated off when there is a Doze-mode request from the system. 0b - Disable 1b - Enable
11 HSEN	Half Speed Serial Flash Memory Access Enable Enables the clock divider to provide a half-speed clock to external serial flash devices (A_SCLK/ B_SCLK) for all commands in SDR and DDR mode. Write 1 to MCR0[MDIS] before changing the value of this field. Failure to do so may cause issues in the internal logic or state machine. 0b - Disable 1b - Enable
10-8 SERCLKDIV	Serial Root Clock Divider Sets divider value for serial root clock. The serial root clock can be divided inside FlexSPI . See Clocking. **NOTE** Do not modify this field while FlexSPI is active (MCR0[MDIS] = 0). 000b - Divided by 1 001b - Divided by 2 010b - Divided by 3 011b - Divided by 4 100b - Divided by 5 101b - Divided by 6 110b - Divided by 7 111b - Divided by 8
7 ATDFEN	AHB Write Access to IP Transmit FIFO Enable Enables AHB write access to IP transmit FIFO. See Writing data to IP transmit FIFO. 0b - AHB write access disabled. IP bus writes to IP transmit FIFO. AHB bus write access to IP transmit FIFO memory space produces bus error.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - AHB write access enabled. AHB bus writes to IP transmit FIFO. IP Bus write access to IP transmit FIFO memory space is ignored and causes no bus error.
6 ARDFEN	AHB Read Access to IP Receive FIFO Enable Enables AHB read access to IP receive FIFO. See Reading data from IP receive FIFO. 0b - AHB read access disabled. IP bus reads IP receive FIFO. AHB Bus read access to IP receive FIFO memory space produces bus error. 1b - AHB read access enabled. AHB bus reads IP receive FIFO. IP Bus read access to IP receive FIFO memory space returns data zero and causes no bus error.
5-4 RXCLKSRC	Sample Clock Source for Flash Reading Selects sampling clock source for flash memory reading. See Receive clock source features. 00b - Dummy Read strobe that FlexSPI generates, looped back internally 01b - Dummy Read strobe that FlexSPI generates, looped back from DQS pad 10b - Reserved 11b - Flash-memory-provided read strobe and input from DQS pad
3-2 —	Reserved
1 MDIS	Module Disable Disables FlexSPI module. When the module is disabled, AHB and serial clock are gated off internally to save power. Only register access is allowed, except for the LUT, IP receive FIFO, and IP transmit FIFO. 0b - No impact 1b - Module disable
0 SWRESET	Software Reset Resets the internal FlexSPI state machine and aborts any transactions in progress. Hardware automatically writes 0 to this field after software reset is done. Configuration registers are not reset. 0b - No impact 1b - Software reset

31.7.2.3 Module Control 1 (MCR1)

Offset

Register	Offset
MCR1	4h

Function

Controls basic functions of FlexSPI module

Diagram

Fields

Field	Function
31-16 SEQWAIT	Command Sequence Wait Sets wait time for command sequence. Command sequence execution times out and aborts after (SEQWAIT × 1024) serial root clock cycles. When this timeout occurs, if the interrupt is enabled (INTEN[SEQTIMEOUTEN] = 1), an INTR[SEQTIMEOUT] interrupt is generated. Also, the arbitrator ignores AHB commands. **NOTE** You cannot write 0 to this field.
15-0 AHBBUSWAIT	AHB Bus Wait Sets wait time for AHB bus. When data is not received from or transmitted to serial flash memory space after (AHBBUSWAIT × 1024) AHB clock cycles, the read or write access times out. When this timeout occurs, the AHB bus receives an error response, and an interrupt is generated (INTEN[AHBBUSERROREN]). When INTR[AHBBUSERROREN] = 1, the arbitrator ignores AHB commands. **NOTE** You cannot write 0 to this field.

31.7.2.4 Module Control 2 (MCR2)

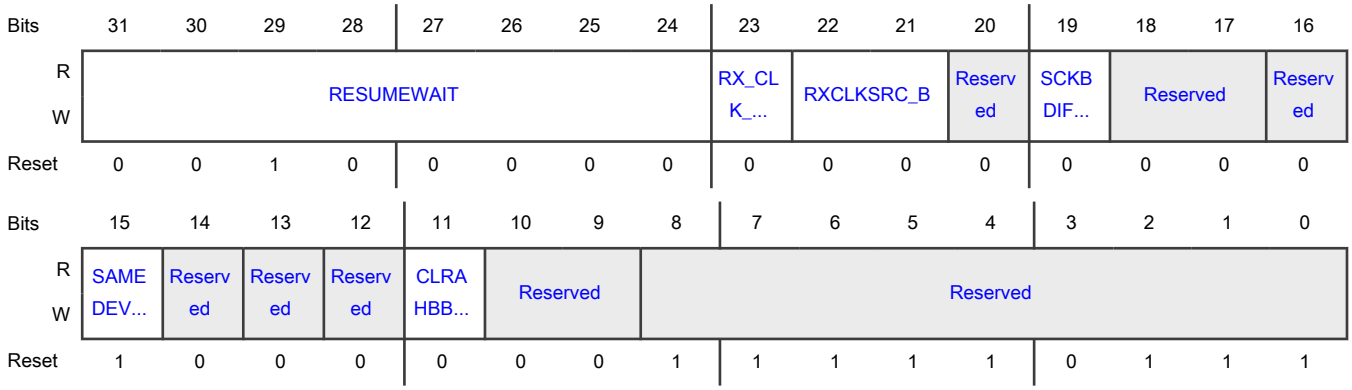
Offset

Register	Offset
MCR2	8h

Function

Controls basic functions of FlexSPI module.

Diagram



Fields

Field	Function
31-24 RESUMEWAIT	Resume Wait Duration Determines duration (in AHB clock cycles) to remain in idle state before suspended command sequence is resumed. See Command abort and suspend.
23 RX_CLK_SRC_DIFF	Sample Clock Source Different Selects whether to use the same clock source or a different clock source for Port A and Port B. 0b - Use MCR0[RXCLKSRC] for Port A and Port B. MCR2[RXCLKSRC_B] is ignored and MCR0[RXCLKSRC] selects the Sample Clock source for Flash Reading of both ports A and B. 1b - Use MCR0[RXCLKSRC] for Port A, and MCR2[RXCLKSRC_B] for Port B. MCR0[RXCLKSRC] selects the Sample Clock source for Flash Reading of port A (A_SCLK) and MCR2[RXCLKSRC_B] selects the Sample Clock source for Flash Reading of port B (B_SCLK).
22-21 RXCLKSRC_B	Port B Receiver Clock Source Selects Port B sample clock source selection for flash memory reading. 00b - Dummy read strobe that FlexSPI generates, looped back internally. 01b - Dummy read strobe that FlexSPI generates, looped back from DQS pad. 10b - SCLK output clock and looped back from SCLK padReserved 11b - Flash-memory-provided read strobe and input from DQS pad
20 —	Reserved
19 SCKBDIFFOPT	SCLK Port B Differential Output Controls whether to use B_SCLK pad as the Port B SCLK output. Alternatively, B_SCLK pad can be used as A_SCLK differential clock output (inverted clock to A_SCLK). Before changing the value of this field, write 1 to MCR0[MDIS]. After changing the value of this field, write 1 to MCR0[SWRESET].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Use B_SCLK pad as port B SCLK clock output. Port B flash memory access is available. 1b - Use B_SCLK pad as port A SCLK inverted clock output (Differential clock to A_SCLK). Port B flash memory access is not available.
18-17 —	Reserved
16 —	Reserved
15 SAMEDEVICEEN	Same Device Enable Sets all external devices (A1, A2, B1, and B2) to be the same devices (in type and in size). 0b - In Individual mode, FLSHA1CRx and FLSHA2CRx, FLSHB1CRx and FLSHB2CRx settings are applied to Flash A1, A2, B1, B2 separately. In Parallel mode, FLSHA1CRx register setting is applied to Flash A1 and B1, FLSHA2CRx register setting is applied to Flash A2 and B2. FLSHB1CRx and FLSHB2CRx register settings are ignored. 1b - FLSHA1CR0, FLSHA1CR1, and FLSHA1CR2 register settings are applied to Flash A1, A2, B1, B2. FLSHA2CRx, FLSHB1CRx, and FLSHB2CRx settings are ignored.
14 —	Reserved
13 —	Reserved
12 —	Reserved
11 CLRAHBBUFOPT	Clear AHB Buffer Determines whether AHB receive and transmit buffers are cleared automatically when FlexSPI returns Stop mode ACK. If an AHB receive buffer or transmit buffer will be powered off in Stop mode, software should write 1 to this field. Otherwise, an AHB read access after exiting Stop mode may hit either buffer, but their data entries are invalid. 0b - Not cleared automatically 1b - Cleared automatically
10-9 —	Reserved
8-0 —	Reserved

31.7.2.5 AHB Bus Control (AHBCR)

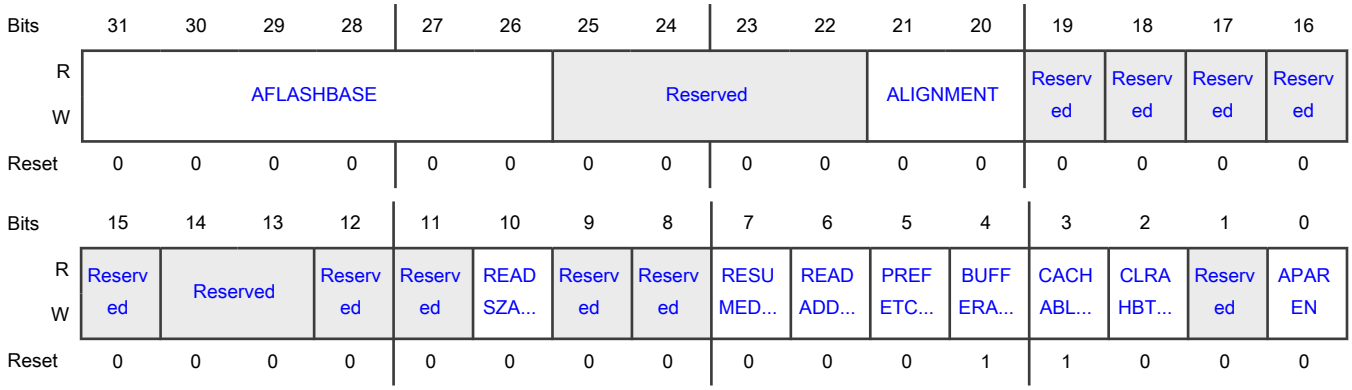
Offset

Register	Offset
AHBCR	Ch

Function

Controls AHB bus interface functions.

Diagram



Fields

Field	Function
31-26 AFLASHBASE	AHB Memory-Mapped Flash Base Address **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
FLEXSPI1	AHBCR[31–27]	AHBCR[26]
FLEXSPI2	AHBCR	—

25-22 —	Reserved
21-20 ALIGNMENT	AHB Boundary Alignment Configures the size of AHB read and write boundary. All accesses that cross the boundary are divided into smaller sub accesses.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - No limit 01b - 1 KB 10b - 512 bytes 11b - 256 bytes
19 —	Reserved
18 —	Reserved
17 —	Reserved
16 —	Reserved
15 —	Reserved
14-13 —	Reserved
12 —	Reserved
11 —	Reserved
10 READSZALIGN	AHB Read Size Alignment Configures how AHB read size is determined. See Table 208. **NOTE** When 1, data prefetching is disabled regardless of other field settings such as PREFETCH_EN and OTFAD_EN. Read size is rounded up to the nearest eight-byte multiple. For example, if current AHB read size is 12 bytes, it is aligned to 16 bytes. When the fetch size must be eight-byte aligned but no speculative fetching is wanted, write 1 to this field. 0b - Register settings such as PREFETCH_EN and OTFAD_EN determine AHB read size. 1b - AHB read size to up size to 8 bytes aligned, no prefetching
9	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
8 —	Reserved
7 RESUMEDISABLE	AHB Read Resume Disable Disables the resumption of AHB read prefetch. **NOTE** When OTFAD is enabled, this field does not affect the resume function; AHB read resume is always disabled. When OTFAD is disabled, suspended AHB read prefetch resumes based on the values of this field and MCR2[RESUMEWAIT]. 0b - Suspended AHB read prefetch resumes when AHB is IDLE. 1b - Suspended AHB read prefetch does not resume once aborted.
6 READADDROPT	AHB Read Address Option Removes AHB burst start address alignment limitation. When the FlexSPI controller is used for FPGA application, this field may be required for FlexSPI to fetch the exact byte number as an AHB burst. In this case, FPGA device should be non-word-addressable and this field must be 0. **NOTE** When OTFAD is enabled, FlexSPI functions as it does when READADDROPT = 1 regardless the value of this field. 0b - AHB read burst start address alignment is limited when flash memory is accessed in parallel mode or flash is word-addressable. 1b - AHB read burst start address alignment is not limited. FlexSPI fetches more data than the AHB burst requires for address alignment.
5 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch. When enabled, FlexSPI fetches more flash read data than the current AHB burst requires. This action reduces the read latency for next AHB read access. **NOTE** When OTFAD is enabled, the AHB prefetch function is enabled regardless of the value of this field. **NOTE** AHB read prefetch is enabled only when both this field and AHBRXBUFnCR0[PREFETCHEN] are 1. 0b - Disable 1b - Enable
4	Bufferable Write Access Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
BUFFERABLEEN	Enables AHB bus bufferable write access. This field affects the last beat of an AHB write access. See AHB write access to flash memory. 0b - Disabled. For all AHB write accesses (bufferable or nonbufferable), FlexSPI returns AHB Bus Ready after transmitting all data and finishing command. 1b - Enabled. For AHB bufferable write access, FlexSPI returns AHB Bus Ready when the arbitrator grants the AHB command. FlexSPI does not wait for the AHB command to finish.
3 CACHABLEEN	Cacheable Read Access Enable Enables AHB bus cacheable read access. 0b - Disabled. When an AHB bus cacheable read access occurs, FlexSPI does not check whether it hit the AHB transmit buffer. 1b - Enabled. When an AHB bus cacheable read access occurs, FlexSPI first checks whether the access hit the AHB transmit buffer.
2 CLRAHBTXBUF	Clear AHB Transmit Buffer Clears status and pointers of AHB transmit buffer. When the clear operation completes, this field clears automatically, so it always reads as 0. 0b - No impact. 1b - Enable clear operation.
1 —	Reserved
0 APAREN	AHB Parallel Mode Enable Enables Parallel mode for AHB-triggered read and write commands. 0b - Flash is accessed in Individual mode. 1b - Flash is accessed in Parallel mode.

31.7.2.6 Interrupt Enable (INTEN)

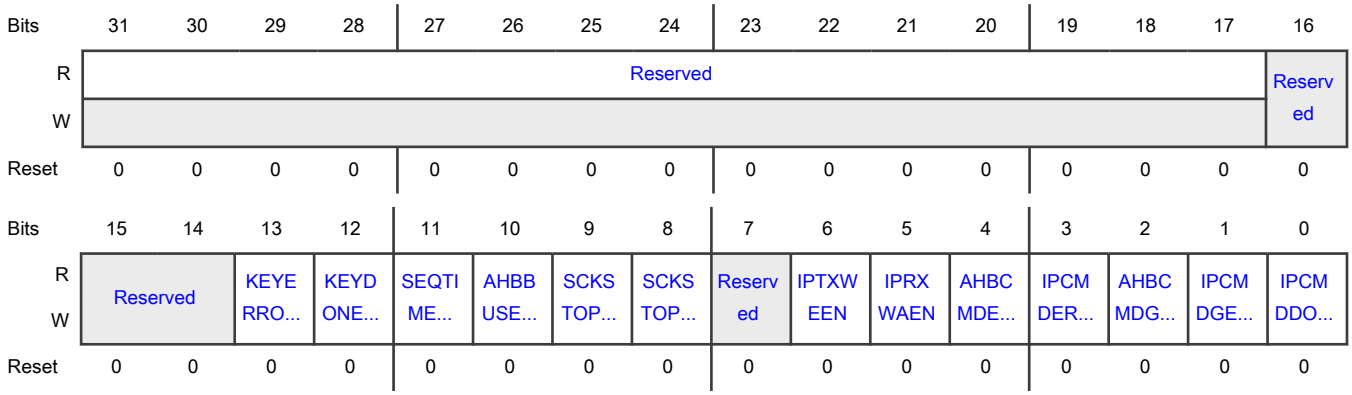
Offset

Register	Offset
INTEN	10h

Function

Includes AHB error response, IPS error response, and ECC error interrupt enables. See Interrupts.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 —	Reserved
15-14 —	Reserved
13 KEYERROREN	OTFAD Key Blob Processing Error Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
12 KEYDONEEN	OTFAD Key Blob Processing Done Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
11 SEQTIMEOUTEN	Sequence execution Timeout Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
10 AHBBUSERROREN	AHB Bus Error Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
9 SCKSTOPBYWREN	SCLK Stopped By Write Interrupt Enable Enables interrupt that indicates SCLK is stopped during command sequence because asynchronous transmit FIFO is empty.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable interrupt or no impact 1b - Enable interrupt
8 SCKSTOPBYRDEN	SCLK Stopped By Read Interrupt Enable Enables interrupt that indicates SCLK is stopped during command sequence because asynchronous receive FIFO is full. 0b - Disable interrupt or no impact 1b - Enable interrupt
7 —	Reserved
6 IPTXWEEN	IP Transmit FIFO Watermark Empty Interrupt Enable Enables interrupt that indicates IP transmit FIFO contains more empty space than watermark level. 0b - Disable interrupt or no impact 1b - Enable interrupt
5 IPRXWAEN	IP Receive FIFO Watermark Available Interrupt Enable Enables interrupt that indicates IP receive FIFO contains more valid data than the watermark level. 0b - Disable interrupt or no impact 1b - Enable interrupt
4 AHBCMDERREN	AHB-Triggered Command Sequences Error Detected Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
3 IPCMDERREN	IP-Triggered Command Sequences Error Detected Interrupt Enable 0b - Disable interrupt or no impact 1b - Enable interrupt
2 AHBCMDGEEN	AHB-Triggered Command Sequences Grant Timeout Interrupt Enable. 0b - Disable interrupt or no impact 1b - Enable interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
12 KEYDONE	OTFAD key blob processing done interrupt.
11 SEQTIMEOUT	Sequence Execution Timeout **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
10 AHBBUSERROR	AHB Bus Error Generated upon an AHB bus timeout or an AHB bus illegal access to flash during OTFAD key blob processing. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
9	SCLK Stopped Due To Empty Transmit FIFO

Table continues on the next page...

Table continued from the previous page...

Field	Function
SCKSTOPBYWR	Generated when SCLK is stopped during command sequence because the asynchronous transmit FIFO is empty. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
8 SCKSTOPBYRD	SCLK Stopped Due To Full Receive FIFO Generated when SCLK is stopped during command sequence because the asynchronous receive FIFO is full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
7 —	Reserved
6 IPTXWE	IP Transmit FIFO Watermark Empty Generated when the IP transmit FIFO contains more empty space than the watermark level. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 IPRXWA	IP Receive FIFO Watermark Available Generated when the IP receive FIFO contains more valid data than the watermark level. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
4 AHBCMDERR	AHB-Triggered Command Sequences Error Generated upon an AHB-triggered command sequence error. When an error is detected for an AHB command, the command is ignored and not executed. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
3 IPCMDERR	IP-Triggered Command Sequences Error Generated upon an IP-triggered command sequence error. When an error is detected for an IP command, the command is ignored and not executed. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
2	AHB-Triggered Command Sequences Grant Timeout

Table continues on the next page...

Table continued from the previous page...

Field	Function
AHBCMDGE	**NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
1 IPCMDGE	IP-Triggered Command Sequences Grant Timeout **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag
0 IPCMDDONE	IP-Triggered Command Sequences Execution Finished Generated upon completion of an IP-triggered command sequence. Also generated when IPCMDGE or IPCMDERR interrupt is generated **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt condition has not occurred 1b - Interrupt condition has occurred When writing 0b - No effect 1b - Clear the flag

31.7.2.8 LUT Key (LUTKEY)

Offset

Register	Offset
LUTKEY	18h

Function

Contains the key to lock and unlock LUT. See Lookup table (LUT).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 KEY	LUT Key Contains key to lock or unlock LUT. The key is 5AF05AF0h. Read value is always 5AF05AF0h.

31.7.2.9 LUT Control (LUTCR)

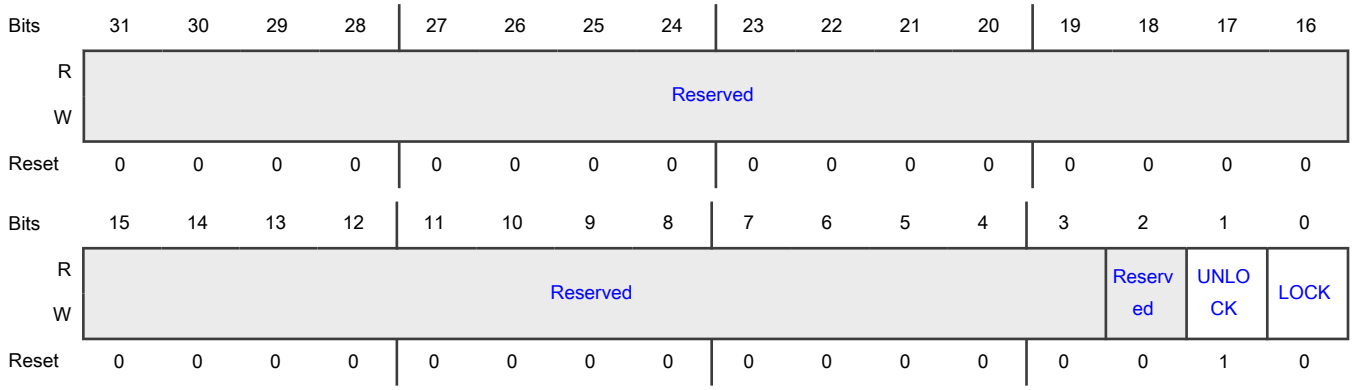
Offset

Register	Offset
LUTCR	1Ch

Function

Used with LUTKEY register to lock or unlock LUT. For the lock or unlock operation to be successful, this register must be written immediately after writing 5AF05AF0h to the LUTKEY register. See Lookup table (LUT) for details on locking and unlocking LUT. You cannot write 00 or 11 to the LOCK and UNLOCK fields.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 —	Reserved
1 UNLOCK	Unlock LUT 0b - LUT is locked (LUTCR[LOCK] must be 1) 1b - LUT is unlocked and can be written
0 LOCK	Lock LUT 0b - LUT is unlocked (LUTCR[UNLOCK] must be 1) 1b - LUT is locked and cannot be written

31.7.2.10 AHB Receive Buffer n Control 0 (AHBRXBUF0CR0 - AHBRXBUF7CR0)

Offset

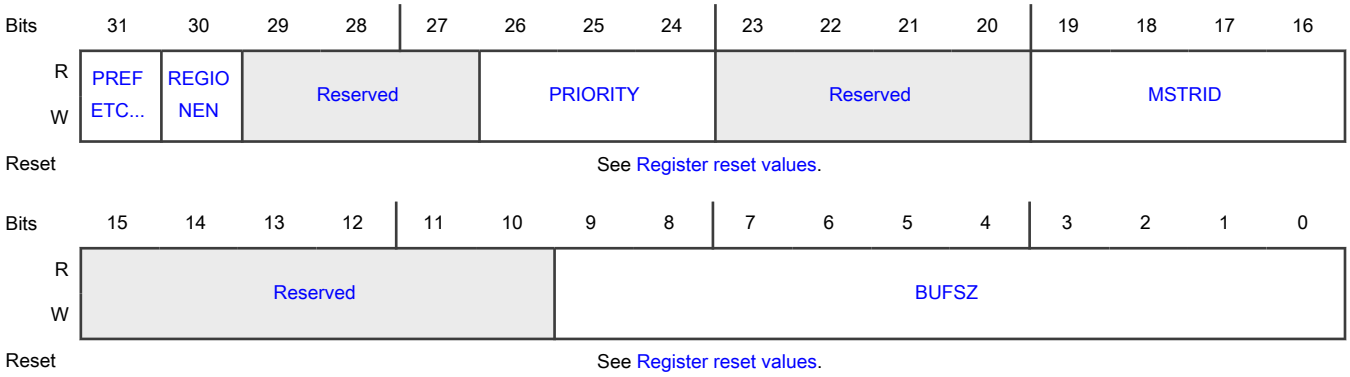
For n = 0 to 7:

Register	Offset
AHBRXBUFnCR0	20h + (n × 4h)

Function

Stores the read data from the SPI interface.

Diagram



Register reset values

Register	Reset value
AHBRXBUF0CR0	FLEXSPI1,FLEXSPI2: 8000_0040h
AHBRXBUF1CR0	FLEXSPI1,FLEXSPI2: 8001_0040h
AHBRXBUF2CR0	FLEXSPI1,FLEXSPI2: 8002_0040h
AHBRXBUF3CR0	FLEXSPI1,FLEXSPI2: 8003_0040h
AHBRXBUF4CR0	FLEXSPI1,FLEXSPI2: 8004_0040h
AHBRXBUF5CR0	FLEXSPI1,FLEXSPI2: 8005_0040h
AHBRXBUF6CR0	FLEXSPI1,FLEXSPI2: 8006_0040h
AHBRXBUF7CR0	FLEXSPI1,FLEXSPI2: 8007_0040h

Fields

Field	Function
31 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch for the controller corresponding to the current AHB receive buffer. The prefetch feature is disabled when AHBCR[PREFETCHEN] is 0. You can use this field to enable or disable prefetch separately for each controller. 0b - Disabled 1b - Enabled when AHBCR[PREFETCHEN] is enabled.
30 REGIONEN	AHB Receive Buffer Address Region Enable Enable prefetch buffer enhancement. **NOTE** Only AHBRXBUF 0-3 have this function. 0b - Disabled. The buffer hit is based on the value of MSTRID only.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled. The buffer hit is based on the value of MSTRID and the address within AHBBUFREGIONSTARTn and AHBREGIONENDn.
29-27 —	Reserved
26-24 PRIORITY	AHB Controller Read Priority Configure the priority for the AHB Controller Read to which this AHB receive buffer is assigned. 7 is the highest priority, 0 the lowest. See Command abort and suspend.
23-20 —	Reserved
19-16 MSTRID	AHB Controller ID Configures the ID of the AHB controller to which this AHB receive buffer is assigned. See AHB receive buffer management.
15-10 —	Reserved
9-0 BUFSZ	AHB Receive Buffer Size Configures the size of the AHB receive buffer in multiples of 64 bits. See AHB receive buffer management.

31.7.2.11 Flash Control 0 (FLSHA1CR0 - FLSHB2CR0)

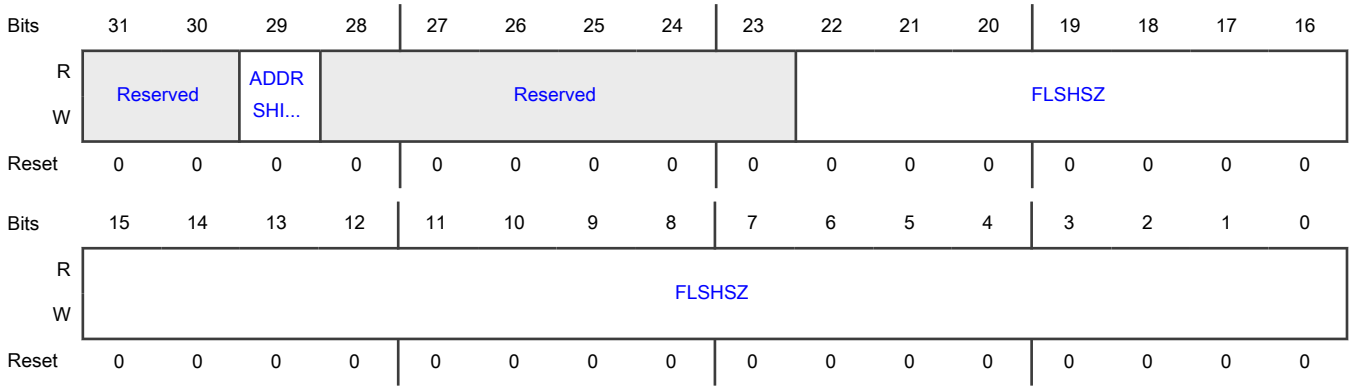
Offset

Register	Offset
FLSHA1CR0	60h
FLSHA2CR0	64h
FLSHB1CR0	68h
FLSHB2CR0	6Ch

Function

Contains flash memory size setting. FlexSPI determines which device is accessed (Chip Select) via this register.

Diagram



Fields

Field	Function
31-30 —	Reserved
29 ADDRSHIFT	AHB Address Shift Function control Used to left-shift five bits for the flash address to support ISSI quad PSRAM. 0b - Disabled 1b - Enabled
28-23 —	Reserved
22-0 FLSHSZ	Flash Size in KB Configures the maximum flash memory size. See the chip-specific section for the maximum flash size supported. When the value of this field is greater than the maximum size, the device flash size is interpreted as the maximum. The maximum flash size is the largest flash size supported for a single device. It is also the maximum total flash size supported for all devices (up to four). If the total flash size is larger than the maximum size, only the maximum flash size address space is accessible. For IPS access, The maximum flash size supported for each device is 4 GB. When the value of this field is greater than 400000h, the device flash size is taken as 4 GB. The max total flash size supported (for all 4 devices) is also 4 GB. If the total flash size is larger than 4 GB, only 4 GB of address space is accessible.

31.7.2.12 Flash Control 1 (FLSHA1CR1 - FLSHB2CR1)

Offset

Register	Offset
FLSHA1CR1	70h

Table continues on the next page...

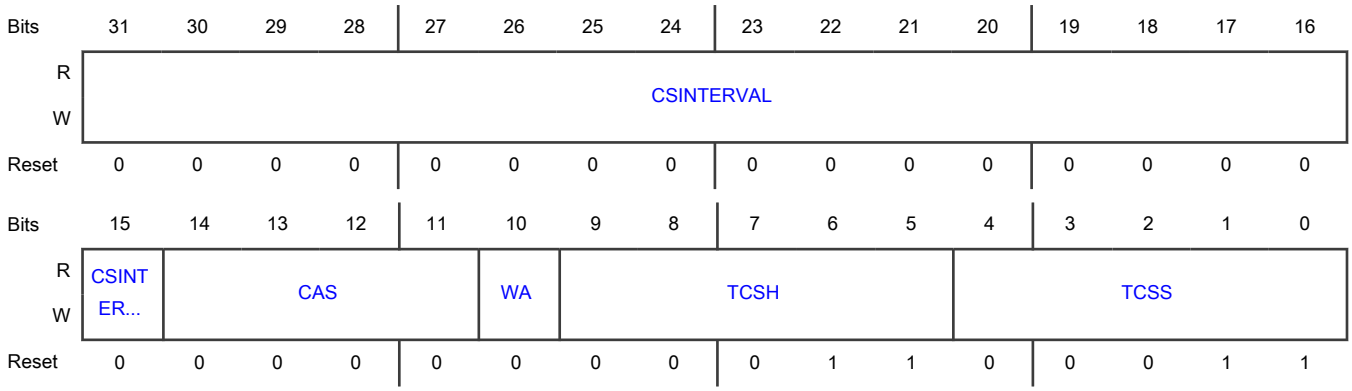
Table continued from the previous page...

Register	Offset
FLSHA2CR1	74h
FLSHB1CR1	78h
FLSHB2CR1	7Ch

Function

Contains settings for flash device-specific timings and flash internal address space.

Diagram



Fields

Field	Function
31-16 CSINTERVAL	Chip Select Interval Configures the minimum interval between flash device chip select deassertion and chip select assertion. If the external flash device has a limitation on the interval between command sequences, configure this field accordingly. If there is no limitation, write 0h to this field. When CSINTERVALUNIT = 0, the chip select invalid interval is: CSINTERVAL × 1 serial clock cycle; When CSINTERVALUNIT = 1, the chip select invalid interval is: CSINTERVAL × 256 serial clock cycles. **NOTE** The minimum chip select interval is 2 cycles, even when the value of CSINTERVAL is less than 2.
15 CSINTERVALUNIT	Chip Select Interval Unit Configures the interval unit for chip select. 0b - 1 serial clock cycle 1b - 256 serial clock cycles
14-11 CAS	Column Address Size

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When external flash memory has a separate address field for rows and columns, this field configures the flash column address bit width. FlexSPI automatically splits a flash-mapped address into row address and column address according to the values of this field and the WA field. When the external flash memory does not support column address, write 0 to this field. FlexSPI transmits all flash address bits as Row address. For flash address mapping, see Flash address sent to flash memory devices.
10 WA	Word-Addressable Configures whether external flash memory is word-addressable or byte-addressable. If flash memory is word-addressable, it should be accessed in multiples of 16 bits. Currently, FlexSPI does not transmit flash address bit 0 to external flash memory. For flash address mapping, see Flash address sent to flash memory devices. 0b - Byte-addressable 1b - Word-addressable
9-5 TCSH	Serial Flash CS Hold Time Used to meet flash TCSH timing requirement. Serial flash CS Hold time that FlexSPI promises is: (TCSH + 1/2) serial clock cycles for DDR mode, and TCSH serial clock cycles for SDR mode. See Output timing between chip select and SCLK.
4-0 TCSS	Serial Flash CS Setup Time Used to meet flash TCSS timing requirement. Serial flash CS Setup time that FlexSPI promises is: (TCSS + 1/2) serial root clock cycles for SDR and DDR mode. See Output timing between chip select and SCLK.

31.7.2.13 Flash Control 2 (FLSHA1CR2 - FLSHB2CR2)

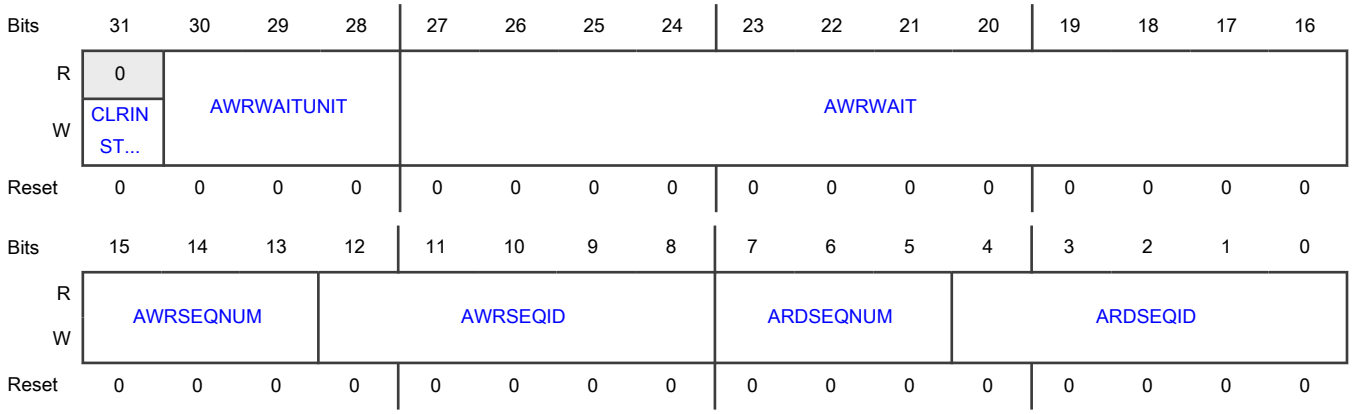
Offset

Register	Offset
FLSHA1CR2	80h
FLSHA2CR2	84h
FLSHB1CR2	88h
FLSHB2CR2	8Ch

Function

Contains fields to configure AHB bus access. If the four external devices are different types, AHB read and write commands may use different command sequences; AHB bus ready wait time may also differ.

Diagram



Fields

Field	Function
31 CLRINSTRPTR	Clear Instruction Pointer Clears the instruction pointer, which is the pointer that JMP_ON_CS saves internally. See Programmable sequence engine. This field is used for AHB read access to external flash memory supporting Execute-In-Place (XIP) mode.
30-28 AWRWAITUNIT	AWRWAIT Unit Configures the unit of AHB write wait time, as the value of AWRWAIT determines, in terms of AHB clock cycles. 000b - 2 001b - 8 010b - 32 011b - 128 100b - 512 101b - 2048 110b - 8192 111b - 32768
27-16 AWRWAIT	AHB Write Wait Configures AHB write wait time, with the AWRWAITUNIT field. Certain devices (such as FPGA) require time to write data into internal memory after the command sequences finished on the FlexSPI interface. If another read command sequence arrives before the current programming finishes internally, the read data may be wrong. This field is used to hold the AHB bus ready for AHB write access, waiting until the programming is finished in the external device. This hold ensures that no AHB read command is triggered before the programming finishes in the external device. The wait cycle between an AHB-triggered command sequence finishing on FlexSPI and the AHB return bus being ready is: AWRWAIT × AWRWAITUNIT.
15-13	Sequence Number for AHB Write-Triggered Command

Table continues on the next page...

Table continued from the previous page...

Field	Function
AWRSEQNUM	Configures the sequence number of an AHB read-triggered command. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash programming access is done via several command sequences. An AHB write command triggers (AWRSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: AWRSEQID + AWRSEQNUM < 32 • Software must ensure that the AWRSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
12-8 AWRSEQID	Sequence Index for AHB Write-Triggered Command
7-5 ARDSEQNUM	Sequence Number for AHB Read-Triggered Command Configures the sequence number of an AHB read-triggered command in the lookup table. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash read access is done via several command sequences. An AHB read command triggers (ARDSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: ARDSEQID + ARDSEQNUM ≤ 32. • Software must ensure that the ARDSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
4-0 ARDSEQID	Sequence Index for AHB Read-Triggered Command in LUT

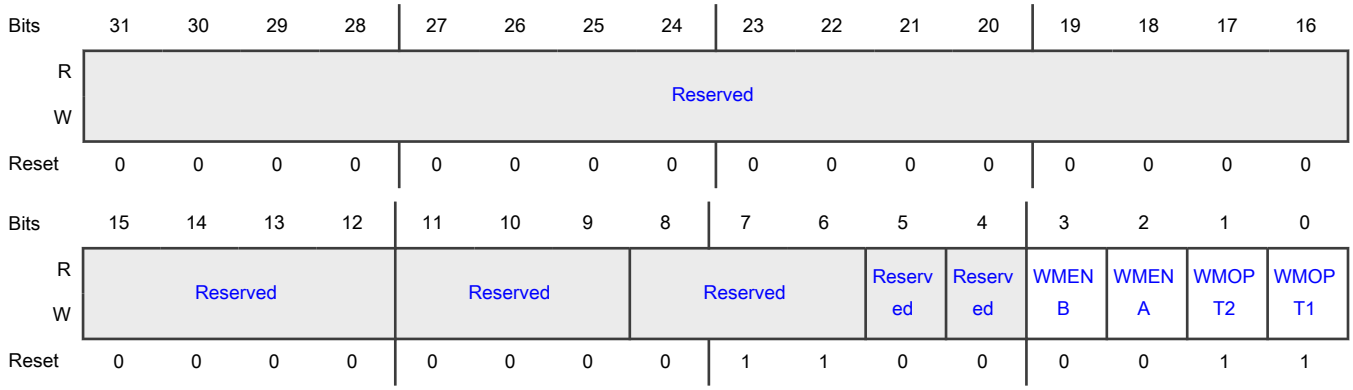
31.7.2.14 Flash Control 4 (FLSHCR4)

Offset

Register	Offset
FLSHCR4	94h

Function
Provides configuration for all external devices.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-9 —	Reserved
8-6 —	Reserved
5 —	Reserved
4 —	Reserved
3 WMENB	Write Mask Enable for Port B Enables write mask for flash device on port B. 0b - Disabled. When writing to external device, DQS(RWDS) pin is not driven. 1b - Enabled. When writing to external device, FlexSPI drives DQS(RWDS) pin as write mask output.
2 WMENA	Write Mask Enable for Port A Enables write mask for flash device on port A. 0b - Disabled. When writing to external device, DQS(RWDS) pin is not driven. 1b - Enabled. When writing to external device, FlexSPI drives DQS(RWDS) pin as write mask output.
1 WMOPT2	Write Mask Option 2

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When using AP memory, used to remove AHB or IP write burst minimum length limitation. When using this field, FLSHCR4[WMOPT1] should be 1. 0b - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is not limited. 1b - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is limited. The minimum write burst length should be 4.
0 WMOPT1	Write Mask Option 1 Used to remove AHB and IP write burst start address alignment limitation. 0b - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is not limited. 1b - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is limited.

31.7.2.15 IP Control 0 (IPCR0)

Offset

Register	Offset
IPCR0	A0h

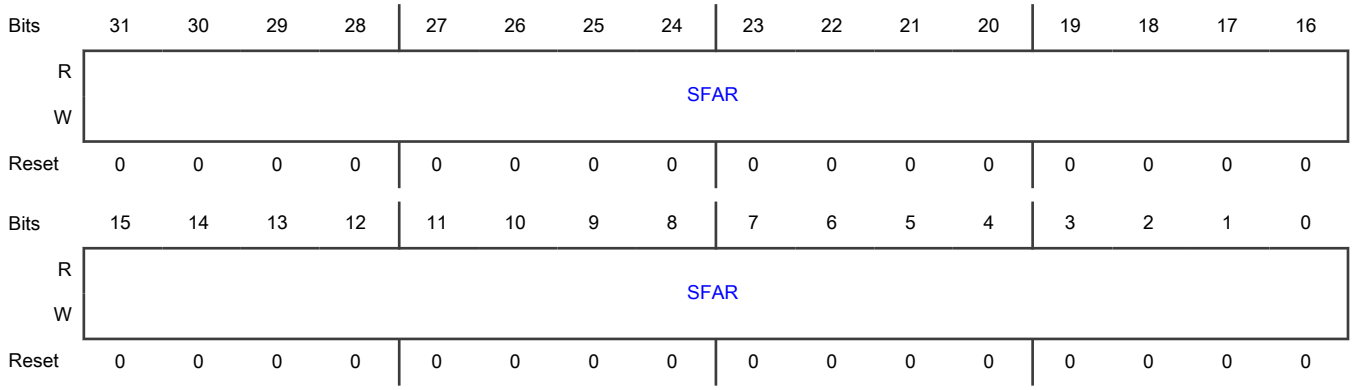
Function

Provides all configuration required for IP commands. Provides the start address for the flash device, instead of the chip address, to be accessed for IP command. FlexSPI determines the chip select automatically according to this start address.

NOTE

- You cannot issue an IP command that crosses flash device boundaries. If you do so, it generates an IPCMDERR interrupt.
- Configure this register before an IP command is triggered.
- Do not change the values in this register while an IP command is in progress.

Diagram



Fields

Field	Function
31-0 SFAR	Serial Flash Address Configures the serial flash address for IP commands. The address should be the address of the flash device without the base address.

31.7.2.16 IP Control 1 (IPCR1)

Offset

Register	Offset
IPCR1	A4h

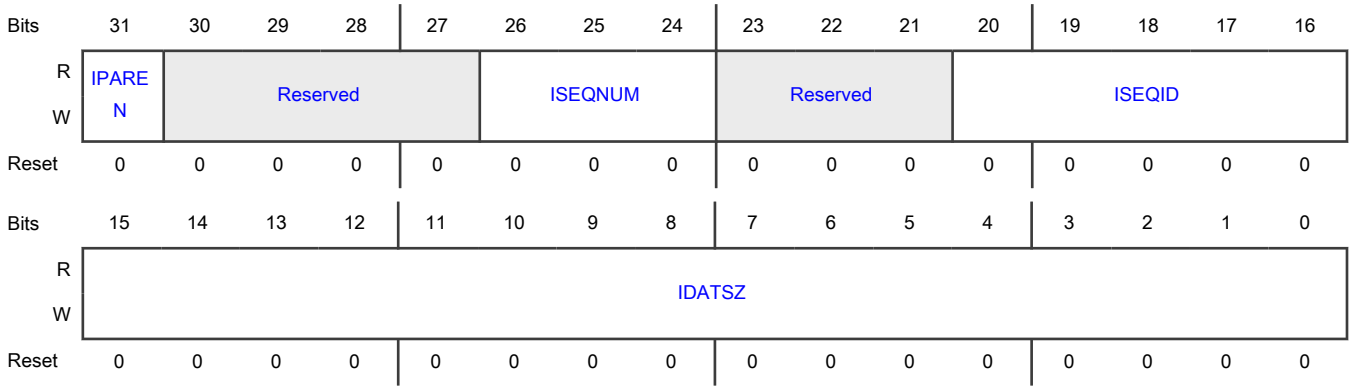
Function

Provides all configuration required for IP commands. Provides the flash read and program data size, sequence index in LUT, sequence number and individual/parallel mode settings for IP commands.

NOTE

- Configure this register before an IP command is triggered.
- Do not change the values in this register while an IP command is in progress.

Diagram



Fields

Field	Function
31 IPAREN	Parallel Mode Enable for IP Commands 0b - Disabled. Flash memory is accessed in Individual mode. 1b - Enabled. Flash memory is accessed in Parallel mode.
30-27 —	Reserved
26-24 ISEQNUM	Sequence Number for IP command: ISEQNUM+1.
23-21 —	Reserved
20-16 ISEQID	Sequence Index in LUT for IP command.
15-0 IDATSZ	Flash Read/Program Data Size (in bytes) for IP command.

31.7.2.17 IP Command (IPCMD)

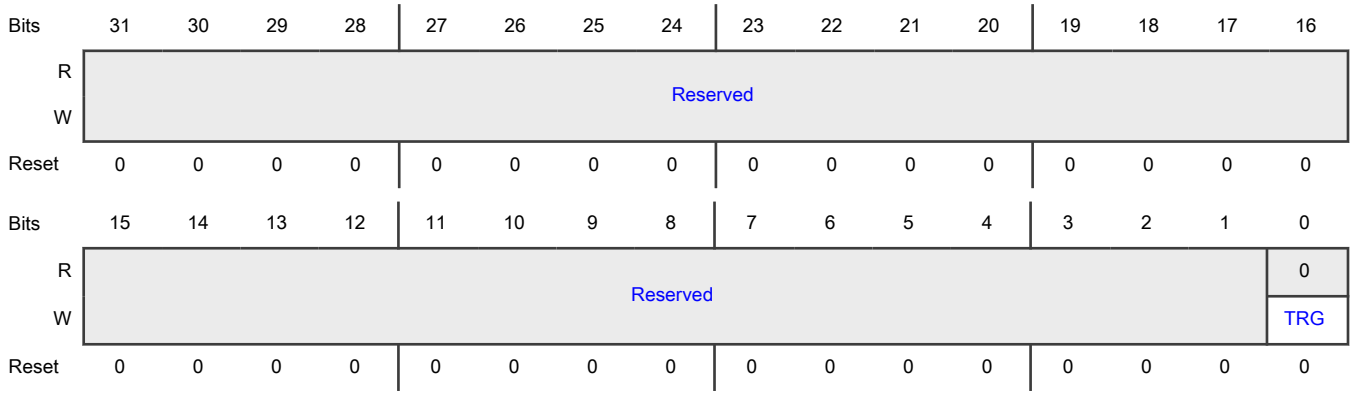
Offset

Register	Offset
IPCMD	B0h

Function

Used to trigger an IP command to access external flash device. When the arbitrator grants the IP command, the command is executed on the FlexSPI interface.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 TRG	Command Trigger Triggers an IP command. This field clears automatically after it has been written and always reads as 0. **NOTE** You cannot trigger another IP command before the previous IP command finishes on the FlexSPI interface. Software must poll INTR[IPCMDDONE] or wait for this interrupt. 0b - No action 1b - Start the IP command that the IPCR0 and IPCR1 registers define.

31.7.2.18 IP Receive FIFO Control (IPRXFCR)

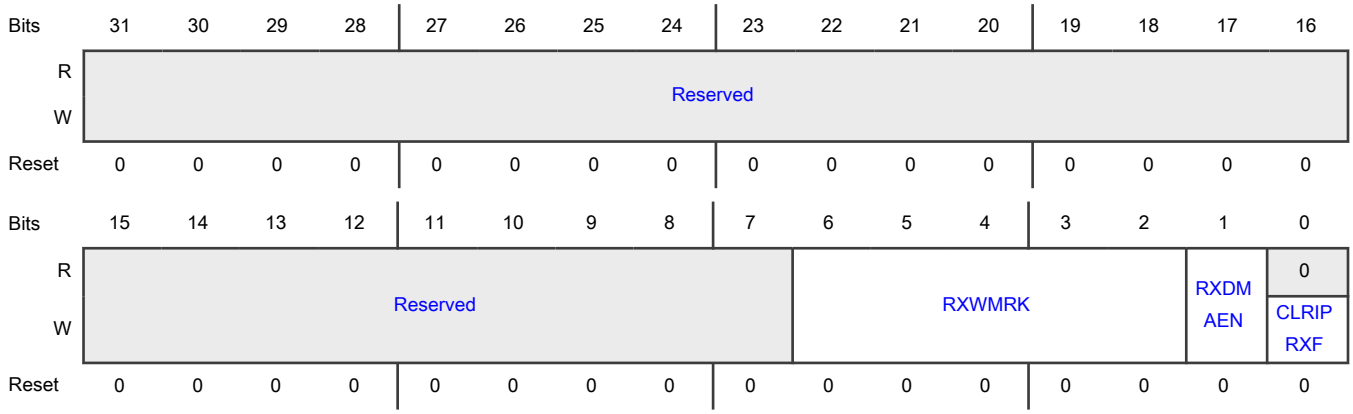
Offset

Register	Offset
IPRXFCR	B8h

Function

Provides the configuration fields for IP receive FIFO management.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-2 RXWMRK	IP Receive FIFO Watermark Level Configures the watermark level for the IP receive FIFO. The watermark level is (RXWMRK + 1) × 64 bits. The INTR[IPRXWA] interrupt is set when FlexSPI fills the IP receive FIFO ≥ the watermark level. A DMA request occurs when the fill level is ≥ the watermark level and IPRXFCR[RXDMAEN] = 1. When the fill level is ≥ the watermark level and INTEN[IPRXWAEN] = 1, an INTR[IPRXWA] interrupt is generated. **NOTE** After writing 1 to INTR[IPRXWA] to clear it, the read address should be rolled back to the start address (memory mapped). If the IP bus reads the IP receive FIFO, the read address should roll back to RFDR0. If the AHB bus reads the IP receive FIFO, the read address should roll back to ARDF_BASE.
1 RXDMAEN	IP Receive FIFO Reading by DMA Enable 0b - Disabled. The processor reads the FIFO. 1b - Enabled. DMA reads the FIFO.
0 CLRIPRXF	Clear IP Receive FIFO Clears all valid data entries in IP receive FIFO. Resets the read and write pointers in IP receive FIFO. 0b - No function 1b - A clock cycle pulse clears all valid data entries in IP receive FIFO.

31.7.2.19 IP Transmit FIFO Control (IPTXFCR)

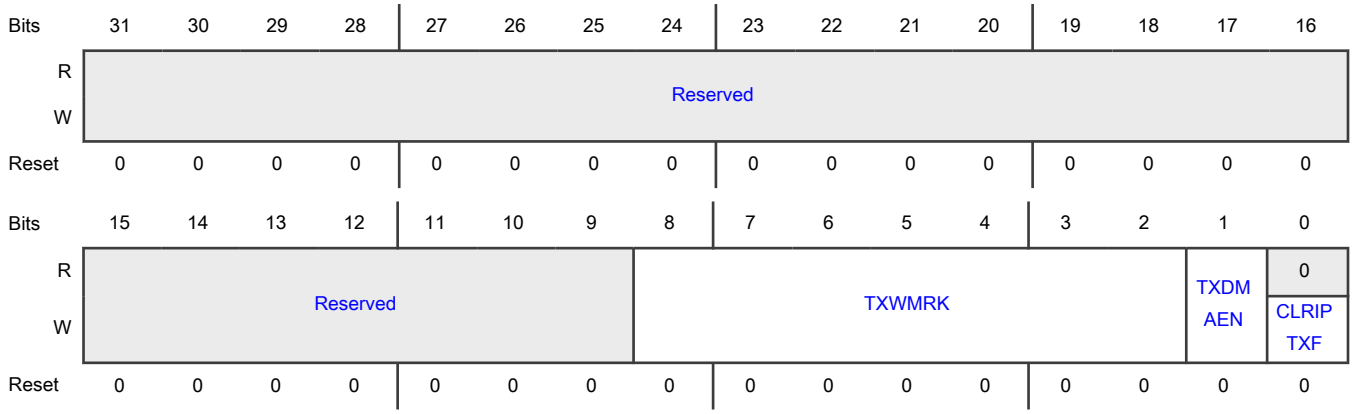
Offset

Register	Offset
IPTXFCR	BCh

Function

Provides the configuration fields for IP transmit FIFO management.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-2 TXWMRK	Transmit Watermark Level Sets the transmit watermark level. The watermark level is (TXWMRK + 1) × 64 bits. INTR[IPTXWE] is set when FlexSPI empties the IP transmit FIFO ≥ the watermark level. When the empty level ≥ the watermark level and IPTXFCR[TXDMAEN] = 1, a DMA request occurs. When the empty level ≥ the watermark level and INTEN[IPTXWEEN] = 1, an INTR[IPTXWE] interrupt is generated. **NOTE** • The watermark level should not be larger than the write window. • The watermark level should not be larger than the IP transmit FIFO size. • The write address to the IP receive FIFO should roll back to the start address of the write window. After pushing the IP transmit fifo, you should write 1 to INTR[IPTXWE] to clear it, which will perform the rollback.
1 TXDMAEN	Transmit FIFO DMA Enable Selects whether DMA or processor fills IP transmit FIFO.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Processor 1b - DMA
0 CLRIPTXF	Clear IP Transmit FIFO Clears all valid data entries in IP transmit FIFO. The read and write pointers in IP transmit FIFO are reset. 0b - No function 1b - A clock cycle pulse clears all valid data entries in the IP transmit FIFO.

31.7.2.20 DLL Control 0 (DLLACR - DLLBCR)

Offset

Register	Offset
DLLACR	C0h
DLLBCR	C4h

Function
Configures Flash A and B sample clock DLL.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19-17	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
16-15 REFPHASEGAP	Reference Clock Delay Line Phase Adjust Gap. REFPHASEGAP setting of 2h is recommended if DLLEN is set.
14-9 OVRDVAL	Target Clock Delay Line Override Value Configures the override value for the target clock line delay cell number. When OVRDEN = 1, the delay cell number in DLL is OVRDVAL + 1. See DLL configuration for sampling.
8 OVRDEN	Target Clock Delay Line Override Value Enable Enables the override value for the target clock line delay cell number. 0b - Disable 1b - Enable
7 —	Reserved
6-3 SLVDLYTARGET	Target Delay Line Configures the target delay line for the target. The delay target for target delay line is: ((SLVDLYTARGET+1) × 1/32 × clock cycle of reference clock (serial root clock). If serial root clock is ≥ 100 MHz, DLLEN is set to 1, OVRDEN is set to 0, then SLVDLYTARGET setting is up to flash parameters used.
2 —	Reserved
1 DLLRESET	DLL reset Forces a DLL reset. The forced reset causes the DLL to lose lock and recalibrate to detect a ref_clock half-period phase shift. The reset action is edge-triggered, so software must write 0 to this field after writing 1 to it (no delay limitation). 0b - No function 1b - Force DLL reset.
0 DLLEN	DLL Calibration Enable Enables DLL calibration. When DLL calibration is disabled, the delay cell number in the target delay line is always 1. When DLLxCR[OVRDEN] = 1, the target delay line is overridden and this field is ignored. 0b - Disable 1b - Enable

31.7.2.21 Status 0 (STS0)

Offset

Register	Offset
STS0	E0h

Function

Indicates the status of the internal state machine.

7-4 —	Reserved
3-2 ARBCMDSRC	ARB Command Source Indicates the trigger source of current command sequence that the arbitrator has granted. When ARB_CTL is not busy (STS0[ARBIDLE] = 1), the value of this field does not matter. 00b - Trigger source is AHB read command. 01b - Trigger source is AHB write command. 10b - Trigger source is IP command (by writing 1 to IPCMD[TRG]). 11b - Trigger source is a suspended command that has resumed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 ARBIDLE	ARB_CTL State Machine Idle Indicates whether the state machine in ARB_CTL is idle, or a command sequence that the arbitrator granted has not finished on the FlexSPI interface. When idle, no transaction is occurring on the FlexSPI interface (STS0[SEQIDLE] = 1). When waiting for the FlexSPI controller to become idle, poll this field instead of STS0[SEQIDLE]. 0b - Not idle 1b - Idle
0 SEQIDLE	SEQ_CTL State Machine Idle Indicates whether the state machine in SEQ_CTL is idle, or a command sequence is executing on the FlexSPI interface. 0b - Not idle 1b - Idle

31.7.2.22 Status 1 (STS1)

Offset

Register	Offset
STS1	E4h

Function
Indicates the error code of the AHB or IPS interface error response.

31.7.2.24 AHB Suspend Status (AHBSPNDSTS)

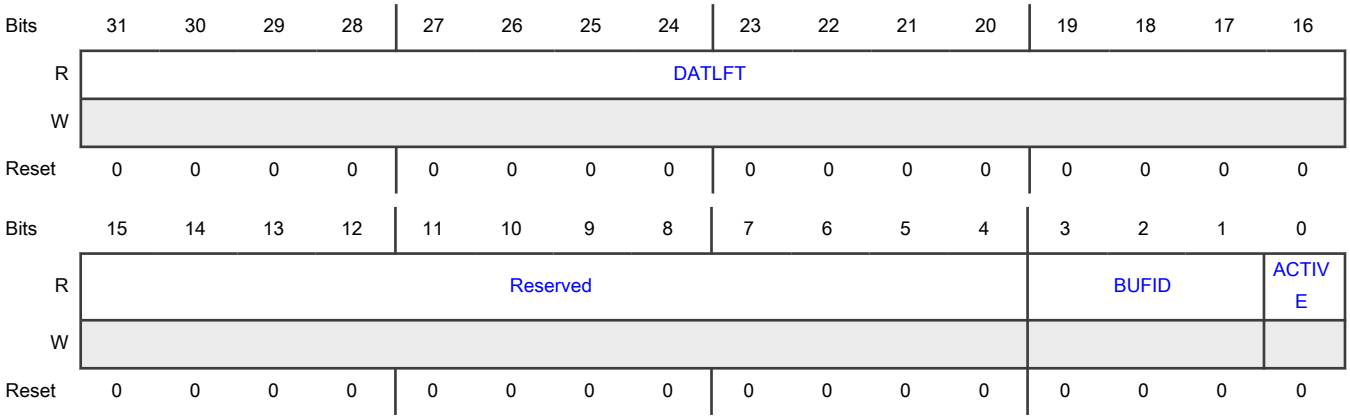
Offset

Register	Offset
AHBSPNDSTS	ECh

Function

Indicates the status of suspended AHB read prefetch command sequence. When an IP or AHB command is triggered while the arbitrator processes an AHB read sequence (prefetching additional data not for current AHB burst), the prefetch sequence is suspended. When there are no longer transactions on FlexSPI, the prefetch sequence may be resumed. FlexSPI saves only one AHB prefetch sequence. When a new prefetch sequence is suspended with an active sequence already suspended, the previous suspended sequence is removed and never resumed. See Command abort and suspend.

Diagram



Fields

Field	Function
31-16 DATLFT	Data Left Contains the data size remaining (in bytes) for a suspended command sequence.
15-4 —	Reserved
3-1 BUFID	AHB Receive Buffer ID for Suspended Command Sequence
0 ACTIVE	Active AHB Read Prefetch Suspended Indicates whether an AHB read prefetch command sequence has been suspended. 0b - No suspended AHB read prefetch command. 1b - An AHB read prefetch command sequence has been suspended.

31.7.2.25 IP Receive FIFO Status (IPRXFSTS)

Offset

Register	Offset
IPRXFSTS	F0h

Function

Indicates the status of IP receive FIFO.

31.8 AHB memory map definition

This section describes FlexSPI module AHB memory map in detail.

31.8.1 AHB memory map for serial flash memory and RAM access

AHB read and write access for serial flash and RAM memory are mapped to a specific address range. See the system memory map for specific address ranges supported.

AHB bus features supported for serial flash and RAM memory reading:

- Cacheable and non-cacheable access
- Prefetch enable and disable
- Burst size: 8, 16, 32, 64 bits
- All burst types: types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

AHB bus features for Serial RAM writing:

- Bufferable and Non-Bufferable access
- Burst size: 8, 16, 32, 64 bits
- All burst types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

See Flash memory access via AHB command for details about AHB access to serial flash memory and RAM.

31.8.2 AHB Memory Map for IP RX FIFO read access

See chip-specific section for the address range mapped for AHB read access.

AHB Bus feature supported for IP RX FIFO reading:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Reading data from IP receive FIFO for more details about IP RX FIFO reading.

31.8.3 AHB Memory Map for IP TX FIFO write access

See chip-specific section for the address range mapped for AHB write access.

AHB Bus feature supported for IP TX FIFO writing:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Writing data to IP transmit FIFO for more details about IP TX FIFO filling.

32.2 Overview

One unmistakable trend in embedded processor design is the increasing need for hardware support of cryptographic calculations required for system security. In particular, there are emerging customer requirements to protect application code and data stored in external memories in an encrypted form and have the embedded processor provide hardware support for "on-the-fly" decryption. As the name suggests, the external memory image of the code and data is always in an encrypted format, and, in response to processor references of the memory space, the memory image is decrypted on the fly, returning the original values to the requesting bus master.

In these applications, the standard Advanced Encryption Standard (AES) [1] is the preferred cryptographic symmetric key block cipher algorithm. The AES function operates on 128-bit (16 byte) data blocks with either 128-, 192- or 256-bit secret keys. For this form of code and data encryption, the AES-128 mode, that is, the use of a 128-bit key is deemed sufficient.

The AES algorithm specifies a variable number of "rounds" be performed in the cryptographic calculation, based on the size of the key. For a 128-bit key, the data is processed through a series of calculations requiring 10 rounds to complete. Each round performs four different data transformations: 1) byte substitution using a substitution table (S-box), 2) shifting rows of the state array by different offsets, 3) mixing the data within each column of the state array, and 4) adding a round key to the state.

Many typical AES hardware implementations perform a single round operation in 1-2 machine cycles, but the performance requirements associated with on-the-fly decryption dictate a far more aggressive implementation.

The on-the-fly decryption engine is combined with the QuadSPI external flash memory controller. The QuadSPI memory controller supports glueless external connections to a wide variety of industry standard external "SPI" flashes. These memories were initially developed as very low pin count alternatives to traditional NOR flash memories with their wide parallel data interfaces. Over time, the complexity of the SPI flash memories has increased (and this trend is continuing) and now, two bank, double data rate interfaces can supply 16 bits of flash data every cycle once the address and command have been sent and the basic access

has been performed. For a 100 MHz DDR Quad SPI external interface, the access time for a 4-beat, 64-bit, 32-byte burst fetch might generate an 18-4-4-4 response at the microprocessor pins. Given these access times, the latest generation of Quad SPI external flash devices provides a cost effective non-volatile memory solution that supports eXecute-in-Place (XiP) capabilities. Stated differently, the combined access speed of these external flash memories, coupled with internal processor-local cache memories, allow the application code to be executed directly from the external memory without the need to copy the code into another (faster) memory. This capability to execute directly from external flash without copying the code to another memory allows an easy migration from MCU to MPU configurations.

The resulting OTFAD engine adds ***zero cycles of additional latency*** to decrypt the code and data fetched from the external flash memory. The combination of the support for the CTR-AES128 mode plus an aggressive, pipelined implementation of the OTFAD performing up to 3 rounds in a single machine cycle allowing the engine to keep pace with the fastest data arrival rates. As a result, the OTFAD engine provides superior cryptographic decryption capabilities without compromising system performance for those embedded processor applications requiring this class of enhanced security.

32.2.1 Block diagram

Figure 229 shows the connection topology of the OTFAD and its relationship to the QuadSPI and its AHB RAM buffer.

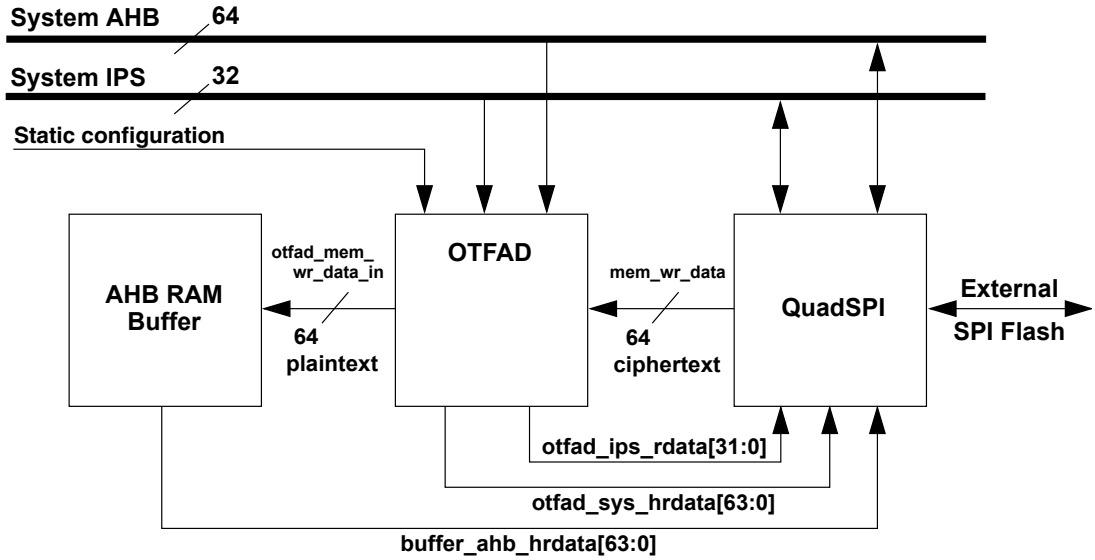

Figure 229. OTFAD and QuadSPI connection topology

32.2.2 Features

The key features of the OTFAD include:

- AES-128 Counter Mode On-the-Fly Decryption
  - 128-bit key and 128-bit data block sizes
    - 128-bit counter includes 64 bits of initialization vector + the 32-bit system address
  - Adds zero cycles of incremental latency for decryption when used with QuadSPI
  - Receives 64-bit encrypted data from QuadSPI, calculates decrypted data which is sent to AHB RAM buffer and bypassed back to system AHB read data bus
- Hardware support for 4 independent decryption segments, known as memory “contexts”
  - Each context has a unique 128-bit key, 64-bit counter and 64-bit memory region descriptor
- Hardware support for unwrapping "key blobs"

  - Key blob data structure prepended to the external flash memory image
  - Implements key blob unwrapping as defined by RFC3394 [3]
  - Each key blob data structure includes all the context registers
  - Initiated under software control after system reset is negated, if properly enabled
  - Unwraps the key blob data structure and loads the contents into the OTFAD registers
- Functionally acts as a slave submodule to the QuadSPI
  - Logically connected between the QuadSPI and its AHB RAM buffer
  - Private 64-bit data buses for encrypted (ciphertext) and decrypted (plaintext) data
- Hardware microarchitecture
  - Heavily pipelined AES engine, optimized for encryption, performing 3 rounds per cycle
  - 64-bit AHB connections for easy integration to system bus fabric and QuadSPI
  - Data storage for two 128-bit encrypted counters and three 64-bit decrypted data buffers
  - Optimized for {32,64}-bit WRAP4 bursts (CPU cache miss fetch size, typical DMA fetch size)

32.2.3 References and terminology

These documents provide specific references to the cryptographic functions supported by the OTFAD:

1. FIPS Publication 197, "Advanced Encryption Standard (AES)", U.S. Department of Commerce, National Institute of Standards and Technology (NIST), November 26, 2001.
2. NIST Special Publication 800-38A, "Recommendation for Block Cipher Modes of Operation: Methods and Techniques", U.S. Department of Commerce, National Institute of Standards and Technology (NIST), December 2001.
3. http://www.ietf.org/rfc/rfc3394.txt, "Advanced Encryption Standard (AES) Key Wrap Algorithm (RFC3394)", J. Schaad, R. Housley, September 2002.

There are numerous names and phrases that are commonly used in describing cryptographic functions. The following table provides a summary of the terms used in describing the OTFAD. It was mostly extracted from Section 4.1, "Definitions and Abbreviations" of [2].

Table 240. Cryptographic terms

Term	Definition
Block Cipher	A family of functions and their inverse functions that is parameterized by cryptographic keys; the functions map bit strings of a fixed length to bit strings of the same length.
Block Size	The number of bits in an input (or output) block of the block cipher. For OTFAD, this is 128 bits (16 bytes).
Ciphertext	Encrypted data.
CTR	Counter.
Cryptographic Key	A parameter used in the block cipher algorithm that determines the forward cipher operation and the inverse cipher operation.
Data Block (Block)	A sequence of bits whose length is the block size of the block cipher.

Table continues on the next page...

Table 240. Cryptographic terms (continued)

Term	Definition
Decryption (Deciphering)	The process of a confidentiality mode that transforms encrypted data into the original usable data.
ECB	Electronic Codebook.
Encrypted Counter (ECTR)	An output in the CTR-AES decryption process, generated by encrypting the unique counter value. Exclusive-OR'ed with the ciphertext to produce plaintext.
Encryption (Enciphering)	The process of a confidentiality mode that transforms usable data into an unreadable form.
Forward Cipher Function (Forward Cipher Operation)	One of the two functions of the block cipher algorithm that is selected by the cryptographic key.
Initialization Vector (IV)	A data block that some modes of operation require as an additional initial input.
Input Block	A data block that is an input to either the forward cipher function or the inverse cipher function of the block cipher algorithm.
Inverse Cipher Function (Inverse Cipher Operation)	The function that reverses the transformation of the forward cipher function when the same cryptographic key is used.
Key Encryption Key (KEK)	Cryptographic key used to wrap and unwrap key data.
Key Wrap	Key Wrap constructions are a class of symmetric encryption algorithms designed to encapsulate (encrypt) cryptographic key material. The constructions are typically built from standard primitives such as block ciphers and cryptographic hash functions.
Least Significant Bit(s)	The right-most bit(s) of a bit string.
Mode of Operation (Mode)	An algorithm for the cryptographic transformation of data that features a symmetric key block cipher algorithm.
Most Significant Bit(s)	The left-most bit(s) of a bit string.
Nonce	A value that is used only once.
OTP key, otp_key	One-time programmable key
Output Block	A data block that is an output of either the forward cipher function or the inverse cipher function of the block cipher algorithm.
Plaintext	Usable data that is formatted as input to a mode.

Table continues on the next page...

Table 240. Cryptographic terms (continued)

Term	Definition
RFC3394	The Advanced Encryption Standard (AES) Key Wrap Algorithm. Specifically defined to implement a key wrapping and unwrapping algorithm and originally intended for use by the Internet community.

32.3 Functional description

This section provides more details on the operation and implementation of the OTFAD.

32.3.1 Modes of operation

The OTFAD supports modes of operation as defined by input configuration (see Static configuration signals) and control signals. The operating mode is signaled in the SR and includes:

1. Logically Disabled Mode (LDM)

   This mode is entered immediately after reset by the assertion of a static configuration input signal, which is treated as the highest priority configuration signal. While in this mode, the OTFAD is logically disabled. Input data from the QuadSPI is simply passed through to the AHB RAM buffer and no data decryptions are performed. The OTFAD's programming model is inaccessible and all attempted accesses are error terminated. If the static configuration input signal is asserted, the OTFAD is always in this mode.

2. Normal Mode (NM)

   This mode is defined when the OTFAD is not in the logically disabled mode. In this mode, the OTFAD functions normally and is capable of performing data decryptions and/or data bypasses as it responds strictly to the memory transactions on its connected system buses. It should be noted the OTFAD operates in this mode regardless of the state of CR[GE]. The assertion of the global enable is required when the OTFAD is to perform data decryptions; if CR[GE] = 0, then the OTFAD simply bypasses all data fetched by the QuadSPI.

   The OTFAD's operating mode is encoded and visible in the SR[MODE] field. For more information, see OTFAD operating modes.

   In normal mode, as a memory-mapped device located in the core platform’s clock domain, it responds based on the memory addresses of its connected system buses. The slave peripheral bus may be used to access the OTFAD’s programming model to configure the module’s operation.

32.3.2 CTR-AES128 mode basics

When processing data fetched from an external memory, the OTFAD implements the CTR-AES128 mode for on-the-fly decryption.

The OTFAD engine implements a block cipher mode of operation, specifically supporting counter mode (CTR). The CTR mode "provides a confidentiality mode that features the application of the forward cipher (encryption) to a set of input blocks, called counters, to produce a sequence of output blocks that are exclusive-ORed with the plaintext to produce the ciphertext, and vice versa." [2]

The CTR-AES128 mode was selected for two reasons: 1) it produces a cryptographically stronger solution than the simple Electronic Cookbook (ECB) mode since each block in the sequence is different than every other block, even for the same input data, and 2) the definition of CTR mode allows the 128-bit counter values to include the system memory address of the referenced flash block and to be computed in advance of their actual usage to convert the ciphertext back into plaintext for the requesting bus master device in the microprocessor - typically the CPU itself.

As a result, the OTFAD module adds zero cycles of additional latency to decrypt the code and data fetched from the external flash memory. The combined support for the CTR-AES128 mode plus an aggressive, pipelined implementation of the OTFAD performing up to 3 rounds in a single machine cycle allows the engine to keep pace with the fastest data arrival rates.

The OTFAD module performs the decryption operation within the overall CTR-AES128 flow, as shown in Figure 230.

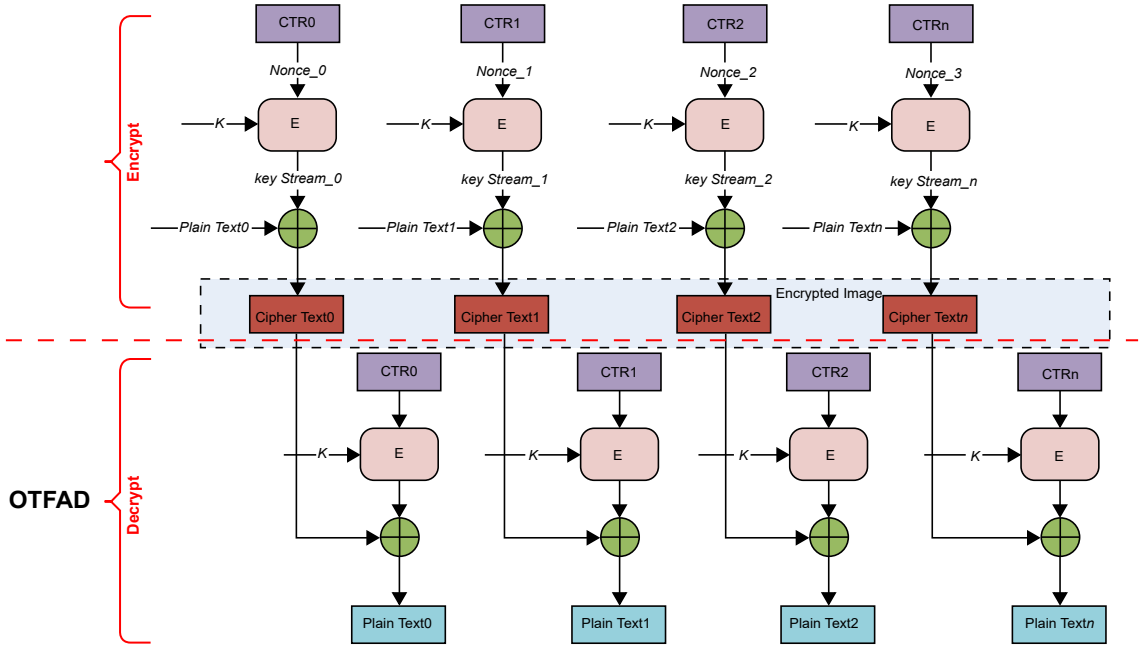

Figure 230. CTR-AES128 encrypt and decrypt overview

As shown in Figure 230, CTR-AES128 scheme combines a unique 128-bit counter (CTR*n*) with a 128-bit key (K) to encrypt (Ciphertext*n*) or decrypt (Plaintext*n*) each 128 bit data block.

Authorized software executes the "encrypt" portion to create the ciphertext image stored in the external memory, while the OTFAD module, in conjunction with the QuadSPI external memory controller, executes the "decrypt" portion.

Consider these two basic operations in more detail.

For encryption, the 0-modulo-16 byte system address is combined with 96 bits of counter information defined in the memory context registers to produce a unique 128-bit CTRn value for each data block. Specifically, the OTFAD's implementation defines the 128-bit CTR*n* for memory context "x" as the concatenation of 4 values:

```
CTRn_x[127-0] = {CTR_W0_x[C0...C3],                      // 32 bits of pre-programmed CTR

                 CTR_W1_x[C4...C7],                      // another 32 bits of CTR

                 CTR_W0_x[C0...C3] ^ CTR_W1_x[C4...C7],  // exclusive-OR of CTR values

                 systemAddress[31-4], 0000b}             // 0-modulo-16 system address
```

NOTE

The addresses used by both (software) encryption and OTFAD decryption are the physical system addresses associated with the QuadSPI, never the code alias addresses.

Software uses this CTR*n* value as the data input to the AES128 encryption process (E) to produce the Key_Stream_*n* output. The final step in encryption is to exclusive-OR the Key_Stream_n value with the data block's plaintext to create the 128-bit block of Ciphertextn which is stored in the external memory. This process is then repeated for each 16-byte data block of the code and data image needing encryption.

The OTFAD's decryption process begins by inputting the same CTRn value and same key K to the AES128 encryption process (E) to generate a 128-bit encrypted counter (ECTR*n*, not explicitly labeled in Figure 230). The ECTR*n* is exclusive-OR'ed with the Ciphertext*n* to produce the Plaintext*n*. The 128-bit key (K) is defined in the KEY_W[0-3]_x registers for context "x".

Since the encrypted counter value is *not* dependent on the ciphertext, it can be pre-calculated in response to a system bus access request such that the OTFAD only needs to perform the exclusive-OR once the ciphertext has been fetched from the external memory. This is the key concept in allowing the OTFAD to add zero incremental cycles of fetch latency.

For additional details on the OTFAD's processing during a 32-byte burst read, see Typical OTFAD CTR-AES128 decryption operation.

32.3.3 Microarchitecture overview

This section provides additional details on the hardware implementation. The following subsections provide details on the hardware decryption operations, and key blob processing. Refer to the block diagram of Figure 229.

32.3.3.1 Context determination

The first step in a CTR-AES128 decryption is the determination of the external memory context.

The OTFAD supports four memory contexts where each has its own 128-bit key, 64-bits of counter and a 64-bit memory region descriptor. The region descriptor includes start and end addresses plus three bits of control and configuration. See AES Region Descriptor Word0 (CTX0_RGD_W0 - CTX3_RGD_W0) and AES Region Descriptor Word1 (CTX0_RGD_W1 - CTX3_RGD_W1) for details.

NOTE

Always use an address range within the physical address space assigned to the QuadSPI module when defining an external memory context in a region descriptor, even if the system application uses the aliased area of the QuadSPI module.

The system address (SYSADDR) is compared to the start and end addresses of each context to determine a region "hit". To determine if the current reference hits in a given context, two magnitude comparators are used in conjunction with the region's start and end addresses. The boolean equation for this portion of the hit determination is defined as:

```
context_hit_n
      = ((addr[31:10] >= rgd_w0_n[srtaddr]) & (addr[31:10] <= rgd_w1_n[endaddr]))
      & rgd_w1_n[vld]
```

where `addr[*]` is the current system reference address, `rgd_w0_n[srtaddr]` and `rgd_w1_n[endaddr]` are the start and end addresses, and `rgd_w1_n[vld]` is the valid bit, all from context region descriptor n.

There are no hardware checks to verify that `rgd_w1_n[endaddr] ≥ rgd_w0_n[srtaddr]`, and it is software's responsibility to load appropriate values into these fields of the context region descriptor.

Recall the context memory regions are defined as modulo-1024 byte values to match the AMBA-AHB protocol requirement that no bursting transfer cross that boundary. The result is that each AHB transfer, regardless of access size or length, is limited to a single context for purposes of AES decryption.

Since each context has unique key and counter values, the OTFAD does not support any form of memory region overlap. For system accesses that hit in multiple contexts or no contexts, the fetched data is simply bypassed.

For accesses that hit in a single context, there is a separate register bit (RGD_W1_n[ADE]) that enables AES decryption or a simple bypass of the fetched data. Based on the hit determination and the state of the ADE indicator, the appropriate 128-bit key and 64 bit counter are selected from the context registers.

32.3.3.2 AES engine and encrypted counter generation

Once the appropriate context has been determined and the corresponding key and counter values selected, the OTFAD proceeds with the generation of the encrypted counters. Since the dominant QuadSPI system bus reference is a 64-bit WRAP4 burst transfer in response to a cache miss, the OTFAD is optimized for this transaction type. The subsequent discussion is described in terms of the 64-bit WRAP4 transfer.

As the 64-bit WRAP4 accesses 32 bytes of data, the OTFAD calculates two 128-bit encrypted counters since there are two AES128 data blocks referenced by this transaction. Since external flash SPI memories typically do not support any type of

address wrapping, the QuadSPI forces the external fetches to begin at the corresponding 0-modulo-size address. Accordingly, the OTFAD calculates the (first) encrypted counter associated with system address 0-modulo-32, and then the (second) address 16-modulo-32. The two encrypted counter calculations are performed in the AES Engine as the QuadSPI is making the external flash fetches.

As each encrypted counter is generated, the 128-bit value is stored in one of the two data registers connected to the AES Engine output.

Recall the OTFAD's AES Engine is heavily pipelined, performing up to 3 rounds per cycle, so the encryption speed (4 cycles total) matches the fastest data arrival rate.

Each AES round performs 4 different data transformations:

- Byte substitution
- State array row shift
- State array column mix
- Round key addition

Recall the QuadSPI initiated the external fetch at a 0-modulo-32 address, so as the encrypted data is fetched and presented to the OTFAD, it uses the first encrypted counter to perform the required exclusive-OR operation to generate the corresponding plaintext. The generated plaintext is output to the QuadSPI's AHB RAM buffer to be written into that memory (which operates as a small cache for QuadSPI accesses). See Figure 229. This process continues as each of the four fetches of the 64-bit WRAP4 burst is presented to the OTFAD, decrypted and then sent to the AHB RAM buffer.

32.3.3.3 Decrypted data buffer operation

Although the QuadSPI initiated its external fetches from a 0-modulo-32 address, the system bus transaction does not have any restrictions about its starting address and can begin at any of the 64-bit addresses. So, as the sequential fetched data is decrypted by the OTFAD, the resulting plaintext is also loaded into three 64-bit decrypted data buffers.

Depending on the original address of the system bus reference, the OTFAD either decrypts and outputs data to *both* the AHB RAM buffer and the system bus, or registers the decrypted data so it can be sourced later after the system bus address "wraps". Consider the following two examples: first, examine the sequencing on a 64-bit WRAP4 with an original address of 0x00, and a second example with a starting address of 0x18.

In both examples, the QuadSPI's fetch addresses are {0x00, 0x08, 0x10, 0x18}. In the first example, the system bus addresses are {0x00, 0x08, 0x10, 0x18}, while in the second example, the sequence is {0x18, 0x00, 0x08, 0x10}. See Table 241 for a description of the operations for these two examples.

Table 241. OTFAD and decrypted data buffer operation

QuadSPI fetch	SystemBus fetch	Description
Example 1		**64-bit WRAP4, miss @ 0×00**
0×00	0×00	OTFAD decrypts data and simultaneously sends to AHB RAM Buffer and SystemBus
0×08	0×08	OTFAD decrypts data and simultaneously sends to AHB RAM Buffer and SystemBus
0×10	0×10	OTFAD decrypts data and simultaneously sends to AHB RAM Buffer and SystemBus
0×18	0×18	OTFAD decrypts data and simultaneously sends to AHB RAM Buffer and SystemBus
Example 2		**64-bit WRAP4, miss @ 0×18**

Table continues on the next page...

Table 241. OTFAD and decrypted data buffer operation (continued)

QuadSPI fetch	SystemBus fetch	Description
0×00	0×18	OTFAD decrypts data, sends to AHB RAM Buffer and loads into Decrypted Data Buffer 0, SystemBus read is stalled
0×08	0×18	OTFAD decrypts data, sends to AHB RAM Buffer and loads into Decrypted Data Buffer 1, SystemBus read is stalled
0×10	0×18	OTFAD decrypts data, sends to AHB RAM Buffer and loads into Decrypted Data Buffer 2, SystemBus read is stalled
0×18	0×18	OTFAD decrypts data and simultaneously sends to AHB RAM Buffer and SystemBus
	0×00	OTFAD sources data from decrypted data buffer 0
	0×08	OTFAD sources data from decrypted data buffer 1
	0×10	OTFAD sources data from decrypted data buffer 2

The resulting behavior from the combined QuadSPI + OTFAD provides the best system performance. For longer burst sizes, for example, 64-bit WRAP8 and 64-bit WRAP16, the implemented number of decrypted data buffers is not sufficient to temporary store the entire burst. In these cases, the three OTFAD buffers are used in conjunction with "hits" from the AHB RAM Buffer to source the decrypted data back to the system bus.

A simplified (partial) timing diagram for the 64-bit WRAP4 burst of Example 1 is shown in Figure 231.

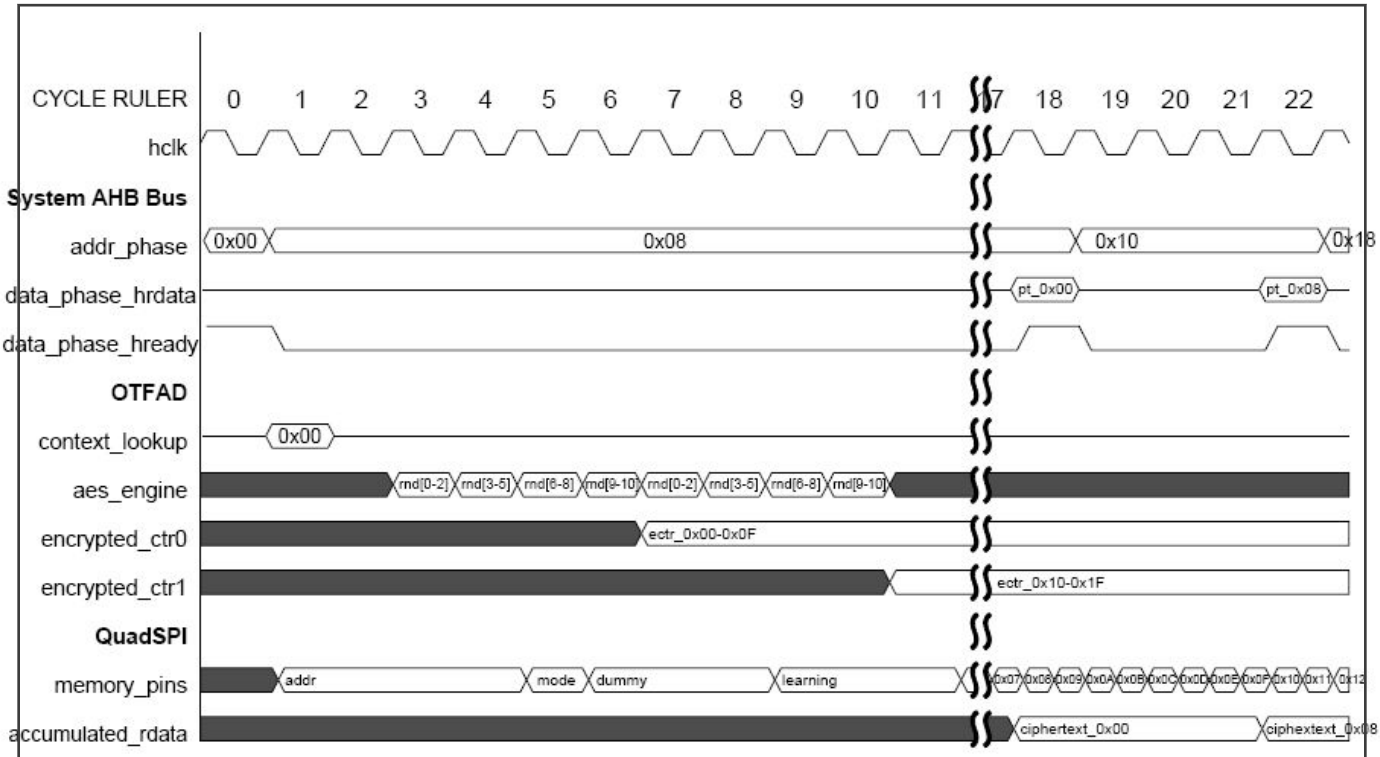

Figure 231. OTFAD 64-bit WRAP4 burst timing diagram

In Figure 231, the system AHB read data bus "pt_<burst_offset>" is meant to refer to decrypted plaintext data. The zero cycle incremental delay to perform the required CTR-AES128 decryption is visible in cycles 18 (the doubleword at burst offset 0×00) and 22 (doubleword at burst offset 0×08).

32.3.4 Clocking

This module has no special clocking considerations.

32.3.5 Interrupts

This module has no interrupts.

32.4 External signals

The OTFAD module does not directly support any external interfaces.

The internal interfaces include the address and attribute input signals from a standard 64-bit AMBA-AHB system bus and a 32-bit IPS slave peripheral bus for all programming model accesses, as shown in Figure 229.

The OTFAD receives the IPS input signals and generates a read data output which is sent to the QuadSPI where it is combined with local signals to form an IPS read data output as well as bus termination control signals. There are also three private 64-bit data buses: one input from the QuadSPI typically providing ciphertext and two outputs containing plaintext data after decryption - one sent to the AHB RAM buffer and another sent back to the QuadSPI for forwarding onto the system AHB read data bus. There is also a 64-bit read data bus from the AHB RAM buffer back to the QuadSPI for servicing system bus accesses which "hit" in the buffer.

32.4.1 Static configuration signals

The specific value settings of the static configuration signals are shown in Table 242.

Table 242. Static configuration signal settings

Configuration Signal	Description	Value
otfad_enable	Enable OTFAD decryption	connected
key_blob_enable	Enable key blob unwrap	connected
enb_otfad_kek_scramble	Enable KEK scramble during key blob processing	connected
restrict_otfad_ips	Restrict access to CR, SR	connected

32.5 Initialization

32.5.1 OTFAD configuration details

The operating configuration of the OTFAD is controlled by a number of static input signals (see Static configuration signals) plus programmable bits in the Control Register. All of the basic modes are discussed in Modes of operation and OTFAD operating modes. This section focuses on the configuration capabilities associated with Normal mode (SR[MODE] = 00).

There are three static input signals and three associated CR bits that define various configuration features of key blob processing. In all cases, the static input signal and the associated CR bit are logically summed (OR'd) together to form an “effective” configuration bit. The combined control is visible via a slave peripheral bus CR read. For a hierarchical view of increasing normal mode capabilities, see Table 243.

Table 243. OTFAD Normal mode configurations

otfad_enable | CR[GE]	key_blob_enable | CR[KBPE]	enb_otfad_kek_scramble | CR[KBSE]	Description
0	—	—	1) OTFAD operates with all data decryption disabled; QuadSPI fetched data is simply bypassed.
1	0	—	2) Basic OTFAD processing is enabled; decryptions are enabled based on context n “hit” and RGD_W1_n[ADE, VLD].
1	1	0	3) Same as #2, plus key blob unwrapping is enabled; KEK = otp_key[127:0].
1	1	1	4) Same as #3 but with KEK scrambling enabled; KEK = f(otp_key[127:0],key_scramble[31:0] key_scramble_align[7:0]).

In addition to the static configuration inputs and associated CR bits shown in Table 243 , there is one additional set: a static configuration input and CR[RRAE]. When either the configuration input signal or CR[RRAE] is asserted, only the CR and SR registers can be accessed; attempted accesses of all other registers are treated as read-as-zero, write-ignore.

For all configuration bits, the intended use case is to layer increasing OTFAD functionality into the system, first using the programmable CR indicators, and then, after the behavior has been fully debugged, to program the corresponding static input signals to define a “permanent” configuration. In the limit, the OTFAD fully initializes all four contexts via its key blob processing and requires no other system programming or interaction.

32.5.2 Key blob processing

32.5.2.1 Overview

Key blob processing is a mechanism where a preloaded data structure, wrapped using the RFC3394 standard, is fetched from the external flash memory after a system reset event (if properly enabled and initiated by the assertion of CSR[SKBP]), unwrapped by the OTFAD hardware and automatically loaded into the four memory context programming model registers. In this manner, the sensitive context data, for example, the 128-bit key and 64 bits of the counter, is unwrapped and handled entirely within the OTFAD.

32.5.2.2 Data structure

Each key blob data structure contains a 128-bit key, 64 bits of counter, a 64-bit memory region descriptor per context. See Figure 232. A C language description of the key blob data structure is presented in Figure 233.

SPI flash base + 64*n offset, n = 0-3

     unsigned char      expanded_wrap_data[8];

     unsigned char      unused_filler[16]

}    otfad_keyblob[4];
```

Figure 233. OTFAD context "n" key blob data structure

32.5.2.3 RFC3394 wrap & unwrap specification overview

The specification “is intended to satisfy the NIST key wrap requirement to: design a cryptographic algorithm called a key wrap that uses the Advanced Encryption Standard (AES) as a primitive to securely encrypt plaintext key(s) with any associated integrity information and data, such that the combination could be longer than the width of the AES block size (128 bits).” [3]

To clarify terminology, be aware that throughout the specification, “any data being wrapped will be referred to as the key data. It makes no difference to the algorithm whether the data being wrapped is a key; in fact there is often good reason to include other data with the key.”

The key used to perform the wrap and unwrap operations is known as the key encryption key (KEK). For the OTFAD, the KEK is a 128-bit key, derived from multiple input signals including a 128-bit one-time programmable key (OTP key), a 32-bit key scramble value and an 8-bit key scramble align control field.

The key wrap and unwrap functions are defined to operate on blocks of 64-bit data with the algorithm being specified in terms of “n” 64-bit data blocks. For the OTFAD implementation, n = 5 as this corresponds to the 40 byte key blob data structure. When executing a wrap operation, the algorithm performs 6 * n AES cipher operations; for the OTFAD implementation, this corresponds to 30 unique AES encryptions plus the generation of an additional 64 bits of wrapped data. This is labeled as Extended Wrap Data and `expanded_wrap_data` in Figure 232 and Figure 233.

When the OTFAD hardware unwraps a key blob, it performs 30 AES inverse cipher operations to recover the original data. Additionally, the wrap implementation uses a 64-bit initialization vector (IV) defined as 0xa6a6a6a6_a6a6a6a6. At the conclusion of the OTFAD's unwrapping, the key blob hardware performs a data integrity check to validate the correct IV was recovered. If the IV integrity check miscompares, then the OTFAD asserts the SR[KBERR] indicator. In the event of this type of error, the contents of the programming model registers of the context being unwrapped are cleared, leaving an invalid context, that is, RGD_W1_n[0] = RGD_W1_n[VLD] = 0.

32.5.2.4 Key blob KEK details

Recall the 128-bit key used in the key blob wrap and unwrap is defined as the key encryption key (KEK). The OTFAD implementation generates the KEK under control of four configuration input signals.

With the scrambled KEK as the output, the 32-bit scrambled key and 8-bit key alignment control provide an optional capability to further randomize the KEK value used for each context. The C language representation of this scrambling is shown in Figure 234.

```
void do_kek_scramble   (unsigned char otp_key[],
                        unsigned char key_scramble[],
                        unsigned int key_scramble_align,
                        unsigned int enb_otfad_kek_scramble,
                        unsigned int context_select,
                        unsigned char scrambled_kek[])
{
    // otp_key[16], key_scramble[4], scrambled_kek[16] are unsigned char arrays

    unsigned int i,j,k;             // local variables
    // copy otp_key[] input to scrambled_kek[] output
    for (i = 0; i < 16; i++) {
        scrambled_kek[i] = otp_key[i];
}
if (enb_otfad_kek_scramble == 1) {
    // retrieve the 2-bit align select from the 8-bit key_scramble_align
    // context_0_select = key_scramble_align[1:0]
    // context_1_select = key_scramble_align[3:2]
    // context_2_select = key_scramble_align[5:4]
    // context_3_select = key_scramble_align[7:6]
    j = 2 * context_select;
    k = (key_scramble_align & (3 << j)) >> j;

    // XOR 4-byte key_scramble[] into appropriate 4-bytes of scrambled_kek[] output
    for (i = 0; i < 4; i++) {
          scrambled_kek[4*k + i] ^= key_scramble[i];
    }
  }
}
```

Figure 234. Language KEK scramble function

32.5.2.5 Key blob wrap

For consistency in data handling as described in Data organization and endianness considerations, the following C code implements the required key blob wrap function using unsigned char input and output data arrays.

The plaintext view of the context's programming model registers is specified as a 40-element byte array. As previously discussed, the number of 64-bit data blocks (N) is 5. The key_wrap function receives the expanded KEK and the input byte array (`plaintext[*]`) as input data and generates the 48-byte wrapped output (`wrapped_ciphertext[*]`). See Figure 235 for the C code. The pseudo-code comments and internal variable names are taken from the RFC3394 spec.

```
extern unsigned char     iv[8];              //  64-bit initialization vector
extern unsigned char     wrapped_ciphertext[8*(N+1)];
extern unsigned char     unwrapped_plaintext[8*(N+1)];

unsigned char               a[8];               //  64-bit integrity check register
unsigned char               b[16];             // 128-bit temp register
unsigned char               r[8*(N+1)];     //   8-bit array of 64-bit registers

//************************************************************************
//************************************************************************

void do_aes128_key_wrap(unsigned char plaintext[],
                                  unsigned char wrapped_ciphertext[],
                                  unsigned int expanded_kek[])
{
     unsigned int           i,j;                  // loop counters
     unsigned char        in[16];             // 128-bit temporary plaintext input vector

     // step 1: initialize the byte-sized data variables
     // set A = IV
     // for i = 1 to n
     //      R[i] = P[i]

     a[0]      = iv[0];
     a[1]      = iv[1];
     a[2]      = iv[2];
     a[3]      = iv[3];
     a[4]      = iv[4];
     a[5]      = iv[5];
     a[6]      = iv[6];
     a[7]      = iv[7];

     for (i = 1; i <= N; i++) {
          r[8*i+ 0] = plaintext[8*(i-1)+ 0];
          r[8*i+ 1] = plaintext[8*(i-1)+ 1];
          r[8*i+ 2] = plaintext[8*(i-1)+ 2];
          r[8*i+ 3] = plaintext[8*(i-1)+ 3];
          r[8*i+ 4] = plaintext[8*(i-1)+ 4];
          r[8*i+ 5] = plaintext[8*(i-1)+ 5];
          r[8*i+ 6] = plaintext[8*(i-1)+ 6];
          r[8*i+ 7] = plaintext[8*(i-1)+ 7];
     }

     // step 2: calculate intermediate values
     // for j = 0 to 5
     //      for i = 1 to n
     //           B = AES(K, A | R[i])
     //           A = MSB(64, B) ^ (n*j)+i
```

```
//           R[i] = LSB(64, B)

for (j = 0; j <= 5; j++) {
     for (i = 1; i <= N; i++) {
          in[0]      = a[0];
          in[1]      = a[1];
          in[2]      = a[2];
          in[3]      = a[3];
          in[4]      = a[4];
          in[5]      = a[5];
          in[6]      = a[6];
          in[7]      = a[7];

          in[8]     = r[8*i+ 0];
          in[9]     = r[8*i+ 1];
          in[10]    = r[8*i+ 2];
          in[11]    = r[8*i+ 3];
          in[12]    = r[8*i+ 4];
          in[13]    = r[8*i+ 5];
          in[14]    = r[8*i+ 6];
          in[15]    = r[8*i+ 7];

          Cipher(in, expanded_kek, 10, b); // perform aes128 encryption

          a[0] = b[0];
          a[1] = b[1];
          a[2] = b[2];
          a[3] = b[3];
          a[4] = b[4];
          a[5] = b[5];
          a[6] = b[6];
          a[7] = b[7] ^ ((N*j)+i);

          r[8*i+ 0]= b[8];
          r[8*i+ 1]= b[9];
          r[8*i+ 2]= b[10];
          r[8*i+ 3]= b[11];
          r[8*i+ 4]= b[12];
          r[8*i+ 5]= b[13];
          r[8*i+ 6]= b[14];
          r[8*i+ 7]= b[15];
     } // end for (i)
} // end for (j)

// step 3: output the results
// set C[0] = A
// for i = 1 to n
// C[i] = R[i]

wrapped_ciphertext[0] = a[0];
wrapped_ciphertext[1] = a[1];
wrapped_ciphertext[2] = a[2];
wrapped_ciphertext[3] = a[3];
wrapped_ciphertext[4] = a[4];
wrapped_ciphertext[5] = a[5];
wrapped_ciphertext[6] = a[6];
wrapped_ciphertext[7] = a[7];

for (i = 1; i <= N; i++) {
     wrapped_ciphertext[8*i+ 0] = r[8*i+ 0];
```

```
            wrapped_ciphertext[8*i+ 1] = r[8*i+ 1];
            wrapped_ciphertext[8*i+ 2] = r[8*i+ 2];
            wrapped_ciphertext[8*i+ 3] = r[8*i+ 3];
            wrapped_ciphertext[8*i+ 4] = r[8*i+ 4];
            wrapped_ciphertext[8*i+ 5] = r[8*i+ 5];
            wrapped_ciphertext[8*i+ 6] = r[8*i+ 6];
            wrapped_ciphertext[8*i+ 7] = r[8*i+ 7];
        }
}
```

Figure 235. C code for OTFAD key blob wrap function (N = 5)

This C key blob wrap implementation has been verified using the (N = 2) “golden” data vectors included in the RFC3394 spec.

As a specific OTFAD example, consider the following key wrap. The data values are described as 32-bit values:

```
kek_w0                                  = 0x33221100
kek_w1                                  = 0x77665544
kek_w2                                  = 0xBBAA9988
kek_w3                                  = 0xFFEEDDCC

// context registers as plaintext
key_w0                                  = 0x03020100          // context key
key_w1                                  = 0x07060504
key_w2                                  = 0x0B0A0908
key_w3                                  = 0x0F0E0D0C
ctr_w0                                  = 0x67452301          // upper 64 bits of counter
ctr_w1                                  = 0xEFCDAB89
rgd_w0                                  = 0x68000000          // srtaddr
rgd_w1                                  = 0x6800FFFB          // endaddr + ade + vld
fill_w0                                 = 0x00000000          // must be all zeroes (always)
fill_w1                                 = 0x00000000          // must be all zeroes (always)
```

Recall the key_wrap function views the entire plaintext data structure as a 40-element *byte array*. For the data set, this means the data is input to the wrap function as:

```
unsigned char plaintext[]   ={0x00, 0x01, 0x02, 0x03,           // key_w0
                              0x04, 0x05, 0x06, 0x07,           // key_w1
                              0x08, 0x09, 0x0A, 0x0B,           // key_w2
                              0x0C, 0x0D, 0x0E, 0x0F,           // key_w3
                              0x01, 0x23, 0x45, 0x67,           // ctr_w0
                              0x89, 0xAB, 0xCD, 0xEF,           // ctr_w1
                              0x00, 0x00, 0x00, 0x68,           // rgd_w0
                              0xFB, 0xFF, 0x00, 0x68,           // rgd_w1
                              0x00, 0x00, 0x00, 0x00,           // fill_w0
                              0x00, 0x00, 0x00, 0x00,           // fill_w1
```

Execution of the key_wrap function generates the following 32-bit view of the 48 bytes of wrapped ciphertext:

```
wrapped_ciphertext_w0           = 0x291F461E
wrapped_ciphertext_w1           = 0x57EF591D
wrapped_ciphertext_w2           = 0x47FB5D63
wrapped_ciphertext_w3           = 0x5497F296
wrapped_ciphertext_w4           = 0xB2571B8C
```

```
wrapped_ciphertext_w5           = 0x57F5B22B
wrapped_ciphertext_w6           = 0x39D320ED
wrapped_ciphertext_w7           = 0xAA7C0A81
wrapped_ciphertext_w8           = 0x567F9FB8
wrapped_ciphertext_w9           = 0x91F32684
wrapped_ciphertext_w10          = 0xDD5E431E
wrapped_ciphertext_w11          = 0xC96FA1FF
```

The four wrapped key blobs are programmed into the external flash memory at the following addresses:

```
Context 0 key blob @ SPI_BASE_ADDRESS + 0x00
Context 1 key blob @ SPI_BASE_ADDRESS + 0x40
Context 2 key blob @ SPI_BASE_ADDRESS + 0x80
Context 3 key blob @ SPI_BASE_ADDRESS + 0xC0
```

If key blob processing is initiated by the assertion of CR[SKBP], the OTFAD fetches each key blob, unwraps it, loads the unwrapped plaintext into the appropriate context registers. *This process is repeated for all four key blobs.*

NOTE

The processing of all four key blobs requires that each plaintext data structure must be programmed with “valid data”. For unused key blobs, an all-zero plaintext data structure defines a valid, but disabled, context.

32.5.2.6 Key blob unwrap

After a system reset event and the assertion of CR[SKBP], if key blob processing is enabled, the QuadSPI fetches the context 0 key blob from the external flash memory, sends the data to the OTFAD which automatically performs the required key blob unwrap function and loads the recovered plaintext data into the context 0 programming model registers. When the context 0 unwrap is completed, the OTFAD continues with the unwrap for context 1, then context 2 and finally context 3. As previously noted, OTFAD always processes key blob data for all four contexts when enabled. Software is responsible for creating and programming the external memory with a valid key wrap for all four contexts, regardless of their actual usage.

The OTFAD’s key blob processing logic provides a hardware implementation of the unwrap process. This section presents a C function of the comparable software implementation. The unwrap operation performs 6 * n AES inverse cipher decryptions (a total of 30 decryptions) to recover the original plaintext data structure.

The input data for the unwrap is specified as a 48-element byte array. Recall from the previous description, the key wrap process generates an “extra” 8 bytes of wrapped_ciphertext output. The number of 64-bit data blocks (N = n) remains as 5. The key_unwrap function receives the expanded KEK and the wrapped data byte array (wrapped_ciphertext[*]) as input data and recovers the original 40-byte unwrapped plaintext data structure (unwrapped_plaintext[*]). See Figure 236 for the C code. As before, the pseudo-code comments and internal variable names are taken from the RFC3394 spec.

```
extern unsigned char      iv[8];            // 64-bit initialization vector
extern unsigned char      wrapped_ciphertext[8*(N+1)];
extern unsigned char      unwrapped_plaintext[8*(N+1)];

unsigned char               a[8];             // 64-bit integrity check register
unsigned char               b[16];           // 128-bit temp register
unsigned char               r[8*(N+1)];    // 8-bit array of 64-bit registers

//************************************************************************
//************************************************************************

unsigned int do_aes128_key_unwrap(unsigned char wrapped_ciphertext[],
                                  unsigned char unwrapped_plaintext[],
                                  unsigned int expanded_kek[])
{
```

```
     signed int             i,j;           // loop counters
     unsigned char      in[16];           // 128-bit temporary ciphertext input vector

     // step 1: initialize variables
     // set A = C[0]
     // for i = 1 to n
     // R[i] = C[i]
     a[0]      = wrapped_ciphertext[0];
     a[1]      = wrapped_ciphertext[1];
     a[2]      = wrapped_ciphertext[2];
     a[3]      = wrapped_ciphertext[3];
     a[4]      = wrapped_ciphertext[4];
     a[5]      = wrapped_ciphertext[5];
     a[6]      = wrapped_ciphertext[6];
     a[7]      = wrapped_ciphertext[7];

     for (i = 1; i <= N; i++) {
          r[8*i+ 0] = wrapped_ciphertext[8*i+ 0];
          r[8*i+ 1] = wrapped_ciphertext[8*i+ 1];
          r[8*i+ 2] = wrapped_ciphertext[8*i+ 2];
          r[8*i+ 3] = wrapped_ciphertext[8*i+ 3];
          r[8*i+ 4] = wrapped_ciphertext[8*i+ 4];
          r[8*i+ 5] = wrapped_ciphertext[8*i+ 5];
          r[8*i+ 6] = wrapped_ciphertext[8*i+ 6];
          r[8*i+ 7] = wrapped_ciphertext[8*i+ 7];
     }

     // step 2: calculate intermediate values
     // for j = 5 to 0
     // for i = n to 1
     // B = AES-1(K, (A ^ (n*j+i) | R[i])
     // A = MSB(64, B)
     // R[i] = LSB(64, B)

     for (j = 5; j >= 0; j--) {
          for (i = N; i >= 1; i--) {
               in[0]      = a[0];
               in[1]      = a[1];
               in[2]      = a[2];

```

```
}
```

Figure 236. C Code for OTFAD Key Blob Unwrap Function (N = 5)

32.5.2.7 Key blob error detection and reporting

At the conclusion of the key unwrap, there is a data integrity check performed to validate the original plaintext data structure has been correctly recovered. As shown in the last section of code in Figure 236, eight bytes of the unwrapped_plaintext[*] are compared with the initialization vector (iv[*]). The OTFAD initialization vector uses the default value specified in RFC3394, the static constant 0xa6a6a6a6_a6a6a6a6.

If the IV integrity check miscompares, then the OTFAD asserts the SR[KBERR] indicator. This indicator is typically configured as an interrupt request to signal the device of the detected error. Additionally, the appropriate bits in SR[CTXIE] and SR[CTXER] are set. The assertion of both SR[CTXIEn] and SR[CTXERn] indicates an integrity check error for context n.

When this error is detected, the contents of the programming model registers of the specific context being unwrapped are cleared, leaving an invalid context, that is, RGD_W1_n[0] = RGD_W1_n[VLD] = 0.

32.6 Application information

32.6.1 OTFAD operating modes

As discussed in Modes of operation, the OTFAD supports two modes of operation as defined by input configuration and control signals. The mode states and their transitions are shown in Figure 237. The states include Normal Mode (00) and Logically Disabled Mode (11). The operating mode state information is visible in the SR[MODE] field.

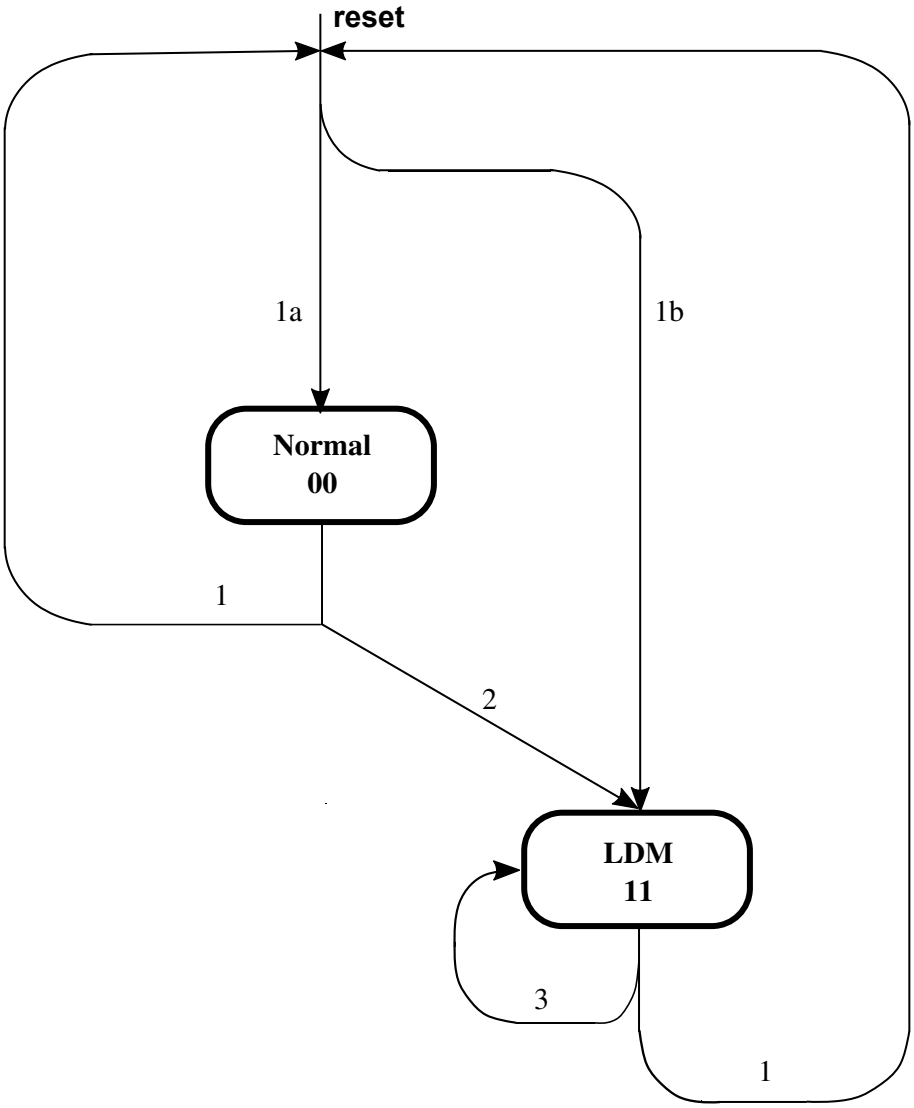

Figure 237. OTFAD Operating Mode States and Transitions

The state transitions are defined in Table 244.

Table 244. OTFAD mode state transitions

Current state	Next state	Transition	Description
–	Normal, LDM	1 -> 1a, 1b	Any reset event initializes the OTFAD mode state.
–	Normal	1a	Any reset, combined with a negated otfad_disable_override configuration input signal, unconditionally forces OTFAD into the Normal state.
–	LDM	1b	Any reset, combined with an asserted otfad_disable_override configuration input signal, unconditionally forces OTFAD into the LDM state.

Table continues on the next page...

Table 244. OTFAD mode state transitions (continued)

Current state	Next state	Transition	Description
Normal	LDM	2	A transition from Normal to LDM is made when the boolean expression (cr[fldm] & ~reset) is true.
LDM	LDM	3	The LDM is retained while reset is not asserted.

32.6.2 Typical OTFAD CTR-AES128 decryption operation

The dominant use case in normal mode is expected to be CTR-AES128 decryption operations performed in response to a 64-bit WRAP4 burst read in response to a processor cache miss. The following C code is a simplified representation of the OTFAD processing associated with this use case. The ciphertext fetched by the QuadSPI is the `spi_ciphertext[32]` byte array, and the resulting decrypted data is `otfad_plaintext[32]`. See Figure 238.

```
void KeyExpansion (unsigned char ckey[], int nbits, unsigned int w[]);
void Cipher (unsigned char cin[], unsigned int w[], int nr, unsigned char cout[]);

unsigned char                          spi_ciphertext[32];
unsigned char                          otfad_plaintext[32];

union context_regs {
     volatile unsigned char      key[16];
     volatile unsigned char      ctr[8];
     volatile unsigned int      rgd[2];
     volatile unsigned int      unused_filler[8]
     } otfad_context[4];

void otfad_32byte_processing (unsigned int sys_addr,
                                        unsigned char spi_ciphertext[],
                                        unsigned char otfad_plaintext[])

{
     unsigned int      i;
     unsigned int      ctx_hit;
     unsigned int      combined_hits;
     unsigned int      enable_decryption;
     unsigned int      w[44];           // expanded key
     unsigned char      encrypted_ctr[2][16];
     unsigned char      temp_ctr[16];
     unsigned int      local_addr;
     unsigned int      hit_addr;

     local_addr &= 0xfffffff0;      // force byte addr to 0-mod-16 (aes size)
     hit_addr = local_addr & 0xfffffc00;      // force hit addr to 0-mod-1K

     // context determination
     combined_hits = 0;           // 4-bit hit indicator: ctx{3,2,1,0}
     for (i = 0; i < 4; i++) {
          ctx_hit = ((hit_addr >= otfad_context[i].rgd[0])      // srtaddr
               & (hit_addr <= otfad_context[i].rgd[1]))      // endaddr
               & (otfad_context[i].rgd[i] & 1);           // vld
          combined_hits += (ctx_hit << i);
     }
     // check combined_hits to determine if decryption is enabled
     enable_decryption = 0;
```

```
switch (combined_hits) {
     case 1:                    // ctx0 hit
          ctx_hit = 0;
          if ((otfad_context[0].rgd[1] & 2) != 0) {      // ade
               enable_decryption = 1;
          }
          break;
     case 2:                    // ctx1 hit
          ctx_hit = 1;
          if ((otfad_context[1].rgd[1] & 2) != 0) {      // ade
               enable_decryption = 1;
          }
          break;
     case 4:                    // ctx2 hit
          ctx_hit = 2;
          if ((otfad_context[2].rgd[1] & 2) != 0) {      // ade
               enable_decryption = 1;
          }
          break;
     case 8:                    // ctx3 hit
          ctx_hit = 3;
          if ((otfad_context[3].rgd[1] & 2) != 0) {      // ade
               enable_decryption = 1;
          }
          break;
     default:                    // none or multiple ctx hits
          ctx_hit = 0;
               enable_decryption = 0;           // no decryption, bypass data
     break;
     }

// clear encrypted counters
for (i = 0; i < 16; i++) {
     encrypted_ctr[0][i] = 0;
     encrypted_ctr[1][i] = 0;
}

// if decryption is enabled, calculate two encrypted counter values
if (enable_decryption == 1) {
     KeyExpansion (&otfad_context[ctx_hit].key[0], 128, w);
     // encrypt the counter for the 1st 16 bytes
          // step 1: generate the 128-bit counter
          // step 1a: first 8 bytes are taken directly from context.ctr[]
          for (i = 0; i < 8; i++) {
               temp_ctr[i] = otfad_context[ctx_hit].ctr[i];
          }
          // step 1b: next 4 bytes are xor of ctr[0-3] ^ ctr[4-7]
          temp_ctr[8] = temp_ctr[0] ^ temp_ctr[4];
          temp_ctr[9] = temp_ctr[1] ^ temp_ctr[5];
          temp_ctr[10] = temp_ctr[2] ^ temp_ctr[6];
          temp_ctr[11] = temp_ctr[3] ^ temp_ctr[7];
          // step 1c: final 4 bytes are local_addr
          temp_ctr[12] = (local_addr & 0xff000000) >> 24;
          temp_ctr[13] = (local_addr & 0x00ff0000) >> 16;
          temp_ctr[14] = (local_addr & 0x0000ff00) >> 8;
          temp_ctr[15] = (local_addr & 0x000000ff);

     // step 2: perform the 1st counter encryption
     Cipher (&temp_ctr[0], w, 10, &encrypted_ctr[0][0]);
```

```
          // encrypt the counter for the 2nd 16 bytes
               // step 1a: increment the local_addr by 16
               local_addr += 16;
               // step 1b: final 4 bytes of counter are new local_addr
               temp_ctr[12] = (local_addr & 0xff000000) >> 24;
               temp_ctr[13] = (local_addr & 0x00ff0000) >> 16;
               temp_ctr[14] = (local_addr & 0x0000ff00) >> 8;
               temp_ctr[15] = (local_addr & 0x000000ff);

          // step 2: perform the 2nd counter encryption
          Cipher (&temp_ctr[0], w, 10, &encrypted_ctr[1][0]);
          }

          // generate plaintext data = f(encrypted_ctr[][], spi_ciphertext[])
          // for bypass operations, the encrypted_ctr[][] = 0, so plain = cipher
          // since spi_ciphertext arrives 8 bytes at a time, code does the same...
          for (i = 0; i < 8; i++)
               otfad_plaintext[i]      = encrypted_ctr[0][i]      ^ spi_ciphertext[i];
          for (i = 8; i < 16; i++)
               otfad_plaintext[i]      = encrypted_ctr[0][i]      ^ spi_ciphertext[i];
          for (i = 16; i < 24; i++)
               otfad_plaintext[i]      = encrypted_ctr[1][i-16]      ^ spi_ciphertext[i];
          for (i = 24; i < 32; i++)
               otfad_plaintext[i]      = encrypted_ctr[1][i-16]      ^ spi_ciphertext[i];
}
```

Figure 238. Basic OTFAD 32-byte decryption processing

32.7 Register descriptions and data organization

The registers of the OTFAD programming model can only be accessed while in secure privileged mode. Unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted accesses in a different operating mode, using unsupported write data sizes, writes to read-only resources, or to reserved spaces are terminated with an error unless noted otherwise. See also Data organization and endianness considerations.

The programming model associated with each memory context follows the same data structure as the key blobs stored in the external flash.

In the registers named *CTXn_<regname>*, the "n" is the context number.

Note that in a fully secure operating environment, the *CTXn_<regname>* registers are loaded by the OTFAD hardware during key blob processing. Software access in this environment may be considerably reduced based on the state of the CR[RRAE] and static chip configuration inputs (see Static configuration signals). For the affected *CTXn_<regname>* registers, their access values are shown as "RW" in this section; however, these registers are treated as read-as-zero/write-ignore (RAZ/WI) if operating in the restricted register access mode (CR[RRAE] = 1 and SR[RRAM] = 1). See the individual register descriptions for more information.

32.7.1.2 Control Register (CR)

Offset

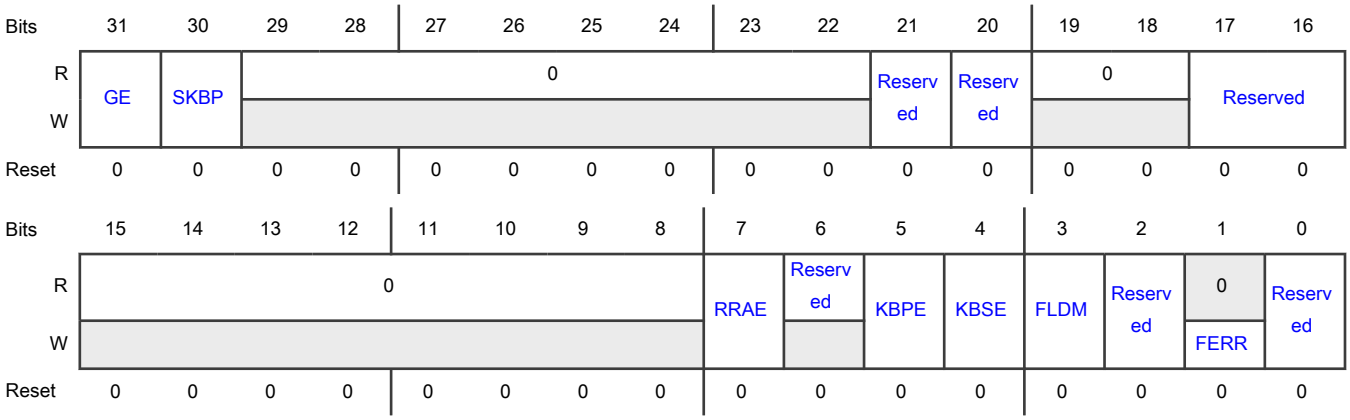
Register	Offset
CR	C00h

Function

This register defines the operating configuration of the OTFAD including a global enable indicator.

There are 5 register fields in the CR that control the OTFAD configuration, especially related to key blob processing after the negation of system reset. These fields (GE, RRAE, KBCE, KBPE, KBSE) are generated based on both the contents of the CR plus static input configuration signals. For all 5 bits, the contents of the CR flag is logically summed (OR'd) with the static input configuration signals to form the actual control used by the OTFAD. Reads of the CR return the logical summation of these configuration controls. Entry into the LDM mode clears all 5 indicators. The initiation of properly-enabled key blob processing is enabled by the assertion of the SKBP flag. For more details, see OTFAD configuration details.

Diagram



Fields

Field	Function
31 GE	Global OTFAD Enable This field enables the OTFAD operation.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The global enabled/disabled state of the OTFAD module is based on the logical OR of the value written to GE and the value of the static input *otfad_enable*. For example, if *otfad_enable* = 1, the OTFAD module is always enabled. Reading GE returns the global enabled/disabled state of the OTFAD module. It is cleared by entry into the LDM mode. 0b - OTFAD has decryption disabled. All data fetched by the QuadSPI bypasses OTFAD processing. 1b - OTFAD has decryption enabled, and processes data fetched by the QuadSPI as defined by the hardware configuration.
30 SKBP	Start key blob processing When set and key blob processing enabled (as signaled by CR[KBPE] asserted), the OTFAD initiates key blob processing. The simultaneous assertion of SKBP and KBPE initiates key blob processing. **NOTE** When the static configuration input key_blob_enable is set on a given device, key blob processing is always enabled. To initiate key blob processing in this case, software needs to set SKBP only once after a hard reset. 0b - Key blob processing is not initiated. 1b - Properly-enabled key blob processing is initiated.
29-22 —	Reserved
21 —	Reserved **NOTE** When writing to this register, software must write 0 to this field. This field always reads as zero.
20 —	Reserved **NOTE** When accessing this register, software must write 0 to this field and ignore read values.
19-18 —	Reserved
17-16 —	Reserved **NOTE** When accessing this register, software must write 0s to this field and ignore read values.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7 RRAE	Restricted Register Access Enable If this bit is asserted, only the CR, SR and optional MDPC registers can be accessed; attempted accesses of all other registers are treated as RAZ/WI (read-as-zero/write-ignore). This indicator is sticky; once set, it remains asserted until the next system reset, when it is cleared. It is also asserted by entry into the LDM mode. The value of this field is reflected in the SR[RRAM] flag. 0b - Register access is fully enabled. The OTFAD programming model registers can be accessed “normally”. 1b - Register access is restricted and only the CR, SR and optional MDPC registers can be accessed; others are treated as RAZ/WI.
6 —	Reserved
5 KBPE	Key Blob Processing Enable This field determines if key blob processing is enabled after a system reset. The assertion of CR[SKBP] determines when key blob processing is initiated. It is cleared by entry into the LDM mode. The combined {GE,KBPE,KBSE} control fields define the operating configuration of the OTFAD as: • If {GE,KBPE,KBSE} = 0--, OTFAD has decryption disabled • If {GE,KBPE,KBSE} = 10-, OTFAD has decryption enabled, but no key blob processing • If {GE,KBPE,KBSE} = 110, OTFAD has decryption enabled, key blob processing is enabled, no KEK scrambling • If {GE,KBPE,KBSE} = 111, OTFAD has decryption enabled, key blob processing is enabled with KEK scrambling enabled 0b - Key blob processing is disabled. 1b - Key blob processing is enabled.
4 KBSE	Key Blob Scramble Enable This field determines if key blob KEK scrambling is enabled after a system reset. It is cleared by entry into the LDM mode. The combined {GE,KBPE,KBSE} control bits define the operating configuration of the OTFAD as: • If {GE,KBPE,KBSE} = 0--, OTFAD has decryption disabled • If {GE,KBPE,KBSE} = 10-, OTFAD has decryption enabled, but no key blob processing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If {GE,KBPE,KBSE} = 110, OTFAD has decryption enabled, key blob processing is enabled, no KEK scrambling • If {GE,KBPE,KBSE} = 111, OTFAD has decryption enabled, key blob processing is enabled with KEK scrambling enabled 0b - Key blob KEK scrambling is disabled. 1b - Key blob KEK scrambling is enabled.
3 FLDM	Force Logically Disabled Mode This field is intended to provide a mechanism for software testing of entry into the Logically Disabled Mode (LDM). This indicator is sticky; once set, it remains asserted until the next system reset, when it is cleared. 0b - No effect on the operating mode. 1b - Force entry into LDM after a write with this data bit set. SR[MODE] signals the operating mode.
2 —	Reserved Reserved. Writes to this field should be '0' only.
1 FERR	Force Error A write that sets this field forces the OTFAD's key blob error flag (SR[KBERR]) to be asserted. It is intended to provide a mechanism for software testing of a key blob error handling routine. This field always reads as zero. 0b - No effect on the SR[KBERE] indicator. 1b - SR[KBERR] is immediately set after a write with this data bit set.
0 —	Reserved **NOTE** When writing to this register, software must write 0 for this bit.

32.7.1.3 Status Register (SR)

Offset

Register	Offset
SR	C04h

Function
This register provides OTFAD status information.

Diagram

R	0				CTXER3	CTXER2	CTXER1	CTXER0	NCTX				MODE		MDPCP	KBERR
W																W1C
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Fields

Field	Function
31 KBD	Key Blob Processing Done This field signals the OTFAD has completed key blob processing. This indicator is sticky, that is, once set, it remains set until the next system reset. This field and KBPE can be used for polling purposes to indicate the OTFAD has completed key blob processing. The status of any errors detected during key blob processing is reflected in SR[KBERR] and does not affect the KBD indicator. 0b - Key blob processing was not enabled, or is not complete. 1b - Key blob processing was enabled and is complete.
30 KBPE	Key Blob Processing Enable This field signals if the OTFAD is configured to perform key blob processing. It is a read-only version of the CR[KBPE] indicator. It is included here so it and KBD can easily be used for polling purposes to indicate the OTFAD has completed key blob processing. The combined 2-bit field {KBD,KBPE} signals the key blob processing state: • If {KBD,KBPE} = 00, key blob processing is disabled • If {KBD,KBPE} = 01, key blob processing is enabled, but not yet complete • If {KBD,KBPE} = 11, key blob processing is enabled and complete 0b - Key blob processing is not enabled. 1b - Key blob processing is enabled.
29 GEM	Global Enable Mode This indicator signals the global enabled/disabled state of the OTFAD. This flag is identical to the read value of CR[GE]. 0b - OTFAD is disabled. All data fetched by the QuadSPI bypasses OTFAD processing. 1b - OTFAD is enabled, and processes data fetched by the QuadSPI as defined by the hardware configuration.

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 RRAM	Restricted Register Access Mode This indicator signals that accesses to the slave peripheral bus are operating in a restricted mode, where only the CR, SR and optional MDPC registers can be referenced. This access mode can be defined by the assertion of CR[RRAE] = 1. Attempted accesses to other registers are treated as RAZ/WI. This flag is identical to the read value of CR[RRAE]. 0b - Register access is fully enabled. The OTFAD programming model registers can be accessed “normally”. 1b - Register access is restricted and only the CR, SR and optional MDPC registers can be accessed; others are treated as RAZ/WI.
27-24 HRL	Hardware Revision Level This field reads as zero.
23-20 —	Reserved
19-16 CTXIEn	Context Integrity Error CTXIE*n* signals an integrity error was detected in the corresponding context *n* during key blob processing as signaled by SR[KBERR] = 1. The integrity check specifically refers to the final state after the key unwrapping completes. The assertion of CTXIE*n* always means the comparable CTXER*n* flag is also set. This field is cleared if SR[KBERR] was set in response to a write asserting CR[FERR]. It is also cleared when SR[KBERR] is cleared. 0b - No key blob integrity error was detected for context “n”. 1b - A key blob integrity error was detected in context “n”.
15-12 —	Reserved
11-8 CTXERn	Context Error CTXER*n* signals an error was detected in the corresponding context *n* during key blob processing as signaled by SR[KBERR] = 1. The error condition from the combined CTXER and CTXIE indicators is defined as: • If CTXER*n* = 0 and CTXIE*n* = -, then no error • If CTXER*n* = 1 and CTXIE*n* = 0, then no error • If CTXER*n* = 1 and CTXIE*n* = 1, then integrity error This field is cleared if SR[KBERR] was set in response to a write asserting CR[FERR]. It is also cleared when SR[KBERR] is cleared. 0b - No key blob error was detected for context “n”. 1b - A key blob integrity error might have been detected in context “n”.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-4 NCTX	Number of Contexts This field signals the number of implemented hardware contexts. It reads as 4.
3-2 MODE	Operating Mode This field specifies the OTFAD's operating mode. Input configuration and control signals force entry from normal mode (NRM) into a special operating mode (LDM) . See Modes of operation for more details. 00b - Operating in Normal mode (NRM) 01b - Unused (reserved) 10b - Unused (reserved) 11b - Operating in Logically Disabled Mode (LDM)
1 MDPCP	MDPC Present This field signals the presence of the Multi-Dimensional Parity Checker. For this device, it always has the value 0.
0 KBERR	Key Blob Error This field signals that one or more errors were detected during key blob processing. SR[CTXER] provides the details on which contexts detected errors. This indicator can also be set by writing CR[FERR] = 1 (for testing purposes). 0b - No key blob error detected. 1b - One or more key blob errors has been detected.

32.7.1.4 AES Key Word (CTX0_KEY0 - CTX3_KEY3)

Offset

For n = 0 to 3; m = 0 to 3:

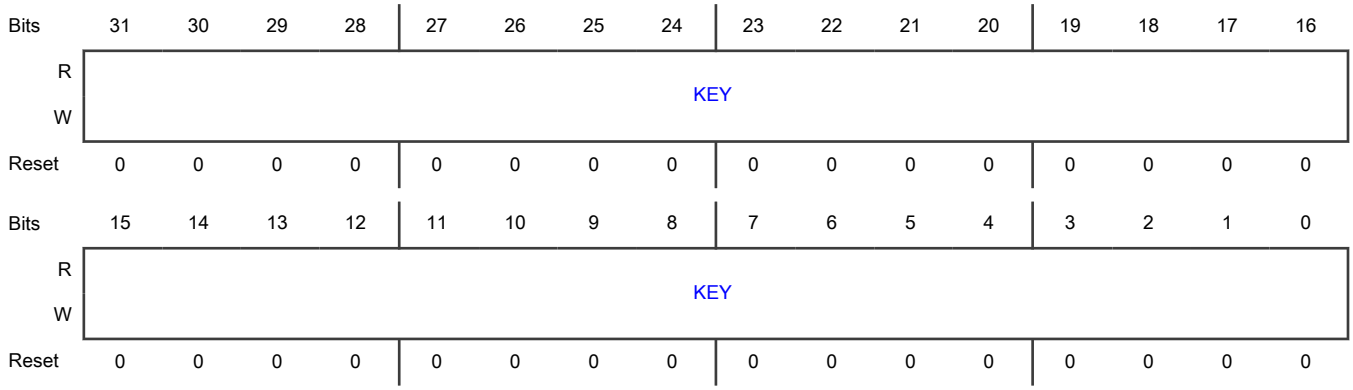
Register	Offset
CTXn_KEYm	D00h + (n × 40h) + (m × 4h)

Function

The CTXn_KEYm registers provide a 2-dimensional data structure for local OTFAD storage of the 128-bit key for context "n". There are four consecutive memory-mapped register words containing the key used for the AES calculations associated with the given context. The programming model view of the CTXn_KEYm registers is a little-endian 16-element byte data array, while the 128-bit key is defined as the concatenation of {A0, A1, A2,..., A14, A15}.

If SR[RRAM] = 1 indicating restricted register access mode, access to these registers is treated as read-as-zero, write-ignored (RAZ/WI).

Diagram



Fields

Field	Function
31-0 KEY	AES Key The key is typically loaded as the corresponding key blob is unwrapped; alternatively, if enabled, it can be written using the slave peripheral bus. The four consecutive little-endian memory-mapped registers provide 128 bits of key storage. Word0: KEY[31:0][A03, A02, A01, A00] Word1: KEY[31:0][A07, A06, A05, A04] Word2: KEY[31:0][A11, A10, A09, A08] Word3: KEY[31:0][A15, A14, A13, A12]

32.7.1.5 AES Counter Word (CTX0_CTR0 - CTX3_CTR1)

Offset

For n = 0 to 3; m = 0 to 1:

Register	Offset
CTXn_CTRm	D10h + (n × 40h) + (m × 4h)

Function

The CTXn_CTRm registers provide a 2-dimensional data structure for local OTFAD storage of 64 bits of the counter value for context “n”. There are two consecutive memory-mapped register words defining the upper 96 bits of the counter used for the AES calculations associated with the given context.

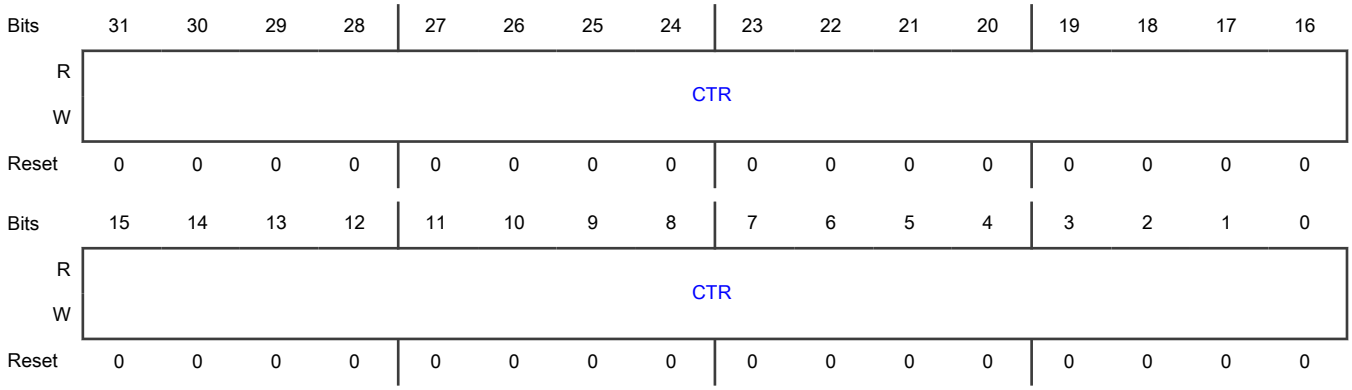
The programming model view of the CTXn_CTRm registers is a little-endian 8-element byte data array.

The entire 128-bit counter value is defined as the concatenation of four 32-bit values:

CTR[127–0] = {CTR0[C0...C3], CTR1[C4...C7], CTR0[C0...C3] ^ CTR1[C4...C7], systemAddress[31–4], 0h}

If SR[RRAM] = 1 indicating restricted register access mode, access to these registers is treated as read-as-zero, write-ignored (RAZ/WI).

Diagram



Fields

Field	Function
31-0 CTR	AES Counter The upper 64 bits of the counter are typically loaded as the corresponding key blob is unwrapped; alternatively, if enabled, it can be written using the slave peripheral bus. The two consecutive memory-mapped registers directly provide the upper 64 bits of counter storage. Word0: CTR[31:0][C3, C2, C1, C0] Word1: CTR[31:0][C7, C6, C5, C4] The third 32-bit portion of the CTR is formed by exclusive-or'ing the upper 64 bits of the counter as two 32-bit values, while the least-significant portion of the counter is the 32-bit 0-modulo-16 byte system address of the external flash memory. CTR[C0...C15] = {CTR[C0...C7], CTR[C0...C3] ^ CTR[C4...C7], systemAddress[31–4], 0h}

32.7.1.6 AES Region Descriptor Word0 (CTX0_RGD_W0 - CTX3_RGD_W0)

Offset

Register	Offset
CTX0_RGD_W0	D18h
CTX1_RGD_W0	D58h
CTX2_RGD_W0	D98h
CTX3_RGD_W0	DD8h

Function

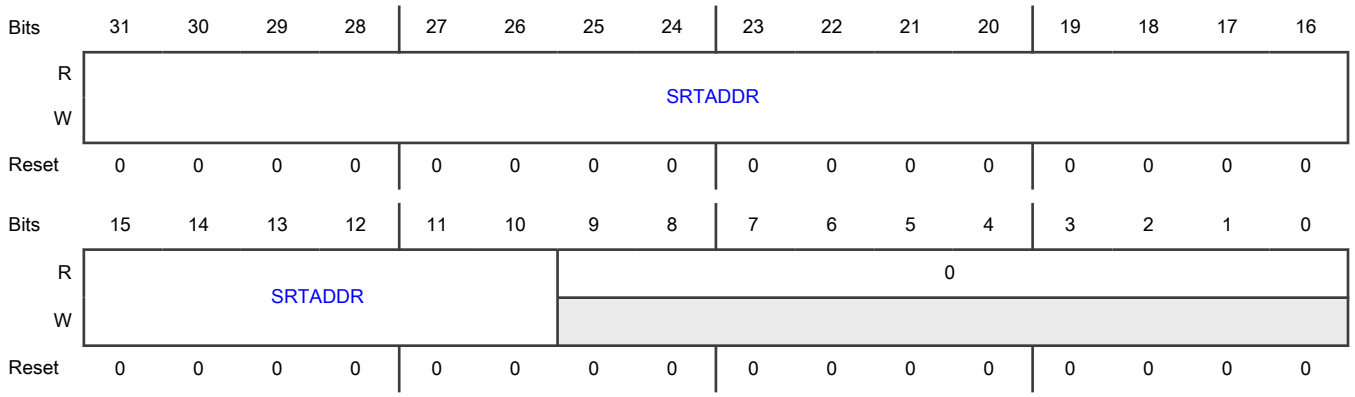
The CTXn_RGD_W0 registers provide a 2-dimensional data structure for local OTFAD storage of 64 bits of memory region descriptor for context “n”. There are two consecutive memory-mapped register words defining the starting and ending addresses for the external flash memory region associated with the given context.

Each memory region context defines a specified section of external flash memory associated with the given context and its associated 128-bit key and 128-bit counter values.

The context memory regions are defined as modulo-1024 bytes to match the AMBA-AHB protocol requirement that no bursting transfer cross that boundary. As a result, no AHB command, either single transfer, or any type of wrapping or incrementing burst, can cross any 1 KB boundary. This means that any AHB transfer is limited to a single context for purposes of AES decryption.

If SR[RRAM] = 1 indicating restricted register access mode, access to these registers is treated as read-as-zero, write-ignored (RAZ/WI).

Diagram



Fields

Field	Function
31-10 SRTADDR	Start Address This field defines the most significant bits of the 0-modulo-1024 byte start address of the memory region for context n.
9-0 —	Reserved

32.7.1.7 AES Region Descriptor Word1 (CTX0_RGD_W1 - CTX3_RGD_W1)

Offset

Register	Offset
CTX0_RGD_W1	D1Ch
CTX1_RGD_W1	D5Ch
CTX2_RGD_W1	D9Ch
CTX3_RGD_W1	DDCh

Function

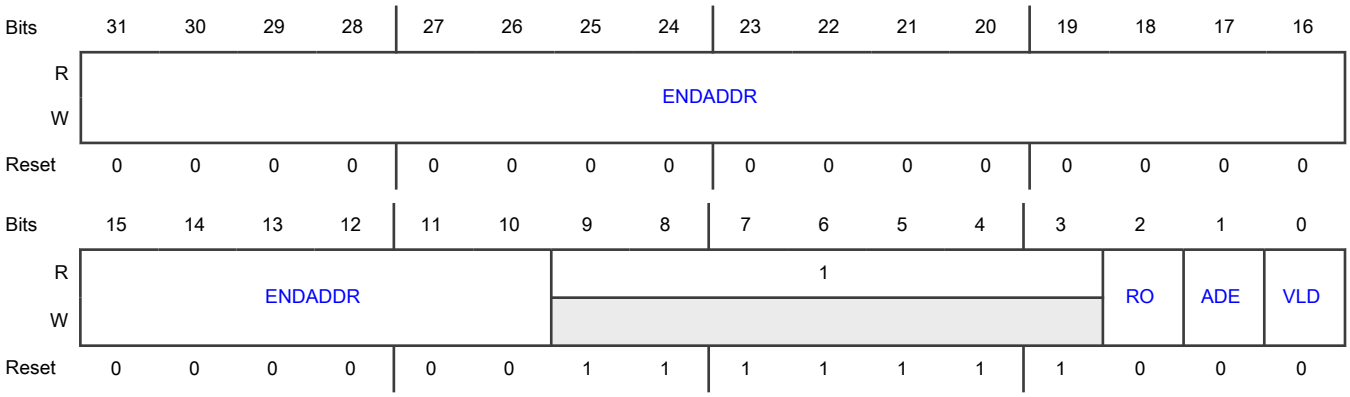
The CTXn_RGD_W1 registers provide a 2-dimensional data structure for local OTFAD storage of 64 bits of memory region descriptor for context “n”. There are two consecutive memory-mapped register words defining the starting and ending addresses for the external flash memory region associated with the given context.

Each memory region context defines a specified section of external flash memory associated with the given context and its associated 128-bit key and 128-bit counter values.

The context memory regions are defined as modulo-1024 bytes to match the AMBA-AHB protocol requirement that no bursting transfer cross that boundary. As a result, no AHB command, either single transfer, or any type of wrapping or incrementing burst, can cross any 1 KB boundary. This means that any AHB transfer is limited to a single context for purposes of AES decryption.

If SR[RRAM] = 1 indicating restricted register access mode, access to these registers is treated as read-as-zero, write-ignored (RAZ/WI).

Diagram



Fields

Field	Function
31-10 ENDADDR	End Address This field defines the most significant bits of the 1023-modulo-1024 byte end address of the memory region for context n.
9-3 —	Reserved
2 RO	Read-Only This field signals that the entire set of context registers (CTXn_KEY[0-3], CTXn_CTR[0-1], CTXn_RGD_W[0-1] are read-only and cannot be modified. This field is sticky and remains asserted until the next system reset. SR[RRAM] provides another level of register access control and is independent of the RO indicator. 0b - The context registers can be accessed normally (as defined by SR[RRAM]). 1b - The context registers are read-only and accesses may be further restricted based on SR[RRAM].
1 ADE	AES Decryption Enable. For accesses hitting in a valid context, this bit indicates if the fetched data is to be decrypted or simply bypassed. 0b - Bypass the fetched data. 1b - Perform the CTR-AES128 mode decryption on the fetched data.
0	Valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
VLD	This field signals if the context is valid or not. 0b - Context is invalid. 1b - Context is valid.

32.7.2 Data organization and endianness considerations

OTFAD implements a little-endian memory organization. This affects the data organization of its programming model registers as well as how it handles memory data.

The OTFAD module follows the standard AES definition on data organization and mapping into the bit-oriented cryptographic algorithms. To review these definitions, recall the following:

"The basic unit for processing the AES algorithm is a byte, a sequence of eight bits treated as single entity. The input, output and Cipher Key bit sequences... are processed as arrays of bytes that are formed by dividing these sequences into groups of eight contiguous bits to form arrays of bytes" [1, pp. 8-9].

Further, if an input, output or key is denoted by the AES standard convention as "a", the bytes in the resulting array can be described as a[*n*], where 0 < *n* < 16. The mapping of this byte array data into the required 128-bit sequence produces:

```
data[127:0] = {a[0], a[1], a[2],..., a[14], a[15]}
```

That is, the 128-bit data is formed as the concatenation of the 0th through the 15th byte array element. The OTFAD hardware performs all the required byte "swapping" to convert the programming model view of the keys and counters, etc. from the little endian 32-bit view into the organization required by the AES standard. As an example, consider the mapping of the 128-bit key from its 32-bit programming model registers for the OTFAD AES engine. Let the little-endian memory image of the 128-bit key be defined as a byte-sized, sixteen element array, a[16]. Note A[16] is intended to be an alternate, but equivalent, description:

```
AES Key Word 0[31:0] = {a[ 3], a[ 2], a[ 1], a[ 0]}

AES Key Word 1[31:0] = {a[ 7], a[ 6], a[ 5], a[ 4]}

AES Key Word 2[31:0] = {a[11], a[10], a[ 9], a[ 8]}

AES Key Word 3[31:0] = {a[15], a[14], a[13], a[12]}
```

This data is converted by the OTFAD into a 128-bit key of the form:

```
AES Key[127:0] = {a[0], a[1], a[2], a[3],..., a[12], a[13], a[14], a[15]}
```

Next, consider the 64-bit counter as an eight element byte array, c[8]:

```
AES Counter Word 0[31:0] = {c[ 3], c[ 2], c[ 1], c[ 0]}

AES Counter Word 1[31:0] = {c[ 7], c[ 6], c[ 5], c[ 4]}
```

Before being used, this data is reorganized into the required 128-bit counter value of the form:

```
AES Counter[127:0]  = {c[ 0], c[ 1], c[ 2], c[ 3],  // bits[127:96]

                       c[ 4], c[ 5], c[ 6], c[ 7],  // bits[ 95:64]

                      {c[ 0], c[ 1], c[ 2], c[ 3]}
```

```
                    ^ {c[ 4], c[ 5], c[ 6], c[ 7]}, // bits[ 63:32]

                      sysAddr[31:4], 4'b0000}      // bits[ 31: 0]
```

To summarize, the OTFAD programming model registers are organized as little-endian byte-size data arrays and the hardware automatically reorganizes the register data into the 128-bit formats required by AES.

Note that since OTFAD is a little-endian design, it processes each 64 bits of external memory data fetched by the QuadSPI using the following mapping for data byte array:

```
mem_wr_data[63:0]

= {data[i+7],data[i+6],data[i+5],data[i+4],data[i+3],data[i+2],data[i+1],data[i+0]}
```

Chapter 33
Ultra Secured Digital Host Controller (uSDHC)

33.1 Chip-specific uSDHC Information

Table 245. Reference links to related information

Topic	Related module	Reference
System memory map	-	System memory map
Clocking	CCM ANADIG - XTALOSC, PLL	Clock Generation Overview Clock Control Module (CCM) ANADIG - Crystal Oscillator (XTALOSC) ANADIG - Phase Locked Loop (PLL)
Power management	ANADIG - PMU	Power management ANADIG - Power Management Unit (PMU)
Signal multiplexing	IOMUXC BLK_CTRL_AON BLK_CTRL_WAKEUP	External signals and pin multiplexing IOMUX Controller (IOMUXC) Block Control, AON Domain (BLK_CTRL_AON) Block Control, Wakeup Domain (BLK_CTRL_WAKEUP)
Interrupts, DMA Events and XBAR Assignments	-	Interrupts, DMA Events and XBAR Assignments

There are two instances of uSDHC instances. The suggested frequency for uSDHC1 is 200 MHz with boot support for SD/SDIO 3.0 compliance with 200 MHz SDR signaling to support up to 100 MB/s. The suggested frequency for uSDHC2 is 400 MHz with boot support for eMMC 5.1 compliance with HS400 DDR signaling to support up to 400 MB/s.

33.2 Overview

uSDHC provides the interface between the host system and the eMMC, SD card, and SDIO as shown in Figure 240. The module acts as a bridge, passing host bus transactions to the eMMC, SD card, and SDIO by sending commands and performing data accesses to/from the cards. It handles the SD card/SDIO/eMMC protocols at the transmission level.

33.2.1 Block diagram

The following figure illustrates the block diagram for uSDHC. Dual port SRAM is FIFO for write/read. For more information, see Data buffer.

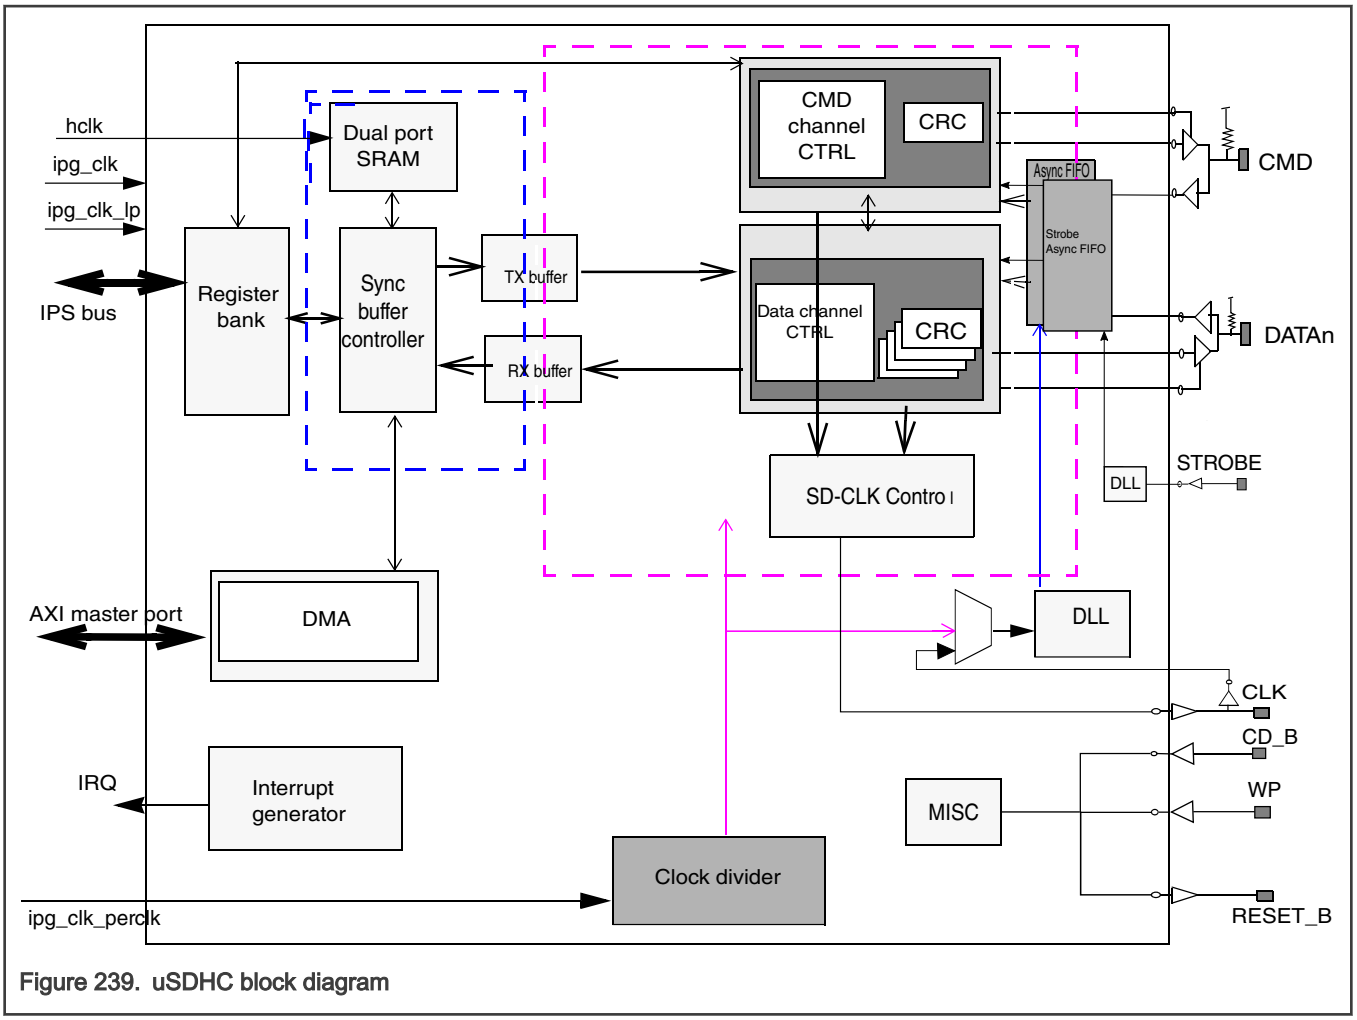


Figure 239. uSDHC block diagram

The figure below shows the System connection of uSDHC:

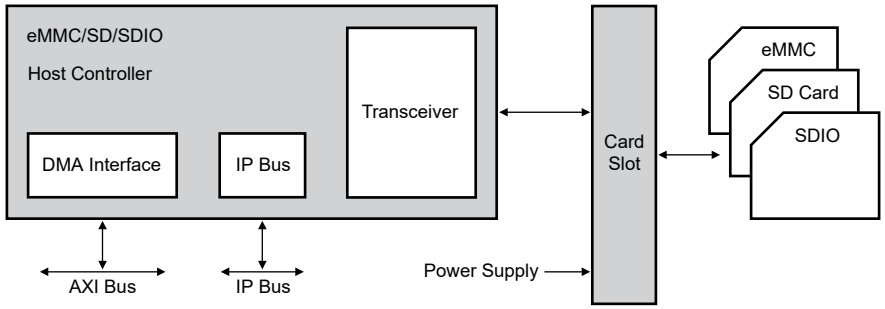

Figure 240. System connection of uSDHC

The following are brief descriptions of the cards supported by uSDHC:

- The Embedded MultiMediaCard (eMMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous eMMC were based on a 7-pin serial bus with a single data pin, while the new high speed eMMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.
- The Secure Digital Card (SD) is an evolution of the old eMMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic

devices. The physical form factor, pin assignment, and data transfer protocol are backward compatible with the old eMMC (with some additions).

- Under the SD protocol, system connection can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI (Secure Digital Music Initiative) standard. The I/O card, which is also known as SDIO, provides high-speed data I/O with low-power consumption for mobile electronic devices.

33.2.2 Features

The list given below shows the features of the uSDHC module:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the eMMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0/5.1
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, eMMC, MMC plus, and MMC RS cards
- For card bus clock frequency: See the product Data Sheet for the clock frequency of each supported mode.
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit eMMC modes
  - Up to 832 Mbps of data transfer for SDIO using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 832 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 1600 Mbps of data transfer for eMMC using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 3200 Mbps of data transfer for eMMC using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Embodies two fully configurable 256x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Supports voltage selection by configuring vendor-specific register bit
- Supports Advanced DMA to perform linked memory access
- Supports Command Queue mechanism

NOTE

This block can support all the above-listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

33.3 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AXI interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

33.3.1 Modes and operations

33.3.1.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- eMMC 1-bit
- eMMC 4-bit
- eMMC 8-bit
- Identification mode (up to 400 kHz)
- eMMC full-speed mode (up to 26 MHz)
- eMMC high-speed mode (up to 52 MHz)
- eMMC HS200 mode (up to 200 MHz)
- eMMC HS400 mode (200 MHz both edges)
- eMMC DDR mode (52 MHz both edges)
- SD card or SDIO full-speed mode (up to 25 MHz)
- SD card or SDIO high-speed mode (up to 50 MHz)
- SD card or SDIO UHS-I mode (up to 208 or 100 MHz in SDR mode, up to 50 MHz in the DDR mode)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

33.3.2 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced extensible interface (AXI) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock). The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. When using internal DMA mode, The watermark level for read should be configured to 16 and watermark level for write should be configured to integral multiple of 16 to get max AXI bus throughput. The next figure provides the uSDHC buffer scheme as buffer control and buffer RAM wrapper.

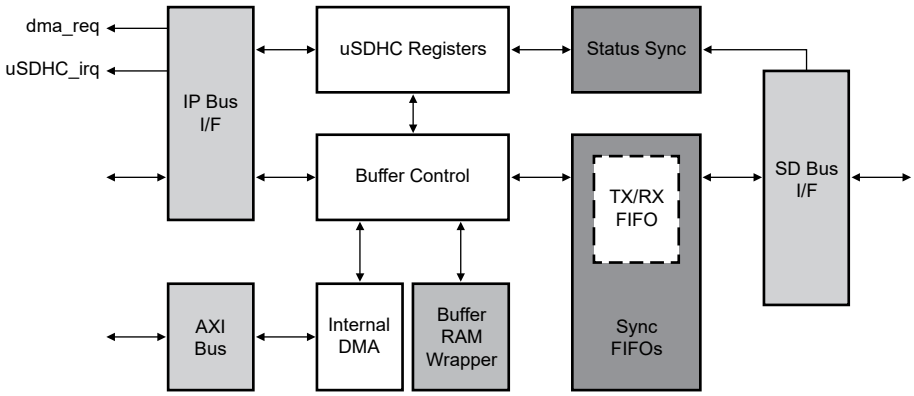

Figure 241. uSDHC buffer scheme

Here are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AXI bus.

For a read operation, when there are more words in the buffer than the amount set in WTMK_LVL[RD_WML], the internal DMA starts fetching data over the AXI bus.

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

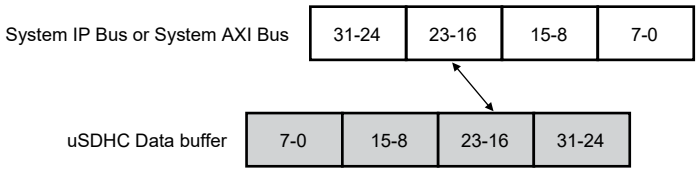

Figure 242. Data swap between system bus and uSDHC data buffer in the byte little endian mode

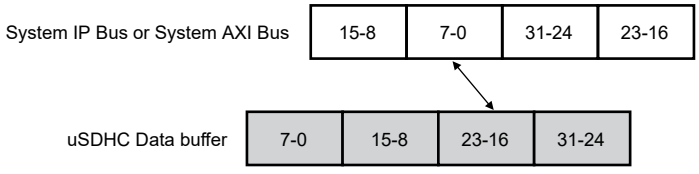

Figure 243. Data swap between system bus and uSDHC data buffer in half word big endian mode

33.3.2.1 Write operation sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in WTMK_LVL[WR_WML] and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the buffer has been filled with the number of words set in the WR_WML register. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

33.3.2.2 Read operation sequence

There are 2 ways to read data from the buffer when the data is received from the card:

- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset (in register RSTD) for data be applied before the transfer is restarted.

For any read transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

33.3.2.3 Data buffer and block size

In the uSDHC module, the data buffer can hold up to 256 words (32-bit) and the watermark levels for write and read can be configured accordingly. The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. The host driver may configure the value according to the system and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes). That means, the largest block size is 512 bytes.

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the software side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

33.3.2.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in multiples of block size. If the total data length cannot be divided evenly into a multiple of the block size, then there are two options to transfer the data. These two options depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data. Only for write, uSDHC sends data to the card.

See Figure 244 for an example showing the division of large data transfers, assuming a kind of WLAN SDIO that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

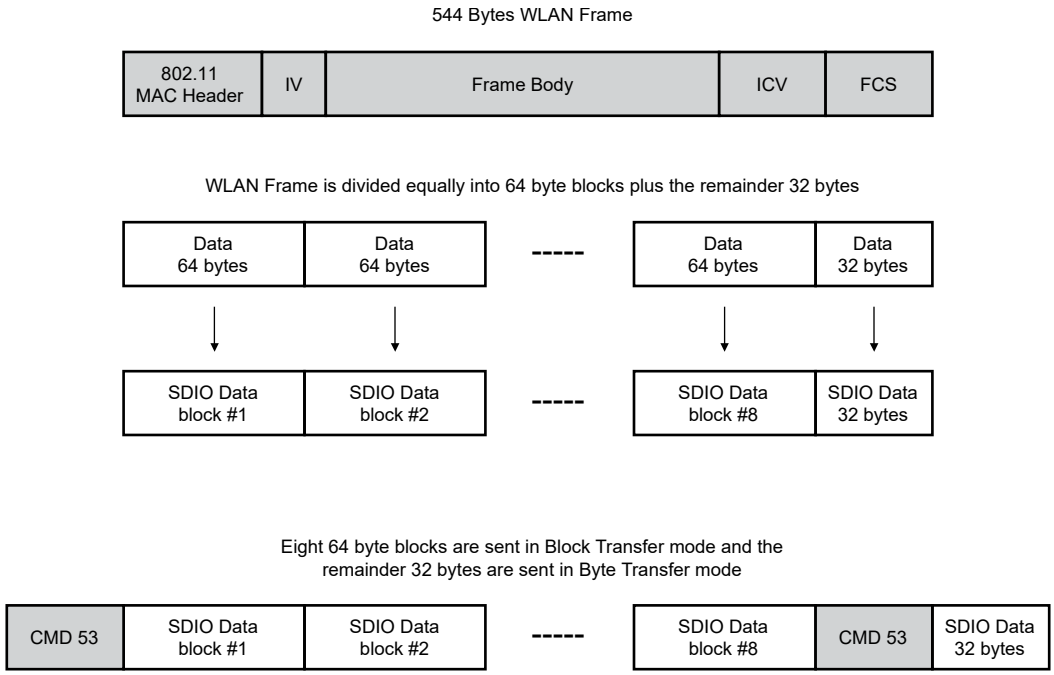

Figure 244. Example for dividing large data transfers

33.3.3 DMA AXI interface

The internal DMA implements a DMA engine and the AXI master. When the internal DMA is enabled, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See Figure 245 for an illustration of the DMA AXI interface block.

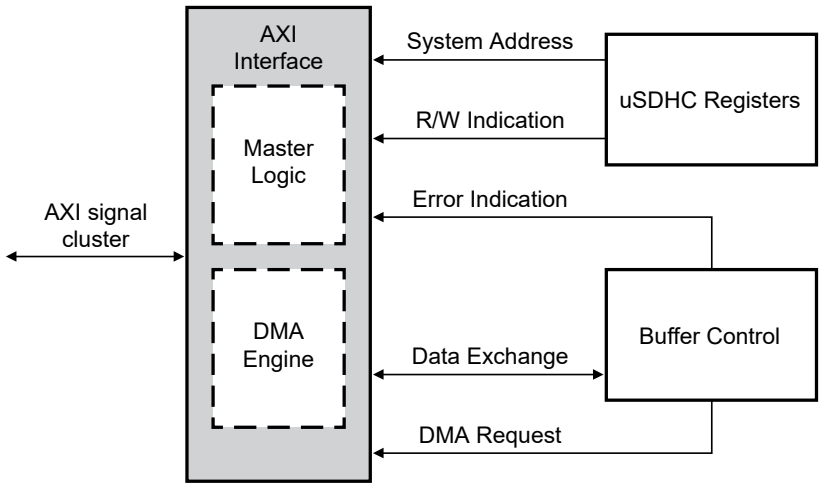

Figure 245. DMA AXI interface block

33.3.3.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AXI interface.

The delay in response from the internal DMA engine depends on the system AXI bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always automatically set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the watermark level set to six words (24 bytes). After the first burst transfer, if there are greater than or equal to two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to transfer for the current block is ceiling((31 - 6 * 4) / 4) = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

33.3.3.2 AXI master interface

It is possible that the internal AXI DMA engine could fail during the data transfer. Upon detection of an AXI bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block.

33.3.3.3 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 eliminates the restriction so that the data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

33.3.3.3.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor (new in ADMA2)
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type descriptor triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so the tran type descriptor itself can start a data transfer.

See Figure 246 for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 246. Format of the ADMA1 descriptor table

See Figure 247 for the concept and access method of the descriptor table for ADMA1.

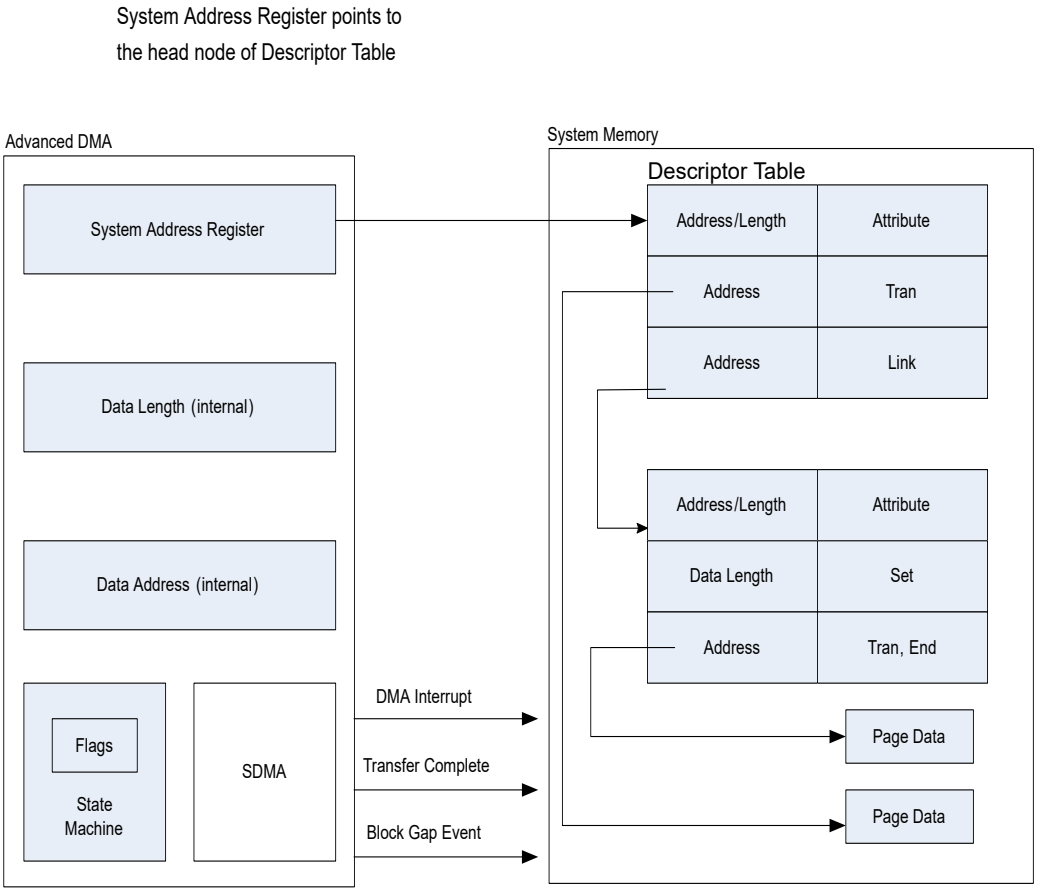

Figure 247. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 248. Format of the ADMA2 descriptor table

See Figure 249 for the concept and access method of the descriptor table for ADMA2.

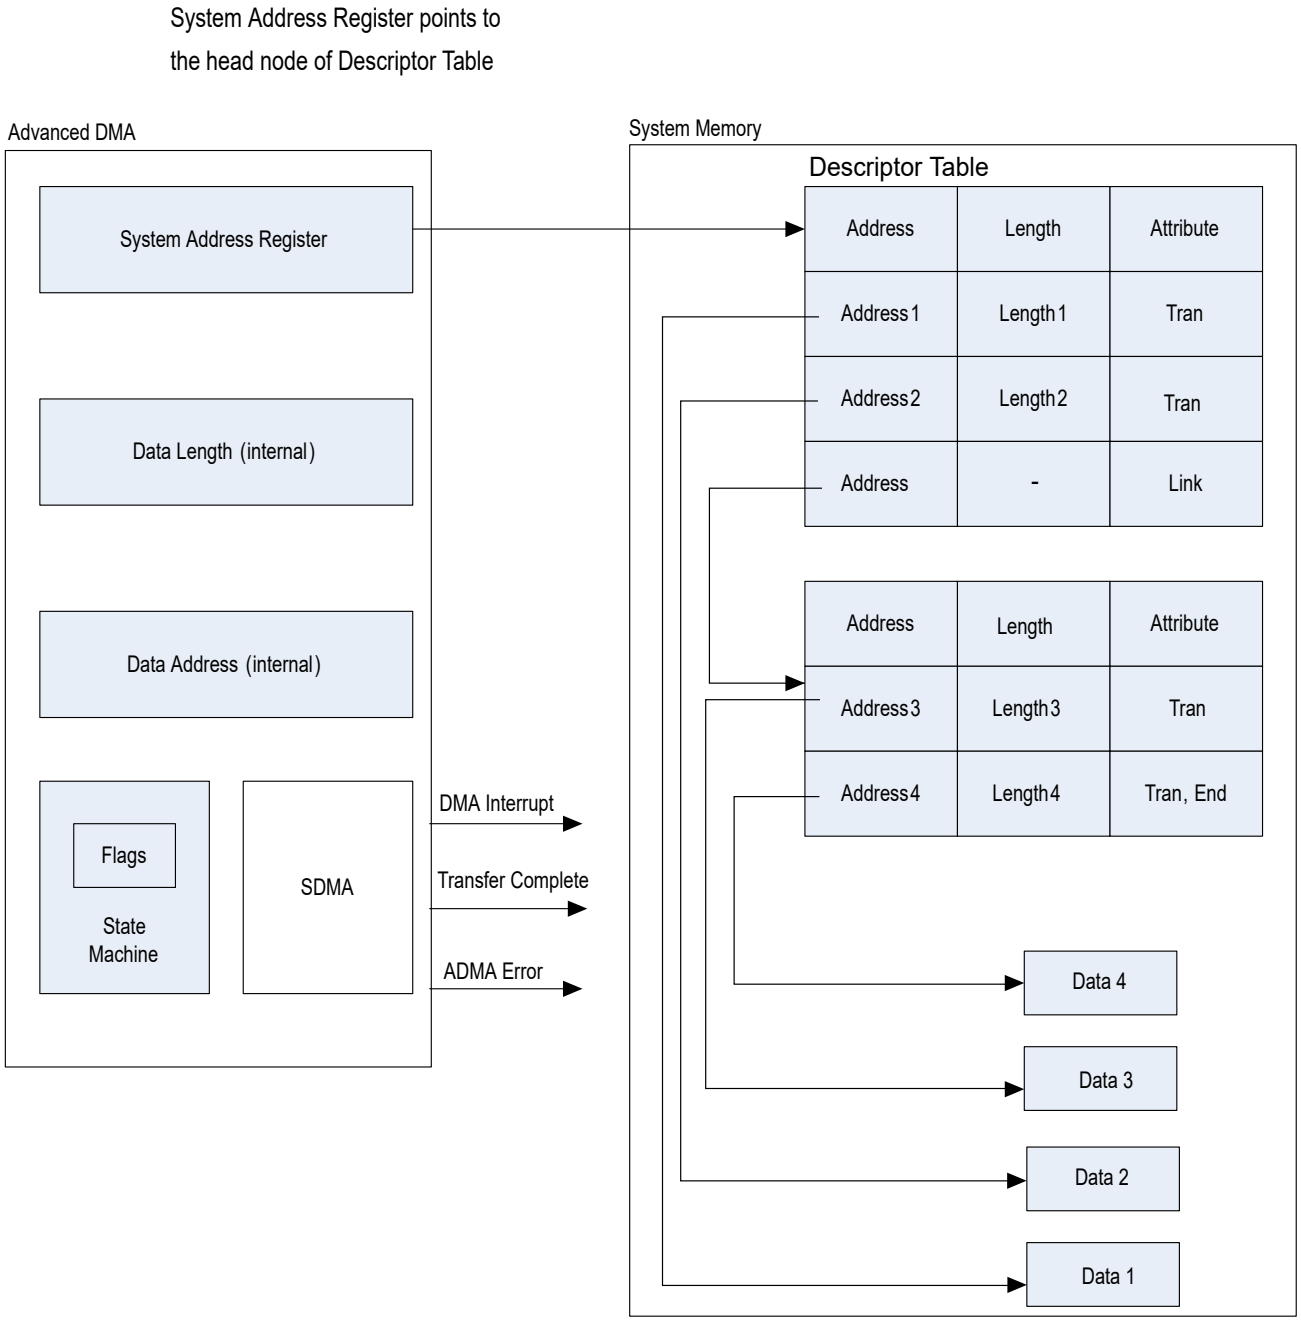

Figure 249. Concept and access method of the ADMA2 descriptor table

33.3.3.3.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.

- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

33.3.3.3.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AXI response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in register BLK_ATT must be equal to the whole data length set in descriptor, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

33.3.4 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank. See Figure 250 for the block diagram.

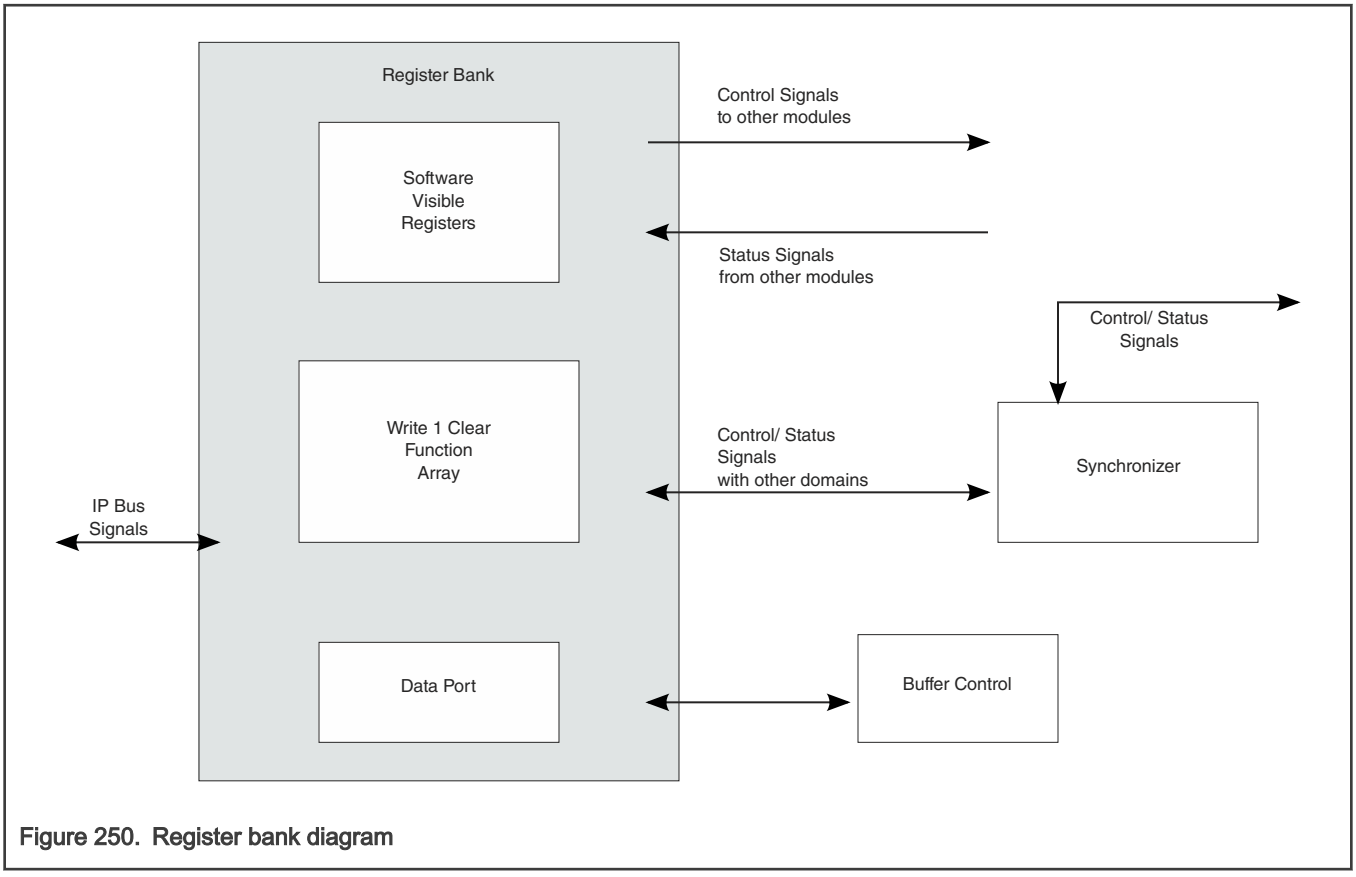

Figure 250. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

Access to an unimplemented address within the register memory map space does not generate a transfer error.

33.3.4.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from SDIO
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four sub-modules:

- SD control misc
- Command control
- Data control
- Clock control

33.3.4.2 SD control miscellaneous

In the SD control miscellaneous unit:

- The card detection (including CD_B and DATA3 for card detection) and card interrupt are implemented.
- The module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.
- The module also detects the Write Protect (WP) line. If WP is active, writes to memory and combo cards are ignored.

33.3.4.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

33.3.4.4 Command control

The Command Control module deals with the transactions on the CMD line.

See Figure 251 for an illustration of the structure for the Command CRC shift register.

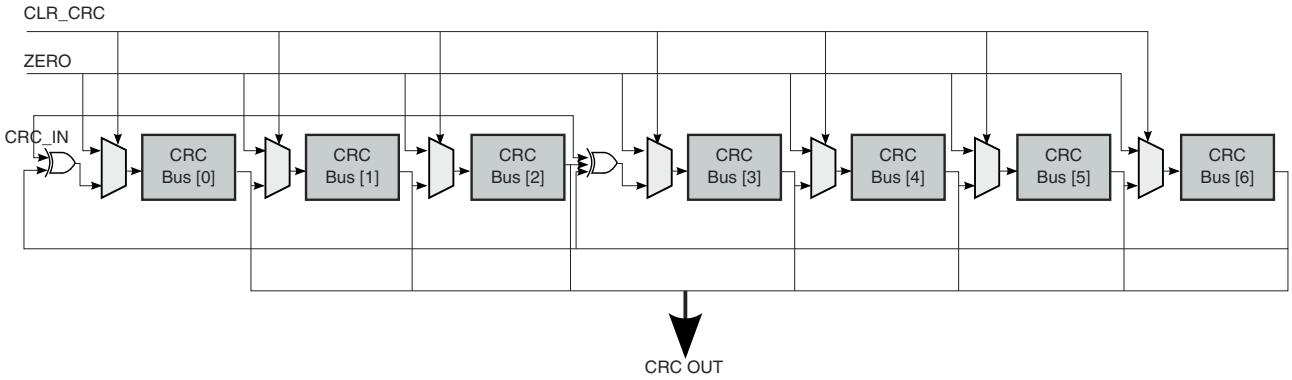

Figure 251. Command CRC shift register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

33.3.4.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1

M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0

CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

33.3.5 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. It is controlled by SoC pad or other logic. When there is no card on the eMMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

33.3.6 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO (not available in multiple block data transfers)

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

33.3.6.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode. Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

33.3.7 eMMC fast boot

The Embedded MultiMediaCard (eMMC4.3 or later) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 or later specification: boot operation and alternative boot operation. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the master (eMultiMediaCard host) can read boot data from the slave (eMMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 setting, please see the eMMC4.3 specification.

33.3.7.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes low. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal eMMC initialization sequence by sending CMD1.

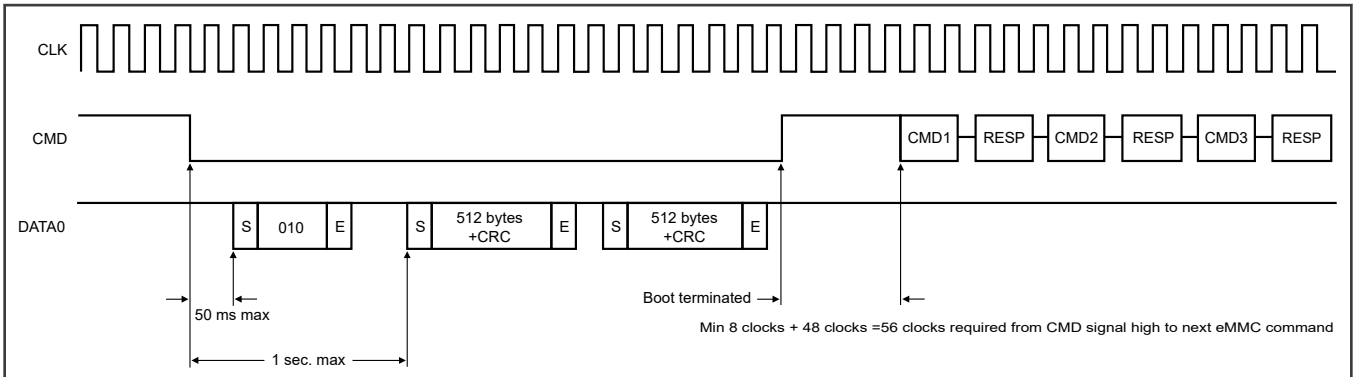

Figure 252. Embedded MultiMediaCard state diagram (normal boot mode)

33.3.7.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave must send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal eMMC initialization sequence by sending CMD1.

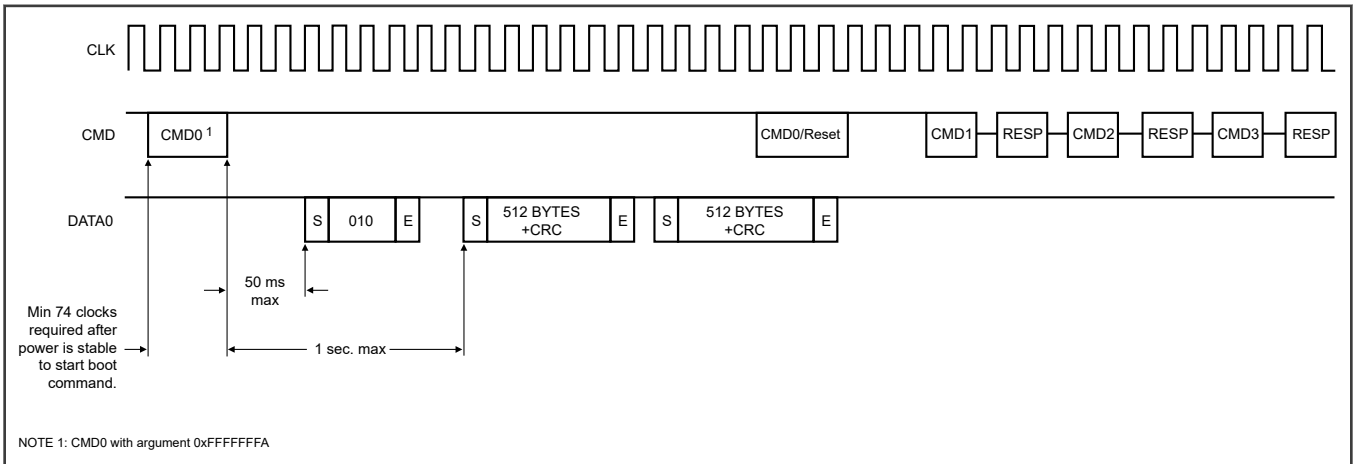

Figure 253. Embedded MultiMediaCard state diagram (alternative boot mode)

33.3.8 Commands for SD card, SDIO, and eMMC

A table containing the list of commands for the eMMC/SD card/SDIO is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the SD card, SDIO, and eMMC:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DATA
- Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 246. Commands for eMMC/SD card/SDIO

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all eMMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all eMMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The

Table continues on the next page...

Table 246. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
		[23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set			Embedded MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.

Table continues on the next page...

Table 246. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	adtc	[31:0] stuff bits	R1	SEND_TUNING_BLOCK	128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection.
CMD22	Reserved				
CMD23	ac	[31] reliable write request [30:16] set to 0 [15:0] number of blocks	R1	SET_BLOCK_COUNT	Defines the number of blocks (read/write) and the reliable writer parameter (write) for a block read or write command.
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.

Table continues on the next page...

Table 246. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register,

Table continues on the next page...

Table 246. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
		[14:8] register address [7:0] register data			and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the eMMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the

Table continues on the next page...

Table 246. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
		[15:8] stuff bits [7:0] byte count			device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for eMMC and SD cards. For eMMC, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed eMMC and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed eMMC. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 247.

4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are listed in the following table.

Table 247. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

33.3.9 SDIO interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

33.3.9.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from SDIO, until the interrupt service is finished to clear the interrupt.

33.3.9.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides samples the level on pin 8 during the interrupt period. At all other times, the host treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle, then pulls high for the next clock cycle . On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Specification v1.10 for further information about the SDIO interrupt.

33.3.9.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt, and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from SDIO does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from SDIO and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After

completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See Figure 254 for an illustration of the SDIO interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

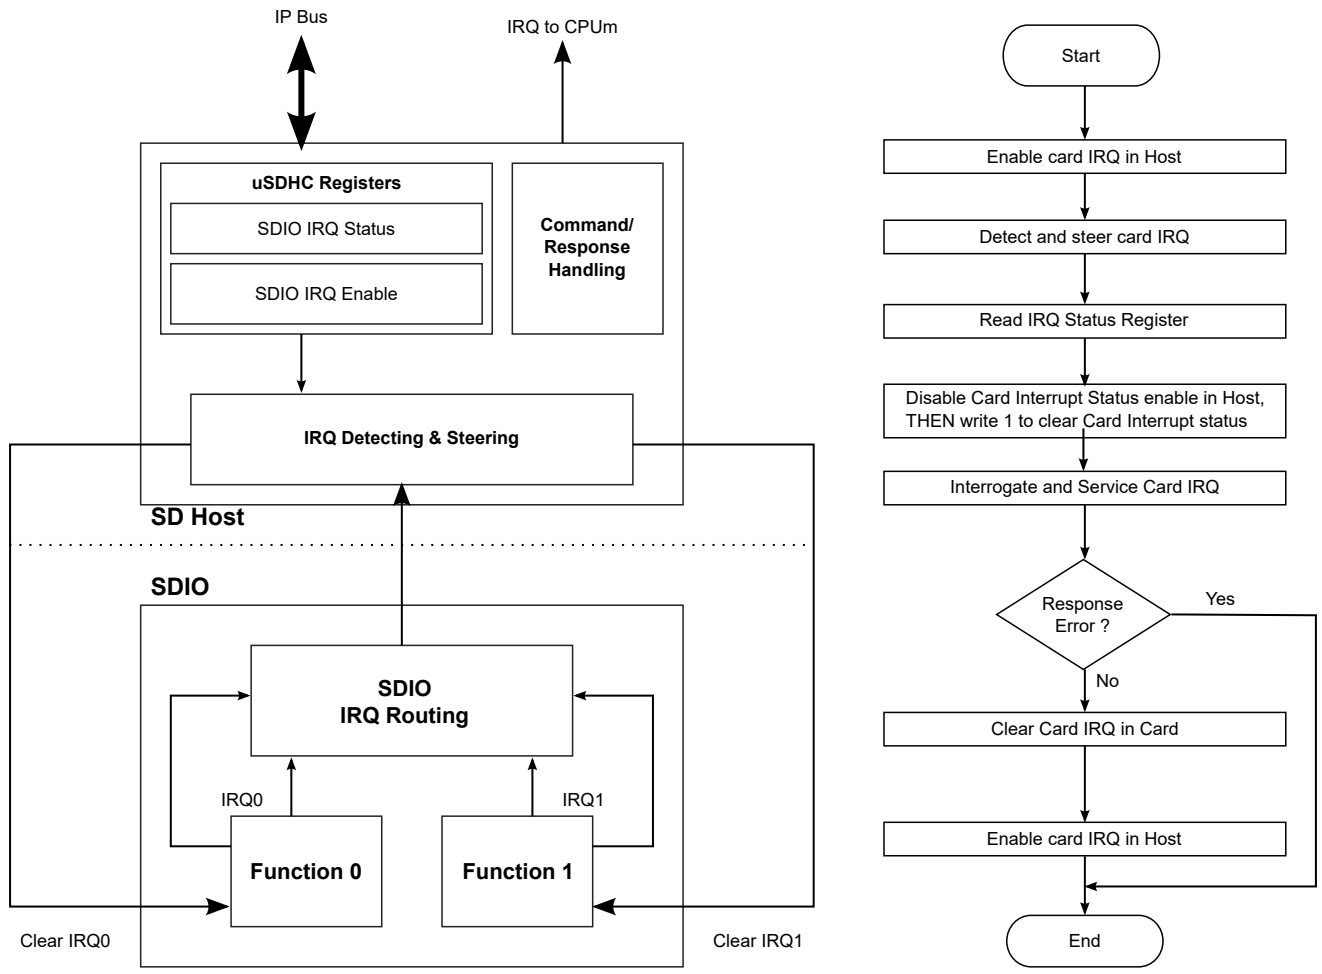

Figure 254. Card interrupt scheme, card interrupt detection, and handling procedure

33.3.10 Speed mode selection

To switch to HS200 or HS400 from High Speed (26 MHz-52 MHz), see the procedure below.

NOTE

While the actual timing change is done, the behavior of any command given (such as CMD13) cannot be guaranteed due to the asynchronous operation. Therefore, you must not use CMD13 to check the busy completion of the timing change indication. In case, CMD13 is used, the host must ignore CRC errors, if appear.

The max frequency for HS200 mode and HS400 mode could be slower than 200 MHz based on the chip implementation, you must set the target frequency for these two speed modes accordingly. Following sections describe the mode selections for HS200 mode and HS400 mode in detail.

33.3.10.1 HS200 mode selection

To switch to HS200, the Driver must perform the following steps:

1. Select the chip (through sending CMD7) and make sure it is unlocked (through CMD42).
2. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate if the chip supports HS200 at the IO voltage appropriate for both host and chip (through CMD8).
3. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported chip Driver Strengths (through CMD8). The default setting is 50 Ohm. The Host Designer might simulate its specific system, using a device driver models. Host can select the optimal Driver Type that might drive the host system load at the required operating frequency with the minimal noise generated.

NOTE

This step can be skipped if changes of Driver strength is not needed.

4. Check the setting of PROT_CTRL[DTW], make sure the data transfer width is set as expected.

   Make sure the I/O pad voltage is 1.8V and corresponding drive strength is set to proper value.

   Set HS200 bit and Driver Strength value in the HS_TIMING [185] field of the Extended CSD register by issuing CMD6. If the host attempts to write an invalid value, the HS_TIMING byte is not changed, the HS200 interface timing is not enabled, the Driver Strength is not changed, and the SWITCH_ERROR field is set. After the chip responds with R1, it might assert Busy signal. Once the busy signal gets de-asserted, the host may send a SEND_STATUS Command (CMD13) using the HS200 timing and after it receives a Trans State indication and No Error it means that the chip is set to HS200 timing and the Driver Strength is set to the selected settings.
5. At this point, the host can set the frequency to ≤ 200 MHz.
6. The host might invoke the HS200 standard tuning procedure, by sending CMD21 to the chip.

NOTE

The host must switch to the required bus width before starting the tuning operation to allow the tuning sequence to be done using the proper bus operating conditions.

33.3.10.2 Standard tuning procedure

By default, lower frequency operation, a fixed sampling clock is used to receive signals on CMD and DAT[3:0]. Before using the HS200, HS400, SDR104, or SDR50 modes, the Host Driver executes the tuning procedure at the mode switch sequence.

1. Issue uSDHC SW reset, set SYS_CTRL[RSTT] to 1.
2. Clear VEND_SPEC[FRC_SDCLK_ON] to 0.
3. Clean the history status by following these steps:
   a. Clear AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] to 0.
   b. Read Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS) until AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] reads 0.
   c. Write 1 to clear INT_STATUS[BRR].
4. Set TUNING_CTRL to 0x01312880 to enable the standard tuning and disable the CMD line check.
5. Start the tuning procedure by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] to 1.
6. Issue CMD19(SD) / CMD21(eMMC) with the proper Command Transfer Type (CMD_XFR_TYP) and Mixer Control (MIX_CTRL) settings.
7. Wait for uSDHC BRR (Buffer Read Ready) interrupt signal is 1.
8. Check AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]. If AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] = 1, write 1 to clear INT_STATUS[BRR] and then repeat steps 6~7. If AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] = 0, standard tuning has completed, or the tuning has not completed within 40 attempts. The Host Driver might abort this loop if the number of loops exceeds 40 or 150 ms timeout occurs. In this case, a fixed sampling clock should be used (AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0).

9. Sampling Clock Select (AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]) is valid after AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] has changed from 1 to 0.
   AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 1, indicates tuning procedure passed.
   AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0, indicates tuning procedure failed. The tuning result is applied to the delay chain, CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) [30:16], upon the successful tuning procedure completion.
10. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

While the tuning sequence is being performed, the Host Controller does not generate interrupts (including Command Complete), except Buffer Read Ready. CMD19 response errors are not indicated.

Writing AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] to 0 forces the Host Controller to use a fixed sampling clock and resets the tuning circuit of the Host Controller.

NOTE

- There could be slight difference on delay cell delay in each project, and this difference can lead to different loop number needed. TUNING_CTRL[TUNING_STEP] can be used to control how may taps are to be added for each step.
- Manual tuning might be required in cases where standard tuning is not able to close passing window with CMD19/21 transfer fail.

33.3.10.3 Manual tuning procedure

Manual tuning controls more details in the tuning procedure, and some corner cases. Manual tuning provides control to tuning start point, tuning steps, and delay chains. To start manual tuning:

1. Clear TUNING_CTRL[STD_TUNING_EN] to 0.
2. Clear VEND_SPEC[FRC_SDCLK_ON] and MIX_CTRL[FBCLK_SEL] to 0, set MIX_CTRL[SMP_CLK_SEL] and MIX_CTRL[EXE_TUNE] to 1 to start tuning.
3. Set SYS_CTRL[RSTA] to 1, and wait for self-clear.
4. Config delay chain, CLK_TUNE_CTRL_STATUS[DLY_CELL_SET_PRE] with the valueA.

NOTE

The valueA must start from 0.

5. Set SYS_CTRL[RST_FIFO] to 1 and wait for self-clear.
6. Send CMD19/21 to card.
7. Poll for CC, CIE, CEBE, CCE and CTOE of Interrupt Status (INT_STATUS) assertion.
8. Poll for TC, DEBE, DCE and DTOE of Interrupt Status (INT_STATUS) assertion.
9. Check TP of Interrupt Status (INT_STATUS); TP = 1 & no command/data error indicates the current CMD19/21 transfer is passed; otherwise, indicates failed.
10. If TP = 0 or command/data error is observed, increase the valueA with the required tuning step(1 to 127) and repeat steps 3~9.
11. If TP = 1 & no command/data error is met after a loop with TP=0 (or command/data error), save the current valueA as value_start. Increase valueA with the required tuning step, and repeat steps 3~9 until TP = 0 (or command/data error) again. Save the current valueA as value_end.
12. Clear MIX_CTRL[EXE_TUNE] to 0.
13. Set SYS_CTRL[RSTA] to 1, and wait for self-clear.
14. Set MIX_CTRL[SMP_CLK_SEL] to 1.

15. Set bit[14:0] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) with the output of expression {[(((value_start+value_end)/2)< < 8)& 0xffffff00] -0x300 } | 0x33.
16. Poll bit[30:16] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) until the value written in the previous step is read.
17. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

The manual tuning procedure defines a passing window, inside which the tuned clock can capture the correct data, and delay chain is to be configured as centered within the passing window.

It is not a fixed flow as the standard tuning. Any step can be changed based on the real case. In cases where passing window is not closed with a tuning fail, the center of the passing region must be applied for the delay chain setting. In cases where two passing windows separated by tuning fail(s) is observed, the center of the first passing window must be applied for the delay chain setting.

NOTE

Both the standard tuning and manual tuning are only for tuning of SD_CLK, cannot be used to tune STROBE clock of HS400 and HS400 enhanced mode.

33.3.10.4 Switch to HS400 mode

The valid IO voltage for HS400 is 1.8 V. The bus width is set to only DDR 8bit in HS400 mode. HS400 supports the same commands as DDR52. To switch to HS400 mode, the host must perform the following steps:

1. Initialize chip with “Backward Compatible Timings", after power-on or software reset (CMD0), the interface timing of the chip is set as the default "Backward Compatible Timing".
2. Select the chip with CMD7.
3. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate whether the chip supports HS400 by sending CMD8.
4. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported chip's Driver Strengths by sending CMD8.

NOTE

You may skip this step if changes of driver strength is not needed.

5. Set the "Selected Driver Strength" parameter in the HS_TIMING [185] field of the Extended CSD register to the appropriate driver strength for HS400 operation and set the "Timing Interface" parameter to 0x2 to switch to HS200 mode with CMD6. Send CMD13 to make sure mode switch to HS200 mode has been successfully done.
6. Perform the tuning procedure (standard or manual) at the HS400 target operating frequency, save the tuning result (68h [30:16]) and clear std_tuning_en.

NOTE

Tuning procedure in HS200 mode is required to synchronize the command response on the CMD line to CLK for HS400 operation.

7. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x1 to switch to High Speed mode with CMD6 and then set the clock frequency to a value not greater than 52 MHz.
8. Set BUS_WIDTH[183] to 0x06 to select the dual data rate x8 bus mode. Check the setting of PROT_CTRL[DTW]. Make sure the data transfer width is set as expected.
9. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x3 to switch to HS400 mode with CMD6. Set the MIX_CTRL[DDR_EN] and MIX_CTRL[HS400_MODE] to 1 to enable HS400 mode in controller.
10. Set bit[14:0] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) with saved tuning result value of 0x68 from standard tuning flow in step 6).

11. Poll bit[30:16] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) until the value written in the step 10 is read.
12. Set MIX_CTRL[SMP_CLK_SEL] to 1'b1 to apply the delay on capture clock of CMD channel, then set the clock frequency to ≤ 200 MHz.

    Ensure that uSDHC function clock source is 2x HS400 mode target frequency, and both SDCLKFS and DVS are configured to 0.
13. Set Strobe DLL control (STROBE_DLL_CTRL) to 0x00400039 to have strobe clock automatically tuned to 1/4 cycle of input ipp_strobe to capture data. Ensure that both STROBE_DLL_STATUS[STROBE_DLL_STS_REF_LOCK] and STROBE_DLL_STATUS[STROBE_DLL_STS_SLV_LOCK] are set before any transfer is started.

NOTE

For speed mode switch like from High Speed mode to HS200 mode or HS400(enhanced) mode, you must calibrate the right configuration of slew rate and drive strength for chip pad that are used for uSDHC.

33.3.10.5 Switch to HS400 enhanced mode

This selection flow describes how to initialize the eMMC device in HS400 mode while enabling enhanced strobe without the need for tuning procedure. To switch to HS400 mode with enhanced strobe, the host must perform the following steps:

1. Initialize device with "Backward Compatible Timings", after power-on or software reset (CMD0), the interface timing of the device is set as the default "Backward Compatible Timing".
2. Select the device with CMD7
3. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate whether the device supports HS400 with CMD8.
4. Read the STROBE_SUPPORT[184] field of the Extended CSD register to validate whether the device supports enhanced strobe with CMD8.
5. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x1 to switch to High Speed mode by sending CMD6 and then set the clock frequency to a value not greater than 52 MHz.
6. Set BUS_WIDTH[183] to 0x86 to select the dual data rate x8 bus mode and enable enhanced strobe (this is active only after HS400 mode is selected) with CMD6. Check the setting of PROT_CTRL[DTW]. Make sure the data transfer width is set as expected.
7. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported device Driver Strengths with CMD8.

NOTE

You may skip this step if changes of driver strength is not needed, if needed host may change the device Driver Strength.

8. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x3 to switch to HS400 mode with CMD6.
9. Set the MIX_CTRL[DDR_EN], MIX_CTRL[HS400_MODE], and MIX_CTRL[EN_HS400_MODE] bits to 1 to enable enhanced HS400 mode in controller.
10. Host may set the clock frequency to a value not greater than 200 MHz. Ensure uSDHC function clock source is 2x HS400 mode target frequency, and both SDCLKFS and DVS are configured to 0 .
11. Set Strobe DLL control (STROBE_DLL_CTRL) to 0x00400039 to have strobe clock automatically delayed 1/4 cycle of input ipp_strobe to capture data. Make sure both STROBE_DLL_STATUS[STROBE_DLL_STS_REF_LOCK] and STROBE_DLL_STATUS[STROBE_DLL_STS_SLV_LOCK] are set before any transfer is started.

NOTE

For speed mode switch like from high speed mode to HS200 mode or HS400(enhanced) mode, may must calibrate the right configuration of slew rate and drive strength for chip pad that are used for uSDHC.

33.3.11 Software restrictions

33.3.11.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

33.3.11.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

33.3.11.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by SDIO, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is aborted and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

33.3.11.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

ADMA1 is 4KB aligned.

33.3.11.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

33.3.11.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

33.3.11.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

33.3.11.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for eMMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

33.3.12 Clocking

The table found here describes the clock sources for uSDHC. For more information on clocking, see the Clocking chapter.

Table 248. Clocks

Clock name	Description
hclk	Bus clock
ipg_clk	Peripheral clock
ipg_clk_perclk	Base clock
ipg_clk_lp	Low power clock

33.3.12.1 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

33.3.12.2 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL[SDCLKFS] for prescaler configuration while the [DVS] for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock (see ipg_clk_perclk in Table 248).

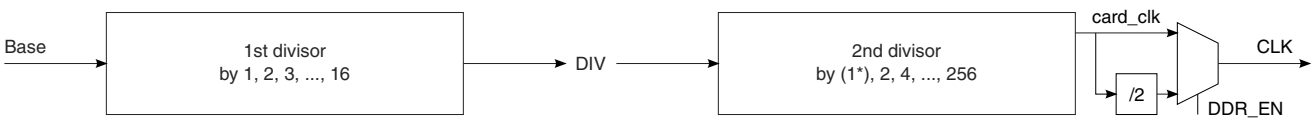

Figure 255. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 241) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

$$f_{card\_clk} = \frac{f_{Base}}{SYS\_CTRL[DVS] \times SYS\_CTRL[SDCLKFS]}$$

$$f_{CLK} = f_{card\_clk}$$

Equation 2. Equation for f_{card_clk} in SDR mode

For HS200 mode, if the source clock f_{Base} = 400 MHz, and the target clock f_{CLK} = 200 MHz, then configuring DVS to 'h00 and SDCLKFS to 'h01, the mapping value of SYS_CTRL[DVS] is 1 and the mapping value of SYS_CTRL[SDCLKFS] is 2.

$$f_{card\_clk} = \frac{400MHz}{1x(2)} = 200MHz$$

$$f_{CLK} = f_{card\_clk} = 200\ MHz$$

- In the DDR mode, CLK is equal to card_clk/2

$$f_{card\_clk} = \frac{f_{Base}}{SYS\_CTRL[DVS] \times (SYS\_CTRL[SDCLKFS]/2)}$$

$$f_{CLK} = \frac{f_{card\_clk}}{2}$$

Equation 3. Equation for f_{card_clk} in DDR mode

For HS400 mode, if the source clock f_{Base} = 400 MHz, and the target clock f_{CLK} = 200 MHz, then configuring DVS to 'h00 and SDCLKFS to 'h00, the mapping value of SYS_CTRL[DVS] is 1 and the mapping value of SYS_CTRL[SDCLKFS] is 2.

$$f_{card\_clk} = \frac{400MHz}{1x(2/2)} = 400MHz$$

$$f_{CLK} = \frac{f_{card\_clk}}{2} = \frac{400MHz}{2} = 200MHz$$

33.3.13 Command Queuing (CQE) operation

To facilitate command queuing in eMMC, the device manages an internal task queue that the host can queue data transfer tasks. Initially, the task queue is empty. Every task is issued by the host and initially queued as pending. The device controller works to prepare the pending tasks for execution. The software flow is described below:

1. Read CMDQ_SUPPORT[308] and CMDQ_DEPTH[307] of the extended CSD register (through CMD8) to verify eMMC chip support of command queue.
2. Set CMDQ_MODE_EN in CMD_MODE_EN[15] field of the extended CSD by issuing CMD6.
3. Send CMD13 to ensure a successful mode switch.
4. Define Task Descriptor List (TDL) comprised of task descriptor and transfer descriptor sets.
    a. 0x0010002b,0x00000000,0x20000023,0x34300000, //Write example
    b. 0x0010102b,0x00000000,0x20000023,0x34500000, //Read example
5. Set PROT_CTRL[DMASEL] to 2 to select ADMA2. CMDQ descriptors are in ADMA2 format.

6. Set CQSSC2[SSC2] to RCA.
7. Set Command Queuing Task Descriptor List Base Address (CQTDLBA) and Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU) to TDL start address.
8. Set CQCFG[CQUE] to 1 to enable the command queuing.
9. Set CQTDBR[TDBR] field(s) to trigger the required task(s).
10. Read CQTCN[TCN] field(s) to confirm the task completion(s).
11. Set CQTCN[TCN] field(s) to 1 to clear status.

33.4 External signals

The following table describes the uSDHC external signals:

Table 249. uSDHC external signals

Signal	Description	Direction
CLK	Is an Internally generated clock used to drive the eMMC, SD card, and SDIO.	O
CMD	Is used to send commands and receive responses to and from the card.	I/O
DAT7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DAT6	DAT6 line in the 8-bit mode — Not used in other modes	I/O
DAT5	DAT5 line in the 8-bit mode — Not used in other modes	I/O
DAT4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
NOTE If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.		
DAT3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DAT2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DAT1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DAT0	DAT0 line in all the modes Also, used to detect busy state	I/O

Table continues on the next page...

Table 249. uSDHC external signals (continued)

Signal	Description	Direction
CD_B	Card detection signal directly routed from the socket. Low value (0) indicates there is a card inserted. In the case the pin is not used (for the embedded memory), tie low. Optional for system implementation.	I
WP	Write protection signals directly routed from the socket. Low value (0) indicates it is not write protected. In the case the pin is not used (for the embedded memory), tie low. Optional for system implementation.	I
RESET_B	Is used to reset the eMMC.	O
VSELECT	Is used to change the voltage of the external power supplier. Optional for system implementation.	O
STROBE	Input clock for eMMC HS400 mode. **NOTE** If the uSDHC does not support the HS400 mode, STROBE can also be optional and tied to low.	I

33.5 Application information

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, eMMC are in the open-drain mode to avoid bus contention. See Commands for SD card, SDIO, and eMMC for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, for eMMC, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. See Commands for SD card, SDIO, and eMMC for the commands of ac and adtc categories.

33.5.1 Command send and response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)

{

    WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner

    wCmd = (<cmd_index> & 0x3f) << 24; // set the first 8 bits as '00'+<cmd_index>

    set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL according to the command index;

    if (internal DMA is used) wCmd |= 0x1;
```

```
    if (multi-block transfer) {

        set MSBSEL bit;

        if (finite block number) {

            set BCEN bit;

            if (auto12 command is to use) set AC12EN bit;

        }

    }

    write_reg(CMDARG, <cmd_arg>); // configure the command argument

    write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command

}

wait_for_response(cmd_index)

{

    while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set

    read IRQ Status register and check if any error bits about Command are set

    if (any error bits are set) report error;

    write 1 to clear CC bit and all Command Error bits;

}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

33.5.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for eMMC.

33.5.2.1 Card detect

See Figure 256 for a flow diagram showing the detection of SD card and SDIO using uSDHC.

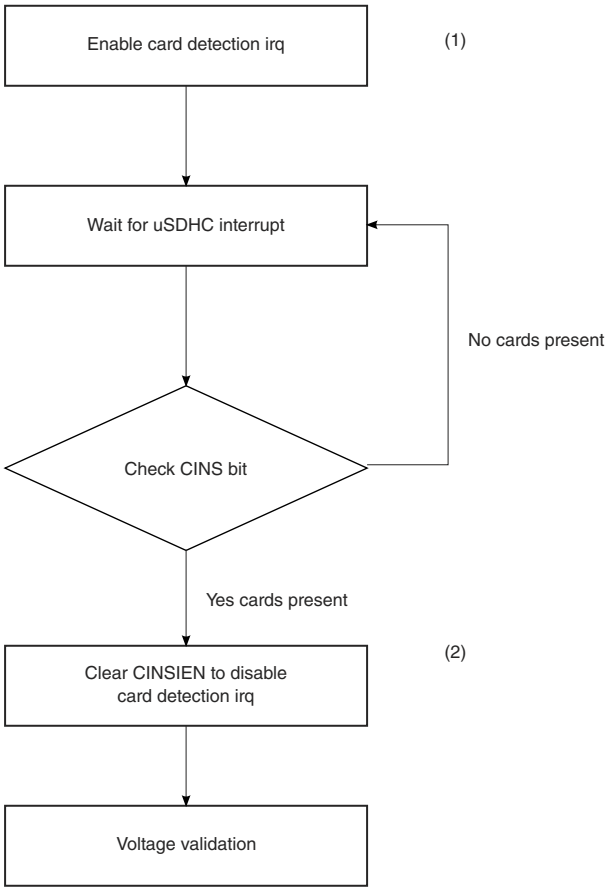

Figure 256. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

33.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).
- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of eMMC and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SDIO, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

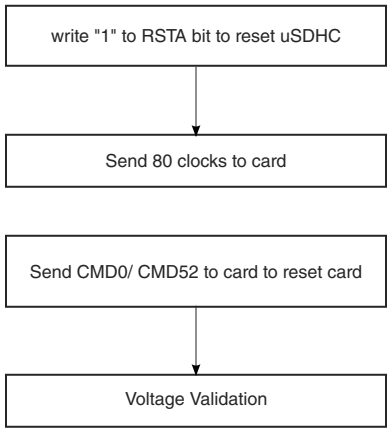

Figure 257. Flow chart for resetting uSDHC and SD card or SDIO

```
software_reset() {
    set_bit(SYSCTRL, RSTA); // software reset the Host set DTOCV and SDCLKFS fields to get the CLK of
    //frequency around 400kHz
    //configure IO pad to set the power voltage of external card to around 3.0V
    //poll bits CIHB and CDIHB
    //bits of PRSSTAT to wait both fields are cleared
    set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
    send_command(CMD_GO_IDLE_STATE, <other parameter>); // reset the card with CMD0 or
    send_command(CMD_IO_RW_DIRECT, <other parameter>);
}
```

33.5.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for eMMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_argument) {
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO operation
voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
```

```
            while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO)
            Label the card as SDCombo; //this is an SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labeled as SDIO)
        return; // card type is identified and voltage range is set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameter>); // CMD55, Application specific CMD prefix
    if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range for
memory part or SD card
        wait_for_response(SD_APP_OP_COND); // voltage range is set
        if (card type is UNKNOWN)
           label the card as SD;
        return; //
    } // end of if (no error ...
    else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
    } // of else if (response time-out
    else { // CMD55 is refuse, it must be eMMC
        if (card is already labeled as SDCombo) { // change label
            re-label the card as SDIO;
            ignore the error or report it;
            return; // card is identified as SDIO
        } // end of if (card is ...
        send_command(SEND_OP_COND, <voltage range>, <...>);
        if(RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
            either label the card as UNKNOWN;
            return;
        } // end of if (RESP_TIMEOUT ...
    } // end of else
}
```

33.5.2.4 Card registry

This section briefly describes the registry flow. For details, please refer to the card specifications. Card registry for the eMMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For eMMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions

(CMD1). The response to CMD1 is the "wired AND " operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using eMMC:

```
card_registry() {
    do { // decide RCA for each card until response time-out
        if(card is labelled as SDCombo or SDIO) { // for SDIO like device
            send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO to publish its RCA
            retrieve RCA from response;
        } // end if (card is labelled as SDCombo ...
        else if (card is labelled as SD) { // for SD card
            send_command(ALL_SEND_CID, <...>);
            if(RESP_TIMEOUT == wait_for_response(ALL_SEND_CID))
                break;
            send_command(SET_RELATIVE_ADDR, <...>);
            retrieve RCA from response;
        } // else if (card is labelled as SD ...
        else if (card is labelled as eMMC) {
            send_command(ALL_SEND_CID, <...>);
            rca = 0x1; //arbitrarily set RCA, 1 here for example
            send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16 bits
        } // end of else if (card is labelled as eMMC...
    } while (response is not time-out);
}
```

33.5.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

33.5.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

33.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write-protected area.

For eMMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card that incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

33.5.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

   NOTE

   For eMMC, block length only can be set to 512byte.

2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Set the eMMC, SD card, or SDIO to high-speed mode and use SWITCH(CMD6).
4. Set the eMMC bus or SD with 4-bit/8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred or another error that occurred during the auto12 command sending and response receiving.

33.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol

Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred or some another error that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this, it is recommended to avoid using the Suspend command for SDIO. This is because when such a command is sent, uSDHC interprets the system that switches to another function on SDIO and flush the data buffer. uSDHC takes the Resume command as a normal command with data transfer, and it is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC module automatically sends a CMD12 to mark the end of the multi-block transfer.

33.5.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

33.5.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card that incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

33.5.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status and wait until the card is ready for data.

NOTE

For eMMC, block length can be set to only 512 bytes.

2. Set the uSDHC number block register (NOB) where nob is 5, for instance.
3. Set the eMMC, SD card, or SDIO to high-speed mode and use SWITCH (CMD6).
4. Set the eMMC bus or SD with 4-bit /8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

33.5.3.2.3 Read with Pause

The read operation is not generally able to pause. Only SDIO (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If SDIO supports Read Wait (SRW bit in CCCR register is 1), the host driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, ensure that the RWCTL bit in the Protocol Control register is set, otherwise uSDHC does not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit after the Read Wait capability of SDIO is recognized.

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on SDIO to confirm that the card supports the Read Wait mode.
2. Set the RWCTL bit.

3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. No matter if the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

33.5.3.2.4 Delay Line (DLL) in read path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the eMMC and SD cards DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As you might change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. If DLL is to be used, make sure SDCLKFS is used (at least be set to divided by 2) so that the REF_CLK generated are the same frequency as card_clk. There are

two DLLs, PARTS DLL and STROBE DLL. PARTS DLL controls the SD_CLK loop back delay for which DLL (Delay Line) Control (DLL_CTRL) and DLL Status (DLL_STATUS) are used. STROBE DLL controls the STROBE loop back delay for which Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) are used. For PARTS DLL, below flow can be taken as reference. For STROBE DLL, similar register field with prefix STROBE in Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) must be used.

Step 1: Set the DLL_CTRL_RESET and DLL_CTRL_ENABLE fields

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET field

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

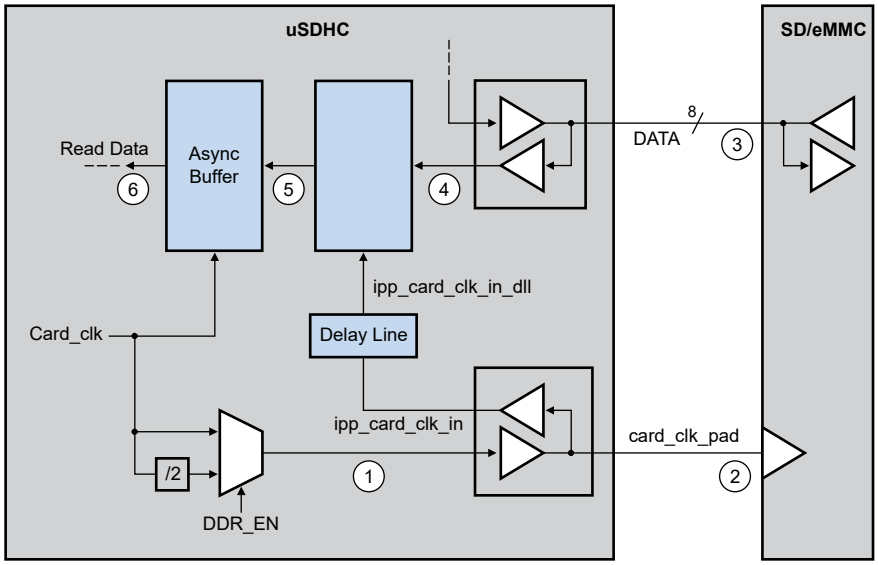

Figure 258. DLL in read path

33.5.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO, although slightly different than the suggested implementation of Suspend in the SDIO specification.

33.5.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of SDIO. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", (that is, setting the CMDTYP bits to 01). Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on SDIO.

33.5.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bit fields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer is resumed.

33.5.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to prepare the correct descriptor chain are these:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors matches the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

33.5.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

33.5.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver

issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

33.5.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AXI bus, the DMA operation is aborted, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs. The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined.To use this method, MIX_CTRL[BCEN] bit has to be set to enable Block Attribute register update.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

33.5.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AXI transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AXI transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

33.5.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.
- Auto CMD12 response CRC error: As the card responds to CMD12, it aborts the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

33.5.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For SDIO, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from SDIO must be serviced before the CINT bit is cleared. Refer to Card interrupt handling for the card interrupt handling flow.

33.5.4 Switch function

A switch command is issued by the host driver to enable new features added to the eMMC and SD cards. The eMMC and SD cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO, the high-speed mode /DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed as high. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For eMMC, the high-speed mode HS200 or HS400 is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of eMMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudo-code examples do not show current capability check, which is recommended in the function switch process.

33.5.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report SDIO does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of the desired value below 25MHz;
(data transactions like normal peers)
}
```

33.5.4.2 Query, enable, and disable SD high-speed mode/DDR50 /SDR50 /SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;(high speed
mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
      send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
check if the bit field 379~376 is 0xF;
```

```
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

33.5.4.3 Query, enable, and disable eMMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support high speed mode and return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this eMMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report eMMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

33.5.4.4 Set eMMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support multiple bit width and return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-bit,
x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
```

```
(data transactions like normal peers)
}
```

33.5.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

33.5.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

33.5.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
```

```
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

33.5.6 Fast boot operation

33.5.6.1 Normal fast boot flow

Here are the steps for normal fast boot flow:

1. Software must configure the SYS_CTRL[INITA] bit to make sure that 74 card clocks are finished.
2. Software must configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure eMMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure eMMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. You must reset the host and begin the normal process.

33.5.6.2 Alternative fast boot flow

Here are the steps for alternative fast boot flow:

1. Software needs to configure SYS_CTRL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.

4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the eMMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. You must reset the host and begin the normal process.

33.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during eMMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.
7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.

9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the eMMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

- When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
- Need a few words length memory to keep descriptor.
- For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

33.6 uSDHC memory map and register definition

33.6.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

33.6.1.1 uSDHC memory map

USDHC1 base address: 4285_0000h

USDHC2 base address: 4286_0000h

33.6.1.2 DMA System Address (DS_ADDR)

Offset

Register	Offset
DS_ADDR	0h

Function

This register contains the physical system memory address used for DMA transfers.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DS_ADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DS_ADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 DS_ADDR	System address **DMA system address / argument 2** When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both ADMA1 and ADMA2. This register is used only for Argument2 and SDMA may use Auto CMD23. 1. **SDMA system address** Because the address must be word (4 bytes) aligned, the least two bits are reserved and always set to 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA field in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

33.6.1.3 Block Attributes (BLK_ATT)

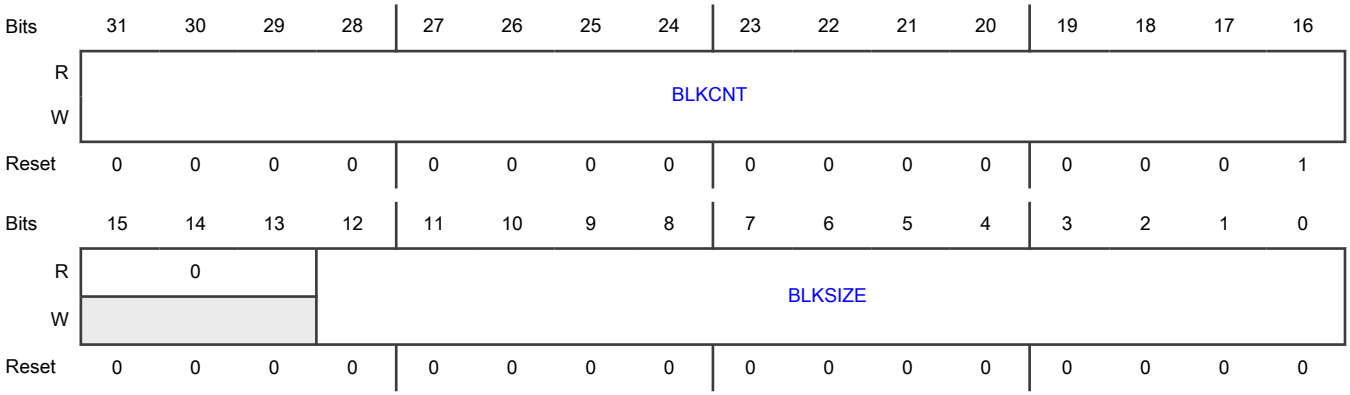
Offset

Register	Offset
BLK_ATT	4h

Function

This register is used to configure the number of data blocks and the number of bytes in each block.

Diagram



Fields

Field	Function
31-16 BLKCNT	Blocks count for current transfer This field is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this field always reads as 1. The host driver sets this field to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This field should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this field may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this field. The reading of this field should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as aborted and change the BLKCNT field back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000_0000_0000_0000b - Stop count 0000_0000_0000_0001b - 1 block 0000_0000_0000_0010b - 2 blocks 1111_1111_1111_1111b - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This field specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0_0000_0000_0000b - No data transfer 0_0000_0000_0001b - 1 byte 0_0000_0000_0010b - 2 bytes 0_0000_0000_0011b - 3 bytes 0_0000_0000_0100b - 4 bytes 0_0001_1111_1111b - 511 bytes 0_0010_0000_0000b - 512 bytes 0_1000_0000_0000b - 2048 bytes 1_0000_0000_0000b - 4096 bytes

33.6.1.4 Command Argument (CMD_ARG)

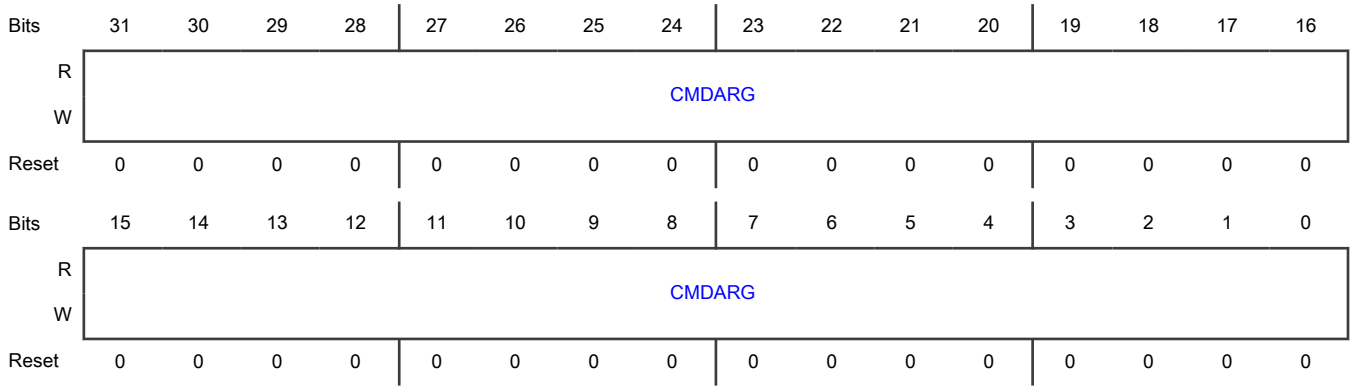
Offset

Register	Offset
CMD_ARG	8h

Function

This register contains the SD/eMMC command argument.

Diagram



Fields

Field	Function
31-0 CMDARG	Command argument The SD/eMMC command argument is specified as bits 39-8 of the command format in the SD or eMMC specification. This field is write protected when the Command Inhibit (CMD) field in the Present State register is set.

33.6.1.5 Command Transfer Type (CMD_XFR_TYP)

Offset

Register	Offset
CMD_XFR_TYP	Ch

Function

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, uSDHC also ignores the command.

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and aborts the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC

does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 250. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 251. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

Diagram

Fields

Field	Function
31-30 —	Reserved
29-24 CMDINX	Command index These fields are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These fields are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00b - Normal other commands 01b - Suspend CMD52 for writing bus suspend in CCCR 10b - Resume CMD52 for writing function select in CCCR 11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No data present 1b - Data present
20 CICEN	Command index check enable If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0b - Disable command index check 1b - Enables command index check
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0b - Disables command CRC check 1b - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00b - No response 01b - Response length 136 10b - Response length 48 11b - Response length 48, check busy after response
15-8 —	Reserved
7 AC23EN	AC23EN This field is read when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is tied to '0'. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register. 0b - Disable 1b - Enable
6 NIBBLE_POS	NIBBLE_POS This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
5 MSBSEL	MSBSEL This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Disable 1b - Enable
4 DTDSEL	DTDSEL This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0b - Disable 1b - Enable
3 DDR_EN	DDR_EN Dual data rate mode selection. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0b - Disable 1b - Enable
2 AC12EN	AC12EN Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	BCEN This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0	DMAEN

Table continues on the next page...

Table continued from the previous page...

Field	Function
DMAEN	This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

33.6.1.6 Command Response0 (CMD_RSP0)

Offset

Register	Offset
CMD_RSP0	10h

Function

This register is used to store part 0 of the response bits from the card.

33.6.1.8 Command Response2 (CMD_RSP2)

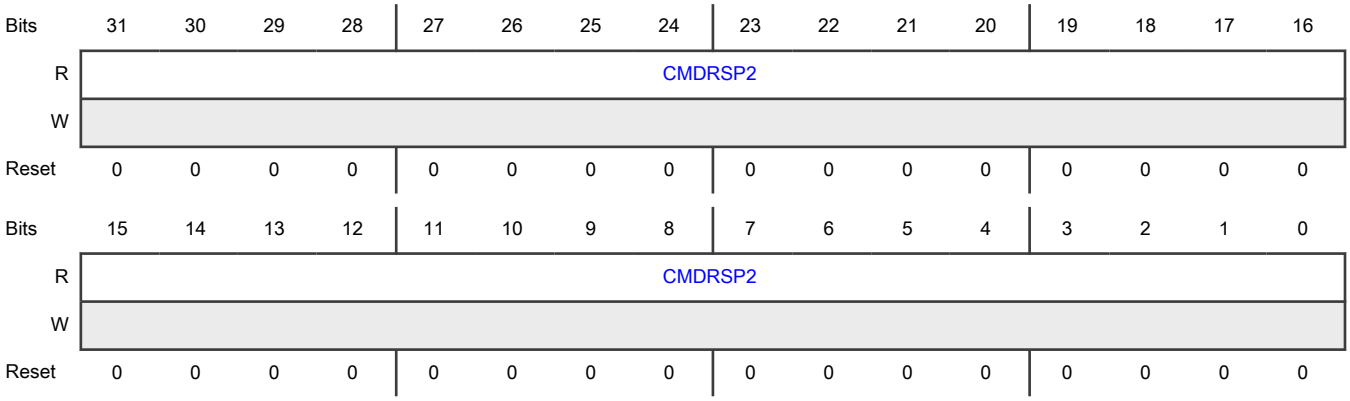
Offset

Register	Offset
CMD_RSP2	18h

Function

This register is used to store part 2 of the response bits from the card.

Diagram



Fields

Field	Function
31-0 CMDRSP2	Command response 2 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

33.6.1.9 Command Response3 (CMD_RSP3)

Offset

Register	Offset
CMD_RSP3	1Ch

Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 252. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}

Table continues on the next page...

Table 252. Response bit definition for each response type (continued)

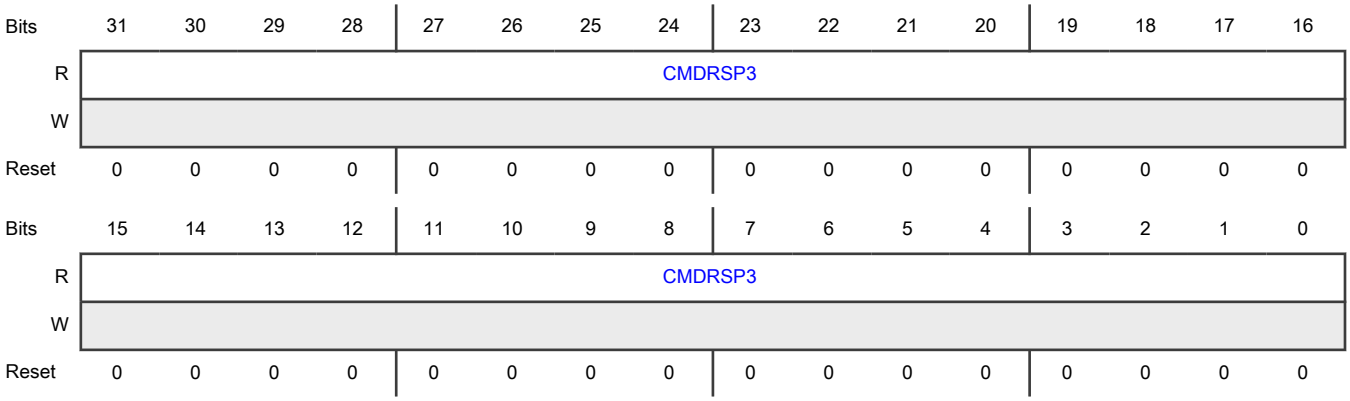
Response type	Meaning of response	Response field	Response register
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Diagram



Fields

Field	Function
31-0 CMDRSP3	Command response 3 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

33.6.1.10 Data Buffer Access Port (DATA_BUFF_ACC_PORT)

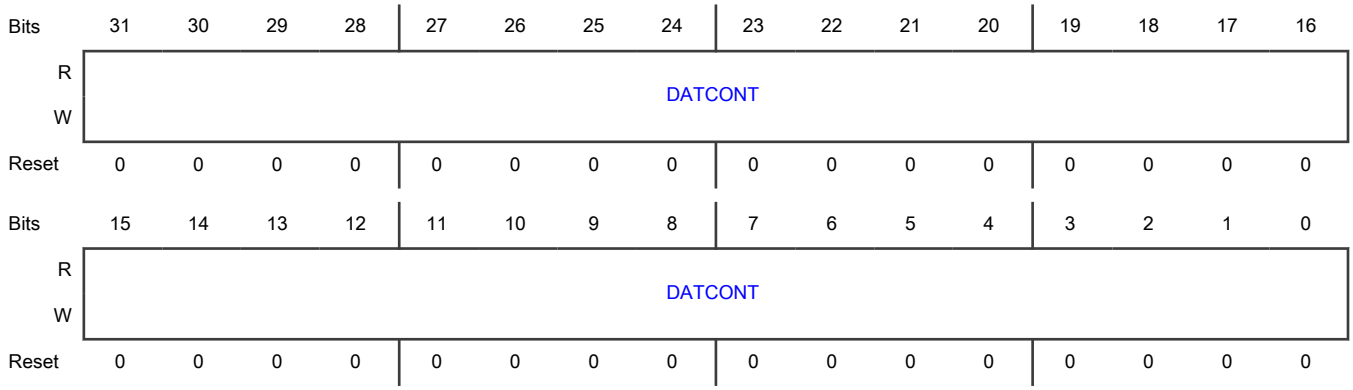
Offset

Register	Offset
DATA_BUFF_ACC_PORT	20h

Function

The Buffer Data Port register is for 32-bit data access by the Arm platform. When the internal DMA is enabled, any write to this field is ignored, and any read from this field always yields 0s.

Diagram



Fields

Field	Function
31-0 DATCONT	Data content This field is used to access the internal buffer.

33.6.1.11 Present State (PRES_STATE)

Offset

Register	Offset
PRES_STATE	24h

Function

The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State register depends on board connectivity.

Diagram

Fields

Field	Function
31-24 DLSL	DATA[7:0] line signal level This field is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 0000_0000b - Data 0 line signal level 0000_0001b - Data 1 line signal level 0000_0010b - Data 2 line signal level 0000_0011b - Data 3 line signal level 0000_0100b - Data 4 line signal level 0000_0101b - Data 5 line signal level 0000_0110b - Data 6 line signal level 0000_0111b - Data 7 line signal level
23 CLSL	CMD line signal level This field is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-20 —	Reserved
19	Write protect switch pin level

Table continues on the next page...

Table continued from the previous page...

Field	Function
WPSPL	The Write Protect switch is supported for memory and combo cards. This field reflects the inverted value of the WP pin of the card socket. A software reset does not affect this field. The reset value is affected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this field is high and write is enabled. 0b - Write protected (WP = 1) 1b - Write enabled (WP = 0)
18 CDPL	Card detect pin level This field reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this field. This field may be valid, but is not guaranteed, because of propagation delay. Use of this field is limited to testing because it must be debounced by software. A software reset does not affect this field. A write to the Force Event Register does not affect this field. The reset value is affected by the external card detection pin. This field shows the value on the CD_B pin (that is, when a card is inserted in the socket, it is 0 on the CD_B input, and consequently, the CDPL reads 1. 0b - No card present (CD_B = 1) 1b - Card present (CD_B = 0)
17 —	Reserved
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0b - Power on reset or no card 1b - Card inserted
15 TSCD	Tap select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0b - Delay cell select change is not finished. 1b - Delay cell select change is finished.
14-13 —	Reserved
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode, and eMMC HS200 mode) Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is cleared when a command is issued with setting Execute Tuning field in MIX_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIX_CTRL register is set to 0 (using fixed sampling clock). 0b - Fixed or well tuned sampling clock 1b - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0b - Read disable 1b - Read enable
10 BWEN	Buffer write enable This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT (Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0b - Write disable 1b - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0b - No valid data

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state. 0b - No valid data 1b - Transferring data
7-4 —	Reserved
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0b - Clock is changing frequency and not stable. 1b - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the read command

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0b - DATA line inactive 1b - DATA line active
1 CDIHB	Command Inhibit Data (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / eMMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0. 0b - Can issue command that uses the DATA line 1b - Cannot issue command that uses the DATA line

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / eMMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0b - Can issue command using only CMD line 1b - Cannot issue command

33.6.1.12 Protocol Control (PROT_CTRL)

Offset

Register	Offset
PROT_CTRL	28h

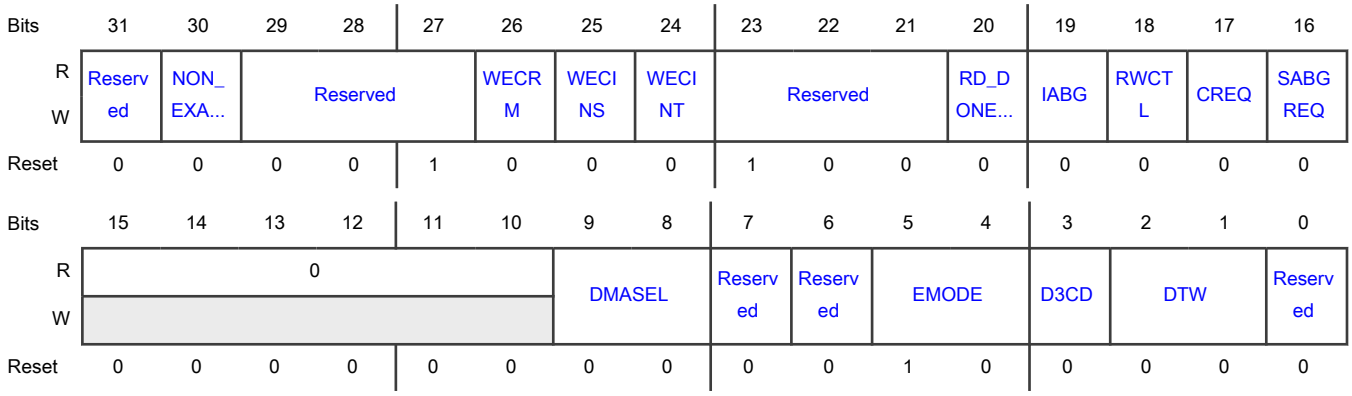
Function

This register controls three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

Diagram



Fields

Field	Function
31 —	Reserved Always write as 0
30 NON_EXACT_BLK_RD	Non-exact block read Current block read is non-exact block read. It is only used for SDIO. 0b - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1b - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 —	Reserved
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0b - Disables wakeup event enable on SD card removal 1b - Enables wakeup event enable on SD card removal
25 WECINS	Wakeup event enable on SD card insertion This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0b - Disable wakeup event enable on SD card insertion 1b - Enable wakeup event enable on SD card insertion

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wakeup Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0b - Disables wakeup event enable on card interrupt 1b - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20 RD_DONE_NO_8CLK	Read performed number 8 clock According to the SD/eMMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), eight clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data. In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.
19 IABG	Interrupt at block gap This field is valid only in 4-bit mode, of SDIO, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If SDIO cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. 0b - Disables interrupt at block gap 1b - Enables interrupt at block gap
18 RWCTL	Read wait control The read wait function provided by this field is optional for SDIO. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. If the card does not support read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0b - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1b - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set
17	Continue request

Table continues on the next page...

Table continued from the previous page...

Field	Function
CREQ	This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0b - No effect 1b - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that SDIO support read wait. Therefore, the host driver does not set this field during read transfers unless SDIO supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 0b - Transfer 1b - Stop
15-10 —	Reserved
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00b - No DMA or simple DMA is selected. 01b - ADMA1 is selected. 10b - ADMA2 is selected. 11b - Reserved
7 —	Reserved
6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-4 EMODE	Endian mode This field supports all three endian modes in data transfer. See Data buffer for more details. 00b - Big endian mode 01b - Half word big endian mode 10b - Little endian mode 11b - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support. 0b - DATA3 does not monitor card insertion 1b - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00b - 1-bit mode 01b - 4-bit mode 10b - 8-bit mode 11b - Reserved
0 —	Reserved

33.6.1.13 System Control (SYS_CTRL)

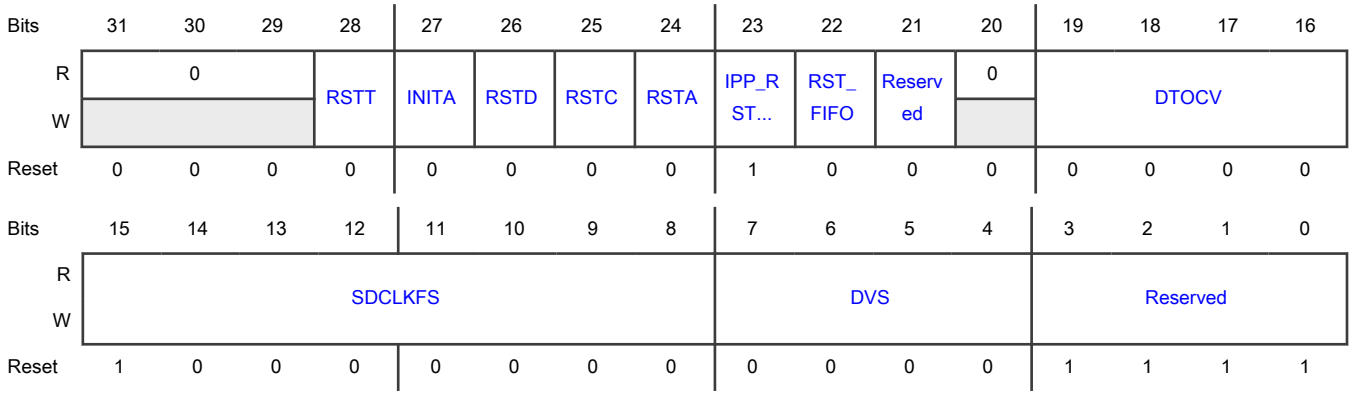
Offset

Register	Offset
SYS_CTRL	2Ch

Function

This register provides control of the system. See detail in the field description.

Diagram



Fields

Field	Function
31-29 —	Reserved
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.
26 RSTD	Software reset for data line Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Data Port register — Buffer is cleared and initialized • Present State register — Buffer read enable — Buffer write enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	— Read transfer active — Write transfer active — DATA line active — Command Inhibit (DATA) • Protocol Control register — Continue request • Interrupt Status register — Buffer read ready — Buffer write ready — DMA interrupt — Block gap event — Transfer complete **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
25 RSTC	Software reset for CMD line Only part of the command circuit is reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Present State Register — Command Inhibit (CMD) • Interrupt Status Register — Command Complete 0b - No reset 1b - Reset
24 RSTA	Software reset for all This reset affects the entire host controller except for the card detection circuit. RSTA resets all the registers that can be reset by RSTC/RSTD. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear. In tuning process, after every CMD19 is finished, this field is set to retest uSDHC.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
23 IPP_RST_N	Hardware reset This field's value is output to card through pad directly to hardware reset pin of the card if the card supports this feature.
22 RST_FIFO	Reset the async FIFO Reset the async FIFO between card interface and the internal logic. After this field is set, the software waits for self-clear.
21 —	Reserved
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value. The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 0000b - SDCLK x 2^{32} 0001b - SDCLK x 2^{33} 0010b - SDCLK x 2^{18} 0011b - SDCLK x 2^{19} 1101b - SDCLK x 2^{29}, recommend to use for supported speed modes except HS200, HS400, SDR104 mode 1110b - SDCLK x 2^{30}, recommend to use for HS200 and SDR104 mode 1111b - SDCLK x 2^{31}, recommend to use for HS400 mode
15-8 SDCLKFS	SDCLK frequency select This field is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this field holds the prescaler (of this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0')

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed: 80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2 When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.), SDCLKFS is highly recommended. For HS400 mode, SDCLKFS must be used so that REF_CLK, generated for STROBE DLL, is at the same frequency as STROBE clock. For HS200 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK. For SDR104 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK.
7-4 DVS	Divisor This field is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows: 0000b - Divide-by-1 0001b - Divide-by-2 1110b - Divide-by-15 1111b - Divide-by-16
3-0 —	Reserved Always write as 1.

33.6.1.14 Interrupt Status (INT_STATUS)

Offset

Register	Offset
INT_STATUS	30h

Function

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 253. uSDHC status for command timeout error/command complete bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 254. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 255. uSDHC status for command CRC error/command timeout error bit combinations

Command CRC error	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Fields

Field	Function
31 —	Reserved
30-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0b - No error 1b - Error
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode and eMMC HS200 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning. This field is relevant in combination with the bus error only and must be cleared prior to all the write and read transactions.
25 —	Reserved
24 AC12E	Auto CMD12 error Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0b - No error 1b - Error
23 —	Reserved
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No error 1b - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0b - No error 1b - Error
20 DTOE	Data timeout error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. This field is not asserted in tuning process. 0b - No error 1b - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response. This field is not asserted in tuning process. 0b - No error 1b - Error
18 CEBE	Command end bit error Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0b - No error 1b - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC aborts the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is not asserted in tuning process. 0b - No error 1b - CRC error generated
16 CTOE	Command timeout error Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is aborted by uSDHC. This field is not asserted in tuning process. 0b - No error 1b - Time out
15 ERR_INT_STATUS	Error Interrupt Status This bit is set when any of the error status bit DMAE, AC12E, DEBE, DCE, DTOE, CIE, CEBE, CCE and CTOE is set.
14 CQI	Command queuing interrupt This interrupt is asserted when at least one of the bits in CQIS register is set. This interrupt is cleared only by clearing the source interrupt in CQIS register.
13 TP	Tuning pass:(only for SD3.0 SDR104 mode and eMMC HS200 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode and eMMC HS200 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 0b - Re-tuning is not required. 1b - Re-tuning should be performed.
11 —	Reserved
10-9 —	Reserved
8 CINT	Card interrupt This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from SDIO and the interrupt to the host system. Writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	this field to 1 can clear this field, but as the interrupt source from SDIO does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in SDIO and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0b - No card interrupt 1b - Generate card interrupt
7 CRM	Card removal This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or inserted 1b - Card removed
6 CINS	Card insertion This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or removed 1b - Card inserted
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0b - Not ready to read buffer 1b - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0b - Not ready to write buffer 1b - Ready to write buffer

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set. 0b - No DMA interrupt 1b - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function. In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0b - No block gap event 1b - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed. In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0b - Transfer does not complete 1b - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0b - Command not complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Command complete

33.6.1.15 Interrupt Status Enable (INT_STATUS_EN)

Offset

Register	Offset
INT_STATUS_EN	34h

Function

Setting any bit in this register to 1 enables the corresponding interrupt status be requested to the system. If any bit is set to 0, the corresponding interrupt request gets blocked.

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

33.6.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

Offset

Register	Offset
INT_SIGNAL_EN	38h

Function

This register is used to select which interrupt status is indicated to the host system as the interrupt. These status fields all share the same interrupt lines. Setting any of these fields to 1 enables interrupt generation. The corresponding Status register field generates an interrupt when the corresponding interrupt signal enable field is set.

33.6.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

Offset

Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

Function

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 256. Relationship between command CRC error and command timeout error for auto CMD12

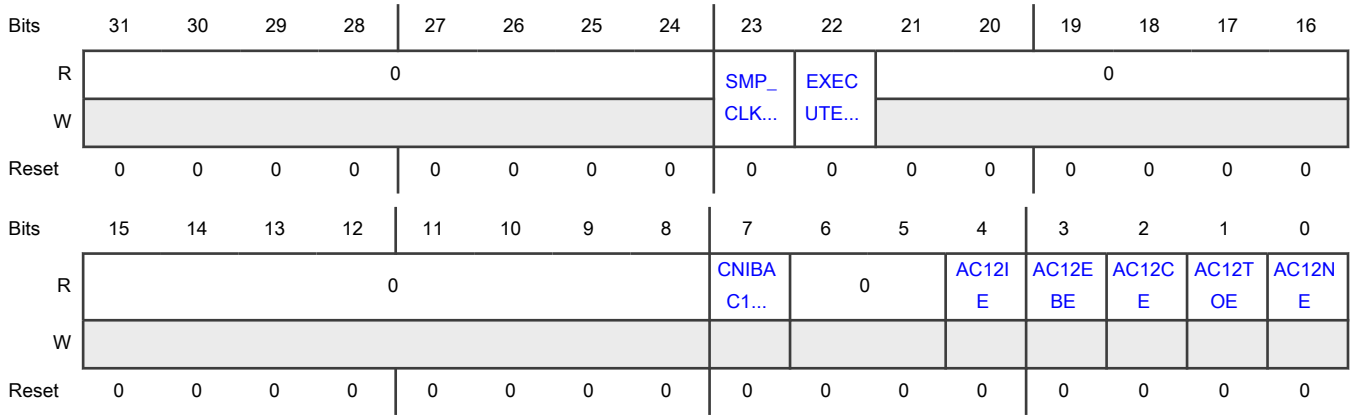
Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued
- At the end field of an Auto CMD12 response
  - Check errors correspond to fields 1-4
  - Set fields 1-4 corresponding to detected errors
  - Clear fields 1-4 corresponding to detected errors
- Before reading the Auto CMD12 Error Status field 7
  - Set field 7 to 1 if there is a command that can't be issued
  - Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 SMP_CLK_SEL	Sample clock select This field is used to select sampling clock to receive CMD and DATA. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is controlled by re-tuning procedure and is valid after the tuning procedure is complete (AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=0). A value of '1' means that tuning has been completed successfully and a value of '0' implies the tuning has failed. Writing '1' to this field is meaningless and ignored when the tuning has failed. The tuning circuit is reset by writing '0' to this field. This field can be cleared by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=1. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field as 1 to perform the re-tuning sequence in a short time. This field cannot be changed while the Host controller is receiving response or a read data block. 0b - Fixed clock is used to sample data 1b - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute tuning This field is used to start the tuning procedure. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]. 0b - Tuning procedure is aborted 1b - Start tuning procedure
21-8 —	Reserved
7	Command not issued by Auto CMD12 error

Table continues on the next page...

Table continued from the previous page...

Field	Function
CNIBAC12E	Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0b - No error 1b - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command. 0b - No error 1b - Error, the CMD index in response is not CMD12/23
3 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0b - No error 1b - End bit error generated
2 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0b - No CRC error 1b - CRC error met in Auto CMD12/23 response
1 AC12TOE	Auto CMD12 / 23 timeout error Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0b - No error 1b - Time out
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0b - Executed 1b - Not executed

33.6.1.18 Host Controller Capabilities (HOST_CTRL_CAP)

Offset

Register	Offset
HOST_CTRL_CAP	40h

Function

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

Diagram

0 SDR50_SUPPORT	SDR50 support This field indicates support of SDR50 mode.

33.6.1.19 Watermark Level (WTMK_LVL)

Offset

Register	Offset
WTMK_LVL	44h

Function

This register indicates configurability of write and read watermark levels (FIFO threshold). Their value can range from 1 to 128 words.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-29 —	Reserved
28-24 —	Reserved
23-16 WR_WML	Write watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.When using internal DMA, WR_WML can be set any value between 1 and 128. To get max AXI throughput, we recommend to use integer multiple of 16.
15-13 —	Reserved
12-8 —	Reserved
7-0 RD_WML	Read watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.When using internal DMA mode, RD_WML must be set to the value less than 16. To get max AXI throughput, recommend to use 16.

33.6.1.20 Mixer Control (MIX_CTRL)

Offset

Register	Offset
MIX_CTRL	48h

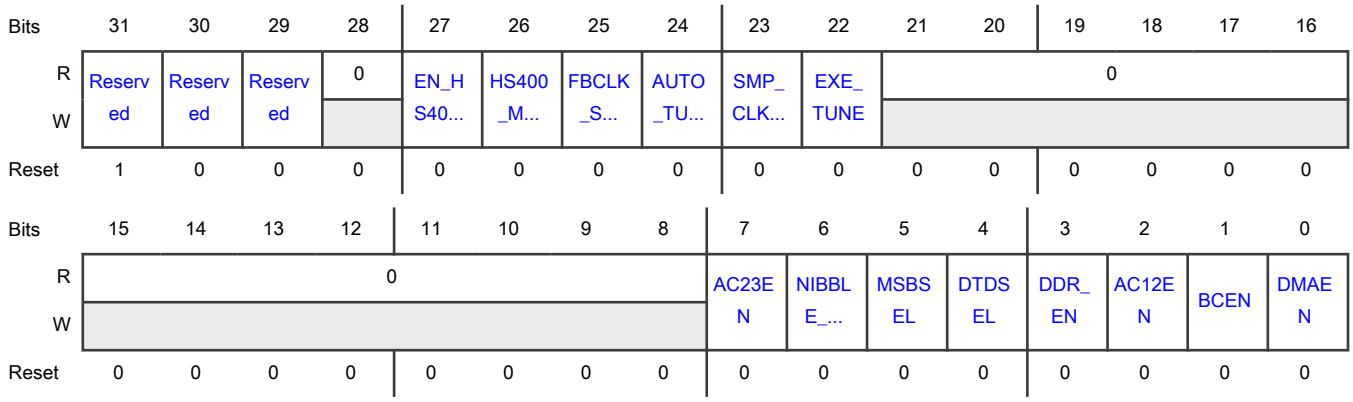
Function

This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 257. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

Diagram



Fields

Field	Function

27 EN_HS400_MODE	Enable enhance HS400 mode Enhance HS400 enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
26 HS400_MODE	Enable HS400 mode HS400 Enable
25 FBCLK_SEL	Feedback clock source selection (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0b - Feedback clock comes from the loopback CLK 1b - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto tuning enable (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0b - Disable auto tuning 1b - Enable auto tuning
23 SMP_CLK_SEL	Clock selection When TUNING_CTRL[STD_TUNING_EN] is 0, this field is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0b - Fixed clock is used to sample data / cmd 1b - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute tuning: (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) When TUNING_CTRL[STD_TUNING_EN] is 0, this field is set to 1 to indicate the host driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 0b - Not tuned or tuning completed 1b - Execute tuning
21-8 —	Reserved
7 AC23EN	Auto CMD23 enable This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Single block 1b - Multiple blocks
4 DTDSEL	Data transfer direction select This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0b - Write (Host to card) 1b - Read (Card to host)
3 DDR_EN	Dual data rate mode selection This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only.
2 AC12EN	Auto CMD12 enable Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0 DMAEN	DMA enable This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

33.6.1.21 Force Event (FORCE_EVENT)

Offset

Register	Offset
FORCE_EVENT	50h

Function

This register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding field of Interrupt Status register. A read from this register always results in 0's. to change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

Diagram

33.6.1.22 ADMA Error Status (ADMA_ERR_STATUS)

Offset

Register	Offset
ADMA_ERR_STATUS	54h

Function

When an ADMA Error Interrupt has occurred, the ADMA error sates field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.

The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

Table 258. ADMA error state coding

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0b - No error 1b - Error
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No error 1b - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

33.6.1.23 ADMA System Address (ADMA_SYS_ADDR)

Offset

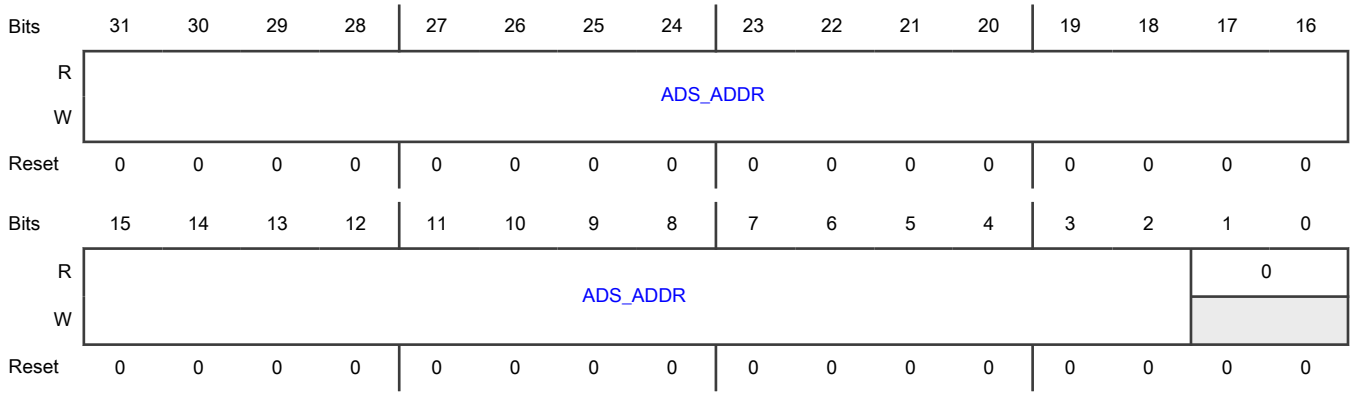
Register	Offset
ADMA_SYS_ADDR	58h

Function

This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.

Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.

Diagram



Fields

Field	Function
31-2	ADMA system address

Table continues on the next page...

Table continued from the previous page...

Field	Function
ADS_ADDR	This field contains the physical system memory address used for ADMA transfers.
1-0 —	Reserved

33.6.1.24 DLL (Delay Line) Control (DLL_CTRL)

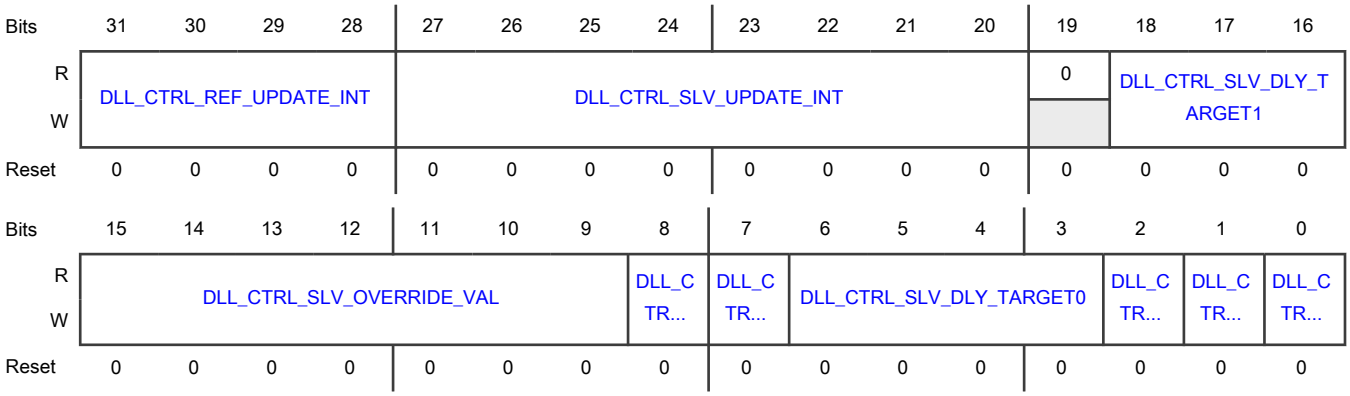
Offset

Register	Offset
DLL_CTRL	60h

Function

This register contains control fields for DLL.

Diagram



Fields

Field	Function
31-28 DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20	Slave delay line update interval If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
DLL_CTRL_SLV_UPDATE_INT	Note that the slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL slave delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL slave override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL slave override Set this field to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_GATE_UPDATE	DLL gate update Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL slave delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is (({DLL_CTRL_SLV_DLY_TARGET1,DLL_CTRL_SLV_DLY_TARGET0} +1)* REF_CLOCK / 2) / 16 So the input read-clock can be delayed relative input data from (REF_CLOCK / 2) / 16 to REF_CLOCK * 4. **NOTE** For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK/16 and REF_CLOCK*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK*2.
2 DLL_CTRL_SLV_FORCE_UPD	DLL slave delay line Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ENABLE	DLL and delay chain Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

33.6.1.25 DLL Status (DLL_STATUS)

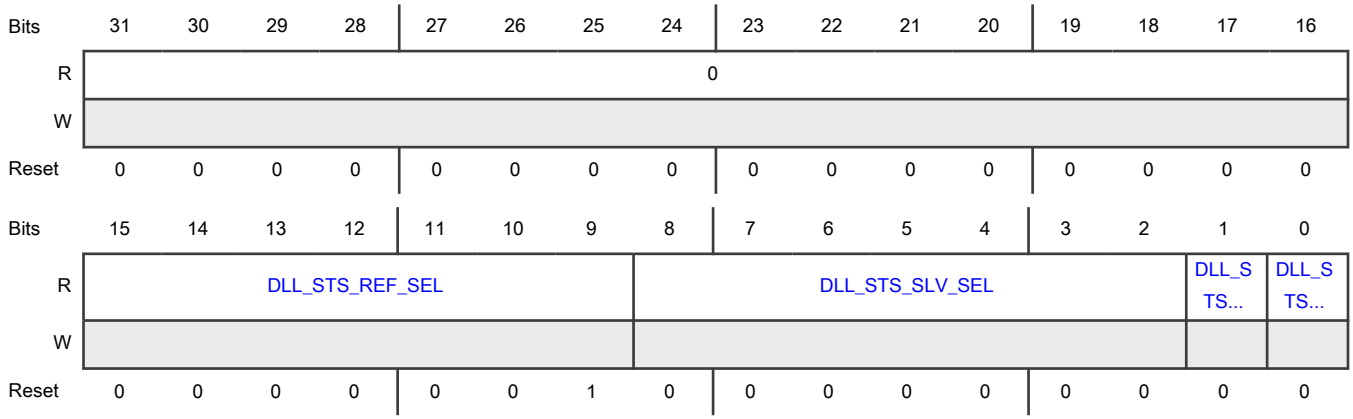
Offset

Register	Offset
DLL_STATUS	64h

Function

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-9	Reference delay line select taps

Table continues on the next page...

Table continued from the previous page...

Field	Function
DLL_STS_REF_SEL	This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Slave delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

33.6.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)

Offset

Register	Offset
CLK_TUNE_CTRL_STATUS	68h

Function

This register contains the Clock Tuning Control status information. This register is added to support SD3.0 UHS-I SDR104 mode and eMMC HS200 mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PRE_ERR	TAP_SEL_PRE							TAP_SEL_OUT				TAP_SEL_POST

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	NXT_ERR	DLY_CELL_SET_PRE							DLY_CELL_SET_OUT				DLY_CELL_SET_POST			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8 DLY_CELL_SET_PRE	delay cells on the feedback clock between the feedback clock and CLK_PRE Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7-4 DLY_CELL_SET_OUT	Delay cells on the feedback clock between CLK_PRE and CLK_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
3-0 DLY_CELL_SET_POST	Delay cells on the feedback clock between CLK_OUT and CLK_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

33.6.1.27 Strobe DLL control (STROBE_DLL_CTRL)

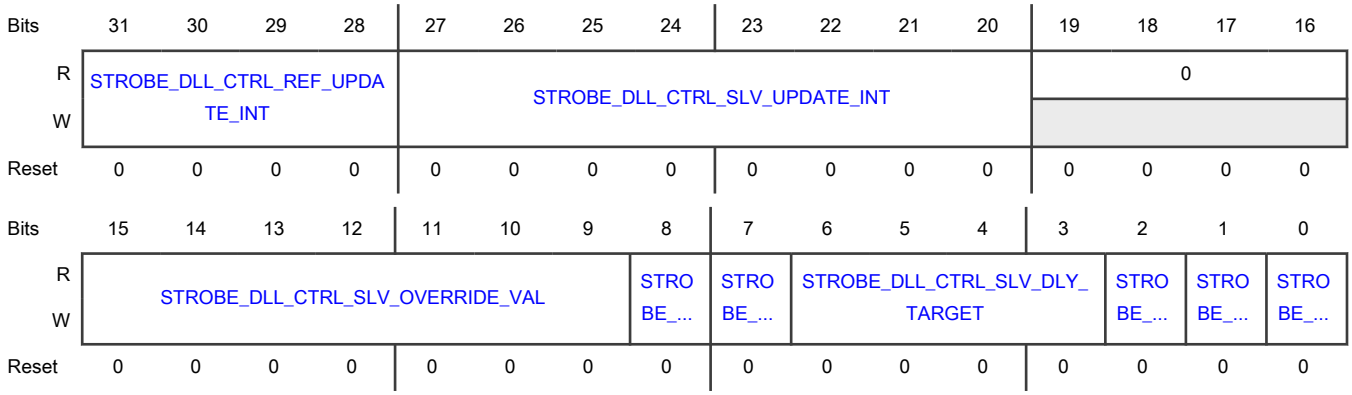
Offset

Register	Offset
STROBE_DLL_CTRL	70h

Function

This register contains the strobe DLL control information.

Diagram



Fields

Field	Function
31-28 STROBE_DLL_CTRL_REF_UPDATE_INT	Strobe DLL control reference update interval The interval cycle is (2 + STROBE_REF_UPDATE_INT) * STROBE_REF_CLOCK. By default, the DLL control loop updates every two STROBE_REF_CLOCK cycles. **NOTE** Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 STROBE_DLL_CTRL_SLV_UPDATE_INT	Strobe DLL control slave update interval Slave delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on. **NOTE** software can always cause an update of the slave-delay line using the STROBE_SLV_FORCE_UPDATE register. The slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL	Strobe DLL control slave Override value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL control slave override Set this field to 1 to Enable manual override for slave delay chain using STROBE_SLV_OVERRIDE_VAL; set this field to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 STROBE_DLL_CTRL_GATE_UPDATE	Strobe DLL control gate update Set this field to 1 to prevent the DLL from updating (because when STROBE_CLOCK_IN exists, glitches might appear during DLL updates). This field can be used by software if such a condition occurs. Clear the field to 0 to allow the DLL to update automatically.
6-3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Slave Delay Target The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is ((STROBE_DLL_CTRL_SLV_DLY_TARGET + 1) * STROBE_REF_CLOCK / 2) / 16, So, the input read-clock can be delayed relative input data from (STROBE_REF_CLOCK / 2) / 16 to (STROBE_REF_CLOCK *8)/16. **NOTE** For the restrictions of delay cell implementation, the minimum delay target that can be set is REF_CLOCK/16.
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL control slave force updated Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 STROBE_DLL_CTRL_RESET	Strobe DLL control reset Setting this field to 1 to force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL control enable Set this field to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. **NOTE** Using the slave delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

33.6.1.28 Strobe DLL status (STROBE_DLL_STATUS)

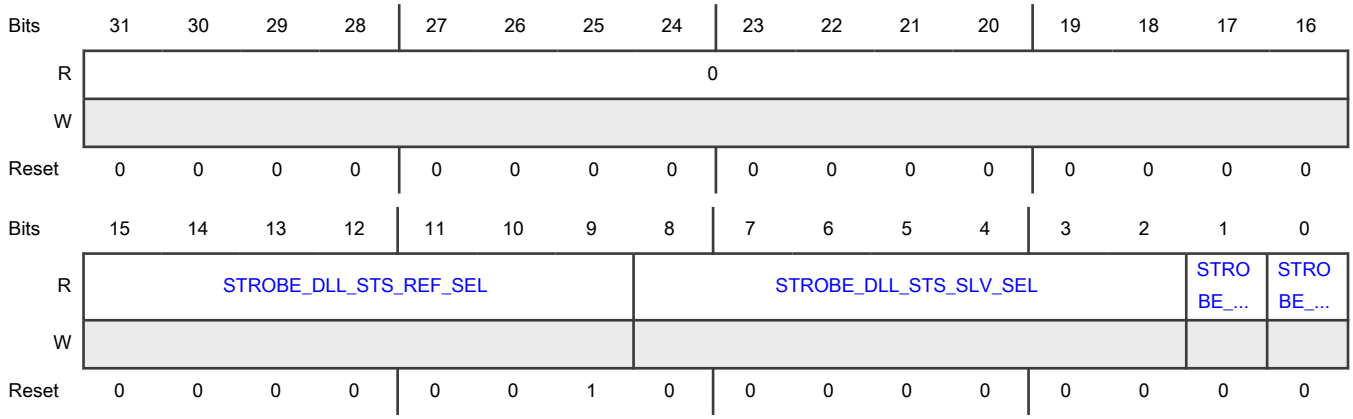
Offset

Register	Offset
STROBE_DLL_STATUS	74h

Function

This register contains the strobe DLL status information. All fields are read only and read the same as the power-reset value.

Diagram



Fields

Field	Function
31-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_STS_REF_SEL	Strobe DLL status reference select Reference delay line select taps. This is encoded by 7 fields for 127 taps.
8-2 STROBE_DLL_STS_SLV_SEL	Strobe DLL status slave select Slave delay line select status. This is the instant value generated from reference chain. Because the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_STS_REF_LOCK	Strobe DLL status reference lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the slave delay-line to perform programmed clock delays.
0 STROBE_DLL_STS_SLV_LOCK	Strobe DLL status slave lock Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line, and the slave-delay line is implementing the programmed delay value.

33.6.1.29 Vendor Specific Register (VEND_SPEC)

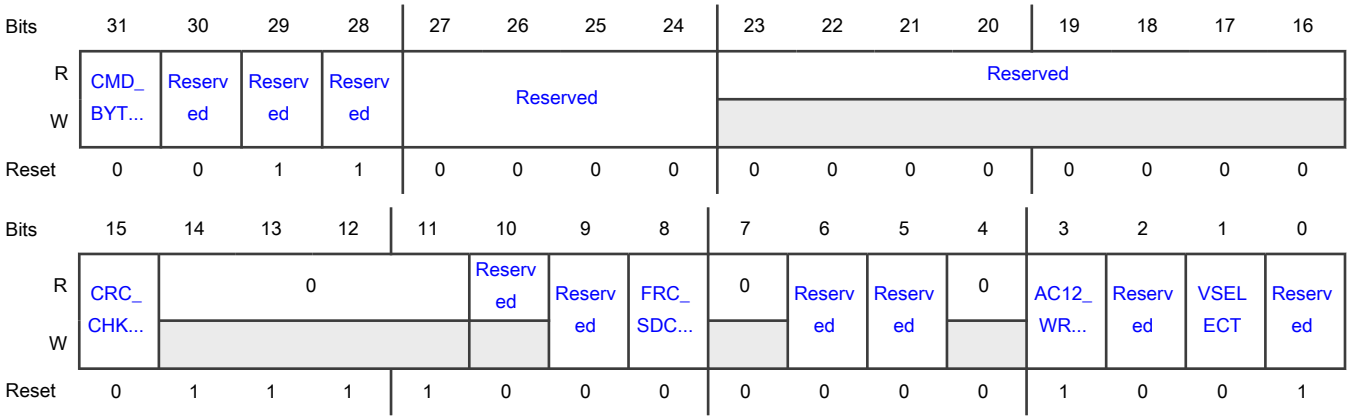
Offset

Register	Offset
VEND_SPEC	C0h

Function

This register contains the vendor specific control/status register.

Diagram



Fields

Field	Function
31 CMD_BYTE_EN	Register byte access for CMD_XFR_TYP This field controls the register byte access for Command Transfer Type (CMD_XFR_TYP). If this field is enabled, the register can be configured through byte write enable. IPS_bus can write only one byte once for one write operation. 0b - Disable. MIX_CTRL[7:0] is read/write and CMD_XFR_TYP[7:0] is read-only. 1b - Enable. MIX_CTRL[7:0] is read-only and CMD_XFR_TYP[7:0] is read/write.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 1
28 —	Reserved Always write as 0.
27-24 —	Reserved Always write as 4'b0000.
23-16 —	Reserved Always write as 8'h00.
15 CRC_CHK_DIS	CRC Check Disable 0b - Check CRC16 for every read data packet and check CRC fields for every write data packet

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ignore CRC16 check for every read data packet and ignore CRC fields check for every write data packet
14-11 —	Reserved Reserved
10 —	Reserved Always write as 0.
9 —	Reserved Always write as 0.
8 FRC_SDCLK_ON	Force CLK Force CLK output active Do not set this bit to 1 unless it is necessary. Also, make sure that this bit is cleared when uSDHC's clock is about to be changed (frequency change, clock source change, or delay chain tuning). 0b - CLK active or inactive is fully controlled by the hardware. 1b - Force CLK active
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 —	Reserved
3 AC12_WR_CHKBUSY_EN	Check busy enable Check busy enable after auto CMD12 for write data packet 0b - Do not check busy after auto CMD12 for write data packet 1b - Check busy after auto CMD12 for write data packet
2 —	Reserved
1 VSELECT	Voltage selection Change the value of output signal VSELECT to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Change the voltage to high voltage range, around 3.0 V 1b - Change the voltage to low voltage range , around 1.8 V
0 —	Reserved Always write as 0.

33.6.1.30 eMMC Boot (MMC_BOOT)

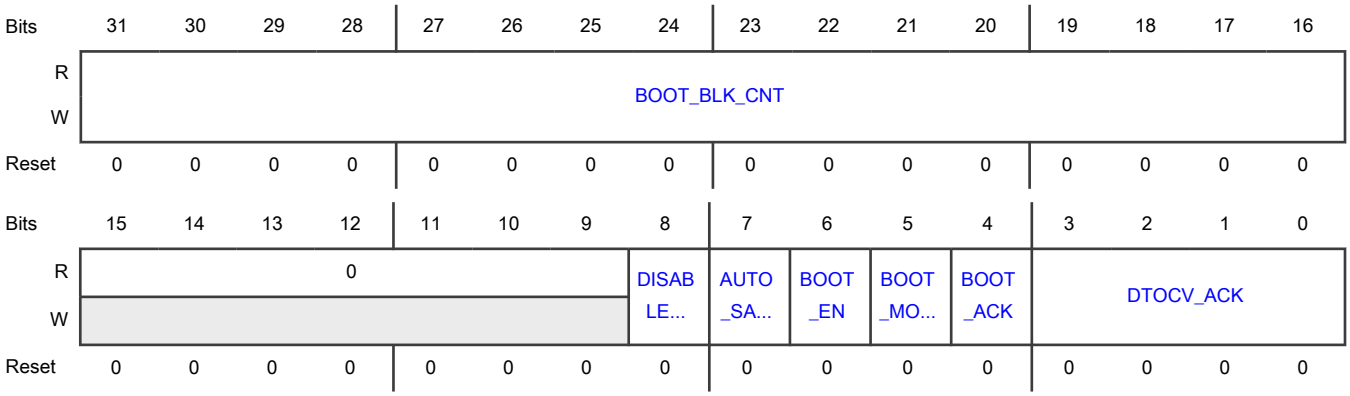
Offset

Register	Offset
MMC_BOOT	C4h

Function

This register contains the eMMC Fast Boot control register.

Diagram



Fields

Field	Function
31-16 BOOT_BLK_CNT	Stop At Block Gap value of automatic mode The value defines the Stop At Block Gap value of automatic mode. When received, card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Attributes Register, field 31 - 16 of 0x04.
15-9 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 DISABLE_TIME_OUT	Time out **NOTE** When this field is set, there is no timeout check no matter whether BOOT_EN is set or not. 0b - Enable time out 1b - Disable time out
7 AUTO_SABG_EN	Auto stop at block gap During boot, enable auto stop at block gap function. This function is triggered, and host stops at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot enable Boot mode enable 0b - Fast boot disable 1b - Fast boot enable
5 BOOT_MODE	Boot mode Boot mode select 0b - Normal boot 1b - Alternative boot
4 BOOT_ACK	BOOT ACK Boot ACK mode select 0b - No ack 1b - Ack
3-0 DTOCV_ACK	DTOCV_ACK Boot ACK time out counter value 0000b - SDCLK x 2^32 0001b - SDCLK x 2^33 0010b - SDCLK x 2^18 0011b - SDCLK x 2^19 0100b - SDCLK x 2^20 0101b - SDCLK x 2^21 0110b - SDCLK x 2^22 0111b - SDCLK x 2^23 1110b - SDCLK x 2^30 1111b - SDCLK x 2^31

33.6.1.31 Vendor Specific 2 Register (VEND_SPEC2)

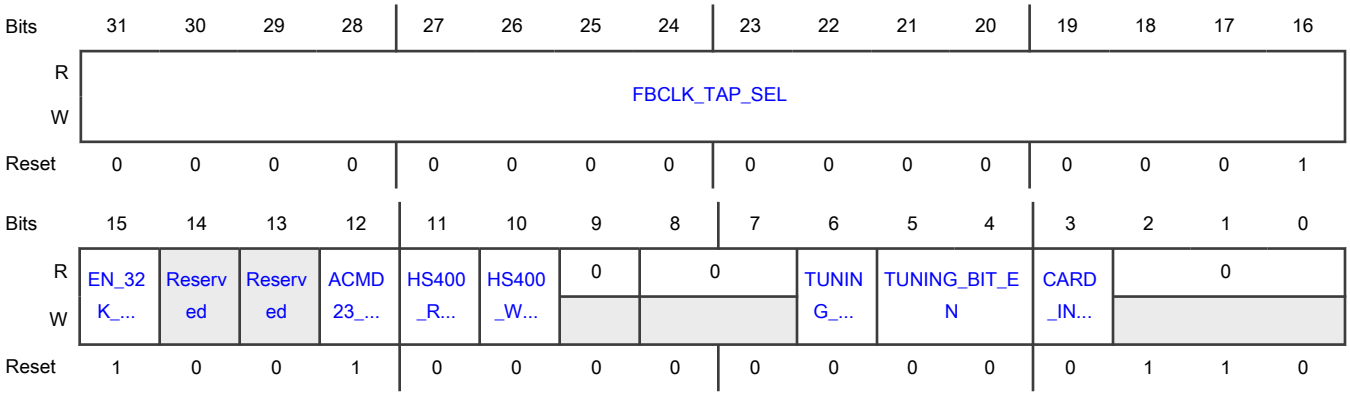
Offset

Register	Offset
VEND_SPEC2	C8h

Function

This register contains the vendor specific control 2 register.

Diagram



Fields

Field	Function
31-16 FBCLK_TAP_SEL	Enable extra delay on internal feedback clock It is a hot code. The default value is 16'h0001 that means the length of feedback delay chain is 1. The value of 16'h8000 means the length of feedback delay chain is 16.
15 EN_32K_CLK	Select the clock source for host card detection. It can use low power clock for card detection, by setting this bit to 1. 0b - Use the peripheral clock (ipg_clk) for card detection. 1b - Use the low power clock (ipg_clk_lp) for card detection.
14 —	Reserved
13 —	Reserved
12 ACMD23_ARGU2_EN	Argument2 register enable for ACMD23 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Argument2 register enable for ACMD23 sharing with SDMA system address register. Default is enabled.
11 HS400_RD_CLK_STOP_EN	HS400 read clock stop enable Only stop clock at read block gap.
10 HS400_WR_CLK_STOP_EN	HS400 write clock stop enable Only stop clock at write block gap.
9 —	Reserved
8-7 —	Reserved
6 TUNING_CMD_EN	Tuning command enable Enable the auto tuning circuit to check the CMD line. 0b - Auto tuning circuit does not check the CMD line. 1b - Auto tuning circuit checks the CMD line.
5-4 TUNING_BIT_EN	Tuning bit enable Enable the auto tuning circuit to check the DATA[7:0]. The value option is as the list below. **NOTE** In SDIO mode, auto-tuning only supports 1-bit (i.e. DATA[0]) tuning, and the 4-bit (i.e. DATA[3:0]) auto tuning is **not** supported for SDIO mode. SD mode supports 1-bit/4-bit (DATA[0] and DATA[3:0]) auto tuning. eMMC mode supports 1-bit/4-bit/8-bit (DATA[0], DATA[3:0] and DATA[7:0]) auto tuning. 00b - Enable Tuning circuit for DATA[3:0] 01b - Enable Tuning circuit for DATA[7:0] 10b - Enable Tuning circuit for DATA[0] 11b - Invalid
3 CARD_INT_D3_TEST	Card interrupt detection test This field is used only for debugging. 0b - Check the card interrupt only when DATA3 is high. 1b - Check the card interrupt by ignoring the status of DATA3.
2-0	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function

Field	Function
31-12 —	Reserved
11-8 MAJOR_VN	eMMC major version number Digit right of decimal point, in BCD format
7-4 MINOR_VN	eMMC minor version number Digit right of decimal point, in BCD format
3-0 VERSION_SUFFIX	eMMC version suffix The second digit right of decimal point, in BCD format

33.6.1.34 Command Queuing Capabilities (CQCAP)

Offset

Register	Offset
CQCAP	104h

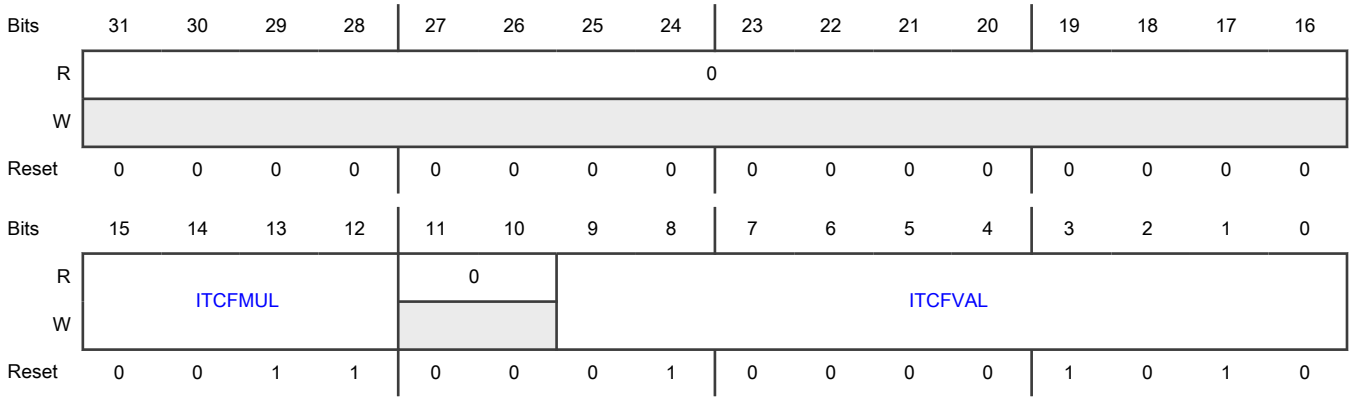
Function

This register indicates hardware capabilities.

NOTE

This register must not be configured and must be used as a read-only register. Writing to the read-write fields of this register does not affect any functionality. Reset values reflect the correct capability information.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-12 ITCFMUL	Internal timer clock frequency multiplier ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the SQS polling period. See ITCFVAL definition for details. 0001b - 0.001 MHz 0010b - 0.01 MHz 0011b - 0.1 MHz 0100b - 1 MHz 0101b - 10 MHz 0110b-1001b - Reserved
11-10 —	Reserved
9-0 ITCFVAL	Internal timer clock frequency value ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the polling period when using periodic SEND_QUEUE_ STATUS (CMD13) polling. The clock frequency is calculated as ITCFVAL* ITCFMUL. For example, to encode 19.2 MHz, ITCFVAL is C0h (= 192 decimal) and ITCFMUL is 3h (0.1 MHz): 192 * 0.1 MHz = 19.2 MHz.

33.6.1.35 Command Queuing Configuration (CQCFG)

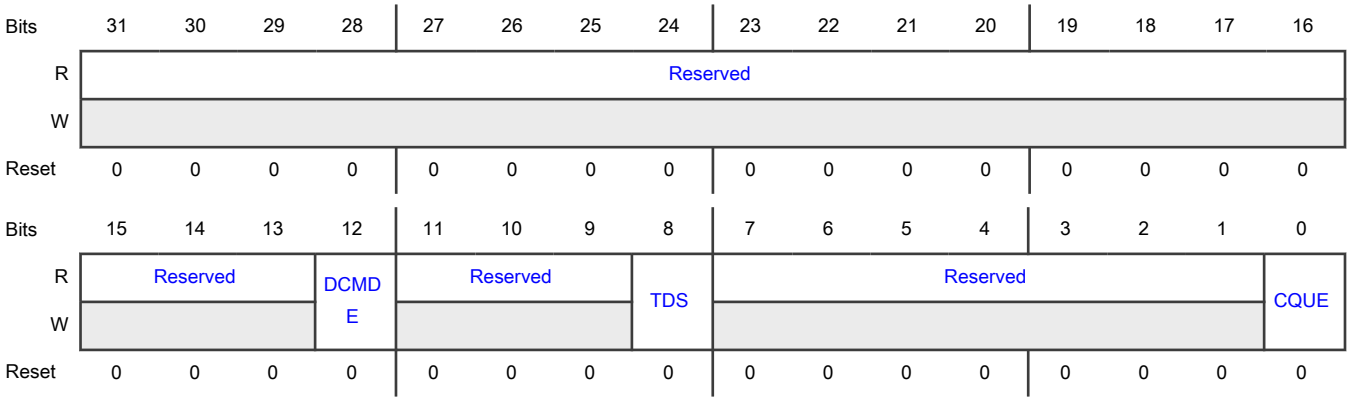
Offset

Register	Offset
CQCFG	108h

Function

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Diagram



Fields

Field	Function
31-13 —	Reserved
12 DCMDE	Direct command (DCMD) enable This bit indicates to the hardware whether the Task Descriptor in slot #31 of the TDL is a Data Transfer Task Descriptor, or a Direct Command Task Descriptor. CQE uses this bit when a task is issued in slot #31, to determine how to decode the Task Descriptor. 0b - Task descriptor in slot #31 is a Data Transfer Task Descriptor 1b - Task descriptor in slot #31 is a DCMD Task Descriptor
11-9 —	Reserved
8 TDS	Task descriptor size This bit indicates whether the task descriptor size is 128 bits or 64 bits as detailed in Data Structures section. This bit can only be configured when Command Queuing Enable bit is ‘0’ (command queuing is disabled)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Task descriptor size is 64 bits 1b - Task descriptor size is 128 bits
7-1 —	Reserved
0 CQUE	Command queuing enable Software shall write '1' this bit when in order to enable command queuing mode (for example, enable CQE). When this bit is 0, CQE is disabled and software controls the eMMC bus using the legacy eMMC host controller. Before software writes '1' to this bit, software shall verify that the eMMC host controller is in idle state and there are no commands or data transfers ongoing. When software wants to exit command queuing mode, it shall clear all previous tasks if such exist before setting this bit to 0.

33.6.1.36 Command Queuing Control (CQCTL)

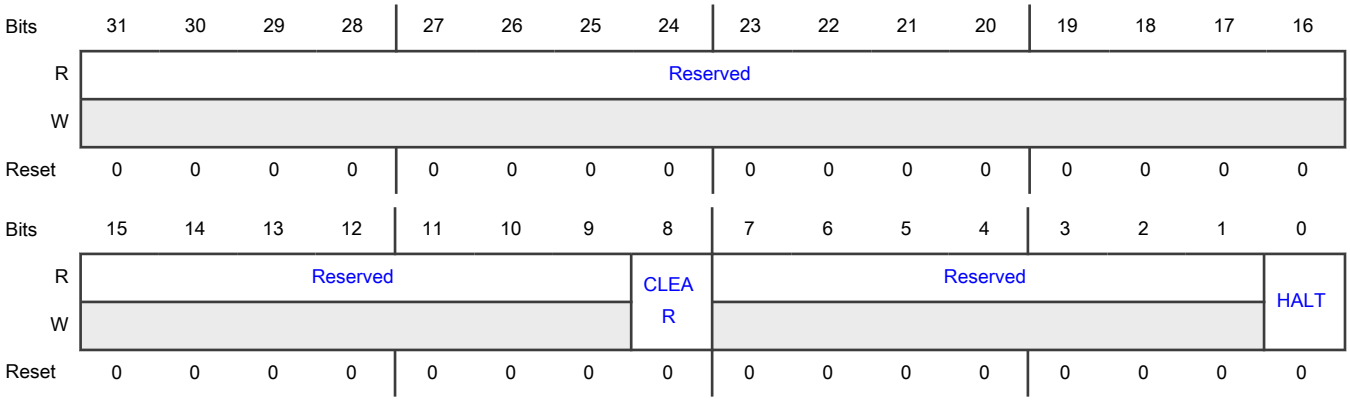
Offset

Register	Offset
CQCTL	10Ch

Function

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 CLEAR	Clear all tasks Software shall write '1' this bit when it wants to clear all the tasks sent to the chip. This bit can only be written when CQE is in halt state (for example, Halt bit is 1). When software writes 1, the value of the register is updated to '1', and CQE shall reset CQTDBR register and all other context information for all unfinished tasks. Then CQE will clear this bit. Software should poll on this bit until it is set to back 0 and may then resume normal operation, by clearing the Halt bit. CQE does not communicate to the chip that the tasks were cleared. It is software's responsibility to order the chip to discard the tasks in its queue using CMDQ_TASK_MGMT command. Writing '0' to this register shall have no effect.
7-1 —	Reserved
0 HALT	Halt Host software shall write '1' to the bit when it wants to acquire software control over the eMMC bus and disable CQE from issuing commands on the bus. For example, issuing a Discard Task command (CMDQ_TASK_MGMT) When software writes '1', CQE shall complete the ongoing task if such a task is in progress. Once the task is completed and CQE is in idle state, CQE shall not issue new commands and shall indicate so to software by setting this bit to 1. Software may poll on this bit until it is set to 1, and may only then send commands on the eMMC bus. In order to exit halt state (for example, resume CQE activity), software shall clear this bit (write '0'). Writing '0' when the value is already '0' shall have no effect.

33.6.1.37 Command Queuing Interrupt Status (CQIS)

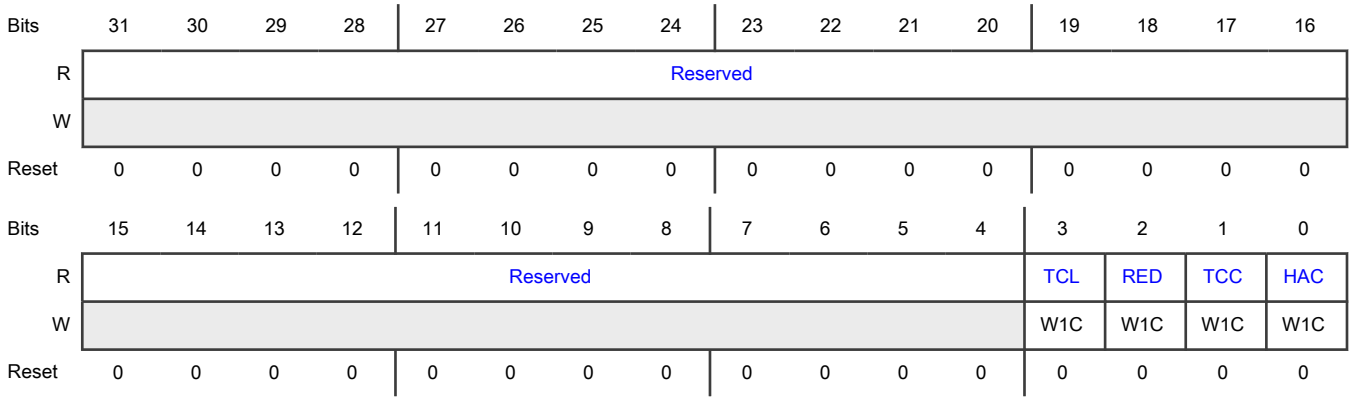
Offset

Register	Offset
CQIS	110h

Function

This register indicates pending interrupts that require service. Each bit in this registers is asserted in response a specific event, only if the respective bit is set in CQISTE register.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 TCL	Task cleared This status bit is asserted (if CQISTE[TCL_STE]=1) when a task clear operation is completed by CQE. The completed task clear operation is either an individual task clear (CQTCLR) or clearing of all tasks (CQCTL).
2 RED	Response error detected interrupt This status bit is asserted (if CQISTE[RED_STE]=1) when a response is received with an error bit set in the device status field. The contents of the device status field are listed in 6.13. Software uses CQRMEM register to configure which device status bit fields may trigger an interrupt, and which are masked.
1 TCC	Task complete interrupt This status bit is asserted (if CQISTE[TCC_STE]=1) when at least one of the following two conditions are met: • A task is completed and the INT bit is set in its Task Descriptor • Interrupt caused by Interrupt Coalescing logic (see 0)
0 HAC	Halt complete interrupt This status bit is asserted (if CQISTE[HAC_STE]=1) when halt bit in CQCTL register transitions from 0 to 1 indicating that host controller has completed its current ongoing task and has entered halt state.

33.6.1.38 Command Queuing Interrupt Status Enable (CQISTE)

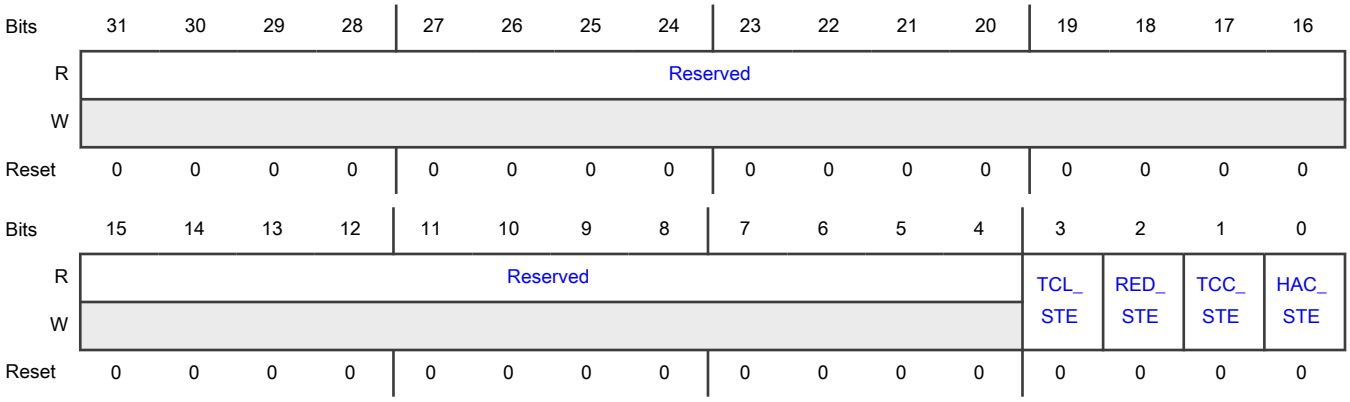
Offset

Register	Offset
CQISTE	114h

Function

This register enables and disables the reporting of the corresponding interrupt to host software in CQIS register. When a bit is set ('1') and the corresponding interrupt condition is active, then the bit is CQIS is asserted. Interrupt sources that are disabled (‘0’) are not indicated in the CQIS register. This register is bit-index matched to CQIS register.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 TCL_STE	Task cleared status enable Related to CQIS[TCL] 0b - CQIS[TCL] is disabled 1b - CQIS[TCL] is set when its interrupt condition is active
2 RED_STE	Response error detected status enable Related to CQIS[RED] 0b - CQIS[RED]is disabled 1b - CQIS[RED] is set when its interrupt condition is active
1 TCC_STE	Task complete status enable Related to CQIS[TCC] 0b - CQIS[TCC] is disabled 1b - CQIS[TCC] is set when its interrupt condition is active
0 HAC_STE	Halt complete status enable Related to CQIS[HAC] 0b - CQIS[HAC] is disabled 1b - CQIS[HAC] is set when its interrupt condition is active

33.6.1.39 Command Queuing Interrupt Signal Enable (CQISGE)

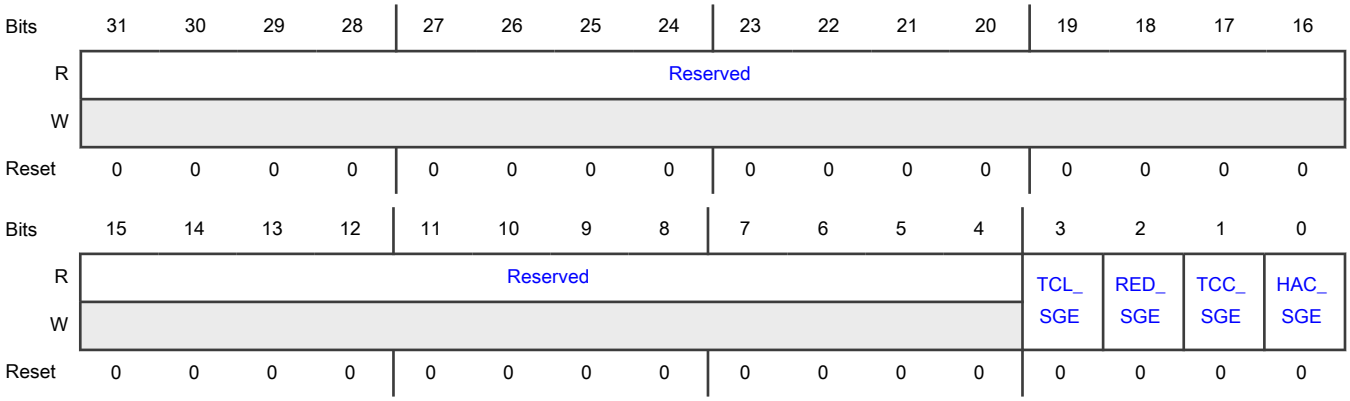
Offset

Register	Offset
CQISGE	118h

Function

This register enables and disables the generation of interrupts to host software. When a bit is set ('1') and the corresponding bit in CQIS is set, then an interrupt is generated. Interrupt sources that are disabled (‘0’) are still indicated in the CQIS register. This register is bit-index matched to CQIS register.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 TCL_SGE	Task cleared signal enable When set and CQIS[TCL] is asserted, the CQE generates an interrupt.
2 RED_SGE	Response error detected signal enable When set and CQIS[RED] is asserted, the CQE generates an interrupt.
1 TCC_SGE	Task complete signal enable When set and CQIS[TCC] is asserted, the CQE generates an interrupt.
0 HAC_SGE	Halt complete signal enable When set and CQIS[HAC] is asserted, the CQE generates an interrupt.

33.6.1.40 Command Queuing Interrupt Coalescing (CQIC)

Offset

Register	Offset
CQIC	11Ch

Function

This register controls the interrupt coalescing feature.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ICENDIS	Reserved										ICSB	Reserved			
W																ICCTR
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R		Reserved			ICCTH					ICTOVAL...			ICTOVAL			
W	ICCTHWEN															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 ICENDIS	Interrupt coalescing enable/disable When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
30-21 —	Reserved
20 ICSB	Interrupt coalescing status This bit indicates to software whether any tasks (with INT=0) have completed and counted towards interrupt coalescing (for example, ICSB is set if and only if IC counter > 0). 0b - No task completions have occurred since last counter reset (IC counter =0) 1b - At least one task completion has been counted (IC counter >0)
19-17 —	Reserved
16 ICCTR	Counter and timer reset When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 ICCTHWEN	Interrupt coalescing counter threshold write enable When software writes ‘1’, the value ICCTH is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICCTH is not updated. **NOTE** Write operations to ICCTH are only allowed when the task queue is empty.
14-13 —	Reserved
12-8 ICCTH	Interrupt coalescing counter threshold Software uses this field to configure the number of task completions (only tasks with INT=0 in the Task Descriptor) which are required in order to generate an interrupt. Counter Operation: As data transfer tasks with INT=0 complete, they are counted by CQE. The counter is reset by software during the interrupt service routine. The counter stops counting when it reaches the value configured in ICCTH. The maximum allowed value is 31. **NOTE** When ICCTH is 0, task completions are not counted, and counting-based interrupts are not generated. In order to write to this field, the ICCTHWEN field must be set at the same write operation.
7 ICTOVALWEN	Interrupt coalescing timeout value write enable When software writes ‘1’, the value ICTOVAL is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICTOVAL is not updated. **NOTE** Write operations to ICTOVAL are only allowed when the task queue is empty.
6-0 ICTOVAL	Interrupt coalescing timeout value Software uses this field to configure the maximum time allowed between the completion of a task on the bus and the generation of an interrupt. Timer Operation: The timer is reset by software during the interrupt service routine. It starts running when a data transfer task with INT=0 is completed, after the timer was reset. When the timer reaches the value configured in ICTOVAL field it generates an interrupt and stops. The timer’s unit is equal to 1024 clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 01h (1024 clock periods) and the maximum value is 7Fh (127*1024 clock periods). For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in ICTOVAL is 10h, the calculated polling period is 16*1024*52.08 ns= 853.33 us

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When ICTOVAL is 0, the timer is not running, and timer-based interrupts are not generated. In order to write to this field, the ICTOVALWEN bit must be set at the same write operation.

33.6.1.41 Command Queuing Task Descriptor List Base Address (CQTDLBA)

Offset

Register	Offset
CQTDLBA	120h

Function

This register is used for configuring the lower 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TDLBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TDLBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TDLBA	Task descriptor list base address This register stores the LSB bits (bits 31:0) of the byte address of the head of the Task Descriptor List in system memory. The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This address shall be set on 1 KByte boundary: The lower 10 bits of this register shall be set to 0 by software and shall be ignored by CQE.

33.6.1.42 Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU)

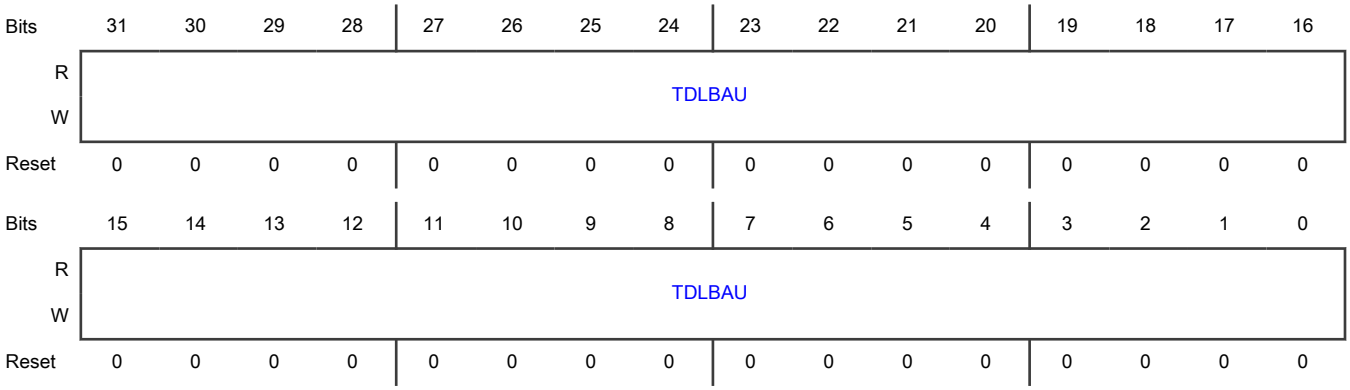
Offset

Register	Offset
CQTDLBAU	124h

Function

This register is used for configuring the upper 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

Diagram



Fields

Field	Function
31-0 TDLBAU	Task descriptor list base address This register stores the MSB bits (bits 63:32) of the byte address of the head of the Task Descriptor List in system memory. The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This register is reserved when using 32-bit addressing mode.

33.6.1.43 Command Queuing Task Doorbell (CQTDBR)

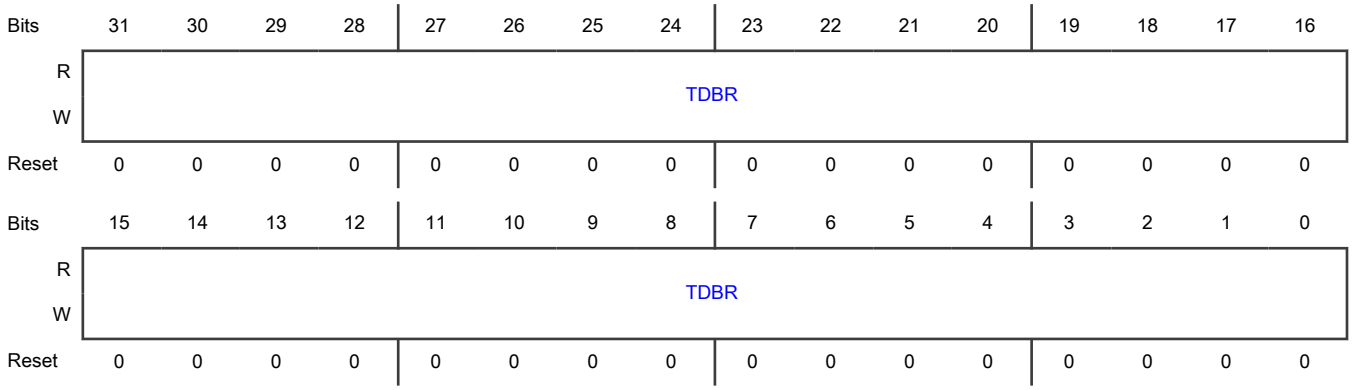
Offset

Register	Offset
CQTDBR	128h

Function

Using this register, software triggers CQE to process a new task.

Diagram



Fields

Field	Function
31-0 TDBR	Task doorbell Software configures TDLBA and TDLBAU, and enable CQE in CQCFG before using this register. Writing 1 to bit n of this register triggers CQE to start processing the task encoded in slot n of the TDL. CQE always processes tasks in-order according to the order submitted to the list by CQTDBR write transactions. CQE processes Data Transfer tasks by reading the Task Descriptor and sending QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) commands to the device. CQE processes DCMD tasks (in slot #31, when enabled) by reading the Task Descriptor, and generating the command encoded by its index and argument. The corresponding bit is cleared to '0' by CQE in one of the following events: 1. When a task execution is completed (with success or error) 2. The task is cleared using CQTCLR register 3. All tasks are cleared using CQCTL register 4. CQE is disabled using CQCFG register Software may initiate multiple tasks at the same time (batch submission) by writing 1 to multiple bits of this register in the same transaction. In the case of batch submission: CQE shall process the tasks in order of the task index, starting with the lowest index. If one or more tasks in the batch are marked with QBR, the ordering of execution will be based on said processing order. Writing 0 by software shall have no impact on the hardware, and will not change the value of the register bit.

33.6.1.44 Command Queuing Task Completion Notification (CQTCN)

Offset

Register	Offset
CQTCN	12Ch

Function

This register is used by CQE to notify software about completed tasks.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	TCN															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TCN															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TCN	Task complete notification CQE shall set bit n of this register (at the same time it clears bit n of CQTDBR) when a task execution is completed (with success or error). When receiving interrupt for task completion, software may read this register to know which tasks have finished. After reading this register, software may clear the relevant bit fields by writing 1 to the corresponding bits.

33.6.1.45 Command Queuing Device Queue Status (CQDQS)

Offset

Register	Offset
CQDQS	130h

Function

This register stores the most recent value of the device’s queue status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DQS															
W

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DQS															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 DQS	Device queue status Every time the Host controller receives a queue status register (QSR) from the device, it updates this register with the response of status command (For example, the chip's queue status).

33.6.1.46 Command Queuing Device Pending Tasks (CQDPT)

Offset

Register	Offset
CQDPT	134h

Function

This register indicates to software which tasks are queued in the device, awaiting execution.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DPT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 DPT	Device pending tasks Bit n of this register is set if and only if QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) were sent for this specific task and if this task hasn't been executed yet. CQE shall set this bit after receiving a successful response for CMD45. CQE shall clear this bit after the task has completed execution. Software needs to read this register in the task-discard procedure, when the controller is halted, to determine if the task is queued in the device. If the task is queued, the driver sends a CMDQ_TASK_MGMT (CMD48) to the device ordering it to discard the task. Then software clears the task in the CQE. Only then the software orders CQE to resume its operation using CQCTL register.

33.6.1.47 Command Queuing Task Clear (CQTCLR)

Offset

Register	Offset
CQTCLR	138h

Function

This register is used for removing an outstanding task in the CQE. The register should be used only when CQE is in Halt state.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TCLR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TCLR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TCLR	Task clear Writing 1 to bit n of this register orders CQE to clear a task which software has previously issued. This bit can only be written when CQE is in Halt state as indicated in CQCFG register Halt bit.

Table continues on the next page...

Field	Function
	When software writes ‘1’ to a bit in this register, CQE updates the value to ‘1’, and starts clearing the data structures related to the task. CQE clears the bit fields (sets a value of 0) in CQTCLR and in CQTDBR once clear operation is complete. Software should poll on the CQTCLR until it is cleared to verify clear operation was complete. Writing to this register only clears the task in the CQE and does not have impact on the device. In order to discard the task in the device, host software shall send CMDQ_TASK _MGMT while CQE is still in Halt state. Host driver is not allowed to use this register to clear multiple tasks at the same time. Clearing multiple tasks can be done using CQCTL register. Writing 0 to a register bit shall have no impact.

33.6.1.48 Command Queuing Send Status Configuration 1 (CQSSC1)

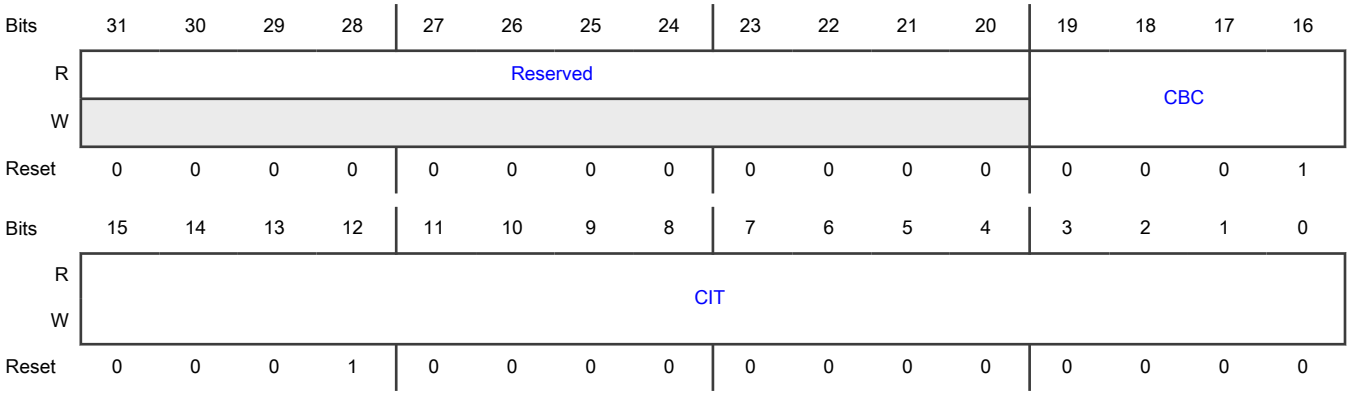
Offset

Register	Offset
CQSSC1	140h

Function

The register controls the when SEND_QUEUE_STATUS commands are sent.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16	Send status command block counter

Table continues on the next page...

Table continued from the previous page...

Field	Function
CBC	This field indicates to CQE when to send SEND_QUEUE_STATUS (CMD13) command to inquire the status of the device's task queue. A value of *n* means CQE sends status command on the CMD line, during the transfer of data block BLOCK_CNT-n, on the data lines, where BLOCK_CNT is the number of blocks in the current transaction. A value of 0 means that SEND_QUEUE_STATUS (CMD13) command is not sent during the transaction. Instead it will be sent only when the data lines are idle. A value of 1 means that STATUS command is to be sent during the last block of the transaction.
15-0 CIT	Send status command idle timer This field indicates to CQE the polling period to use when using periodic SEND_QUEUE_STATUS (CMD13) polling. Periodic polling is used when tasks are pending in the device, but no data transfer is in progress. When a SEND_QUEUE_STATUS response indicating that no task is ready for execution, CQE counts the configured time until it issues the next SEND_QUEUE_STATUS. Timer units are clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 0001h (1 clock period) and the maximum value is FFFFh (65535 clock periods). Default interval is: 4096 clock periods. For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in CQSSC1.CIT is 1000h, the calculated polling period is 4096*52.08 ns= 213.33 us

33.6.1.49 Command Queuing Send Status Configuration 2 (CQSSC2)

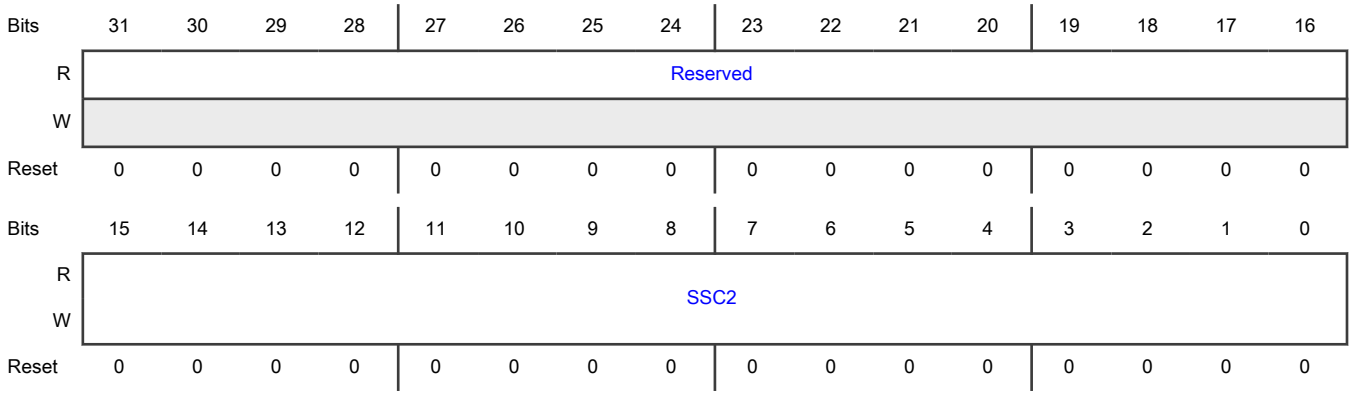
Offset

Register	Offset
CQSSC2	144h

Function

This register is used for configuring RCA field in SEND_QUEUE_STATUS command argument.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 SSC2	Send queue status RCA This field provides CQE with the contents of the 16-bit RCA field in SEND_QUEUE_ STATUS (CMD13) command argument. CQE copies this field to bits 31:16 of the argument when transmitting SEND_ QUEUE_STATUS (CMD13) command.

33.6.1.50 Command Queuing Command Response for Direct-Command Task (CQCRDCT)

Offset

Register	Offset
CQCRDCT	148h

Function

This register is used for passing the response of a DCMD task to software.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CRDCT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CRDCT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 CRDCT	Direct command last response This register contains the response of the command generated by the last direct-command (DCMD) task which was sent. CQE updates this register when it receives the response for a DCMD task. This register is considered valid only after bit 31 of CQTDBR register is cleared by CQE.

33.6.1.51 Command Queuing Response Mode Error Mask (CQRMEM)

Offset

Register	Offset
CQRMEM	150h

Function

This register controls the generation of Response Error Detection (RED) interrupt.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	RMEM															
W																
Reset	1	0	1	0	0	0	0	0	1	0	0	0	0	0	0	0

Fields

Field	Function
31-0 RMEM	Response mode error mask This bit is used as in interrupt mask on the device status filed which is received in R1/R1b responses. The reset value of this register is set to trigger an interrupt on all “Error” type bits in the device status, as defined in 6.13. **NOTE** Responses to CMD13 (SQS) encode the QSR, so they are ignored by this logic. 0000_0000_0000_0000_0000_0000_0000_0000b - When a R1/R1b response is received, bit i in the device status is ignored 0000_0000_0000_0000_0000_0000_0000_0001b - When a R1/R1b response is received, with bit i in the device status set, a RED interrupt is generated

33.6.1.52 Command Queuing Task Error Information (CQTERRI)

Offset

Register	Offset
CQTERRI	154h

Function

This register is updated by CQE when an error occurs on data or command related to a task activity.

When such error is detected by CQE or indicated by the eMMC controller CQE stores in CQTERRI the task IDs and the command indices of the commands which were executed on the command line and data lines when the error occurred.

Software is expected to use this information in the error recovery procedure. See B.2.8 for more details.

Diagram

AXI TX BUFFER size	(2^7)*8=1K Byte
AXI TX BUFFER Address Range	0x00 – 0x7F

34.2 Overview

FlexSPI_FLR is a Serial Peripheral Interface (SPI) block working as an SPI follower. It communicates with other chips or with FPGA by using the SPI bus protocol.

A remote chip with an SPI leader can read or write this block's internal registers. Alternatively, it can access the chip address via this block's AXI bus.

34.2.1 Block diagram

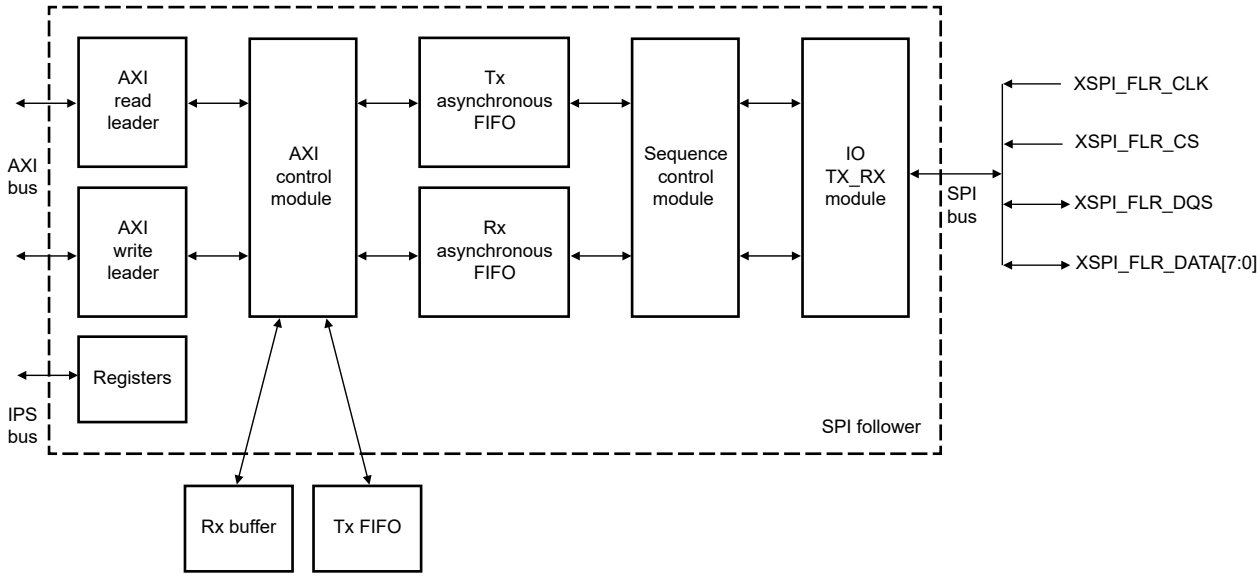

Figure 259. Block diagram

34.2.2 Features

- SPI support for these modes:
  - DDR
  - SDR
  - Octal
  - Quad
- DQS output during read commands, assisting the SPI leader with data sampling
- DQS input during write commands, as DATA strobe only in Octal DDR mode to support unaligned writes
- Automatic stop of DQS toggling during read commands to avoid FIFO underflow
- Memory read and write commands, and register read and write commands with configurable command code and dummy cycles
- Inter-Processor Communication (IPC) protocol for SPI leader and follower communication
- 9x32-bit mailbox registers which are writable and readable via the SPI leader, and are only readable via the chip
- Asynchronous interrupt through mailbox which can be set by the SPI leader
- Independent AXI write and read leaders
- Four independent read leaders
- Two different pairs of SPI memory read and write commands to access two different locations in the chip via the AXI bus
- Configurable AXI memory-base-address and address-range setting via register
- Blocking of AXI reads and writes to ignore requests from the SPI leader

34.3 Functional description

34.3.1 Modes

34.3.1.1 SDR and DDR modes

In SDR mode, FlexSPI_FLR captures the received data on the SCK rising edge. The FlexSPI leader must center-align the SCK and write data. FlexSPI_FLR sends the read data after the SCK falling edge. DQS also toggles a half cycle before the valid data emerges. See Application information.

During DDR mode, FlexSPI_FLR captures the received data on both the rising edge and SCK falling edge. The FlexSPI leader center-aligns both edges of SCK with write data. FlexSPI_FLR sends out the read data after the rising edge of SCK. DQS also toggles with the same phase as valid data. See Application information.

34.3.1.2 Quad and Octal modes

In Quad mode, FlexSPI captures and sends data through XSPI_FLR_DATA[3:0]. FlexSPI_FLR does not drive the upper four bits, and the bits are inputs relative to the block.

In Octal mode, FlexSPI captures and sends data through XSPI_FLR_DATA[7:0]. DQS is also sampled during the bit-capture phase.

34.3.1.3 Low-power modes

FlexSPI_FLR's AXI clock and module clock can shut down to enter a power-saving mode. The SPI clock, however, must remain active to allow the remote SPI leader to wake the block. When neither an AXI nor module clock exists, the remote SPI leader cannot issue memory reads or writes. The mailbox inside FlexSPI_FLR is accessible via register read and write commands. The remote SPI leader sets the interrupt inside the mailbox. The SPI clock domain sets the block's interrupt signal. After the system sees this interrupt, it can restart the AXI clock and module clock signals and clear the interrupt when the system is ready.

Meanwhile, the remote SPI leader polls the interrupt signal in the mailbox. After the leader sees that the interrupt field is cleared, you can safely issue further SPI commands.

34.3.1.4 Debug mode

FlexSPI_FLR does not support this mode.

34.3.2 Operations

34.3.2.1 Read memory

If an incoming SPI command matches the memory read command set, FlexSPI_FLR triggers an AXI read to carry read data from the chip memory. The chip access base address and address range are configurable via registers, and you can configure the shift address directly from the SPI bus.

NOTE

If an incoming request exceeds the access address range, the part beyond the range will not be read from the AXI bus, and FlexSPI_FLR's AXI interface sends no AXI read request.

The following figure shows the flow of filling the read data into the AXI RX buffer. Meanwhile, internal logic dynamically monitors the valid content inside the AXI RX buffer. After, the read data becomes valid, it is pushed into IO TX FIFO. The IO TX FIFO starts to pop the read data when it reaches the dummy cycles.

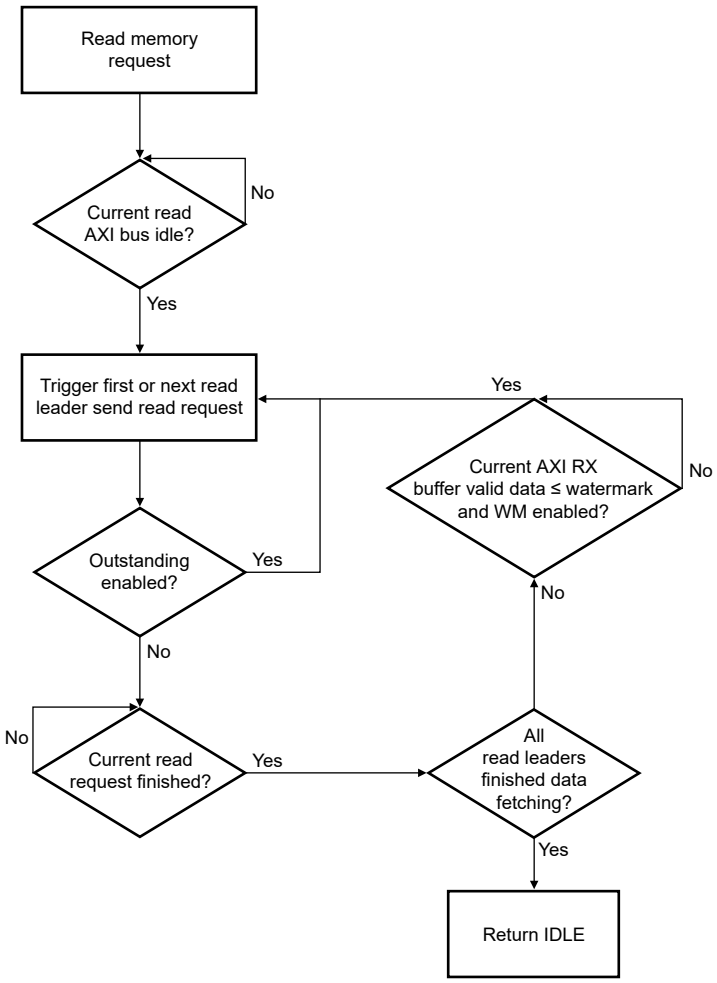

Figure 260. AXI read data flow

RDFETCHSIZE defines the maximum size for AXI fetch data. The leader must not issue a read request size larger than the limit; otherwise, the return data wraps back to address 0 of the AXI RX buffer.

If a previous request-triggered AXI read is still ongoing, the upcoming read request must wait until the current AXI read becomes idle, and the previous read request latency is added to the current read. If any read leader does not send a read request and sees the CS signal assert, it terminates the waiting and returns to idle. It is useful when the general SPI read size is small.

34.3.2.2 Write memory

If an incoming SPI command matches the memory write command set, FlexSPI_FLR triggers an AXI write to carry write data to the chip memory. The chip access base address and address range are configurable via registers, and you can configure the shift address directly from the SPI bus.

NOTE

If an incoming request exceeds the access address range, the part beyond the range is not written to the AXI bus. Additionally, FlexSPI_FLR's AXI interface does not send any more AXI write requests. All incoming write data is discarded inside the block.

The AXI write operation does not support multi-leader outstanding with only the bus leader inside of the IP. The internal logic continuously pushes write data into the AXI TX FIFO. The module monitors the filling level of AXI TX FIFO in real time.

After the filling level exceeds the watermark level that WRM sets, a write request is sent to the AXI write leader.

If the XSPI_FLR_CS signal is deasserted, all FIFO content is pushed in one request.

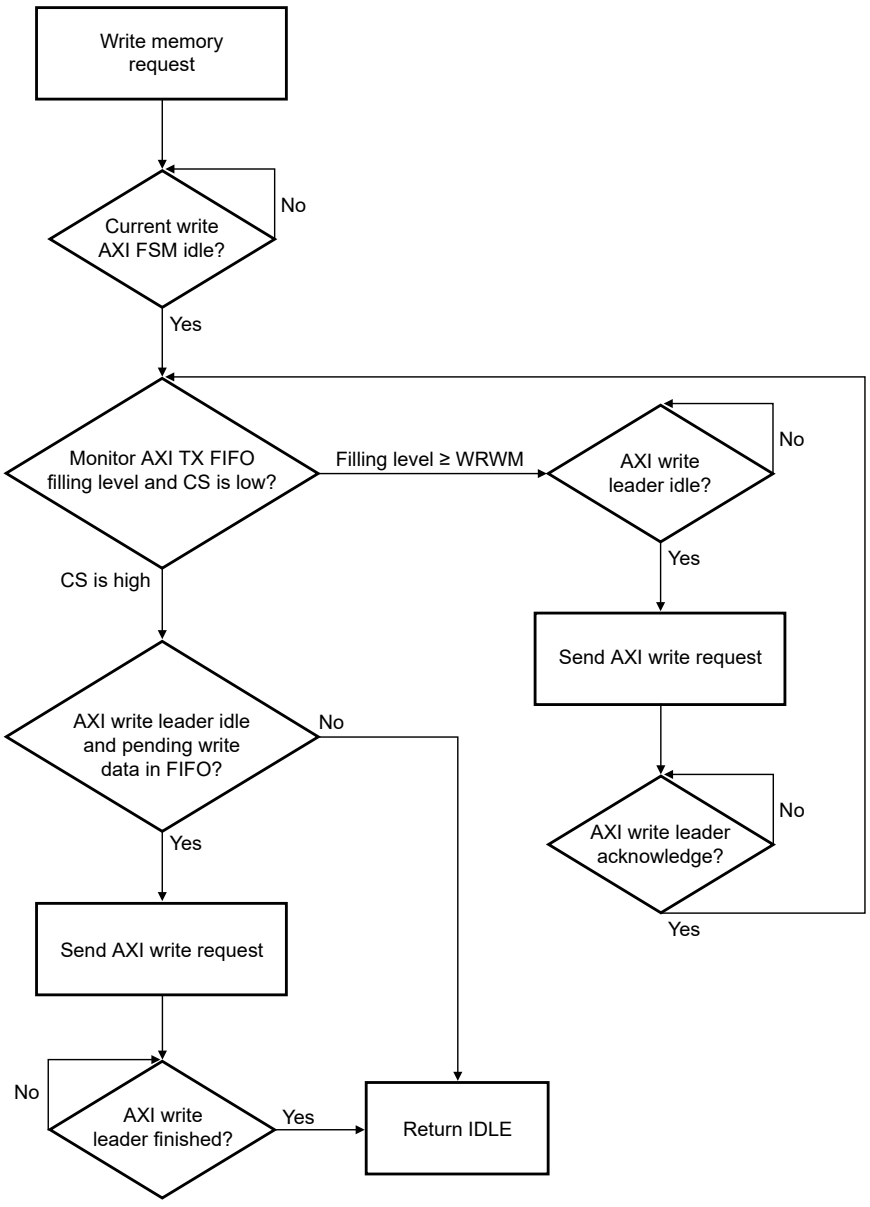

Figure 261. AXI write data flow

FlexSPI_FLR cannot accept a new write request until it finishes the current memory write command. If you attempt a write in this case, you may write the data into the wrong location.

Because the module monitors the TX FIFO in real time, the AXI bus speed restricts the maximum write size that the module can accept. To avoid a potential overflow, do not transfer a write size larger than the TX FIFO depth.

34.3.2.3 Read/write registers

If FlexSPI_FLR decodes an incoming SPI command as a register read or write, FlexSPI_FLR temporarily takes control of the IPS bus for a register read or write. Any read or write register request from the chip causes assertion of IPS_bus_transfer_wait.

There is an internal command FIFO for register reads and writes, with the default FIFO depth set to 16, which means that if the IPS domain is slow, the maximum command it can receive is 16.

For a register write operation, FlexSPI_FLR only takes the first 32 bits of data from the SPI bus as written data. Any subsequent incoming write data is received but discarded. The FlexSPI leader can only write to SPIMAIL*n* registers; writes to other internal registers in the module are discarded.

For a register read operation, if the CS signal is asserted, IO continuously sends out the same register read value. The FlexSPI leader can only read from the SPIMAIL*n* registers and FlexSPI_FLR status register. Reading from other registers returns read data 0.

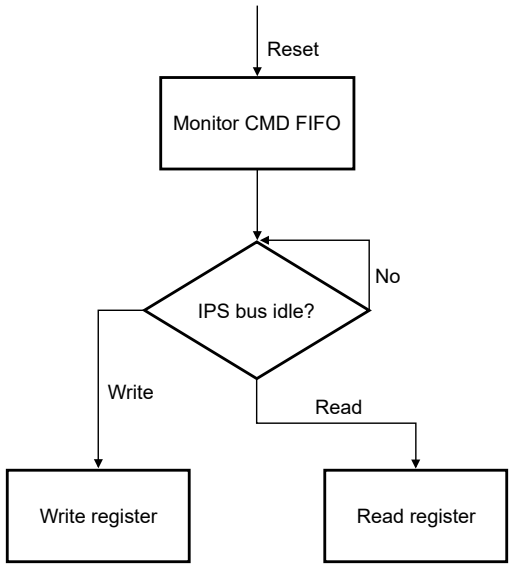

Figure 262. Read and write register flow

34.3.2.4 AXI read and write blocking

FlexSPI_FLR supports block AXI reads and writes via MODULE_CONTROL[5:10].

MODULE_CONTROL[BLKWRITE] and MODULE_CONTROL[BLKREAD] can block AXI reading and writing completely. After these fields become 1, any incoming write command is accepted, but the write data is discarded, and any incoming read command is accepted, but all returned read data are 0s. No action occurs on FlexSPI_FLR's AXI leader interface.

MODULE_CONTROL[BLKNXTWR] and MODULE_CONTROL[BLKNXTRD] control the SPI leader's access frequency.

After MODULE_CONTROL[BLKNXTRD], MODULE_CONTROL[BLKNXTWR] or both are 1, the module only supports the next incoming SPI read or write request. (An ongoing SPI read or write also counts, so the upper-level software controls access.) After FlexSPI_FLR finishes processing one more read or write, any further incoming write is accepted but discarded, and any incoming read returns zeroes.

When MODULE_CONTROL[BLKNXTRD] or MODULE_CONTROL[BLKNXTWR] is 1, you can allow one more read or write by writing MODULE_CONTROL[ALLONERD] or MODULE_CONTROL[ALLONEWR]. (An ongoing SPI read or write also counts, so the upper-level software controls the access.) It is self-cleared. It allows the SPI leader to access the SPI follower one more time.

34.3.3 Clocking

In FlexSPI_FLR:

- The AXI clock, module clock, and SPI clock are fully asynchronous.
- The SCK clock from the SPI leader is asynchronous with all internal clocks from the chip.

Due to bandwidth concerns, the AXI clock must be fast enough to handle the data input or output on the SPI bus. The AXI bus bandwidth is roughly equal to 8 bytes × AXI clock speed.

The frequency of the module clock impacts the performance of SPI register read or write commands, but normally the impact is small.

Set the frequency of SPI clock = 2 × XSPI_FLR_CLK. This frequency allows FlexSPI_FLR to respond quickly to the requests from the SPI bus.

34.3.4 Reset

FlexSPI_FLR has an internal synchronization module to synchronize the reset release in the AXI, SPI, and module domain. The reset is released after AXI clock, SPI clock, and module clock start to toggle.

The reset assert is fully asynchronous; it does not require a clock.

34.3.5 Interrupts

Table 261. Interrupts

Interrupt	Description
IO TX FIFO underflow	If the DQS stop feature is disabled (MODULE_CONTROL[DQSSTOP] = 0), it is possible that the AXI bus returns data too slowly to meet the SPI bus bandwidth during a read command. This causes a TX FIFO overflow in the IO module. The SPI leader side receives the wrong data. If MODULE_CONTROL[DQSSTOP] = 1, this interrupt only indicates that a DQS stop happened during a read command.
IO RX FIFO overflow	If the AXI and root clock domain is too slow to handle the received data from the SPI bus, an IO RX FIFO overflow occurs. After that it drops any following data coming through the IO RX FIFO. If the command is a write command, no write data is written through the AXI write leader. If it is a read command, the block ignores this overflow during the read data phase, because the IO RX FIFO is not used during that time.
Error command received	If an incoming command does not match any command set within the block, then the block ignores this command and waits for CS to deassert.
SPIMAIL interrupt	The SPI leader can write 1 to SPIMAIL0[0] to generate this interrupt; the chip can clear this.

34.4 External signals

Table 262. External signals

Signal	Description	Direction
XSPI_FLR_CLK	Clock input from SPI leader	I
XSPI_FLR_CS	Chip select input from SPI leader	I
XSPI_FLR_DQS	Input DQS as write mask from SPI leader, output DQS to SPI leader	I/O
XSPI_FLR_DATA[7:0]	Data I and O to SPI leader	I/O

34.5 Initialization

To initialize FlexSPI_FLR:

1. Enable the clock (AXI clock, IP bus clock, or root clock) for XSPI_SLV.
2. Write 1 to MODULE_CONTROL[SWRESET] to initiate software reset. Then, write 0 to this field.
3. Configure MODULE_CONTROL[IOMODE] to select I or O mode.
4. Configure RW_COMMAND_BASE[ADDRBASE2] or RW_COMMAND_BASE[ADDRBASE1] to set the read and write base address.

5. Write 1 to MODULE_CONTROL[CMDRANGEBASEUPDATE] to update the AXI command's base address.
6. Write the read and write command address range to CMD1_RANGE[RANGE] and CMD2_RANGE[RANGE].
7. Write 1 to MODULE_CONTROL[CMDRANGEBASEUPDATE] to update the AXI command's base address and range.
8. Write 1 to READ_COMMAND_CONTROL[RDWM] and READ_COMMAND_CONTROL[WMEN] to read and write watermark levels.
9. After performing the aforementioned configuration, write 0 to MODULE_CONTROL[CSMASK].

34.6 Application information

34.6.1 Write command

Table 263. Write sequence for FlexSPI_FLR

Instruction #	Command sequence input	Mode select	Settings
1	CMD	SDR write (see Figure 263)	• MODULE_CONTROL[IOMODE] = 00b or 01b • Configure Write Command 1 Setting (WRITE_COMMAND1) and Write Command 2 Setting (WRITE_COMMAND2)
		DDR write (see Figure 264)	• MODULE_CONTROL[IOMODE] = 10b or 11b • Configure WRITE_COMMANDx
2	ADDR	Same as CMD (you must configure the base address and address range.	RW_COMMAND_BASE[ADDRBASEx] is for the base address. CMDx_RANGE[RANGE] is for the address range.
3	DATA	SDR×4	MODULE_CONTROL[IOMODE] = 00b
		SDR×8	MODULE_CONTROL[IOMODE] = 01b
		DDR×4	MODULE_CONTROL[IOMODE] = 10b
		DDR×8	MODULE_CONTROL[IOMODE] = 11b

As seen in Figure 263 and Figure 264:

- Write: Command + Address + Write Data In
- No DQS toggling is allowed for SDR or DDR×4. All incoming CMD, ADDR, and DATA are sampled by the rising edge of SCK.

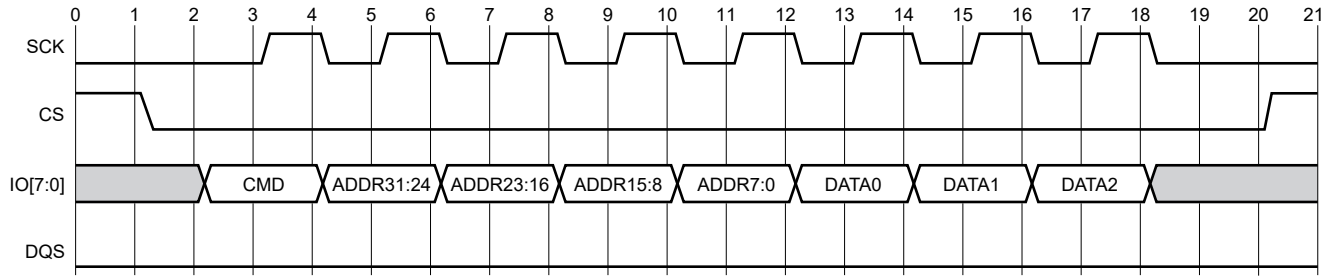

Figure 263. SDR write command

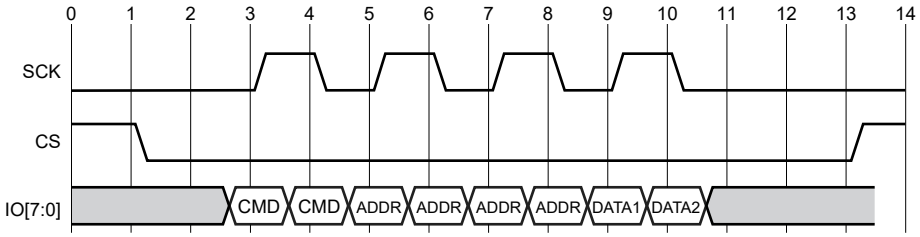

Figure 264. DDR write command

34.6.2 Read command

Table 264. Read sequence for FlexSPI_FLR

Instruction #	Command sequence input	Mode select	Settings
1	CMD	SDR write (see Figure 265 and Figure 266)	• MODULE_CONTROL[IOMODE] = 00b or 01b • Configure Read Command 1 setting (READ_COMMAND1) and Read Command 2 setting (READ_COMMAND2)
		DDR write (see Figure 267 and Figure 268)	• MODULE_CONTROL[IOMODE] = 10b or 11b • Configure READ_COMMANDx
2	ADDR	Same as CMD (you must configure the base address and address range).	RW_COMMAND_BASE[ADDRBASEx] is for the base address. CMDx_RANGE[RANGE] is for the address range.
3	DUMMY_CYCLES	Dummy clock cycles between the ADDR and DATA sequence.	READ_COMMANDx[DUMMYCYCLES] defines dummy cycles.
4	DATA	SDR×4	MODULE_CONTROL[IOMODE] = 00b
		SDR×8	MODULE_CONTROL[IOMODE] = 01b

Table continues on the next page...

Table 264. Read sequence for FlexSPI_FLR (continued)

Instruction #	Command sequence input	Mode select	Settings
		DDR×4	MODULE_CONTROL[IOMODE] = 10b
		DDR×8	MODULE_CONTROL[IOMODE] = 11b

As shown in the following figures:

- Read data: Command + Address + Dummy cycles + Read data out
- Read status: Command + Address+ Dummy cycles + Read status out
- Dummy cycles exist between the ADDR and DATA phases. The clock uses these cycles to process the read command and compensate internal asynchronous FIFO read data transferring latency.
- The SCK falling edge (see Read Command 2 setting (READ_COMMAND2) SCK edge 4) pops out the read data. A chip delay exists between SCK input to I/O valid data output ("chip delay" in Read Command2). This delay could be larger than one cycle of SCK, depending on chip implementation. Therefore, the DQS output must arrive along with valid data from the block. DQS must always be in phase with the read data output. The SPI leader must use DQS to sample the read data.

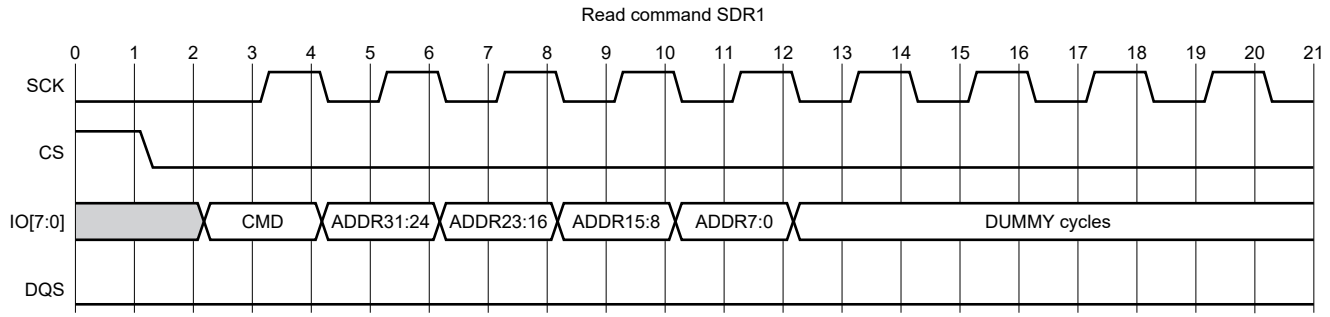

Figure 265. Read command SDR1

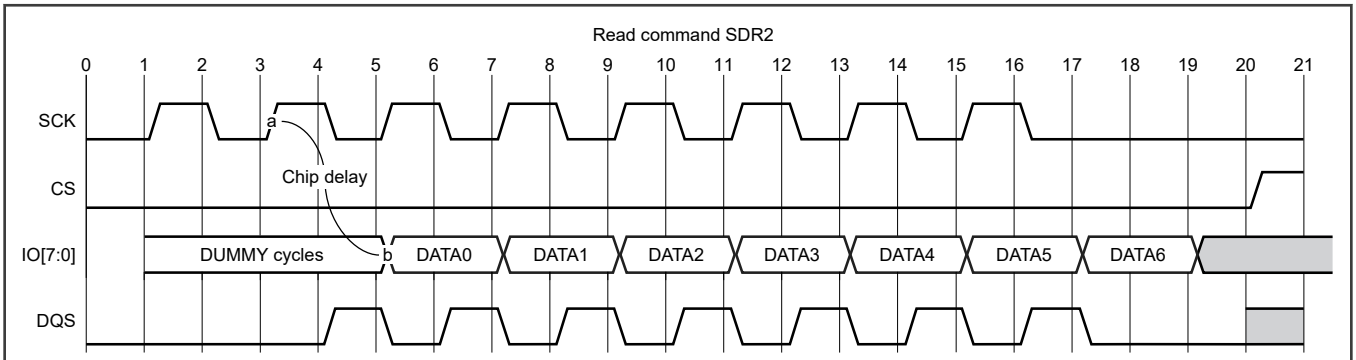

Figure 266. Read command SDR2

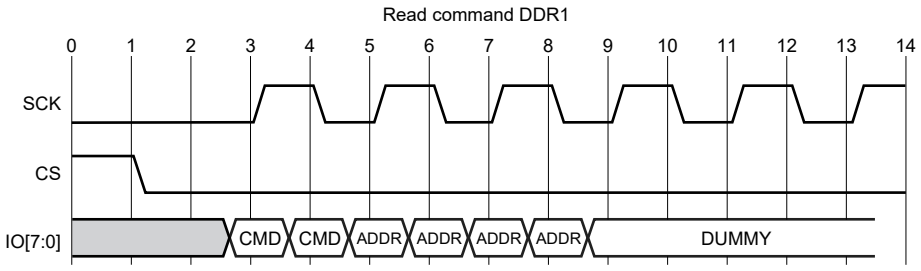

Figure 267. Read command DDR1

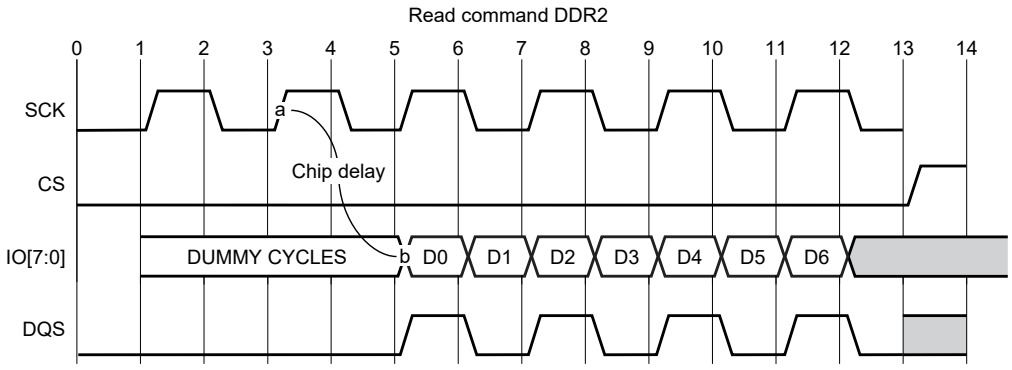

Figure 268. Read command DDR2

NOTE

For DDR×8 read, the start address must be an even address.

34.6.3 CS interval

You must maintain a minimum CS interval between each command to prevent two commands arriving at the SPI follower too closely together. During this period of time, the SPI follower must clean up all redundant data in each stage of the asynchronous FIFO to prepare a clean data path for the next command.

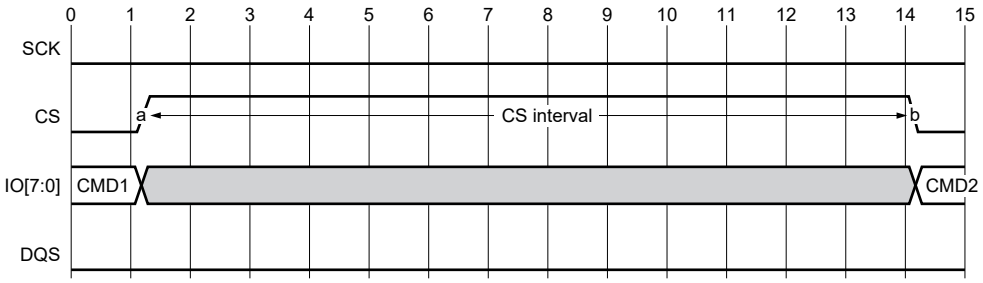

Figure 269. CS interval

34.6.4 TCSS and TCSH timing

TCSH is the period between when SCK stops toggling and CS deasserts. This period of time is necessary for FlexSPI_FLR to clean up the internal state from the previous transaction.

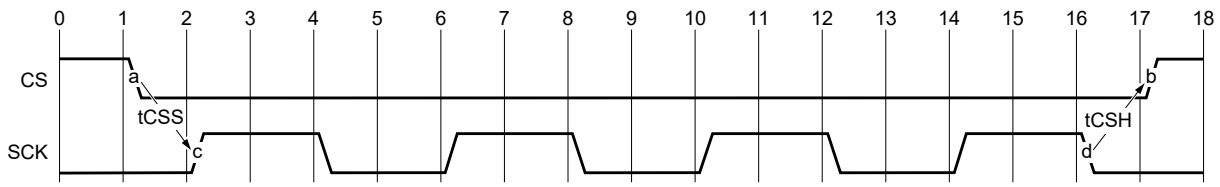

Figure 270. TCSS and TCSH timing

TCSS is the period between CS being asserted and SCK starting to toggle. This period of time is necessary for FlexSPI_FLR to initialize the block's internal IO logic.

34.6.5 Read DQS stop feature in SDR mode

Because of chip bus latency, if read data is not returned quickly enough, it is possible for I/O TX FIFO to be empty. In this case, the IO TX FIFO pop must be negated so that DQS does not toggle.

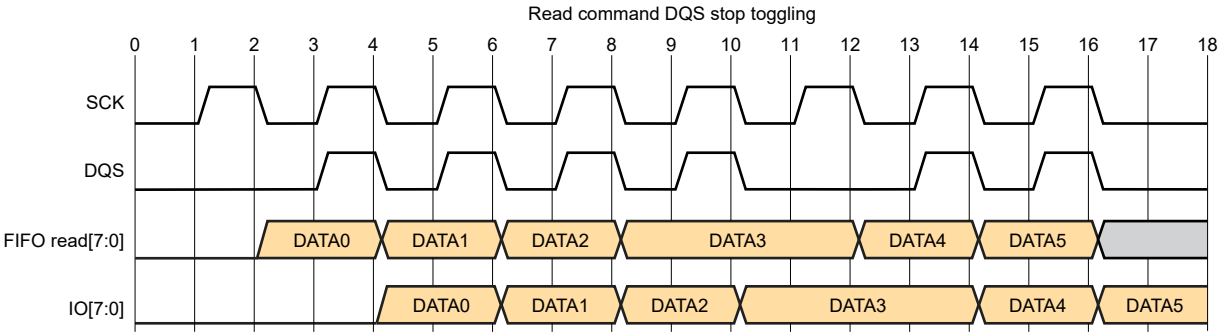

Figure 271. Read command DQS stop toggling

34.6.6 Write DQS mask in DDR mode

DQS working as mask is only supported in DDR×8 mode. In this mode, the start address and write data beat must always be even.

In the following figure, DATA0 and DATA7 are discarded.

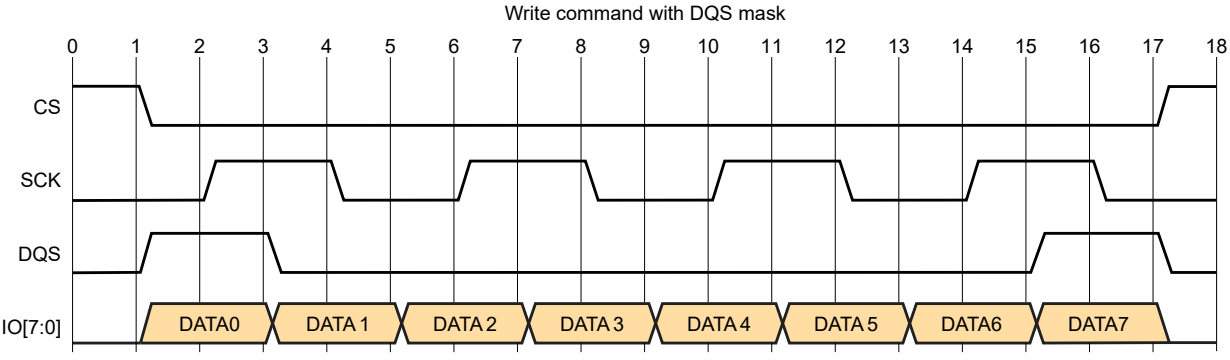

Figure 272. Write command with DQS mask

34.7.1.2 Module Control (MODULE_CONTROL)

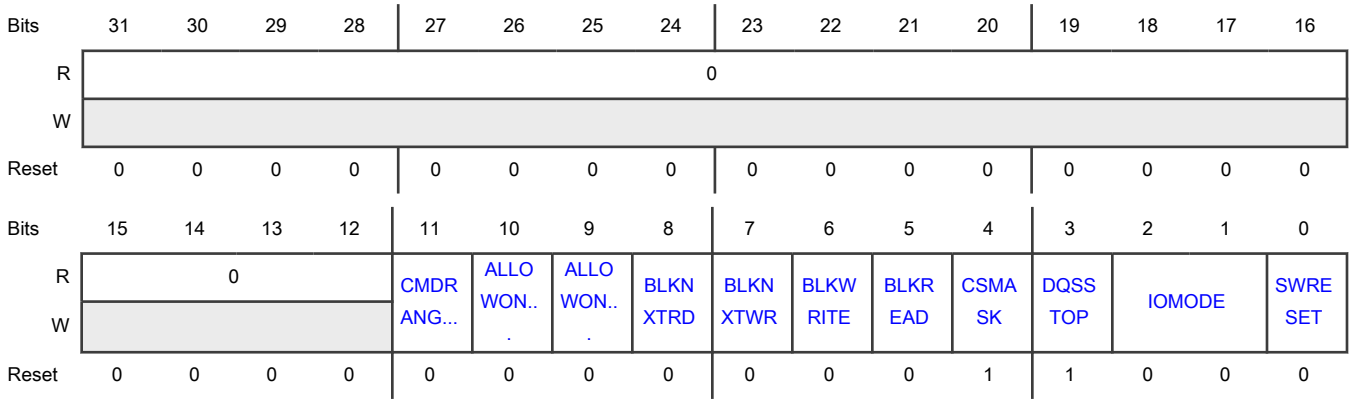
Offset

Register	Offset
MODULE_CONTROL	0h

Function

Contains miscellaneous control fields.

Diagram



Fields

Field	Function
31-12 —	Reserved
11 CMDRANGEBASEUPDATE	AXI Command Range Base Update After changing the AXI command's base address and range, set this field until it is self-cleared. 0b - Not updated 1b - Updated
10 ALLOWONERD	Allow One More Read Specifies whether one or more read command is allowed when BLKNXTRD is 1. You can use this field only when BLKNXTRD is 1. This field automatically becomes 0 if it is 1. 0b - Not allowed 1b - Allowed
9 ALLOWONEWR	Allow One More Write Specifies whether one or more write command is allowed when BLKNXTWR is 1. You can use this only when BLKNXTWR is 1. This field automatically becomes 0 if it is 1. 0b - Not allowed 1b - Allowed
8 BLKNXTRD	Block Next Read Specifies whether the next read command is allowed. If it is blocked, a read command returns all zeros. 0b - Allowed 1b - Blocked
7	Block Next Write Command Specifies whether the next write command is allowed. If not, all incoming write data will be discarded.

Table continues on the next page...

Table continued from the previous page...

Field	Function
BLKNXTWR	0b - Allowed 1b - Blocked
6 BLKWRITE	Block Write Specifies whether the incoming write command is allowed. If this field is 1, all incoming write data is dropped. 0b - Allowed 1b - Blocked
5 BLKREAD	Block Read Specifies whether the incoming read commands are allowed. If not, return 0h to SPI bus. 0b - Allowed 1b - Blocked
4 CSMASK	Chip Select Mask Masks the chip select. You must write 0 to this field after I/O configuration is completed to avoid any mistriggering of internal logic. 0b - Not masked 1b - Masked
3 DQSSTOP	DQS Stop Feature Specifies that when you write 1 to this field during a read command, DQS stops toggling if internal FIFO has no read data to pop out. If this field is 0, the chip must ensure that no FIFO underflow happens. 0b - Disable 1b - Enable
2-1 IOMODE	SPI IO Mode Control 00b - SDR×4 01b - SDR×8 10b - DDR×4 11b - DDR×8
0 SWRESET	Software Reset Specifies whether to initiate software reset. Before writing 1, all state machines must be idle. 0b - Finished 1b - Initiate

34.7.1.3 Read Command Control (READ_COMMAND_CONTROL)

Offset

Register	Offset
READ_COMMAND_CONTROL	4h

Function

Contains read command control fields.

CTI	CTI support	1
WIC	WIC support	0
LOCKSTEP	Dual-redundant (lock-step) CPU functionality	0
RAR	Reset-all-registers	1
DW	Use Synopsys DesignWare	1
ICACHESIZE	I-cache Size (in k Bytes)	32
DCACHESIZE	D-cache Size (in k Bytes)	32

The Cortex-M7 provides access to ITCM and DTCM through a direct SRAM memory port. The address used for the I/DTCM are fixed within the Cortex-M7 IP core. These addresses are:

- ITCM => 0x0000_0000 (of size 0, 256kB, or 512kB)
- DTCM => 0x2000_0000 (of size 0, 256kB, or 512kB)

The system access from non-Cortex-M7 initiators to the TCM is mapped to address:

- ITCM => 0x2038_0000 or 0x3038_0000 (remapped to 0x0000_0000)
- DTCM => 0x2040_0000 or 0x3040_0000 (remapped to 0x2000_0000)

The valid range of these address ranges depends on the value of M7_CFG[TCM_SIZE].

35.2 Overview

Cortex-M7 platform features a single Arm® Cortex®-M7 processor in this chip. The Arm Cortex-M7 processor is a highly efficient, high-performance, embedded processor that features low interrupt latency, low-cost debug, and has backward compatibility with existing Cortex-M profile processors. The processor has an in-order super-scalar pipeline by which many instructions can be dual-issued, including load/load and load/store instruction pairs because of multiple memory interfaces.

Memory interfaces that the processor supports include:

- Tightly-Coupled Memory (TCM)
- Harvard instruction and data caches and AXI Master (AXIM) interface
- Dedicated low-latency AHB-Lite Peripheral (AHBP) interface

35.2.1 Block diagram

A block diagram for Cortex-M7 is given below:

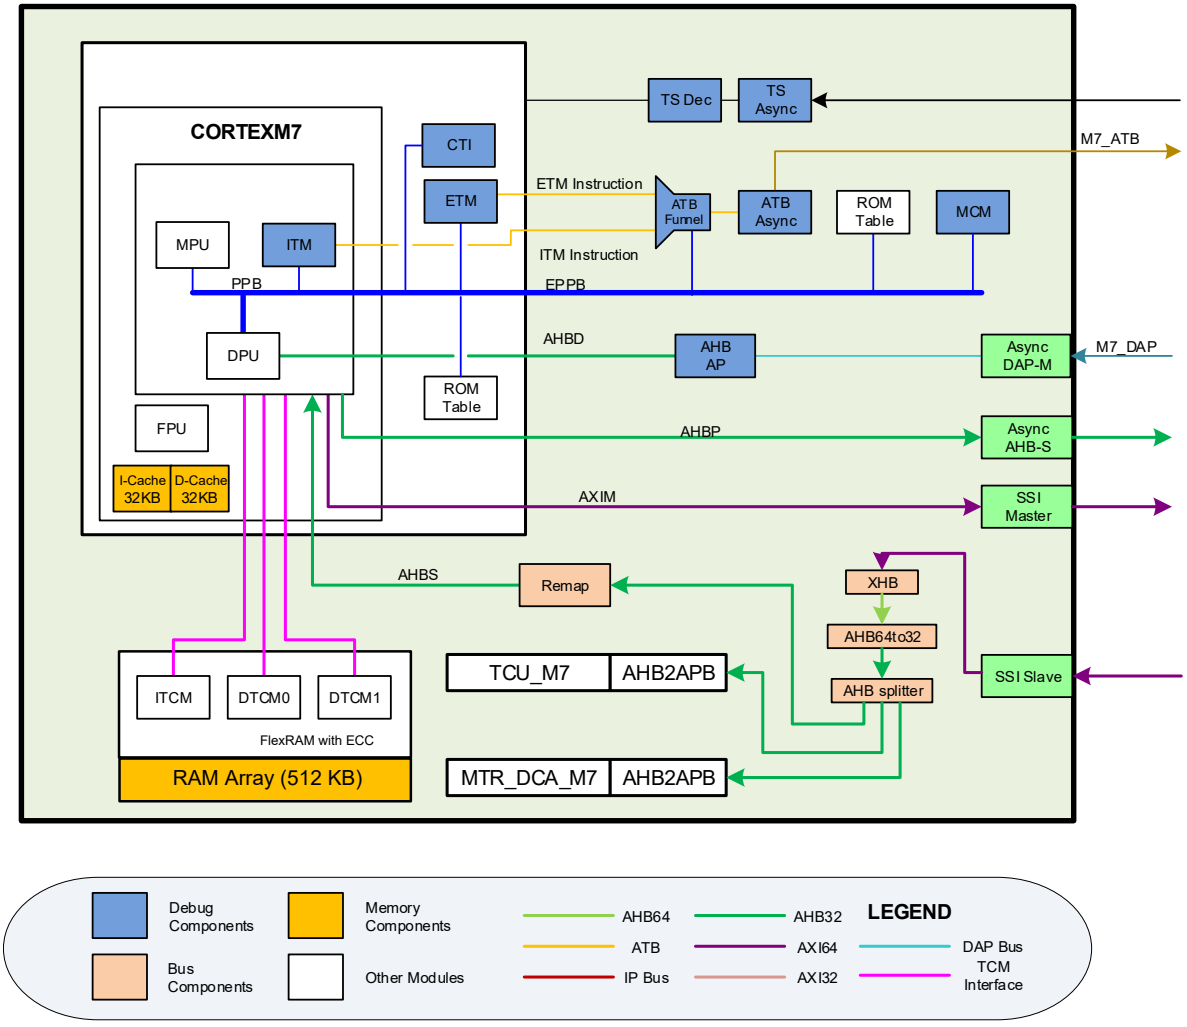

Figure 273. Cortex-M7 Platform Block Diagram

35.2.2 Features

Cortex-M7 platform in this chip has the following features.

- 1× Cortex-M7 processor: architecture Arm v7E-M.
- Floating Point Unit (FPU) FPv5 including single and double precision.
- Bus interface 64-bit AMBA4 AXI, 32-bit AHB peripheral port, 32-bit AMBA AHB slave port, AMBA APB interface for CoreSight debug components.
- 32 KB instruction / 32 KB data L1 caches with ECC.
- Configurable size instruction and data TCM (default 256 KB ITCM / 256 KB DTCM) with ECC interface.
- 16 regions of MPU.
- Non-maskable Interrupt (NMI) + 240 NVIC IRQs.
- 16 interrupt priority levels (4-bits).
- Sleep (WAIT) and deep sleep (STOP) power modes with integrated WFI, WFE, SLEEPONEXIT.
- SWD and JTAG, with up to 8 breakpoints and 4 watchpoints.

35.3 Functional description

35.3.1 CM7_MCM sub-module

CM7_MCM is a miscellaneous control module for ARM Cortex-M7. It is connected onto the Cortex-M7 PPB bus. It mainly contains programming registers to control the ECC features for CM7 ITCM and DTCM (CM7_ECC_MCM registers). It also has registers for Cortex-M7 FPU exceptions (CM7_MCM registers).

35.3.2 Tightly-Coupled Memory (TCM)

The Cortex-M7 uses TCM to perform low-latency memory operations. There are two TCM memory regions called ITCM and DTCM. The ITCM interface has a 64-bit data width and DTCM interface has a 32-bit data width.

The project supports total 512 KB TCM. By default, the ITCM and DTCM are 256 KB each. The valid address ranges of those memories depend on the value of M7_CFG[TCM_SIZE]. See M7_CFG register in BLK_CTRL_S_AONMIX chapter in the chip's Security Reference Manual. M7_CFG[TCM_SIZE] is a 3-bit field with 5 valid encodings:

- 000b - Regular TCM, 256 KB ITCM and 256 KB DTCM
- 001b - Double ITCM, 512 KB ITCM
- 010b - Double DTCM, 512 KB DTCM
- 100b - HALF ITCM, 128 KB ITCM and 384 KB DTCM
- 101b - HALF DTCM, 384 KB ITCM and 128 KB DTCM
- 011b - Reserved
- 110b - Reserved
- 111b - Reserved

When the TCM access is out of its register defined space, then it gets hard fault interrupt for illegal access indication. For example, when the DTCM size is defined to 384 KB size, then the read access on CM7 DTCM gets error response if the address is out of 384 KB space.

NOTE

For CM7 core, the base address of each TCM is fixed:

- ITCM at 0x00000000.
- DTCM at 0x20000000.

For the system access from non-Cortex-M7 initiators to the TCM, the address is remapped. The ITCM and DTCM regions are always in continuous totally 512 KB region, but based on different TCM size configuration, the address has different mapping, only the address defined in the valid 512 KB region is legal, the access out of this 512 KB region are illegal access, and it causes error response by hard fault indication if accessed. For example with following memory map table from CM33 core view, there are following several different memory remaps:

Table 267. CM7 TCM Memory Map Example (CM33 View)

Alias	Start Address(hex) (Non-Secure)	End Address(hex) (Non-Secure)	Start Address (hex) (Secure)	End Address(hex) (Secure)
M7 ITCM	20380000	203BFFFF	30380000	303BFFFF
M7 ITCM	203C0000	203FFFFF	303C0000	303FFFFF
M7 DTCM	20400000	2043FFFF	30400000	3043FFFF
M7 DTCM	20440000	2047FFFF	30440000	3047FFFF

When TCM is configured to 256 KB ITCM and 256 KB DTCM, the ITCM base and DTCM base address are remapped as following mapping:

- ITCM => 0x203C_0000 or 0x303C_0000 (remapped to 0x0000_0000)
- DTCM => 0x2040_0000 or 0x3040_0000 (remapped to 0x2000_0000)

When TCM is configured to 128 KB ITCM and 384 KB DTCM, the ITCM base and DTCM base address are remapped as following mapping:

- ITCM => 0x203E_0000 or 0x303E_0000 (remapped to 0x0000_0000)
- DTCM => 0x2040_0000 or 0x3040_0000 (remapped to 0x2000_0000)

When TCM is configured to 384 KB ITCM and 128 KB DTCM, the ITCM base and DTCM base address are remapped as following mapping:

- ITCM => 0x203A_0000 or 0x303A_0000 (remapped to 0x0000_0000)
- DTCM => 0x2040_0000 or 0x3040_0000 (remapped to 0x2000_0000)

When TCM is configured to 512 KB ITCM and no DTCM, the ITCM base address is remapped as following mapping and since no DTCM is defined, the read access on all address from 0x2040_0000 to 0x2047_FFFF gets error response.

- ITCM => 0x2038_0000 or 0x3038_0000 (remapped to 0x0000_0000)

When TCM is configured to 512 KB DTCM and no ITCM, the DTCM base address is remapped as following mapping and since no ITCM is defined, the read access on all address from 0x2038_0000 to 0x203F_FFFF gets error response.

- DTCM => 0x2040_0000 or 0x3040_0000 (remapped to 0x2000_0000)

In the project, The Cortex-M7 also supports ECC function with Double Error Detection and Single Error Correction (SEC-DED) to the TCM memories. Where, the following features are also supported:

- ECC errors detected are capable of being reported.
- ECC errors are capable of being injected and tested.

  For the details how to inject ECC error and report error, see CM7_ECC_MCM chapter.

35.3.3 Cache

The Cortex-M7 uses the instruction and data caches to provide fast access to frequently accessed data and instructions, that support increased average performance when using system-based memory. Cortex-M7 processor supports following feature on Cache function:

- Two-way set-associative 32 KB Instruction Cache.
- Four-way set-associative 32 KB Data Cache.
- ECC supports for both Instruction Cache and Data Cache with Double Error Detection and Single Error Correction (SEC-DED) on following cache memory region:
  - Instruction cache data RAM.
  - Instruction cache tag RAM.
  - Data cache data RAM.
  - Data cache tag RAM.

For Cache ECC function, it can also support the following features:

- ECC errors detected are capable of being reported.
- ECC errors are capable of being injected and tested.

For the detailed information on how to inject and report ECC error on cache, see Error Injection Module (EIM) and Error Reporting Module (ERM) chapters.

35.3.4 Memory Protection Unit (MPU)

The Cortex-M7 platform supports Memory Protection Unit (MPU). The MPU divides the memory map into a number of regions, and defines the location, size, access permissions, and memory attributes of each region. It supports:

- Independent attribute settings for each region.
- Overlapping regions.
- Export of memory attributes to the system.

The memory attributes affect the behavior of memory accesses to the region. The Cortex-M7 MPU defines up to 16 separate memory regions.

The Cortex-M7 MPU memory map is unified. This means instruction accesses and data accesses have same region settings. If a program accesses a memory location that is prohibited by the MPU, the processor generates a MemManage fault.

For the detailed information about MPU, see "Memory Protection Unit" chapter in DUI0644E_cortex_m7_r1p2_ugrm.pdf.

35.3.5 Clocking

Table 268. Arm Cortex-M7 Clocks

Clock Name	Description
forerun_clk	Clock for trout.ref_clk
osc_24m_clk	Clock for CMU.ref_clk
ccm_m7_clk_root	Clock for arm core / TCM / Cache
ccm_m7_bus_clk_root	Clock for m7 peripherals
ccm_m7_stclk_root	Used as cm7.STCLKEN

Table continues on the next page...

Table 268. Arm Cortex-M7 Clocks (continued)

Clock Name	Description
ssi_ahbs_ssi_fwd_clk	Clock for ssi slave forward direction clock
ssi_ahbs_ssi_rev_clk	Clock for ssi slave reverse direction clock
ssi_axim_ssi_fwd_clk	Clock for ssi master forward direction clock
ssi_axim_ssi_rev_clk	Clock for ssi master reverse direction clock

35.3.6 Reset

CM7_MCM uses reset of Cortex-M7. Cold or soft resetting the CM7 core would also reset this module.

35.3.7 Interrupts

CM7_MCM has three interrupt requests: mcm_irq, tcm_ecc1bit_irq and tcm_ecc2bit_irq.

The mcm_irq asserts when any of the interrupts in register ISCR occurs.

The tcm_ecc1bit_irq asserts when a single bit ECC error is detected on TCM including ITCM, D0TCM and D1TCM and the corresponding interrupt is enabled.

The tcm_ecc2bit_irq asserts when a multi-bit ECC error is detected on TCM including ITCM, D0TCM and D1TCM and the corresponding interrupt is enabled.

35.4 Memory Map and register definition

This section includes CM7_MCM memory map and detailed description of all registers.

35.4.1 CM7_MCM register descriptions

35.4.1.1 CM7_MCM memory map

M7_MCM base address: E008_0000h

Offset	Register	Width (In bits)	Access	Reset value
10h	Interrupt Status and Control Register (ISCR)	32	RW	0000_0000h
14h	SysTick Calibration Register (CFGSTCALIB)	32	RW	0100_0000h
18h	Process ID (PID)	32	RW	0000_0000h

35.4.1.2 Interrupt Status and Control Register (ISCR)

Offset

Register	Offset
ISCR	10h

Function

Defines the configuration and reports the status for a number of core-related interrupt exception conditions. It includes the enable and status bits associated with the core's floating-point exceptions, and bus errors on TCM. The individual event indicators are first qualified with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC. Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these bits are ignored. Once set, the flags remain asserted until software clears the corresponding FPSCR bit.

Diagram

24 FIOCE	FPU Invalid Operation Interrupt Enable 0b - Disable interrupt 1b - Enable interrupt
23-22 —	Reserved
21 WABE	TCM Write Abort Interrupt Enable 0b - Disable interrupt 1b - Enable interrupt
20-16 —	Reserved
15 FIDC	FPU Input Denormal Interrupt Status This read-only bit is a copy of the core's FPSCR[IDC] bit and signals input denormalized number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IDC] bit. 0b - No interrupt 1b - Interrupt occurred
14-13 —	Reserved
12 FIXC	FPU Inexact Interrupt Status This read-only bit is a copy of the core's FPSCR[IXC] bit and signals an inexact number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IXC] bit. 0b - No interrupt 1b - Interrupt occurred
11 FUFC	FPU Underflow Interrupt Status This read-only bit is a copy of the core's FPSCR[UFC] bit and signals an underflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[UFC] bit. 0b - No interrupt 1b - Interrupt occurred
10 FOFC	FPU Overflow Interrupt Status This read-only bit is a copy of the core's FPSCR[OFC] bit and signals an overflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[OFC] bit. 0b - No interrupt 1b - Interrupt occurred

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 FDZC	FPU Divide-by-Zero Interrupt Status This read-only bit is a copy of the core's FPSCR[DZC] bit and signals a divide-by-zero operation has been detected in the processor's FPU. Once set, this bit remains set until software clears FPSCR[DZC] bit. 0b - No interrupt 1b - Interrupt occurred
8 FIOC	FPU Invalid Operation interrupt Status This read-only bit is a copy of the core's FPSCR[IOC] bit and signals an illegal operation has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IOC] bit. 0b - No interrupt 1b - Interrupt occurred
7 —	Reserved
6 WABSO	Write Abort on Slave Overrun Indicates if another write abort is detected before system software has retrieved all the information from the original event. When the WABS is cleared, this bit is also cleared. 0b - No write abort overrun 1b - Write abort overrun occurred
5 WABS	Write Abort on Slave Indicates when a write abort has occurred on AHBS interface. 0b - No abort 1b - Abort
4-0 —	Reserved

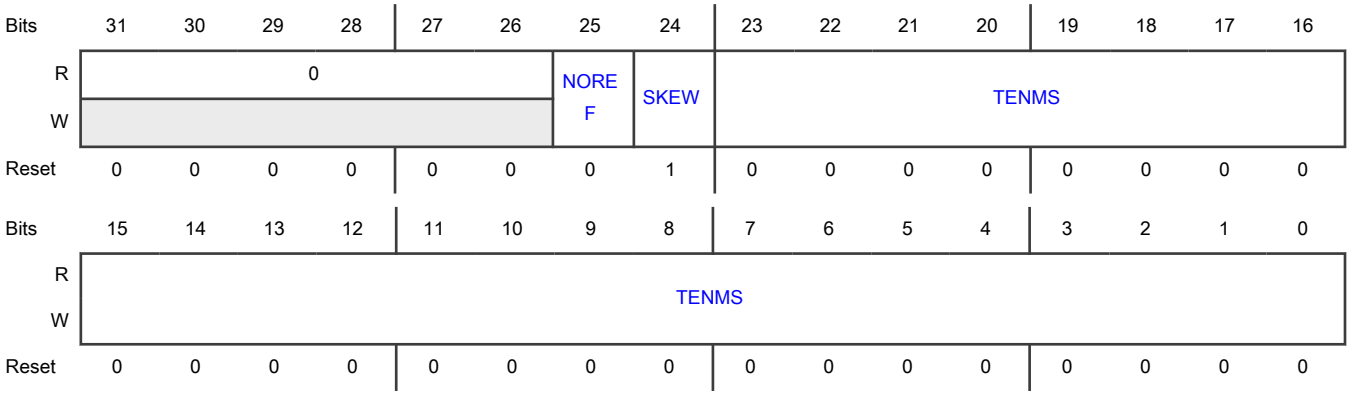
35.4.1.3 SysTick Calibration Register (CFGSTCALIB)

Offset

Register	Offset
CFGSTCALIB	14h

Function
Configures the CM7 SysTick's calibration.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 NOREF	No Reference Clock Indicates that no alternative reference clock source has been integrated in this chip.
24 SKEW	Clock Skew Program this field to 0 if the system timer clock can guarantee an exact multiple of 10ms. Otherwise, write this bit to 1. 0b - No clock skew 1b - Having clock skew
23-0 TENMS	Ten milliseconds Provides an integer value to compute a 10ms (100Hz) delay from the SysTick's clock. For an example, apply the value 0x07A11F if the clock is 50MHz. Apply 0x3E7 if the clock is 100KHz.

35.4.1.4 Process ID (PID)

Offset

Register	Offset
PID	18h

Function

Provides a way for software to write an ID for different processes. Whenever entering a new process, software like OS(Operating System) can write this register to set an ID for the process. The XRDC or TRDC on this chip can use the process ID to control the permission of the process, determining what memories/peripherals can be or cannot be accessed by the specific process.

36.1.1 CM33 Configuration

For this chip, the Cortex-CM33 core configurations are listed in the following table.

Table 270. Cortex-CM33 Core Configuration

Feature	Description	Configuration
FPU	Floating point unit (FPU) configuration	1
DSP	DSP Extensions included	1
SECEXT	Security Extensions included	1
CPIF	Coprocessor interface included (set of 1 if PowerQuad is used)	0
MPU_NS	Non-secure MPU region configuration (CM33 supports 0, 4, 8, 12, 16)	16

Table continues on the next page...

Table 270. Cortex-CM33 Core Configuration (continued)

MPU_S	Secure MPU region configuration	Same as MPU_NS
SAU	Number of Security Attribution Unit regions	8
NUMIRQ	Number of IRQs (rounded to a multiple of 32)	256
IRQLVL	IRQ priority width configuration	4
IRQLATENCY	Individual interrupts with lowest interrupt latency (1=low latency)	X'b1
IRQDIS	Individual interrupts disabled	X'b0
DBGLVL	Debug (breakpoint/watchpoint) configuration	2
ITM	Internal Trace support	1
ETM	ETM support	1
MTB	Micro Trace Buffer trace	1
MTBAWIDTH	MTB RAM interface address width (5-12)	32
WIC	WIC support	1
WICLINES	-	NUMIRQ + 3
CTI	CTI support	1
RAR	Reset-all-registers	1

36.2 Overview

CM33 implements the Armv8-M architecture with main extensions. The Arm Cortex-M33 is a high-efficiency processor with security considerations. CM33 includes:

- A single-precision floating-point unit (FPU)
- A nested vectored interrupt controller (NVIC)
- A flash patch breakpoint (FPB)
- The data watchpoint and trace (DWT) unit
- An instrumentation trace macrocell (ITM)

As shown in Figure 274, the CM33 platform also includes:

- Miscellaneous control module CM33_TCM_MCM, which contains programming registers to control the ECC features for CM33 code TCM and system TCM
- Miscellaneous control module CM33_CACHE_ECC_MCM, which contains programming registers to control the ECC features for TAG0, TAG1, DATA0, and DATA1 in the CM33 code cache and system cache

36.2.1 Block diagram

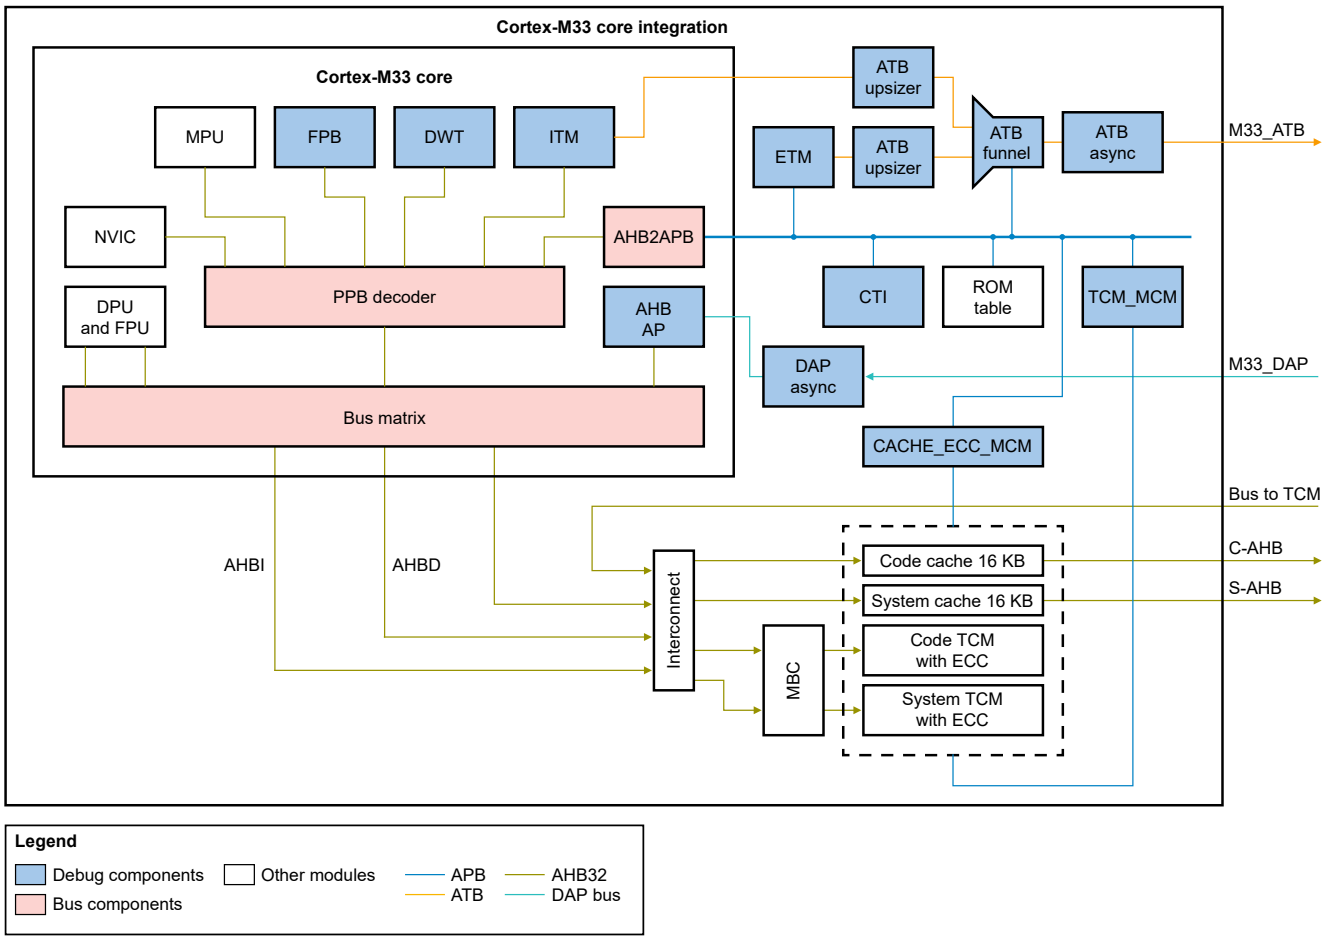

Figure 274. Block diagram

36.2.2 Features

- Cortex-M33 processor
- Single-precision FPU
- NVIC support
- FPB support (does not include patching)
- DWT and ITM support
- ETM support
- Two-way set-associative 16-KB system cache
- Two-way set-associative 16-KB code cache
- Configurable 256-KB tightly coupled memory (TCM):
  - 128-KB system TCM on system bus
  - 128-KB code TCM on code bus
- TCM ECC support
- Cache ECC support

- DSP extensions
- Security extensions
- Nonsecure memory protection unit (MPU) with 16 regions
- Secure MPU with 16 regions
- Cross trigger interface (CTI) support

The AON domain, which incorporates the Cortex-M33 core, includes one messaging unit (MU) and one hardware semaphore (SEMA42) for inter-core communication with the Cortex-M33 core.

For the Cortex-M33 core, the CM33 platform also supports execution in place (XIP) from FlexSPI to facilitate fast power-on wake-up. The Cortex-M33 debug interface is connected to the DAP and CoreSight debug modules in the chip to allow debugging through the JTAG interface. See the "System Debug" chapter for more details.

36.3 Functional description

The following sections contain a high-level overview of the CM33 components.

36.3.1 Cortex-M33 processor

The Cortex-M33 processor is based on the Armv8-M architecture and has a low gate count and high energy efficiency.

36.3.2 NVIC

NVIC supports 6 priority levels for interrupts. The NVIC IPR registers define 4 bits per IRQ.

36.3.3 FPU

The FPU implements FPv5 floating-point extensions, which support these single-precision operations: add, subtract, multiply, divide, multiply and accumulate, and square root. The FPU also provides conversions between fixed-point and floating point data formats, and it provides floating-point constant instructions.

The FPU is compliant with ANSI/IEEE Std 754-2008.

36.3.4 MPU

The MPU has independent attribute settings for each region and can export memory attributes.

CM33 also supports a secure MPU.

When a core access hits an overlapping memory region, the processor generates a fault.

Instruction accesses and data accesses in a given region have the same region settings.

36.3.5 Debug

See the "System Debug" chapter for more information about the CM33 platform debug components.

36.3.6 Code and system TCM

CM33 accesses its code TCM and system TCM through its C-AHB and S-AHB buses, respectively.

By default, the code TCM and system TCM are 128 KB each. The BLK_CTRL_S_AON register field M33_CFG[TCM_SIZE] is a 2-bit field with three valid encodings:

- 00 (default) = REGULAR_TCM: 50% code TCM and 50% system TCM
- 01 = DOUBLE_CODE_TCM: 100% code TCM and 0% system TCM
- 10 = DOUBLE_SYS_TCM: 100% system TCM and 0% code TCM
- 11 = Reserved

NOTE

To avoid unexpected software issues, perform writes to BLK_CTRL_S_AON.M33_CFG[TCM_SIZE] only when the Cortex-M33 core is in reset.

Code TCM is mapped to 0FFE0000h (nonsecure) and 1FFE0000h (secure) (plus the additional 128 KB below this if M33_CFG[TCM_SIZE] = DOUBLE_CODE_TCM)

System TCM is mapped to 20000000h (nonsecure) and 30000000h (secure) (plus the additional 128 KB above this address if M33_CFG[TCM_SIZE] = DOUBLE_DATA_TCM)

The system bus can access both TCM memories as a continuous address space via their aliases:

- Code TCM is mapped to the aliased code TCM base address (plus the additional 128 KB below this if TCM_SIZE = DOUBLE_CODE_TCM)
- System TCM is mapped to the aliased system base address (plus the additional 128 KB above this address if TCM_SIZE = DOUBLE_DATA_TCM)

See the chip's memory map information for aliased code and system TCM base address details.

The valid range of these address ranges depends on the value of BLK_CTRL_S_AON.M33_CFG[TCM_SIZE].

See the M33_CFG register in the BLK_CTRL_S_AON chapter for more information about the CM33 and TCM configuration options.

36.3.6.1 CM33_TCM_MCM

CM33_TCM_MCM is a miscellaneous control module for the Cortex-M33 core. It contains programming registers to control the ECC features of CM33 TCM.

36.3.6.2 CM33 TCM ECC support

You can use the syndrome value for single-bit ECC to locate the error bit in the CM33 system and code TCM. See the following lookup table for these values.

Table 271. Lookup table for 32-bit data single-bit ECC syndrome

Syndrome value	Error bit
07h	31
7Fh	30
6Eh	29
6Dh	28
6Bh	27
67h	26
5Eh	25
5Dh	24
5Bh	23
57h	22
4Fh	21
7Ch	20
7Ah	19

Table continues on the next page...

Table 271. Lookup table for 32-bit data single-bit ECC syndrome (continued)

Syndrome value	Error bit
79h	18
76h	17
75h	16
73h	15
70h	14
68h	13
64h	12
62h	11
61h	10
58h	9
54h	8
52h	7
51h	6
4Ch	5
4Ah	4
49h	3
46h	2
45h	1
43h	0

NOTE

- You cannot use the syndrome value for multibit ECC to locate the error bit in the CM33 system and code TCM.
- You cannot use the syndrome value for single-bit and multibit ECC to locate the error bit in the CM33 system and code cache.

36.3.7 CM33 code and system cache

The following caches are included in the CM33 platform:

- Two-way set-associative 16-KB code cache with ECC and write path error injection support
- Two-way set-associative 16-KB system cache with ECC and write path error injection support

36.3.7.1 CM33_CACHE_ECC_MCM

CM33_CACHE_ECC_MCM is a miscellaneous control module for the Arm Cortex-M33 cache ECC. It contains programming registers to control the ECC features of CM33 TAG0, TAG1, DATA0, and DATA1.

36.3.8 Clocking

See the chip's clocking sections for more information on CM33 clocks.

Table 272. Clocks

Clock name	Description
m33_clk	Main M33 clock
m33_systick_clk	M33 Systick clock

36.3.9 Reset

You can use a CM33 reset to reset the CM33_TCM_MCM and CM33_CACHE_ECC_MCM submodules. Performing a cold or soft reset on the CM33 core also resets the submodules.

36.3.10 Interrupts

Table 273. CM33_TCM_MCM interrupt requests

Interrupt request	Asserted when
tcm_ecc1bit_irq	CM33 detects a single-bit ECC error on TCM (including code and system TCM) and the corresponding interrupt is enabled.
tcm_ecc2bit_irq	CM33 detects a multi-bit ECC error on TCM (including code and system TCM) and the corresponding interrupt is enabled.

Table 274. CM33_CACHE_ECC_MCM interrupt requests

Interrupt request	Asserted when
ecc1bit_irq	CM33 detects a single-bit ECC error on cache (including cache TAG0, cache TAG1, cache DATA0, and cache DATA1) and the corresponding interrupt is enabled.
ecc2bit_irq	CM33 detects a multibit ECC error on cache (including cache TAG0, cache TAG1, cache DATA0, and cache DATA1) and the corresponding interrupt is enabled.

36.4 External signals

The CM33 platform has no external signals.

36.5 Initialization

To initialize CM33:

1. Verify that the clock for CM33 is enabled.
2. Enable the ECC features by writing 0 to the following fields before checking the cache or TCM ECC on read or write data:
   - CACHE_ECCR[RECC_DIS]
   - CACHE_ECCR[WECC_DIS]
   - TCMECCR[RECC_DIS]
   - TCMECCR[WECC_DIS]

36.6 Memory map and register definition

This section includes the memory map and detailed descriptions of all registers.

NOTE

For CM33_TCM_MCM:

- When you configure the code TCM to be double sized (BLK_CTRL_Secure_AON.M33_CFG[TCM_SIZE] = 01b), all of the TCM is used as code TCM.
- When you configure the system TCM to be double sized (BLK_CTRL_Secure_AON.M33_CFG[TCM_SIZE] = 10b), all the TCM is used as system TCM.
- However, the code injection and status register always correspond to the TCM space that starts at FFE0000h, and the system injection and status register always correspond to the TCM space that starts at 20000000h.

36.6.1 CM33_CACHE_ECC_MCM register descriptions

36.6.1.5 Interrupt Enable (INT_SIG_EN)

Offset

Register	Offset
INT_SIG_EN	28h

Function

Selects which interrupt statuses are available to interrupt the host system. All these status fields share the same interrupt line (that is, all interrupts are combined with a logical OR). Writing 1 to any of these fields enables interrupt generation. The corresponding field in Interrupt Status (INT_STATUS) generates an interrupt when the corresponding field in Interrupt Status Enable (INT_STAT_EN) is 1.

22-16 SYSTEM_CACHE_ECCS_EFSYN	System Cache Single-Bit ECC Error Corresponding Syndrome Indicates the corresponding syndrome when a single-bit error is reported. You cannot use the syndrome for single-bit ECC to locate the error bit.
15-14 —	Reserved
13-8 SYSTEM_CACHE_ECCS_EFPRT	System Cache Single-Bit ECC Error Protection Indicates the master access protection attribute of the access creating the error when a single-bit error is reported. For details about the protection attribute decoding, see the Arm AMBA AHB specification.
7-4 SYSTEM_CACHE_ECCS_EFMST	System Cache Single-Bit ECC Error Master Number Indicates the ECC error master number when a single-bit ECC error is reported.
3-2 —	Reserved
1 SYSTEM_CACHE_ECCS_CMD	System Cache Single-Bit ECC Error on Cache Command Indicates whether a system cache single-bit ECC error has occurred on the cache command when a single ECC error is reported. 0b - No error 1b - Error
0 SYSTEM_CACHE_ECCS_TAG	System Cache Single-Bit ECC Error Indicates whether the single-bit ECC error is in the system tag or the system data. 0b - Data 1b - Tag

36.6.1.10 System Cache Single-Bit ECC Error Address (SYSTEM_CACHE_ECC_SINGLE_ERROR_ADDR)

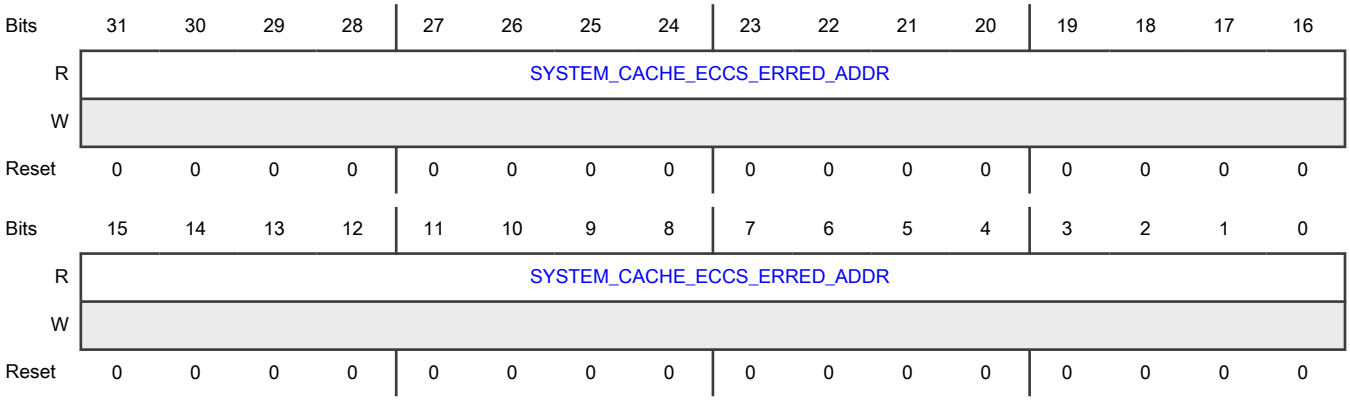
Offset

Register	Offset
SYSTEM_CACHE_ECC_SINGLE_ERROR_ADDR	78h

Function

Stores the error address for a system cache single-bit ECC interrupt.

Diagram



Fields

Field	Function
31-0 SYSTEM_CACHE_ECCS_ERRED_ADDR	System Cache Single-Bit ECC Error Address Stores the error address for the corresponding system cache single-bit ECC interrupt when the interrupt is enabled.

36.6.1.11 System Cache Multibit ECC Error Information (SYSTEM_CACHE_ECC_MULTI_ERROR_INFO)

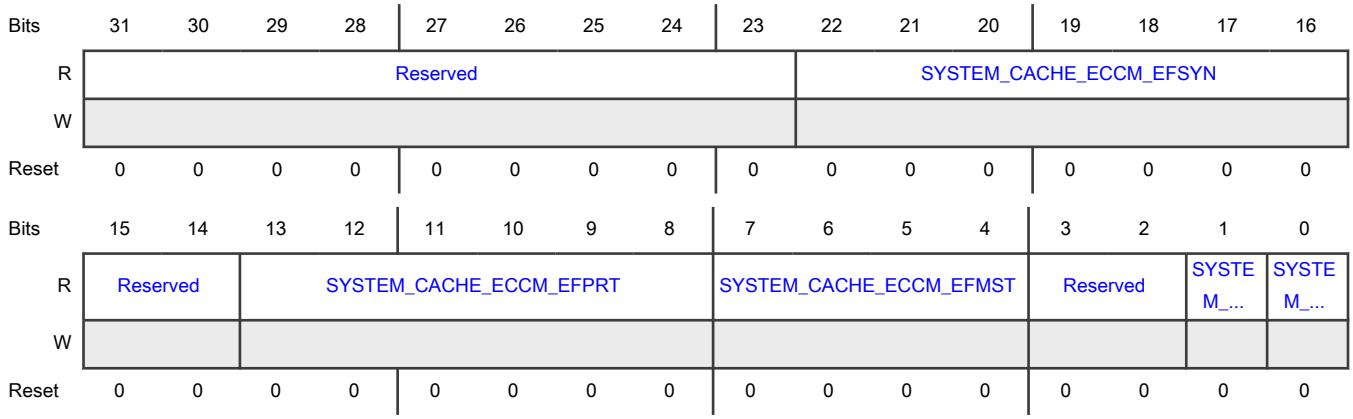
Offset

Register	Offset
SYSTEM_CACHE_ECC_MULTI_ERROR_INFO	80h

Function

Stores error information for the corresponding system cache multibit ECC interrupt when the interrupt is enabled.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 SYSTEM_CACHE_ECCM_EFSYN	System Cache Multibit ECC Error Corresponding Syndrome Indicates the corresponding syndrome when a multibit error is reported. You cannot use the syndrome for multibit ECC to locate the error bit.
15-14 —	Reserved
13-8 SYSTEM_CACHE_ECCM_EFPRT	System Cache Multibit ECC Error Protection Indicates the master access protection attribute of the access that created the error when a multibit error is reported. For details about the protection attribute decoding, refer to the Arm AMBA AHB specification.
7-4 SYSTEM_CACHE_ECCM_EFMST	System Cache Multibit ECC Error Master Number Indicates the ECC error master number when a multibit ECC error is reported.
3-2 —	Reserved
1 SYSTEM_CACHE_ECCM_CMD	System Cache Multibit ECC Error on System Cache Command Indicates whether a system cache multibit ECC error has occurred on a cache command when a multibit ECC error is reported. 0b - No error 1b - Error

Table continues on the next page...

36.6.2.5 Interrupt Enable (INT_SIG_EN)

Offset

Register	Offset
INT_SIG_EN	28h

Function

Selects which interrupt statuses are available to interrupt the host system. All these status fields share the same interrupt line (that is, all interrupts are combined with a logical OR). Writing 1 to any of these fields enables interrupt generation. The corresponding field in Interrupt Status (INT_STATUS) generates an interrupt when the corresponding field in Interrupt Status Enable (INT_STAT_EN) is 1.

37.2 Overview

MU enables two processors on a chip to communicate and coordinate by passing messages (for example, data, status, and control) through the MU interface. MU also allows one processor to signal the other processor using interrupts.

MU must synchronize the accesses from one side to the other because MU can manage messaging between processors using different clocks. MU accomplishes synchronization using two sets of matching registers: processor A-facing and processor B-facing.

37.2.1 Block diagram

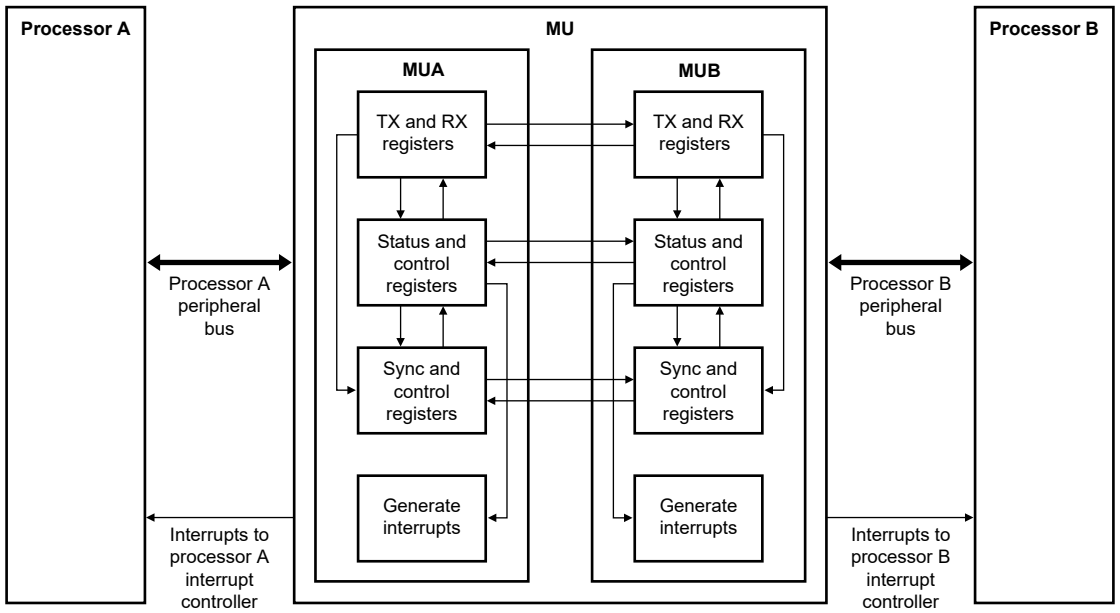

Figure 275. Block diagram

37.2.2 Features

- Memory-mapped registers (MU is connected as a peripheral under the peripheral bus on the processor A-side and processor B-side)
- Synchronized message transfers between cores
  - To send data or messages from one side to the other, messaging unit A (MUA) provides 4 transmit registers and 4 receive registers. Messaging unit B (MUB) provides 4 transmit registers and 4 receive registers.
  - Transmit empty flags (TSR[TEn]) and receive full flags (RSR[RFn]) facilitate the transfer of data or messages between cores on both sides of MU.
  - A synchronization mechanism updates the transmit and receive flags. There is an inherent latency between updating the flag on one side and reflecting its status on the other side. See Event update timing.
  - MU has a 3-bit flag data register, which you can use to send flag data between the two MU sides.
- Interprocessor interrupts
  - MU has 12 interrupt sources on each side (processor A-side, processor B-side) for signaling the other processor. You can use the interrupts for notification of receive and transmit events and for general-purpose signaling between processors. There are 4 general-purpose interrupt requests available and 8 receive and transmit interrupt sources.
- Reset (Each processor can issue a reset to MU via CR[MUR], which is a self-clearing field)

37.3 Functional description

MU enables two cores (processor A and processor B) to communicate with each other:

- By sharing messages and data.
- By enabling one core to wake the other core by using interrupts.

The messaging, control, and status registers of the two cores are mapped to processor A memory and processor B memory as a regular peripheral. The peripheral data bus is 32 bits wide inside MU.

Messaging logic is used with shared memory. Various messaging methods can implement a messaging protocol. For example, a message could mean one of the following:

- A message of *n* words has been written starting at offset *x* in the memory.
- The previous data block that was sent has been read.

The ability to keep messaging logic independent of the shared memory is not restricted to a predefined hardware protocol. The software required to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the processor A side and processor B side. The messaging mechanisms are:

- 4 32-bit transmit registers, which are each reflected in 4 read-only receive registers on the side of the other processor. These registers can transfer 32-bit word messages or the frame information of the messages written to the shared memory. For example, they can transfer the number of words, initial address, and message type code.
- Writing to a transmitter-side transmit register (TR*n*) clears the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]), and sets the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]). Setting the flag on the receiver side can trigger an interrupt on the receiver side (a maskable receive interrupt).
- Reading a receiver-side receive register (RR*n*) clears the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]), and sets the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]). Setting the Transmitter Empty flag can trigger an interrupt on the transmitter side (a maskable transmit interrupt).
- 4 general-purpose interrupt request flags are reflected in General-purpose Status (GSR) on the receiver side.
- 3-bit flag data is transmitted from Flag Control (FCR) to Flag Status (FSR) on the side receiving the flag data. SR[FUP] sets when the flag data is transmitted and clears when the receiving side acknowledges the flag data (the flag is updated).

Writing to a transmit register signals to the receiver side that data is ready for retrieval.

Do not write to the transmit register again without verifying that the data is retrieved. The transmitter side cannot determine the exact time that the receiver attempts to retrieve the data. Before attempting to write to the transmit register again, the transmitter side must wait for the Transmitter Empty interrupt or it must poll TSR[TE*n*].

Reading a receive register signals to the transmitter side that data can be written to that register.

Do not read the receive register again without verifying that the data is written. The receiver side cannot determine the exact time that the transmitter attempts to write the data. Before attempting to read the receive register again, the receiver side must wait for the Receiver Full interrupt or it must poll RSR[RF*n*].

37.3.1 Submodules

37.3.1.1 MUA side

MUA is receives its register configuration via the processor A peripheral bus. It sends or receives messages to or from MUB. Processor A can receive messages by reading MUA registers, and MUA can send interrupts to processor A when interrupts are enabled.

NOTE

Processor B is not allowed to access MUA register. Processor C, if exist, is also not allowed to access MUA register.

TRDC might be needed to prevent such illegal access.

37.3.1.2 MUB side

MUB receives its register configuration via the processor B peripheral bus. It sends or receives messages to or from MUA. Processor B can receive messages by reading MUB registers, and MUB can send interrupts to processor B when interrupts are enabled.

NOTE

Processor A is not allowed to access MUB register. Processor C, if exist, is also not allowed to access MUB register.

TRDC might be needed to prevent such illegal access.

37.3.2 Event update timing

The messaging side of each processor has a hardware mechanism to send event update requests to the other processor. An event occurs when the status register of the receiving processor must reflect any information change. The event update latency is the delay between the event being ready at one processor and the resulting update at the status register of the other processor:

- The minimum event latency is (1 clock cycle of the sending side) + (2.5 clock cycles of the receiving side). This minimum case happens when no event is pending when the new event occurs.
- The maximum event latency is (6 clock cycles of the sending side) + (6.5 clock cycles of the receiving side). The maximum case happens when the event occurs just after a previous event is sent to the other side.

The event update latency varies depending on the time at which the subsequent event is triggered.

37.3.3 Clocking

Table 276. MU clocks

Clock name	Description
Bus clock MUA	Used only for bus accesses to MUA control and configuration registers
Bus clock MUB	Used only for bus accesses to MUB control and configuration registers

37.3.4 Resets

The following sections list the reset sources included in MU. Each reset performs a different function for the MU module compared to the function it performs for the system.

37.3.4.1 Asynchronous system reset

When the asynchronous system reset on either side of MU is asserted, SR[MURS] becomes 1 until the asynchronous system reset sequence on both the MUA and MUB sides ends. Verify that SR[MURS] becomes 0 before accessing MU.

The asynchronous system reset on one side of MU resets the other side of MU. The reset forces all control and status registers to return to their default values and clears all internal states. The following table shows the exceptions to this behavior.

Table 277. Exceptions to asynchronous system reset

MUA-side exceptions	MUB-side exceptions
MUB_CCR0[HR]	MUA_CCR0[HR]
MUB_CCR0[HRM]	MUA_CCR0[HRM]
MUB_CR[MURIE]	MUA_CR[MURIE]
MUB_SR[MURIP]	MUA_SR[MURIP]
MUB_SR[MURS]	MUA_SR[MURS]

37.3.4.2 MU software reset

Writing 1 to CR[MUR] causes most control and status registers to return to their default values and clears all internal states.

The instruction immediately following the assertion of CR[MUR] must not write to the MU registers. The reset sequence may overwrite such a write, with the register retaining the reset value. To know the end of the reset sequence for both processors,

monitor the value of SR[MURS]. After the reset sequence on both processors has ended, a write to the MU registers can be attempted.

NOTE

The process of CR[MUR] becoming 1 is delicate because it asynchronously affects the registers on the other side. CR[MUR] becoming 1 may cause unpredictable behavior if, for example, the other processor is concurrently testing an MU register field (TSR[TE*n*] in the other processor). Before writing 1 to CR[MUR], verify that the other processor is not engaged in an MU signaling activity.

37.3.5 Interrupts

MU controls interrupt requests that one processor makes to the other processor. This section describes all the interrupts that the module generates.

MU can generate these interrupt sources individually to send to the processors:

- 4 receive interrupts (asserted when the Receive Full flags are set in Receive Status (RSR) and enabled in Receive Control (RCR)) for each receive register
- 4 transmit interrupts (asserted when the Transmit Empty flags are set in Transmit Status (TSR) and enabled in Transmit Control (TCR)) for each transmit register
- 4 general-purpose interrupts (asserted when the GIP flags are set in General-Purpose Interrupt Enable (GIER) and enabled in General-Purpose Interrupt Enable (GIER))

All interrupts are maskable in the processor control registers: TCR, RCR, GIER, and CR. MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, receive 0 and receive 1, or any transmit or general-purpose interrupts) can be asserted simultaneously. The interrupt controller must resolve the priority of these interrupts at the chip level.

Triggering any enabled interrupt wakes the processor from below mode before servicing the interrupt

The software (as part of the interrupt handler) must clear the general-purpose interrupt pending flags (GSR[GIP*n*]) to deassert the request to the interrupt controller.

When a processor writes to the general-purpose interrupt (GCR[GIR*n*]), MU synchronizes the write event to the other processor to set the general-purpose interrupt request pending flag (GSR[GIP*n*]). When GSR[GIP*n*] is set and the general-purpose interrupt is enabled on the receiving side (GIER[GIE*n*] is 1), the transmitting-side general-purpose interrupt is issued to the receiving processor, which clears this interrupt by writing 1 to GSR[GIP*n*]. The interrupt is deasserted as soon as the write to GSR[GIP*n*] occurs. MU synchronizes the write event of GSR[GIP*n*] to the other processor. The synchronized signal writes 0 to the GIR*n* interrupt.

Before writing 1 to GCR[GIR*n*], verify that the field is 0, which means that a general interrupt is not pending. Generally, MU ignores writing 1 to this field while the field is already 1, but in some cases it may issue a second interrupt.

37.4 External signals

This module has no external signals.

37.5 Initialization

37.5.1 Sending messages with interrupt

Perform the following procedure in which, for example, processor A sends messages to processor B:

1. Prepare processor A with the data to be sent. Write data to MUA_TR0, MUA_TR1, MUA_TR2, and MUA_TR3.
2. Configure the interrupts.
    a. Write 1 to MUA_TCR[TIE3] to enable the interrupt to processor A.
    b. Write 1 to MUB_RCR[RIE3] to enable the interrupt to processor B.

3. Wait for processor B to enter into interrupt service. Processor B reads MUB_RR0, MUB_RR1, MUB_RR2, and MUB_RR3. If processor B continues to receive data, it can exit the interrupt service program without MUB_RCR[RIE3] becoming 0.

   Because processor B has read all the data, processor A receives the interrupt.

4. Write data to MUA_TR0, MUA_TR1, MUA_TR2, and MUA_TR3. If processor A continues to send data, it can exit the interrupt service program without MUA_TCR[TIE3] becoming 0.

NOTE

The aforementioned example is not the only method to send or receive messages for MU. You must configure MU for methods specific to your application.

37.6 Application information

MU facilitates messages between processors. For example, MU passes:

- Short messages. Transmit registers can pass short messages from 1 to 4 words in length for processor A and from 1 to 4 words for processor B. For example, for a four-word message, only one register must have its corresponding interrupt enabled on the receiving side. The first three words of the message are written to the registers with masked interrupts. The fourth word is written to the last register, triggering an interrupt on the receiving side.
- Frame information. Transmit registers can pass frame information for long messages written to the shared system memory. Such frame information normally includes a start address and a number of words. It can include a message type code.
- Event notices and requests. MU can signal events and requests that do not include data words between processors using general-purpose interrupts. For example, one such event is acknowledging that a long message is read from the shared system memory.
- Fixed-length data. Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use general-purpose interrupts to signal to the other processor that the data is ready.
- Announcements. A processor can use the 3 flags to announce its current program state or other billboard messages to the other processor.

37.6.1 Messaging protocols using interrupts

The example below describes a four-word messaging sequence sent between the processor A and processor B.

The transmitting processor writes to the transmit registers sequentially. When n = 0, 1, and 2, the interrupts are disabled, so no interrupt goes to the processor (although interrupt conditions occur). For n = 3, the interrupt is enabled, and MU generates the last receive interrupt request.

1. Write sequence:
   a. The transmitting processor writes the message information sequentially to its Transmit registers 0, 1, 2.
   b. When the write to Transmit register 3 occurs, RSR[RF3] is set after synchronization. It immediately triggers the receive full 3 interrupt on the receiving processor.
2. Read sequence:
   a. The receiving processor receives the receive full 3 interrupt and starts reading the message transferred from the receive registers.
   b. After the receiving processor reads Receive register 3, MU clears RSR[RF3].

Table 278 and Figure 276 describe the messaging model, using transmit and receive registers and the interrupt messaging protocol.

Table 278. Interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A writes data.	RR*n* on processor B's side reflects a data write to TR*n* by processor A.
2	Clear the transmitter empty flag and set the receiver full flag.	The data write to TR*n*: • Clears TSR[TE*n*] on the processor A side. • Sets RSR[RF*n*] on the processor B side.
3	Generate the receive interrupt request.	Setting RSR[RF*n*] generates a receive interrupt request to processor B.
4	Processor B reads the data.	After receiving the receive interrupt request, processor B performs a data read of RR*n*.
5	Clear the receiver full flag and set the transmitter empty flag.	Reading the data from the RR*n* register: • Clears RSR[RF*n*] on the processor B side. • Sets TSR[TE*n*] on the processor A side.
6	Generate the transmit interrupt request.	Setting TSR[TE*n*] generates a transmit interrupt request to processor A.

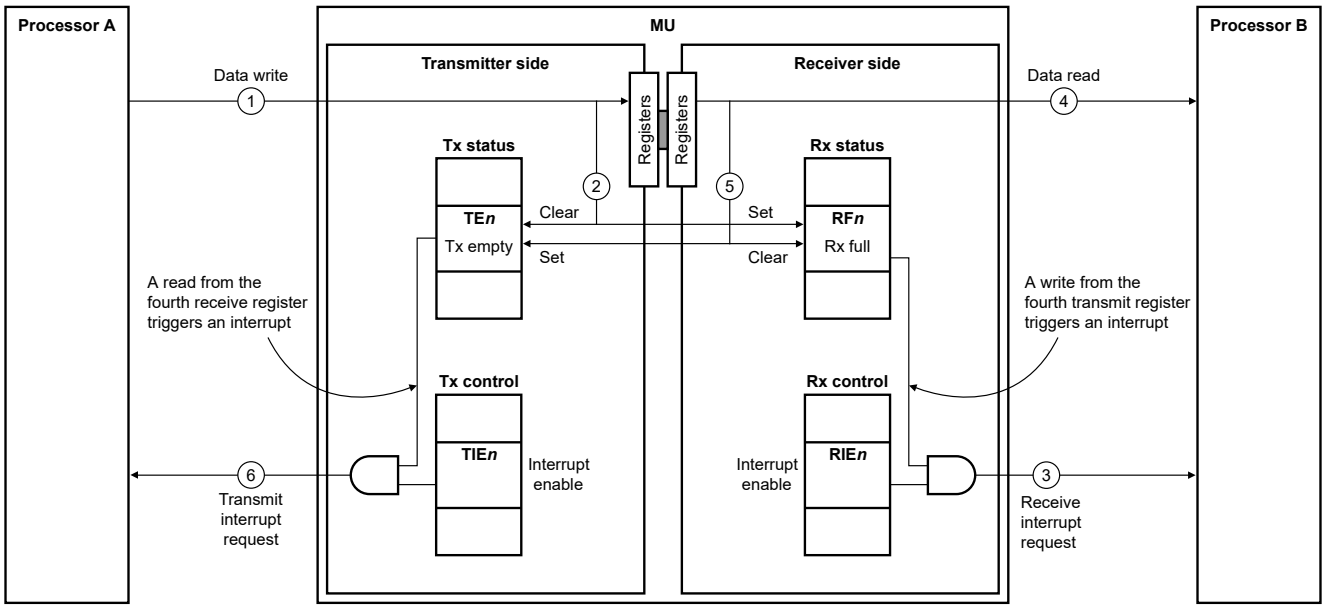

Figure 276. Messaging model using transmit and receive registers

You can use the messaging hardware to implement messaging protocols for an array of message types. MU provides full support for interrupt and polling management schemes.

37.6.2 Messaging protocols using event interrupts

MU can signal events and requests that do not include data words between processors using general-purpose interrupts.

Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use a general-purpose interrupt to signal to the other processor that the data is ready.

A processor can use the 3 flags to announce its current program state (or similar messages) to the other processor.

Table 279 and Figure 277 describe the event steps when the processor triggers a general-purpose interrupt.

Table 279. General-purpose interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A sets its associated general-purpose interrupt request flag.	Processor A sets GCR[GIR*n*].
2	The general-purpose interrupt request pending status flag is set.	GSR[GIP*n*] is set.
3	MU generates the general-purpose interrupt request to processor B.	Setting GSR[GIP*n*] generates the general-purpose interrupt request to processor B. GIER[GIE*n*] must be set for processor B.
4	Processor B reads the status register.	Processor B reads GSR[GIP*n*].
5	Processor B services the interrupt.	—
6	Processor B sets GSR[GIP*n*] to clear the interrupt.	Processor B writes 1 to the corresponding GSR[GIP*n*] flag to clear the interrupt.
7	GCR[GIR*n*] is cleared.	Setting GSR[GIP*n*] clears GCR[GIR*n*] on the processor A side.

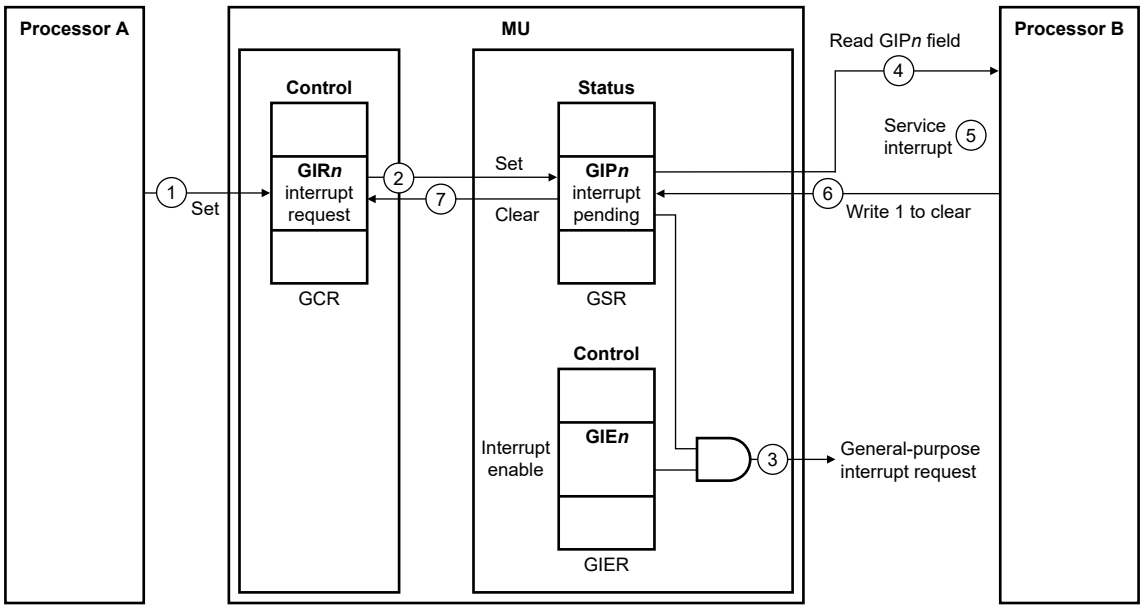

Figure 277. Messaging model using a general-purpose interrupt

37.6.3 Exclusive access to shared memory

MU can signal one processor about its current access to shared memory. This signaling prevents the other processor from overwriting data during the exclusive memory access period.

The following tables describe the signaling protocol that processor A uses to inform processor B about its current access (write) to shared memory:

- Table 280 shows processor A performing an exclusive access to shared memory.
- Table 281 shows processor B scanning for transaction information.
- Table 282 shows processor B accepting exclusive access from processor A.
- Table 283 shows processor B rejecting exclusive access from processor A.

According to the examples shown in the following tables, GCR[GIR*n*], RR*n*, and TR*n* are reserved to support exclusive access to the shared memory protocol.

Table 280. Processor A performs an exclusive access to shared memory

Step	Action	Description
1	Processor A sends the GIR*n* request to processor B using the processor A control register.	Before processor A performs an exclusive access to the shared memory, it sends a GIR*n* request to processor B.
2	Processor A sends an exclusive-access request using a transmit data register (TR*n*).	Processor A sends an exclusive-access request (command, location, and length of target access) to processor B using a selected transmit data register (TR0).
3	Processor A waits for a dedicated interrupt from processor B.	Processor A waits for a dedicated interrupt (as an acknowledgment) triggered by processor B before proceeding.
4	Processor A accesses the shared memory.	After receiving a dedicated interrupt from processor B, processor A proceeds.

Table 281. Processor B scans for transaction information

Step	Action	Description
1	Processor B receives an interrupt from a receive data register (RR*n*).	—
2	Processor B reads the receive data register (RR*n*).	—
3	Processor B scans the receive data register contents.	Processor B scans for transaction information (whether processor A has requested exclusive access).

Table 282. Processor B accepts exclusive access from processor A

Step	Action	Description
1	Processor B triggers a dedicated interrupt.	Processor B acknowledges the request from processor A by triggering a dedicated interrupt (ack) to processor A.
2	Processor B sends a code message to processor A.	With the acknowledge interrupt, processor B sends a code message to processor A through the selected transmit register (TR*n*). The message informs processor A that it can exclusively access the shared memory.

Table 283. Processor B rejects exclusive access from processor A

Step	Action	Description
1	Processor B ignores the request from processor A for exclusive access.	If processor B does not provide permission to processor A, processor B ignores the exclusive-access request.

37.6.4 Packet data transfers

The following table describes an example packet transfer sequence between processor B and processor A subsystems.

Table 284. Packet data transfer sequence

Step	Action	Description
1	Processor B requests DMA.	Processor B sends a DMA request to initiate the packet data transfer.
2	DMA data transfer	DMA acknowledges.
3		DMA starts transferring data from the specified processor B memory location to the specified shared memory.
4		DMA interrupts processor B to signal that the packet transfer has finished.
5	Processor B informs processor A that data is in shared memory.	Using a B-side transmit register, processor B sends a packet information message to processor A about the arrival of new packet data stored in shared memory. The message contains the command, location, and length of packet data.
6	Processor A receives an interrupt.	Processor A receives an interrupt (assuming its corresponding processor A MU-side receive interrupt is enabled). The pending processing task becomes active and processes packet data from memory.
7	Processor A reads data, then writes data.	Processor A reads or processes packet data from shared memory.
8		Processor A writes the result from packet processing to a separate buffer.
9	Processor A informs processor B that the transfer is finished.	After the processing of the packet data finishes, processor A informs processor B (using MU processor A-side transmit register, MUA_TR*n*).
10	Processor A sends an interrupt to processor B (a request for more data).	Processor B receives the next interrupt from processor A, in which processor A requests more packet data.

37.6.5 Freeing a processor from deadlock

During normal operation, one processor may determine that the other processor is not working or is deadlocked. Using Status (SR), the processor can use the methods in the following table to identify and correct the problem.

Table 285. Freeing a processor from deadlock

Processor mode	Technique	Description
—	Processor issues an interrupt.	The other processor can interrupt the processor by issuing one of the 12 (general purpose, receive, or transmit) interrupts.

37.7 Register definition

MU provides transmit and receive data registers (*x*TR0–*n*, *x*RR0–*n*) for communication between processor A and processor B. It also provides control registers (*x*CR) for operations such as interrupts and resets, and status registers (*x*SR) for checking the status of the other MU-side. Figure 278 shows the schematic for MU registers.

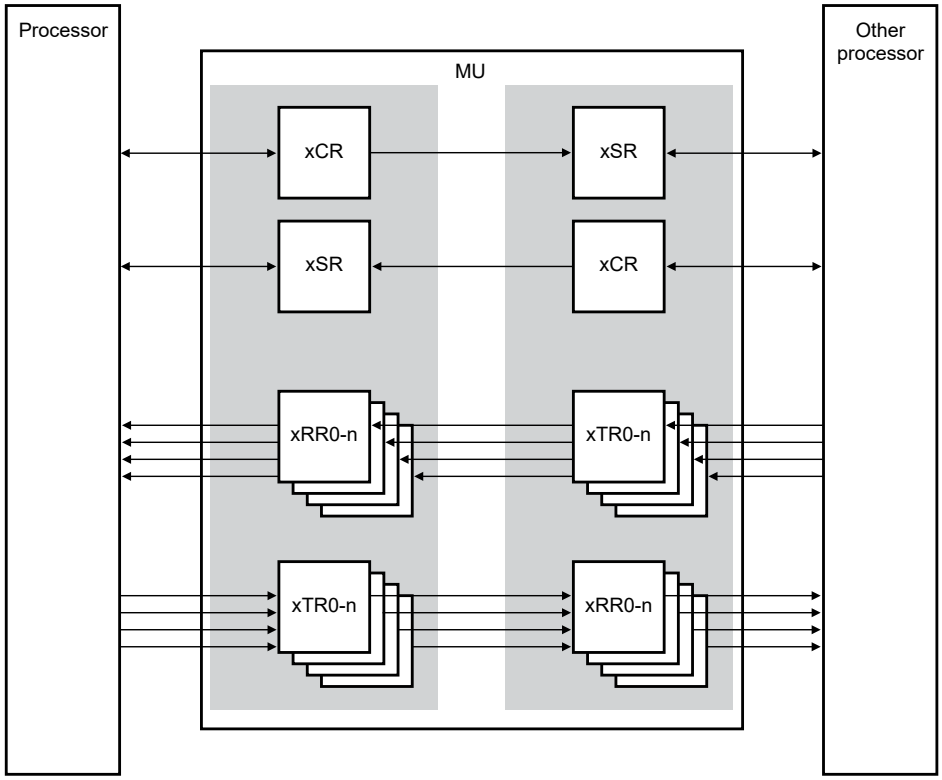

Figure 278. MU registers

37.7.1 MUA register descriptions

This section contains the detailed register descriptions for MUA registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

37.7.1.1 MUA memory map

MU0.MUA base address: 4422_0000h

W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0

Fields

Field	Function
31-24 FLAG_WIDTH	Flag Width Specifies the number of flag bits (3) in the Flag Control (FCR) and Flag Status (FSR) registers.
23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (4).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

37.7.1.4 Control (CR)

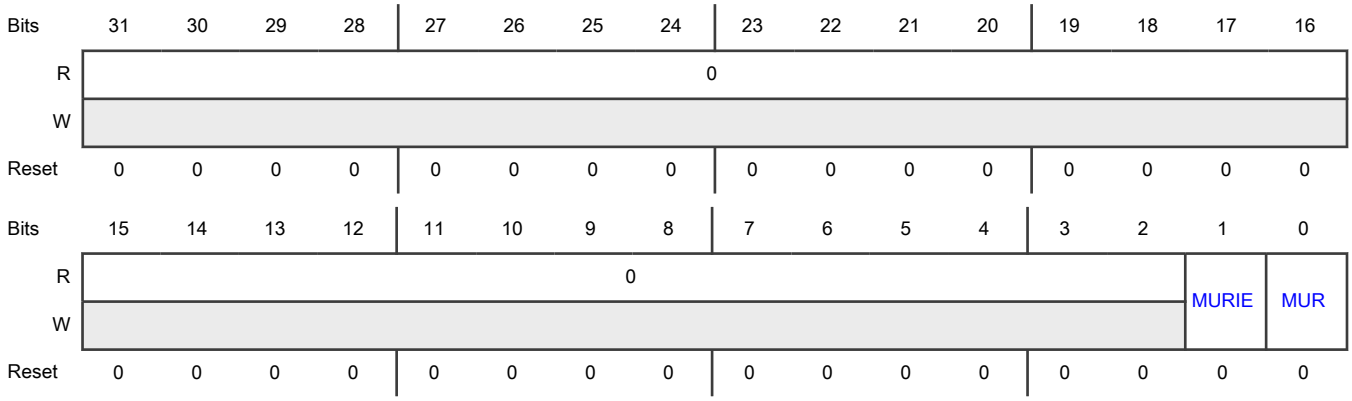
Offset

Register	Offset
CR	8h

Function

Controls MU reset and reset interrupt enable.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 MURIE	MUA Reset Interrupt Enable Enables the processor A-side MU reset interrupt request due to MU reset issued by MUB. If the value of this field is 1, an MU reset interrupt request is issued to processor A when MUA_SR[MURIP] = 1. If the value of this field is 0, MU ignores the value of MURIP and issues no MU reset interrupt request. Only a system reset can reset this field. CR[MUR] cannot reset this field. 0b - Disable 1b - Enable
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUA and MUB sides. All internal states are cleared. It forces all control and status registers to return to their default values (except HR, HRM in MUA/B_CCR0 registers; MURIE in MUA/B_CR registers; MURIP and MURS in MUA/B_SR registers). Before writing 1 to this field, interrupt processor B because writing 1 to this field may affect the ongoing processor B program. After writing 1 to this field, monitor the value of MUA_SR[MURS] to know when the reset sequence on the processor B-side has ended. This field always reads 0, and it becomes 0 during the MU reset sequence. 0b - Idle 1b - Reset

37.7.1.5 Status (SR)

Offset

Register	Offset
SR	Ch

Function

Shows the status of MU resets and the status of pending events and requests.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W															W1C	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	u

Fields

Field	Function
31-8 —	Reserved
7 —	Reserved
6 RFP	MUA Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUB writes to a TR*n* register to send data to MUA. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUA to read it. This field becomes 0 when all MUA RR*n* registers are read, or when MU is reset. 0b - Not pending; MUB is not writing to a Transmit register 1b - Pending; MUB is writing to a Transmit register
5 TEP	MUA Transmit Empty Pending Indicates whether a transmit empty message is pending.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when any TCR[TIE*n*] field is 1 and MUB reads the corresponding Receive (RR*n*) register. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUA to write to it. This field becomes 0 when write operations to all MUA Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0b - Not pending; MUB is reading no Receive (RRn) register 1b - Pending; MUB is reading a Receive (RRn) register
4 GIRP	MUA General-Purpose Interrupt Pending Indicates that MUB has sent a general-purpose interrupt request. This field becomes 1 when the MUB side sends a general-purpose interrupt request to the MUA side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. This field becomes 0 when all MUA_GSR[GIP*n*] fields are cleared, or when MU is reset. 0b - No request sent 1b - Request sent
3 FUP	MUA Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUA_FCR. This field becomes 1 when the MUA side sends a flag update request to the MUB side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUB side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUA_FCR does not generate a flag update event. The F*n*[2:0] bits do not change. If SR[EP] = 1 (event pending), writing to MUA_FCR does not immediately cause this field to become 1. 0b - No pending update flags (initiated by MUA) 1b - Pending update flags (initiated by MUA)
2 EP	MUA Side Event Pending Indicates a pending side event when the MUA side sends an event update request to the MUB side. An event is any hardware message that the Status register on the MUB side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUB, verify that this field is 0. If it is 1, wait and continue to poll this field until it becomes 0. 0b - Not pending 1b - Pending
1	MU Reset Interrupt Pending Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
MURIP	Indicates whether processor B has issued an MU reset. This flag is set after processor B initiates an MU reset by setting MUB_CR[MUR]. If CR[MURIE] = 1, the processor A MU reset interrupt request is issued when processor B writes 1 to MUB_CR[MUR]. Clearing this flag also clears the MU reset interrupt request. Only a system reset can reset this flag. MU reset cannot reset this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Reset not issued 1b - Reset issued When writing 0b - No effect 1b - Clear the flag
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side. This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0b - Out of reset 1b - In reset

37.7.1.6 Core Control 0 (CCR0)

Offset

Register	Offset
CCR0	10h

Function

Allows MUA to control the processor on the MUB side.

Also allows control of the processor A hardware reset mask.

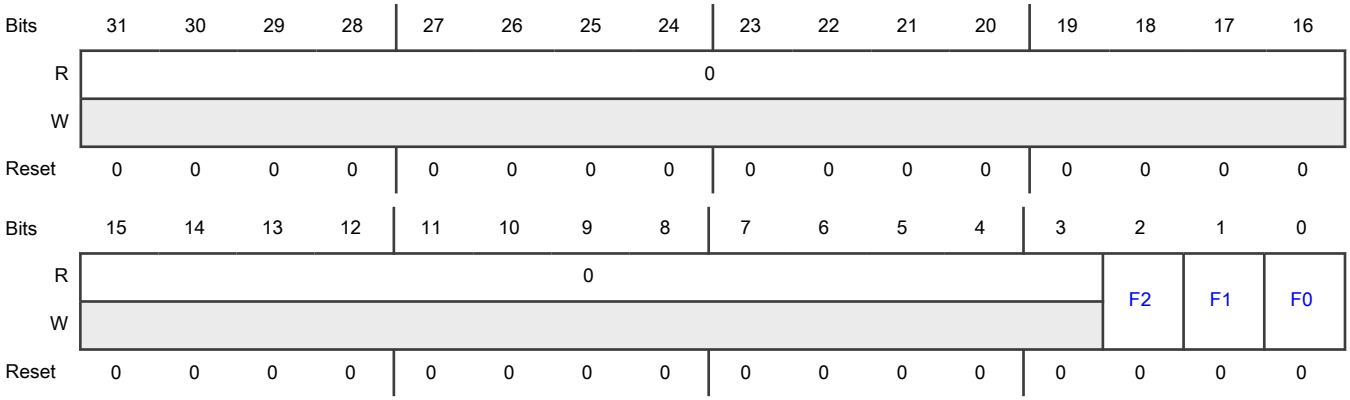
37.7.1.8 Flag Control (FCR)

Offset

Register	Offset
FCR	100h

Function
Configures MUB_FSR[F*n*] flags.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 Fn	MUA to MUB Flag Configures MUB_FSR[F*n*] flags, where *n* = 0 to 2. F*n* configures the corresponding MUB_FSR[F*n*] flag. F*n* becomes 0 when MU resets. 0b - Clear MUB_FSR[Fn] 1b - Set MUB_FSR[Fn]

37.7.1.9 Flag Status (FSR)

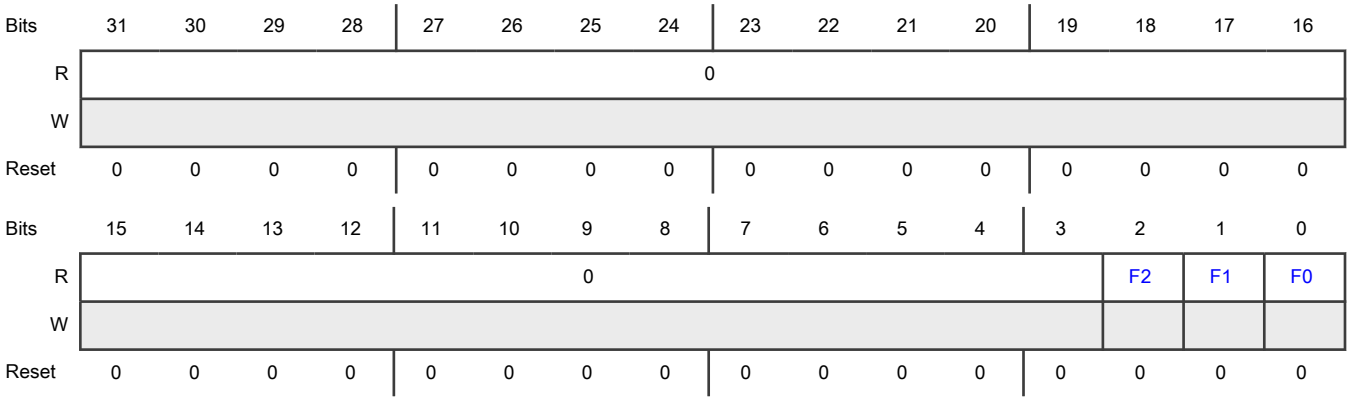
Offset

Register	Offset
FSR	104h

Function

Contains flags configured by the values written to MUB_FCR[F*n*].

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 Fn	MUB to MUA-Side Flag Contains flags configured by the values written to MUB_FCR[F*n*], where *n* = 0 to 2. F*n* is the MUA-side flag configured by the values written to MUB_FCR[F*n*]. When MUB_FCR[F*n*] is written to, the write event updates MUA_FSR[F*n*], after the event update latency. 0b - MUB_FCR[Fn] = 0 1b - MUB_FCR[Fn] = 1

37.7.1.10 General-Purpose Interrupt Enable (GIER)

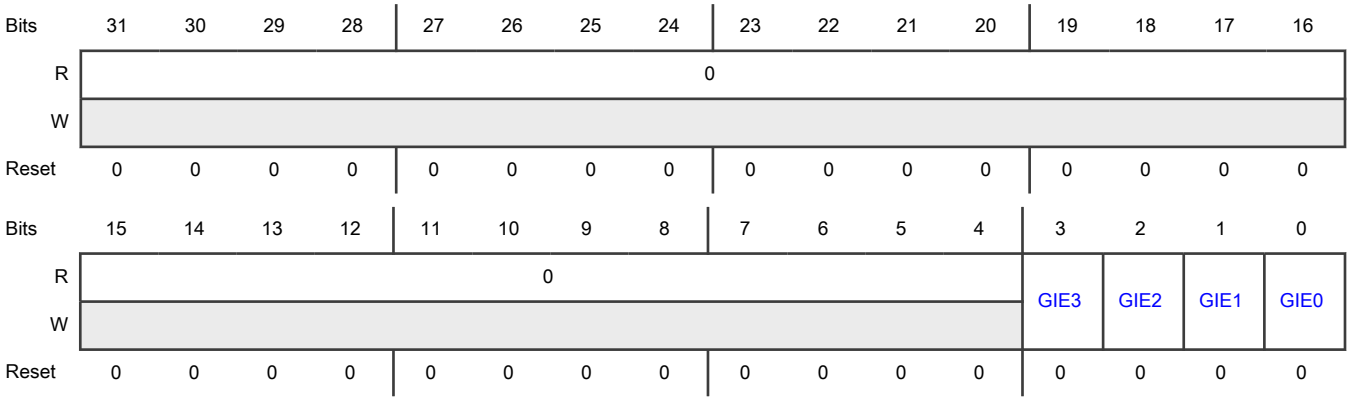
Offset

Register	Offset
GIER	110h

Function

Contains the MUA general-purpose interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIEn	MUA General-purpose Interrupt Enable Enables general-purpose interrupt. There are 4 general-purpose interrupts (*n* = 0 to 3). When GIE*n* = 1, a general-purpose interrupt *n* request is issued to processor A when MUA GSR[GIP*n*] = 1. If GIE*n* = 0, the general-purpose interrupt request pending does not trigger the general-purpose interrupt. GIE*n* becomes 0 when MU resets. 0b - Disable 1b - Enable

37.7.1.11 General-Purpose Control (GCR)

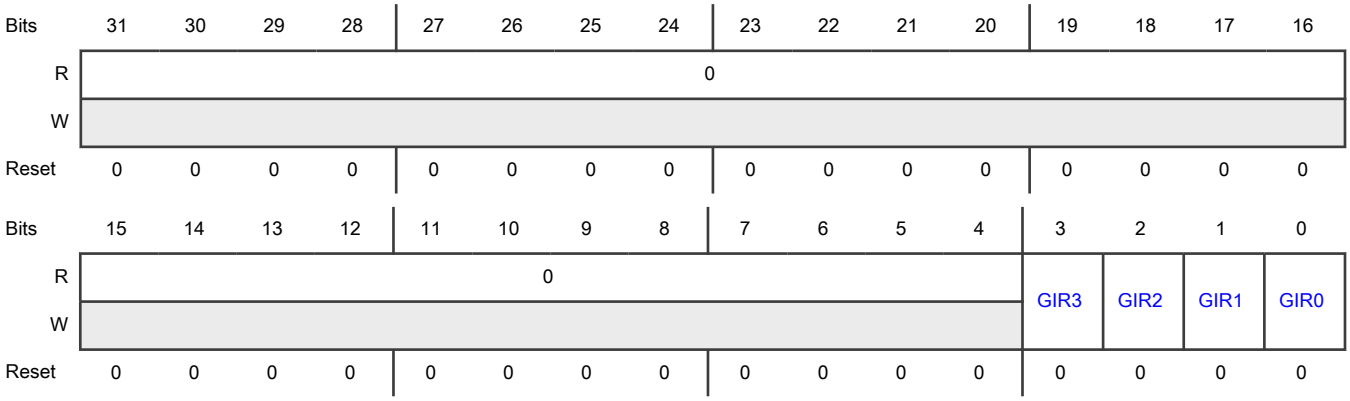
Offset

Register	Offset
GCR	114h

Function

Contains the MUA general-purpose interrupt request fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIRn	MUA General-Purpose Interrupt Request Specifies whether general-purpose interrupts are requested to MUB. There are 4 general-purpose interrupts (*n* = 0 to 3). Writing 1 to GIR*n* sets MUB_GSR[GIP*n*]. If MUB_GIER[GIE*n*] = 1, a general-purpose interrupt request is triggered on processor B. This field becomes 0 when MUB_GSR[GIP*n*] is cleared. This clearing informs MUA that the interrupt is accepted (cleared by software). To ensure proper operations, verify that GIR*n* is 0 (no pending interrupt) before writing 1 to it. This field becomes 0 when MU resets. 0b - Not requested 1b - Requested

37.7.1.12 General-purpose Status (GSR)

Offset

Register	Offset
GSR	118h

Function

Contains the status of the MUA general-purpose interrupt pending requests.

Fields

Field	Function
31-4 —	Reserved
3-0 GIPn	MUA General-Purpose Interrupt Request Pending Indicates whether a general-purpose interrupt request is pending. There are 4 general-purpose interrupts (*n* = 0 to 3). GIP*n* informs MUA that MUB_GCR[GIR*n*] changed from 0 to 1. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is issued to processor A. GIP*n* is cleared when MU resets. After GIP*n* is cleared, if MUA_GIER[GIE*n*] = 1, the general-purpose interrupt request is cleared on the MUA side. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not pending 1b - Pending When writing 0b - No effect 1b - Clear the flag

37.7.1.13 Transmit Control (TCR)

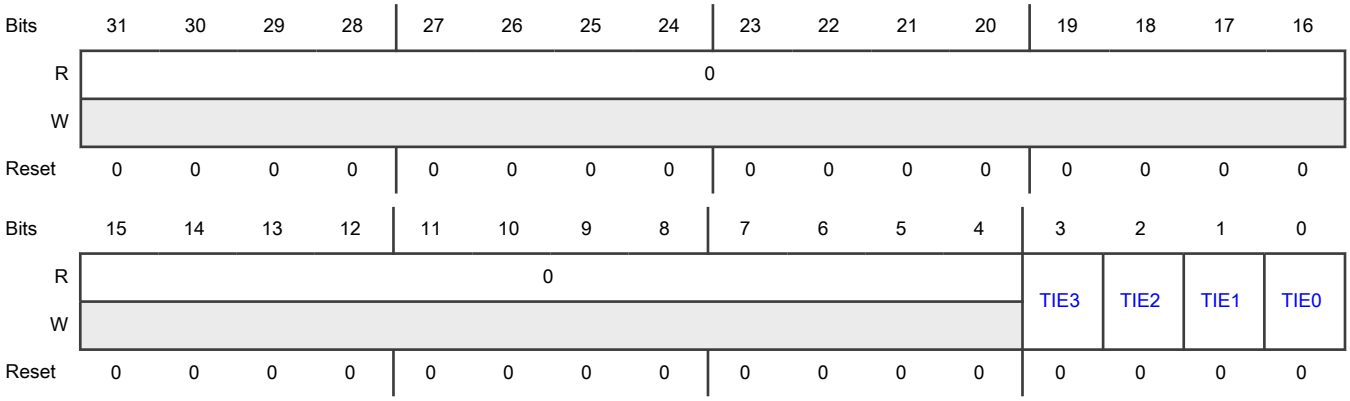
Offset

Register	Offset
TCR	120h

Function

Contains the MUA transmit interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TIEn	MUA Transmit Interrupt Enable Enables MUA transmit interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA transmit interrupt *n* request is issued when MUA_TSR[TE*n*] is set. If this field is 0, MU ignores the value of MUA_TSR[TE*n*], and no MUA transmit interrupt *n* request is issued. 0b - Disable 1b - Enable

37.7.1.14 Transmit Status (TSR)

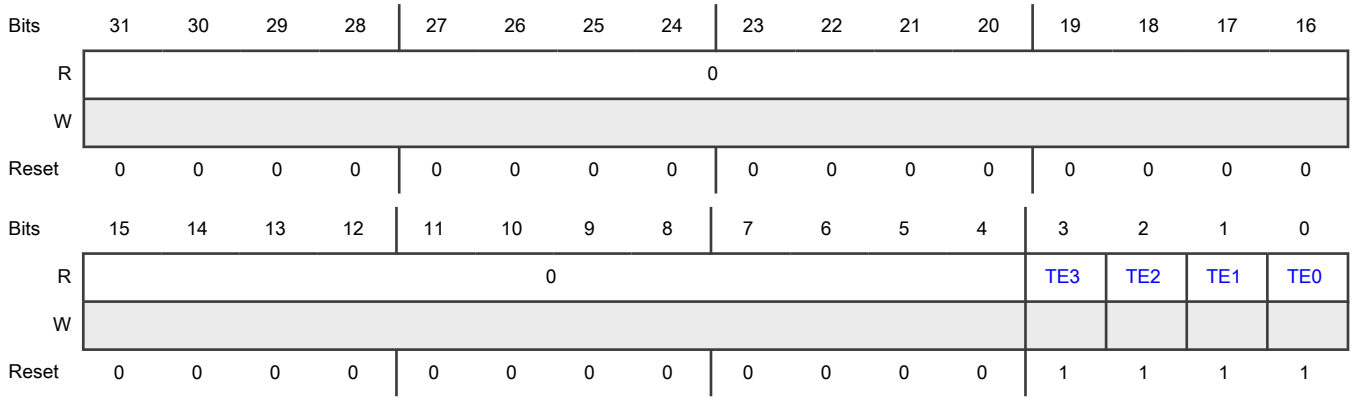
Offset

Register	Offset
TSR	124h

Function

Indicates whether the MUA transmit registers are empty.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TEn	MUA Transmit Empty Indicates whether MUA Transmit (TR*n*) register is empty, where *n* = 0 to 3. This field becomes 1 after the MUB_RR*n* register is read on the MUB side. When TE*n* = 1, it indicates to the MUA side that the MUA_TR*n* register is ready to be written on the MUA side. If MUA_TCR[TIE*n*] = 1, a transmit *n* interrupt is issued on the MUA side. This field becomes 0 after the MUA_TR*n* register is written to on the MUA side. After this field becomes 0, if MUA_TCR[TIE*n*] = 1, the transmit *n* interrupt request is cleared on the MUA side. This field becomes 1 when MU resets. 0b - Not empty 1b - Empty

37.7.1.15 Receive Control (RCR)

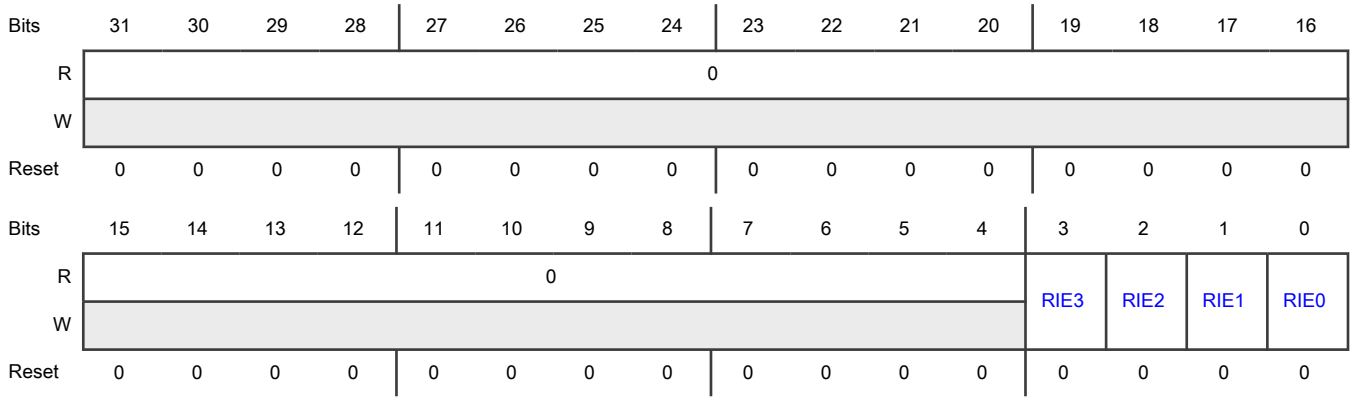
Offset

Register	Offset
RCR	128h

Function

Contains the MUA receive interrupt enables.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RIEn	MUA Receive Interrupt Enable Enables MUA receive interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA receive interrupt *n* request is issued when MUA_RSR[RF*n*] is set. If this field is 0, MU ignores the value of MUA_RSR[RF*n*], and no MUA receive interrupt request is issued. 0b - Disable 1b - Enable

37.7.1.16 Receive Status (RSR)

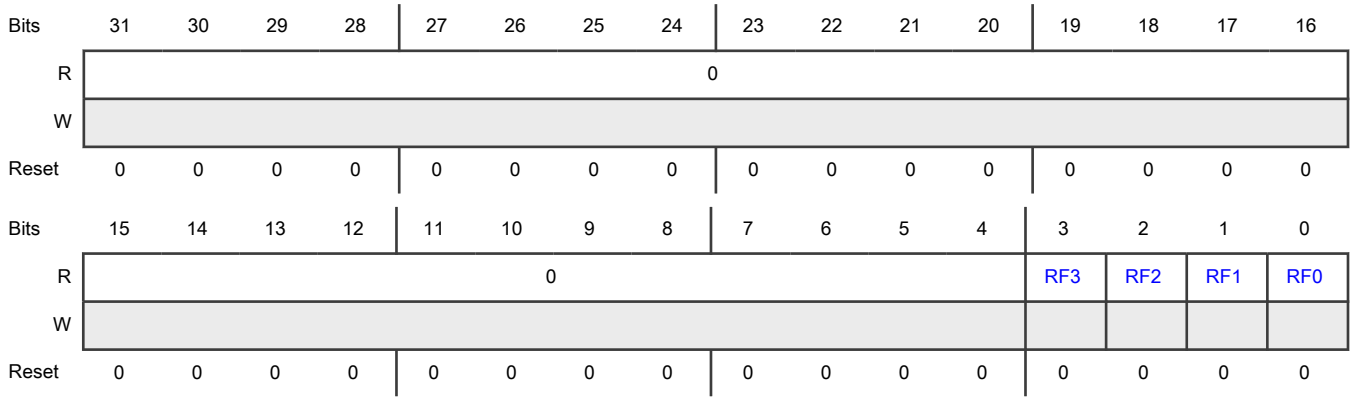
Offset

Register	Offset
RSR	12Ch

Function

Indicates whether the MUA receive registers are full.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RFn	MUA Receive Register Full Indicates whether MUA Receive register (RR*n*) is full, where *n* = 0 to 3. This field becomes 1 when the MUB_TR*n* register is written to on the MUB side. When this field is 1, it indicates to the MUA side that new data in the MUA_RR*n* register is ready for MUA to read it. If MUA_RCR[RIE*n*] = 1, a receive *n* interrupt is issued on the MUA side. This field becomes 0 when the MUA_RR*n* register is read, or when MU is reset. After this field becomes 0, if MUA_RCR[RIE*n*] = 1, the receive *n* interrupt request is cleared on the MUA side. 0b - Not full 1b - Full

37.7.1.17 Transmit (TR0 - TR3)

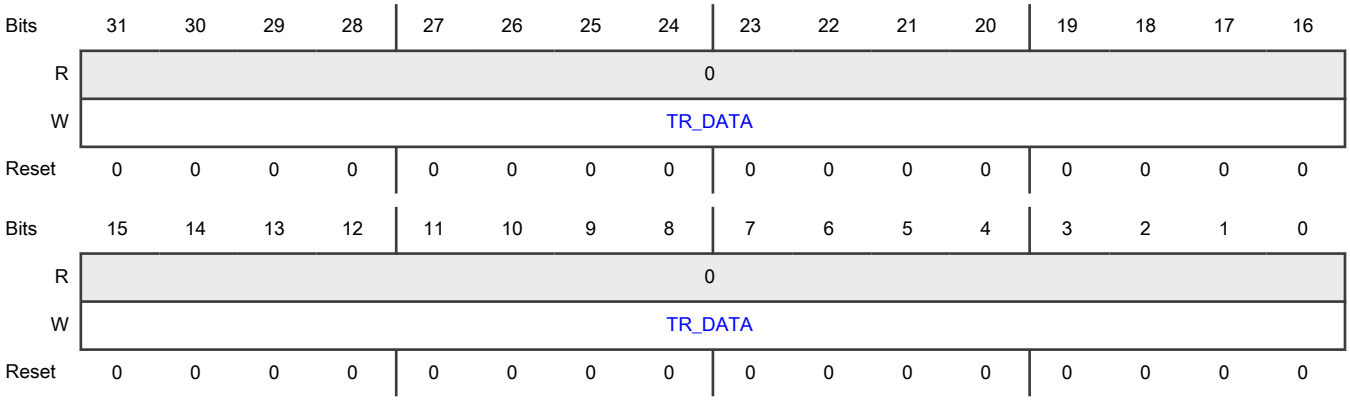
Offset

Register	Offset
TR0	200h
TR1	204h
TR2	208h
TR3	20Ch

Function

Contains MUA transmit data.

Diagram



Fields

Field	Function
31-0 TR_DATA	MUA Transmit Data Contains MUA transmit data. MUB_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUA_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUA_TSR[TE*n*] on the transmitter side, and sets MUB_RSR[RF*n*] on the receiver side. You can write to this register only when MUA_TSR[TE*n*] = 1. Reading this register returns all zeroes.

37.7.1.18 Receive (RR0 - RR3)

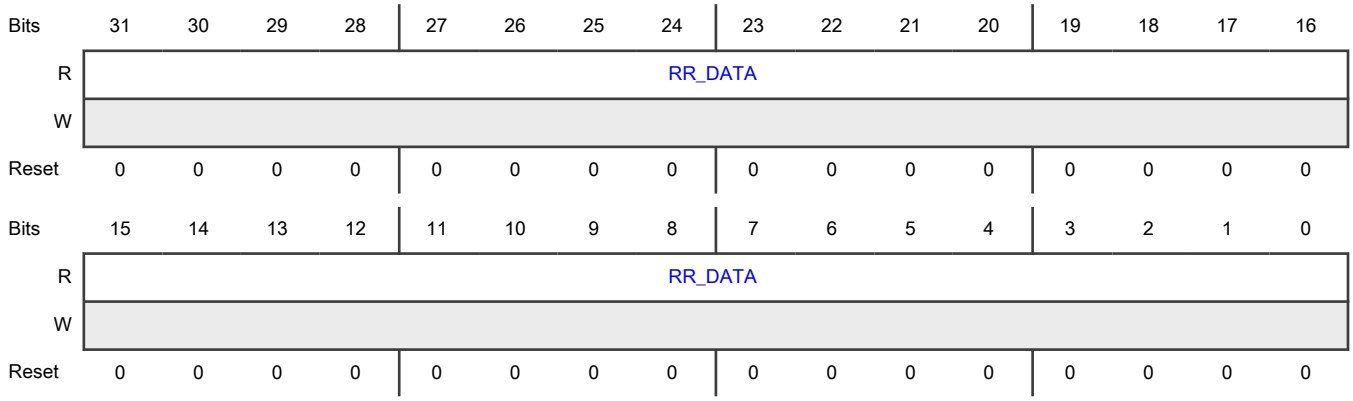
Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Function

Contains MUA receive data.

Diagram



Fields

Field	Function
31-0 RR_DATA	MUA Receive Data Reflects the data written to MUB TR*n*. Reading this register clears MUA_RSR[RF*n*] on the receiver side, and sets MUB_TSR[TE*n*] on the transmitter side. You can read this register only when MUA_RSR[RF*n*] = 1. Reading it before MUA_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUA_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUA.

37.7.2 MUB register descriptions

This section contains the detailed register descriptions for MUB registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

37.7.2.1 MUB memory map

R	RR_NUM								TR_NUM							
W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0

Fields

Field	Function
31-24 FLAG_WIDTH	Flag Width Specifies the number of flag bits (3) in the Flag Control (FCR) and Flag Status (FSR) registers.
23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (4).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

37.7.2.4 Control (CR)

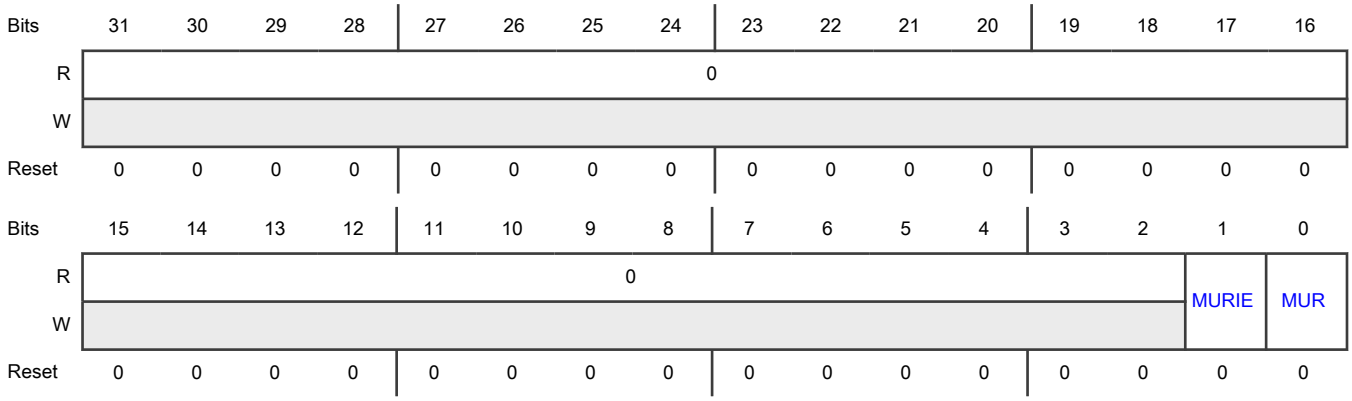
Offset

Register	Offset
CR	8h

Function

Controls MU reset and reset interrupt enable.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 MURIE	MUB Reset Interrupt Enable Enables the processor B-side MU reset interrupt request due to MU reset issued by MUA. If the value of this field is 1, an MU reset interrupt request is issued to processor B when MUB_SR[MURIP] = 1. If the value of this field is 0, MU ignores the value of MURIP and issues no MU reset interrupt request. Only a system reset can reset this field. CR[MUR] cannot reset this field. 0b - Disable 1b - Enable
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUB and MUA sides. All internal states are cleared. It forces all control and status registers to return to their default values (except HR, HRM in MUB/A_CCR0 registers; MURIE in MUB/A_CR registers; MURIP and MURS in MUB/A_SR registers). Before writing 1 to this field, interrupt processor A because writing 1 to this field may affect the ongoing processor A program. After writing 1 to this field, monitor the value of MUB_SR[MURS] to know when the reset sequence on the processor A-side has ended. This field always reads 0, and it becomes 0 during the MU reset sequence. 0b - Idle 1b - Reset

37.7.2.5 Status (SR)

Offset

Register	Offset
SR	Ch

Function

Shows the status of MU resets and the status of pending events and requests.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W															W1C	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	u

Fields

Field	Function
31-8 —	Reserved
7 —	Reserved
6 RFP	MUB Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUA writes to a TR*n* register to send data to MUB. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUB to read it. This field becomes 0 when all MUB RR*n* registers are read, or when MU is reset. 0b - Not pending; MUA is not writing to a Transmit register 1b - Pending; MUA is writing to a Transmit register
5 TEP	MUB Transmit Empty Pending Indicates whether a transmit empty message is pending.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when any TCR[TIE*n*] field is 1 and MUA reads the corresponding Receive (RR*n*) register. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUB to write to it. This field becomes 0 when write operations to all MUB Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0b - Not pending; MUA is reading no Receive (RRn) register 1b - Pending; MUA is reading a Receive (RRn) register
4 GIRP	MUB General-Purpose Interrupt Pending Indicates that MUA has sent a general-purpose interrupt request. This field becomes 1 when the MUA side sends a general-purpose interrupt request to the MUB side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. This field becomes 0 when all MUB_GSR[GIP*n*] fields are cleared, or when MU is reset. 0b - No request sent 1b - Request sent
3 FUP	MUB Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUB_FCR. This field becomes 1 when the MUB side sends a flag update request to the MUA side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUA side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUB_FCR does not generate a flag update event. The F*n*[2:0] bits do not change. If SR[EP] = 1 (event pending), writing to MUB_FCR does not immediately cause this field to become 1. 0b - No pending update flags (initiated by MUB) 1b - Pending update flags (initiated by MUB)
2 EP	MUB Side Event Pending Indicates a pending side event when the MUB side sends an event update request to the MUA side. An event is any hardware message that the Status register on the MUA side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUA, verify that this field is 0. If it is 1, wait and continue to poll this field until it becomes 0. 0b - Not pending 1b - Pending
1	MU Reset Interrupt Pending Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
MURIP	Indicates whether processor A has issued an MU reset. This flag is set after processor A initiates an MU reset by setting MUB_CR[MUR]. If CR[MURIE] = 1, the processor B MU reset interrupt request is issued when processor A writes 1 to MUA_CR[MUR]. Clearing this flag also clears the MU reset interrupt request. Only a system reset can reset this flag. MU reset cannot reset this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Reset not issued 1b - Reset issued When writing 0b - No effect 1b - Clear the flag
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side. This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0b - Out of reset 1b - In reset

37.7.2.6 Core Control 0 (CCR0)

Offset

Register	Offset
CCR0	10h

Function

Allows MUB to control the processor on the MUA side.

Also allows control of the processor B hardware reset mask.

2-0 Fn	MUA to MUB-Side Flag Contains flags configured by the values written to MUA_FCR[F*n*], where *n* = 0 to 2. F*n* is the MUB-side flag configured by the values written to MUA_FCR[F*n*]. When MUA_FCR[F*n*] is written to, the write event updates MUB_FSR[F*n*], after the event update latency. 0b - MUA_FCR[Fn] = 0 1b - MUA_FCR[Fn] = 1

37.7.2.10 General-Purpose Interrupt Enable (GIER)

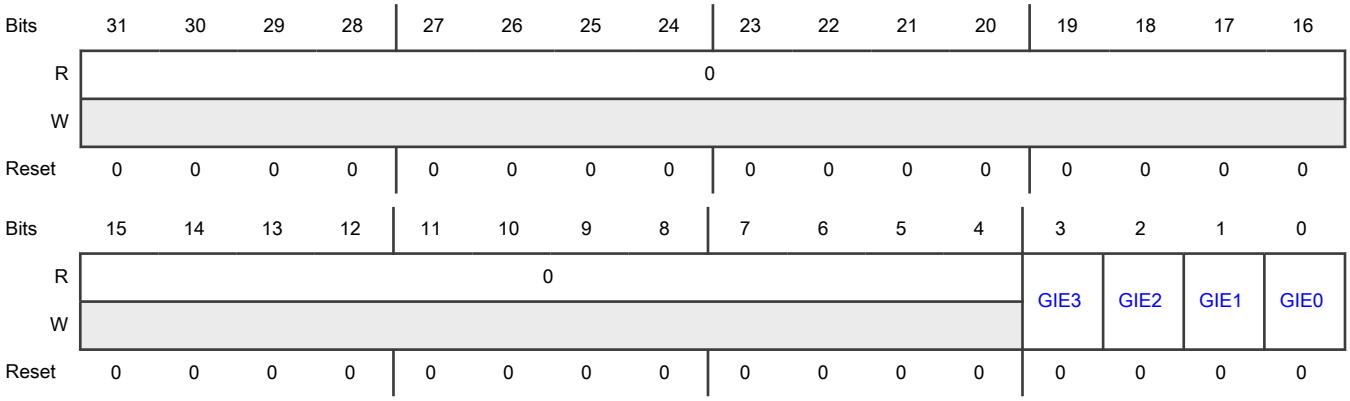
Offset

Register	Offset
GIER	110h

Function

Contains the MUB general-purpose interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIEn	MUB General-purpose Interrupt Enable Enables general-purpose interrupt. There are 4 general-purpose interrupts (*n* = 0 to 3). When GIE*n* = 1, a general-purpose interrupt *n* request is issued to processor B when MUB GSR[GIP*n*] = 1. If GIE*n* = 0, the general-purpose interrupt request pending does not trigger the general-purpose interrupt. GIE*n* becomes 0 when MU resets. 0b - Disable 1b - Enable

37.7.2.11 General-Purpose Control (GCR)

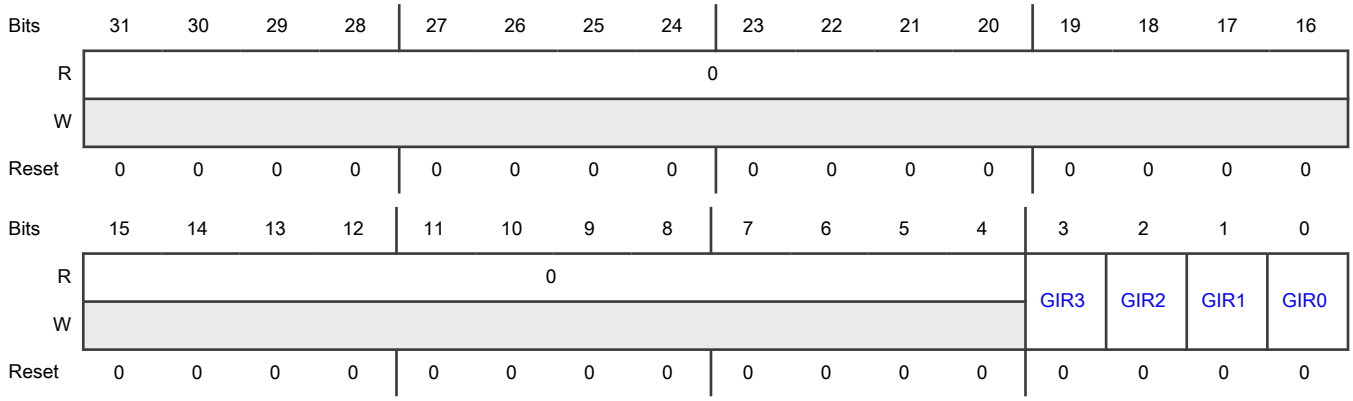
Offset

Register	Offset
GCR	114h

Function

Contains the MUB general-purpose interrupt request fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIRn	MUB General-Purpose Interrupt Request Specifies whether general-purpose interrupts are requested to MUA. There are 4 general-purpose interrupts (*n* = 0 to 3). Writing 1 to GIR*n* sets MUA_GSR[GIP*n*]. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is triggered on processor A. This field becomes 0 when MUA_GSR[GIP*n*] is cleared. This clearing informs MUB that the interrupt is accepted (cleared by software). To ensure proper operations, verify that GIR*n* is 0 (no pending interrupt) before writing 1 to it. This field becomes 0 when MU resets. 0b - Not requested 1b - Requested

37.7.2.12 General-purpose Status (GSR)

Offset

Register	Offset
GSR	118h

Function

Contains the status of the MUB general-purpose interrupt pending requests.

Fields

Field	Function
31-4 —	Reserved
3-0 GIPn	MUB General-Purpose Interrupt Request Pending Indicates whether a general-purpose interrupt request is pending. There are 4 general-purpose interrupts (*n* = 0 to 3). GIP*n* informs MUB that MUA_GCR[GIR*n*] changed from 0 to 1. If MUB_GIER[GIE*n*] = 1, a general-purpose interrupt request is issued to processor B. GIP*n* is cleared when MU resets. After GIP*n* is cleared, if MUB_GIER[GIE*n*] = 1, the general-purpose interrupt request is cleared on the MUB side. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not pending 1b - Pending When writing 0b - No effect 1b - Clear the flag

37.7.2.13 Transmit Control (TCR)

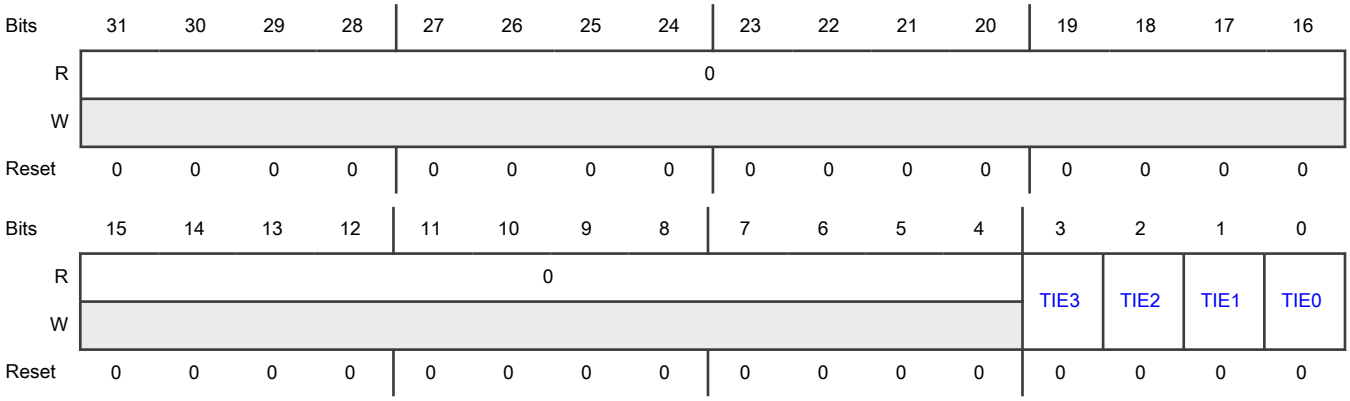
Offset

Register	Offset
TCR	120h

Function

Contains the MUB transmit interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TIEn	MUB Transmit Interrupt Enable Enables MUB transmit interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUB transmit interrupt *n* request is issued when MUB_TSR[TE*n*] is set. If this field is 0, MU ignores the value of MUB_TSR[TE*n*], and no MUB transmit interrupt *n* request is issued. 0b - Disable 1b - Enable

37.7.2.14 Transmit Status (TSR)

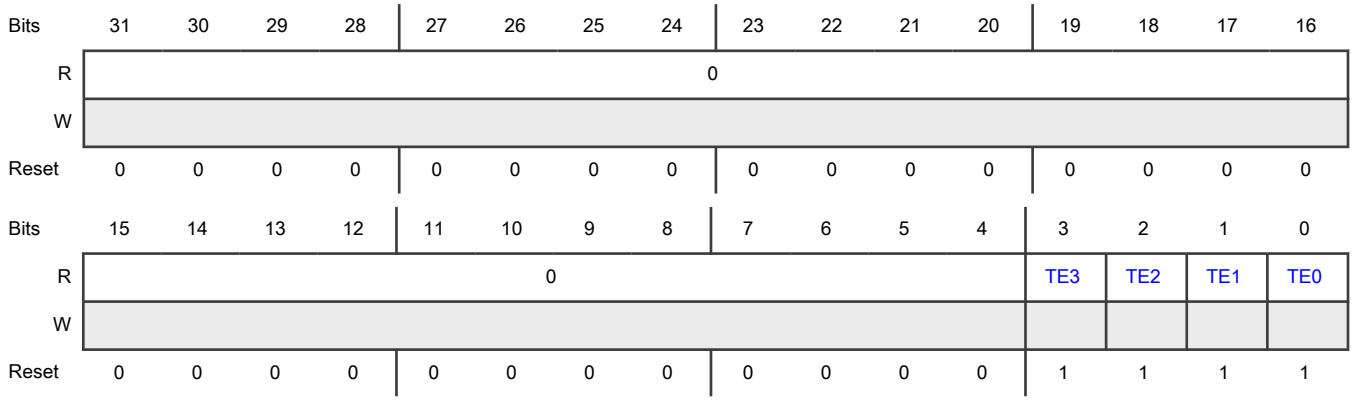
Offset

Register	Offset
TSR	124h

Function

Indicates whether the MUB transmit registers are empty.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TEn	MUB Transmit Empty Indicates whether MUB Transmit (TR*n*) register is empty, where *n* = 0 to 3. This field becomes 1 after the MUA_RR*n* register is read on the MUA side. When TE*n* = 1, it indicates to the MUB side that the MUB_TR*n* register is ready to be written on the MUB side. If MUB_TCR[TIE*n*] = 1, a transmit *n* interrupt is issued on the MUB side. This field becomes 0 after the MUB_TR*n* register is written to on the MUB side. After this field becomes 0, if MUB_TCR[TIE*n*] = 1, the transmit *n* interrupt request is cleared on the MUB side. This field becomes 1 when MU resets. 0b - Not empty 1b - Empty

37.7.2.15 Receive Control (RCR)

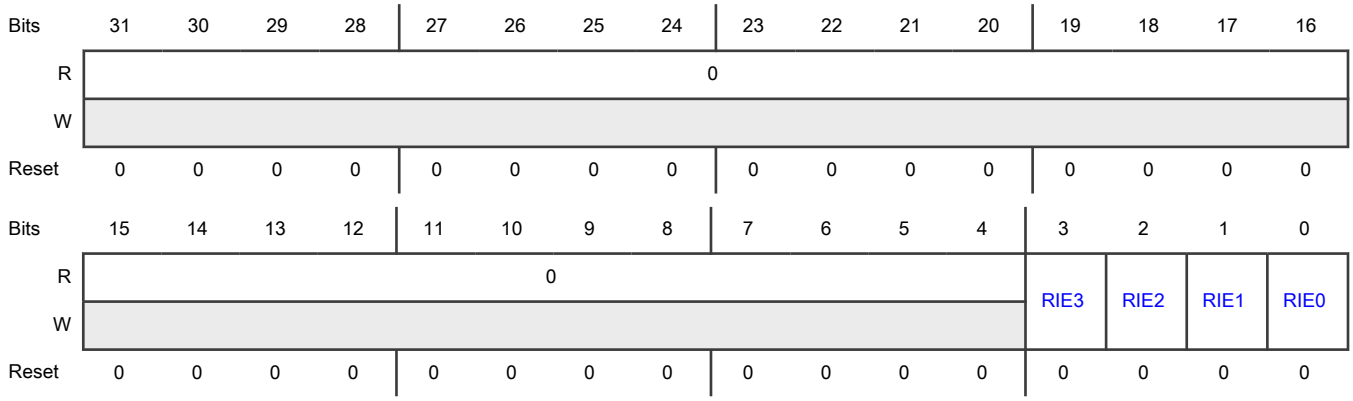
Offset

Register	Offset
RCR	128h

Function

Contains the MUB receive interrupt enables.

Diagram



Fields

Field	Function

R	0															
W	TR_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TR_DATA	MUB Transmit Data Contains MUB transmit data. MUA_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUB_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUB_TSR[TE*n*] on the transmitter side, and sets MUA_RSR[RF*n*] on the receiver side. You can write to this register only when MUB_TSR[TE*n*] = 1. Reading this register returns all zeroes.

37.7.2.18 Receive (RR0 - RR3)

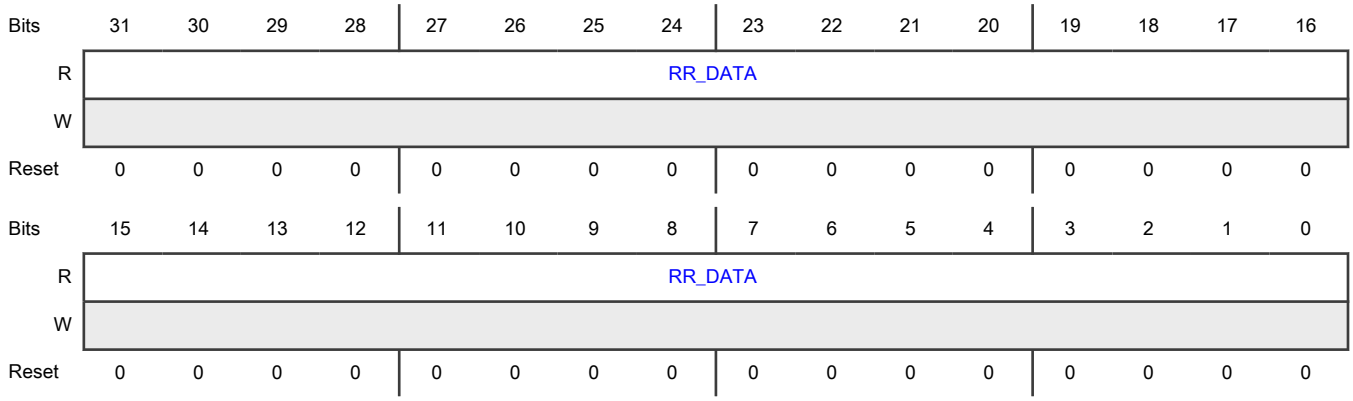
Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Function

Contains MUB receive data.

Diagram



Fields

Field	Function
31-0 RR_DATA	MUB Receive Data Reflects the data written to MUA TR*n*. Reading this register clears MUB_RSR[RF*n*] on the receiver side, and sets MUA_TSR[TE*n*] on the transmitter side. You can read this register only when MUB_RSR[RF*n*] = 1. Reading it before MUB_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUB_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUB.

Chapter 38
Edgelock Messaging Unit (MU)

38.1 Overview

The Messaging Unit module enables two processing elements within the SoC to communicate and coordinate by passing messages (e.g., data, status and control) through its interfaces. The Messaging Unit (ELEMU) is specifically targeted for use in ELE. The ELEMU also provides the ability for one processing element to signal the other processing element using interrupts based on data transmission status.

This module's design is based on synchronous clock domain crossings, that is, each side of the ELEMU operates in a phase-aligned clock domain. The two clock domains may be operating at integer multipliers or dividers, but they are phase aligned so there is no need for logic to handle asynchronous clock domain crossings. The ELEMU accomplishes synchronization using two sets of matching registers (Processor A-facing, Processor B-facing).

In the ELE application, the ELEMU "A-side" port corresponds to the SoC host processor while the ELEMU "B-side" port is the security subsystem.

Throughout this chapter, "ELEMUA" is used to denote hardware resources associated with the "A-side" port, and "ELEMUB" denotes those associated with the "B-side" port. This manual only documents the MU "A-side" programming model as it is visible and accessible to the host processor, while the MU "B-side" programming model is restricted to the internal operation of the EdgeLock enclave and not visible nor accessible to the host processor.

38.1.1 Block Diagram

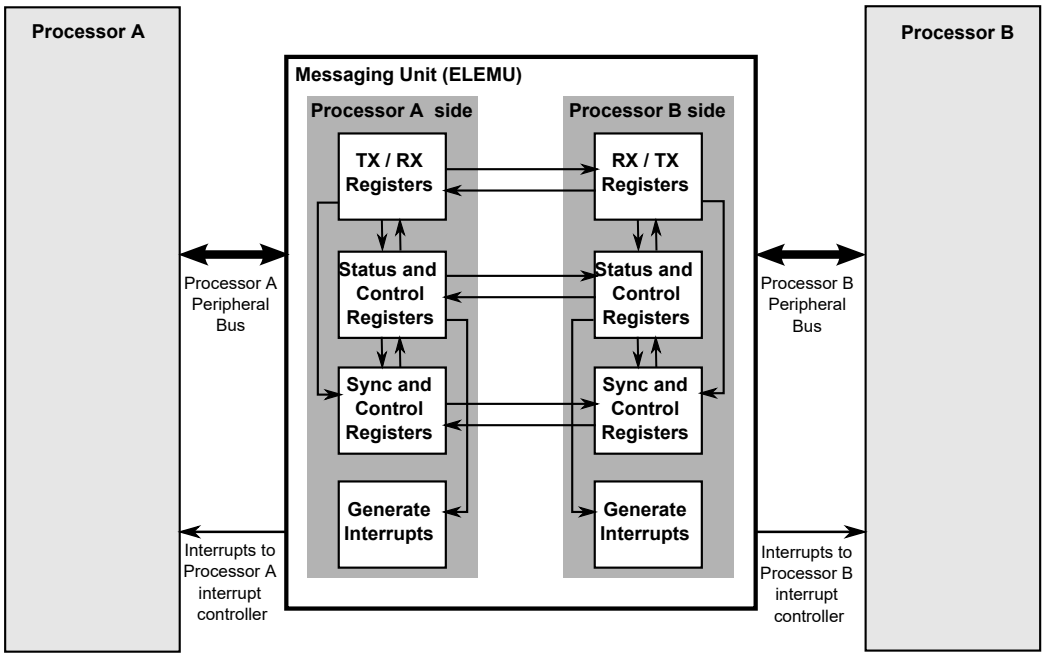


Figure 279. ELEMU Block Diagram

38.1.2 Features

The ELEMU includes the following features:

1. Memory-Mapped Registers

- The ELEMU is connected with separate peripheral buses on Processor A-side and Processor B-side.

2. Synchronous Message Transfers between Processing Elements
   - For sending data or messages between the processing elements, ELEMUA provides 8 transmit registers and 4 receive registers, while ELEMUB provides 4 transmit registers and 8 receive registers.
   - The transfer of data messages between processing elements uses transmit empty and receive full flags provided on both sides of the ELEMU.
   - The update of these transmit and receive flags is accomplished using a fully synchronous mechanism. Upon a register read or write, the corresponding transmit or receive flags are updated at the completion of the register access cycle.

38.2 Functional Description

The Messaging Unit (ELEMU) enables two processing elements (Processor A and Processor B) to communicate with each other, by passing message/data information to each other, and by enabling one side to wake up the other side using data transmission interrupts.

The messaging, control, and status registers of the Processor A and Processor B sides for the ELEMU are mapped to the processing element A and processing element B address spaces using a standard peripheral bridge memory slot. The peripheral data bus is 32 bits wide inside the ELEMU module.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the A-side and the B-side. The messaging mechanisms are:

- 8 32-bit ELEMUA transmit registers, which are each reflected in 8 read-only ELEMUB receive registers. These registers can be used to transfer 32-bit word messages or pass information for messages written to the shared memory (number of words, address pointers, and message type code).
- 4 32-bit ELEMUB transmit registers, which are each reflected in 4 read-only ELEMUA receive registers. These registers can be used to transfer 32-bit word messages or pass information for messages written to the shared memory (number of words, address pointers, and message type code).
- A write to a transmit register clears the corresponding “transmitter empty” bit in the Status Register on the transmitter side, and sets the appropriate “receiver full” bit in the Status Register on the receiver side. The setting of the bit at the receiver side can optionally trigger an interrupt at the receiver side (maskable receive interrupt).
- A read of one of the receive registers clears the corresponding “receiver full” bit in the Status Register at the receiver side, and sets the appropriate “transmitter empty” bit in the Status Register on the transmitter side. The setting of the “transmitter empty” bit can optionally trigger an interrupt at the transmitter side (maskable transmit interrupt).

A write to a transmit register signals the receiver side that data is ready for retrieval.

- Writing to the transmit register again without verifying that the data was retrieved is prohibited, because the transmitter side has no way of knowing the exact time that the receiver retrieves the data.
- Before attempting to write the transmit register again, the transmitter side waits for a “Transmitter Empty” interrupt, or polls the “Transmitter Empty” bit in the Transmit Status Register.

A read of a receive register signals the transmitter side that new data can be written to that register. In the same way, the receiver processor should not read a receive register before receiving a “Receiver Full” interrupt or polling the “Receiver Full” bit in the Receive Status Register.

- Reading the receive register again without verifying that the data was written is prohibited, because the receiver side has no way of knowing the exact time that the transmitter writes the data.
- Before attempting to read the receive register again, the receiver side waits for a “Receiver Full” interrupt, or polls the “Receiver Full” bit in the Receive Status Register.

38.3 Register Definition

The ELEMU provides transmit and receive data registers for the communication between Processor A and Processor B. Some control and status registers to the Processor A and Processor B sides are for control operations (such as interrupts), and for status checking of the other ELEMU-side. The following diagram shows the ELEMU registers schematic.

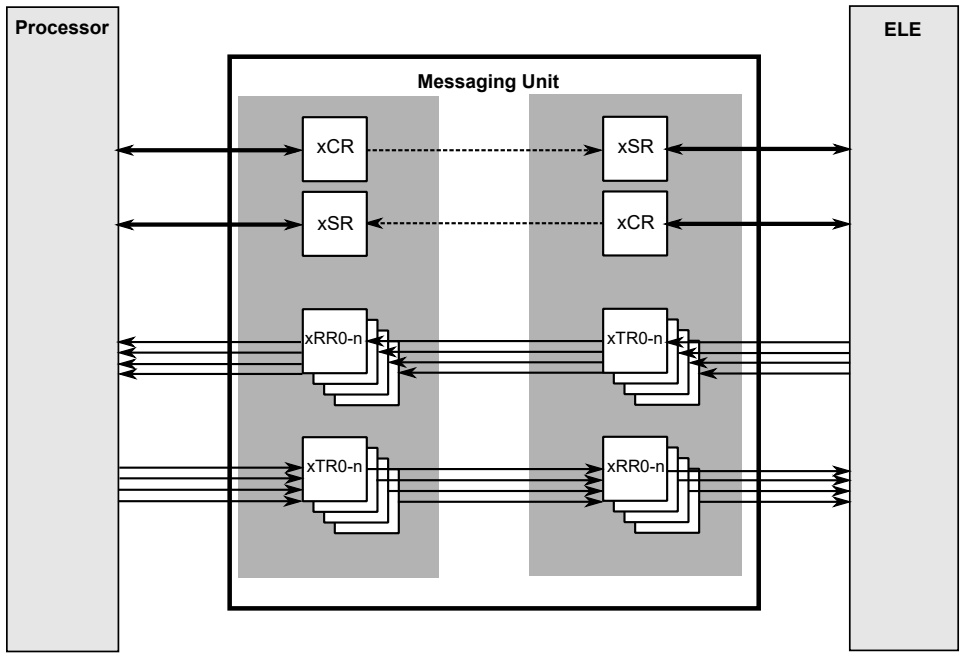

Figure 280. ELEMU Registers

The detailed ELEMU register definition can be found below.

NOTE

Read of a write-only, read zero (WORZ) register returns 0. Writes to a read-only (RO) register are ignored. Byte/halfword accesses are supported.

A read/write access to any illegal location of the ELEMU generates a bus transfer error acknowledge to the Processor A or Processor B. Writes to "RSVD" registers are ignored and reads to "RSVD" registers return 0.

38.3.1 ELEMUA register descriptions

This section contains the detailed register descriptions for the ELEMUA registers.

38.3.1.1 ELEMUA memory map

Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

Fields

Field	Function
31-7 —	Reserved
6 RFP	Receive Full Pending Flag Indicates if any of the receive registers are ready to be read. When the RFP bit is set, then software should check the RSR[RFn] flags to determine which RRn register is ready to be read. 0b - No data is ready to be read. All RSR[RFn] bits are clear. 1b - Data is ready to be read. One or more RSR[RFn] bits are set.
5 TEP	Transmit Empty Pending • The TEP bit reads as "1" when any TSR[TEn] bit is set. • The TEP bit reads as "0" when all TSR[TEn] bits are clear. • When the TEP bit reads as "1", check the TSR[TEn] flags to determine which TRn register is ready to be written.
4-0 —	Reserved

38.3.1.6 Transmit Control Register (TCR)

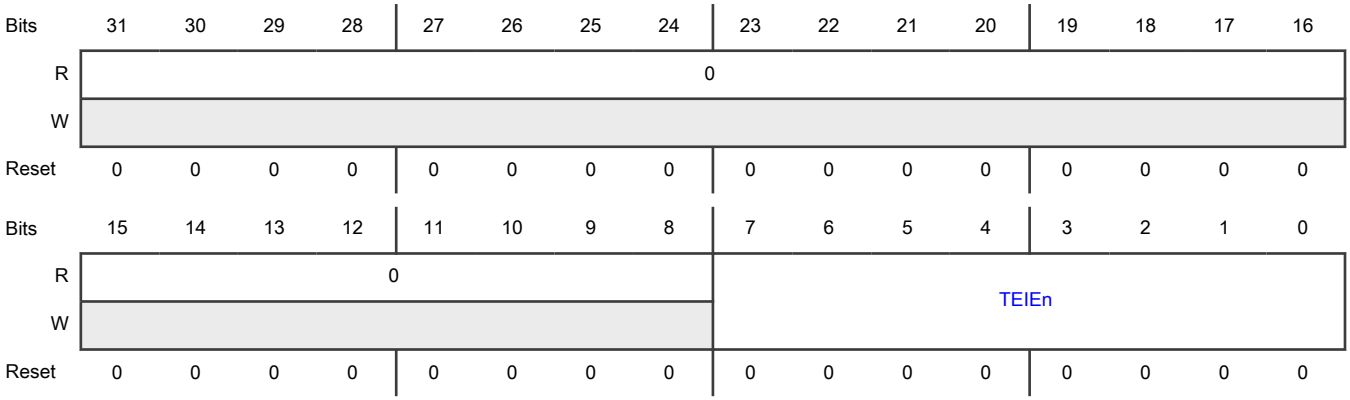
Offset

Register	Offset
TCR	120h

Function

The TCR register is used to configure which Transmit Empty interrupts are generated when the corresponding TSR[TEn] bits are set.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TEIEn	Transmit Register n Empty Interrupt Enable When set, causes a Transmit Empty interrupt to be generated when the corresponding TSR[TEn] bit is set.

38.3.1.7 Transmit Status Register (TSR)

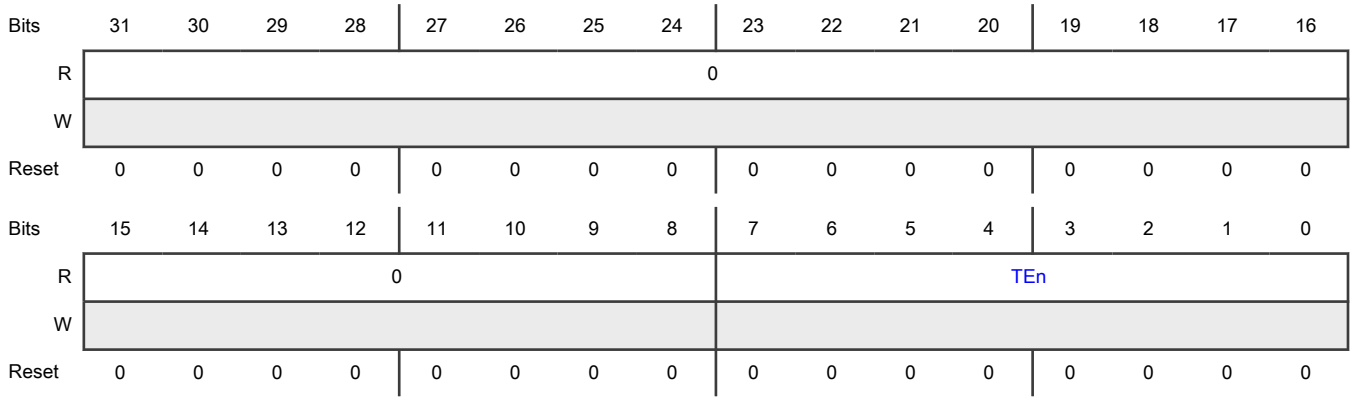
Offset

Register	Offset
TSR	124h

Function

The TSR register shows which TR registers are ready to be written.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TEn	Transmit Register n Empty • The TEn bit is used to indicate to the ELEMUA processing element that the corresponding ELEMUA TRn register is ready to be written. • The TEn bit is set after the corresponding ELEMUB RRn register is read, indicating the ELEMUA TRn register is empty. • The TEn bit is cleared after the ELEMUA TRn register is written, indicating the ELEMUA TRn register is full. • After the TEn bit is cleared, the Transmit Empty interrupt n (if the TCR[TEIEn] bit is set) is cleared on the ELEMUA side.

38.3.1.8 Receive Control Register (RCR)

Offset

Register	Offset
RCR	128h

Function

This register can be used for status, as the receive interrupts are not connected to the host CPU.

NOTE

This cache is for CM33. For further details about cache related information, see AMBA AHB protocol specification.

39.2 Overview

XCACHE is a general-purpose AMBA AHB bus protocol cache. XCACHE provides lower latency access to slower memories.

39.2.1 Block diagram

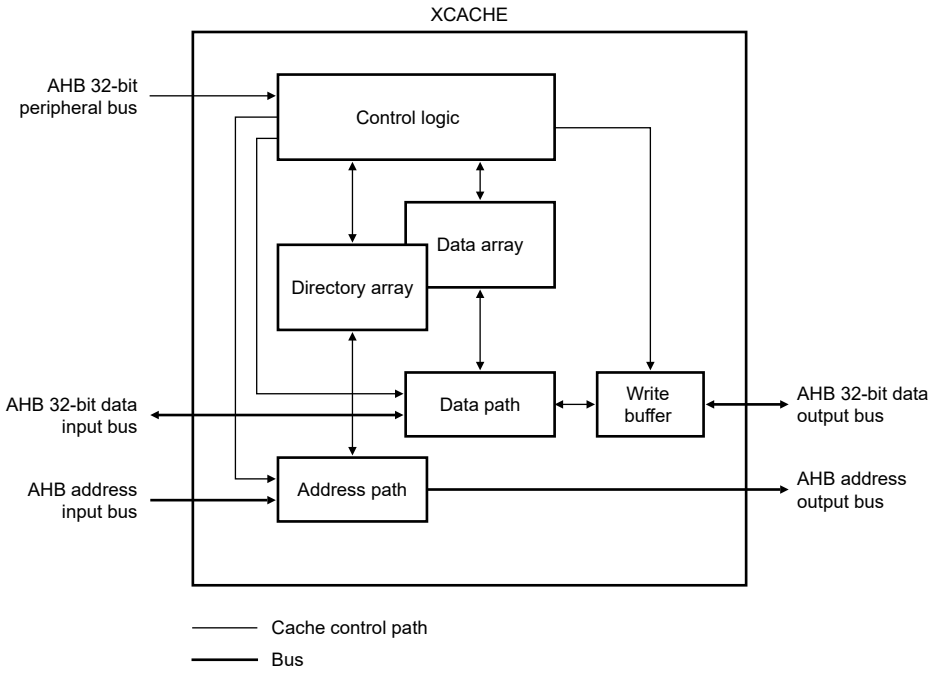

Figure 281. Block diagram

39.2.2 Features

XCACHE is designed to work with AMBA AHB bus systems. It includes:

- An AHB input bus. Accesses have cache mode attributes for cacheable copyback, cacheable write-through, or noncacheable mode operation and write bufferable mode operation on an access-by-access basis.
- 32-bit data path AHB output bus for downstream cache read miss, cache write-through write, and noncacheable accesses.
- Connections to tag and data RAMs to implement the cache functions.
- A peripheral interface for accessing the cache's programming model.

XCACHE includes the following AMBA_AHB buses:

- AHB input bus
- AHB output bus

39.3 Functional description

XCACHE is a block of high-speed memory locations that contains address information (commonly known as a tag) and its associated data. It decreases the average time of a memory access.

XCACHE operates on two principles of locality:

- Spatial locality — Access to one location possibly follows an access from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- Temporal locality — Access to an area of memory possibly repeats within a short period of time (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property groups several locations together, under the same tag. This logical block is commonly known as a cache line.

You achieve temporal locality by retaining recently accessed lines in the cache.

When data loads into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are known as cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the input bus wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- Memory accesses occurring at times other than when the programmer would normally expect them.
- The existence of multiple physical locations where a data item can be held.

39.3.1 Modes of operation

Table 287. Modes of operation

Mode	Description
Write-Through	Access to address spaces with this cache mode are cacheable. • If all cacheable spaces are read-only spaces, then cache contains read-only data and all writes to the cache cause a fault. See the chip-specific cacheable space information. • A read miss on the input bus causes a line read on the output bus of a 16-byte-aligned memory address that contains the desired address. This miss data loads into the cache and marks as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus access. • A write miss bypasses the cache and writes to the output bus (no allocation on write-miss policy for Write-Through mode spaces). • A write hit updates the cache hit line with the write data and writes to the output bus. • The caches are input-bus-local and do not support hardware cache coherency. If the input bus accesses write-through regions and an external input bus (such as DMA), that needs to update these regions, you must first perform explicit cache clears to any needed cache memory range to ensure all modified cache lines update their associated memories before they are modified by external inputs, and subsequent cache input bus accesses get the updated memory.
Write-back	Access to address spaces with this cache mode are cacheable. • A read miss on the input bus causes a line read on the output bus of a 16-byte-aligned memory address that contains the desired address. This miss data loads into the cache and marks as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus access. • A write miss performs a read-to-write (allocate on write miss policy for write-back mode spaces). You perform a line read on the output bus of a 16-byte-aligned memory address containing the desired write address. This

Table continues on the next page...

Table 287. Modes of operation (continued)

Mode	Description
	miss data is loaded into the cache and marked as valid and modified. Then the write data updates the appropriate cache data locations. • A write hit updates the cache hit line with the write data plus marks the line as modified. • Caches do not support hardware cache coherency. If the cache's input bus has written to write-back regions and another input bus that can access the same target memory without going through the cache, to then needs to see these updates, software must perform explicit cache pushes to any needed cache memory range to ensure all modified cache lines update their associated memories before being read by this input. Likewise, if the cache's input bus has accessed write-back or write-through regions and another input bus that can access the same target memory without going through the cache then needs to update these regions, you must first perform explicit cache clears to any needed cache memory range to ensure all modified cache lines update their associated memories before this input modifies them, and subsequent cache input bus accesses get the updated memory.
Non-cacheable	Access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

There is an optional ECC (Error correcting code) support of the cache tag and data storage RAMs. The optional ECC is SECDED (Single error correct, double error detect).

39.3.2 XCACHE function

XCACHE receives bus requests on the input bus.

You can access the programming model for the cache via the XCACHE's AMBA APB bus.

XCACHE then processes the cacheable accesses as needed, when bypassing the noncacheable, cache write-through, cache miss, and cache maintenance accesses to its output bus.

The cache on this chip is structured as follows. The cache has a 2-way set-associative cache structure with a total size of 16 KB for the cache. The caches have 32-bit address and data paths and a 16-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

The TAG contains the required upper address bits, a modify bit, a valid bit, and up to 8 bits of extended address attributes. The extended address attribute field has information such as the supervisor/user and/or domain ID of the accesses that loads this tag. If any extended address attribute bits are provided, for subsequent access that hit a valid tag but has different attributes, the cache coherently forces a miss so downstream memory protection logic can check the access.

For this 16 KB cache, each cache TAG function uses two 512 x 21-bit RAM arrays or optionally two up to 512 x 29-bit RAM arrays (if all 8 bits of the extended address attribute are used). The cache DATA function uses two 2048 x 32-bit RAM arrays. The cache TAG entries store 19 bits of upper address as well as a modified and valid bit per cache line, and any optional extended address attribute bits. The cache DATA entries store four bytes of code or data.

The tag and data RAM ECC codes are stored in RAM arrays with their associated tag and data. The 7Bits tag ECC code word per cache way is stored along side the associated tag way. The 7Bit data ECC code word per cache way is stored along side the associated data way.

All normal cache accesses use physical addresses. This leads to the use of the following cache address:

CACHE - 16 KB size = (512 sets) x (16-byte lines) x (2-way set associative)

Table 288. Tag cache address use

Tag cache address use	Cache
Tag hit address range	Address[31:13]
Tag set select address range	Address[12:4] selects 1 of 512 sets
Not used	Address[3:0]

Table 289. Data cache address use

Data cache address use	System cache
Not used	Address[31:13]
Data set select address range	Address[12:4] used to select one of 512 sets
32-bit word select	Address[3:2] used to select one of four 32-bit words within a set
Byte select	Address[1:0] used to select the byte within the 32-bit word

39.3.3 XCACHE control

The cache is disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable and configure the cache, you must clear the cache commands and initialize the required tag array.

39.3.3.1 XCACHE set commands

The XCACHE set commands may operate on:

- All of way 0
- All of way 1
- All of both ways (complete cache)

Cache set commands are initiated using the upper bits in Cache Control (CCR). Cache set commands perform their operation on the cache independent of CCR[ENCACHE].

You initiate a cache set command by writing 1 to CCR[GO]. This field also acts as a busy bit for set commands. This field remains 1 when the command is active, and XCACHE writes 0 to it after the set command completes.

Supported cache set commands are provided in Table 290. Following are the set commands:

- Invalidate − Unconditionally clears valid and modify bits of a cache entry.
- Push − Pushes a cache entry if it is valid and modified, then clears the modify bit. If the entry is not valid or not modified, leave it as is.
- Clear − Pushes a cache entry if it is valid and modified, then clears the valid and modify bits. If the entry is not valid or not modified, clear the valid bit.

Table 290. Cache set commands

Cache Control (CCR)[27:24]				Command
CCR[PUSHW1]	CCR[INVW1]	CCR[PUSHW0]	CCR[INVW0]	
0	0	0	0	NOP
0	0	0	1	Invalidate all way 0

Table continues on the next page...

Table 290. Cache set commands (continued)

Cache Control (CCR)[27:24]				Command
CCR[PUSHW1]	CCR[INVW1]	CCR[PUSHW0]	CCR[INVW0]	
0	0	1	0	Push all way 0
0	0	1	1	Clear all way 0
0	1	0	0	Invalidate all way 1
0	1	0	1	Invalidate all way 1; invalidate all way 0 (invalidate cache)
0	1	1	0	Invalidate all way 1; push all way 0
0	1	1	1	Invalidate all way 1; clear all way 0
1	0	0	0	Push all way 1
1	0	0	1	Push all way 1; invalidate all way 0
1	0	1	0	Push all way 1; push all way 0 (push cache)
1	0	1	1	Push all way 1; clear all way 0
1	1	0	0	Clear all way 1
1	1	0	1	Clear all way 1; invalidate all way 0
1	1	1	0	Clear all way 1; push all way 0
1	1	1	1	Clear all way 1 and way 0 (clear cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, writing 8500_0001h to Cache Control (CCR) invalidates the cache and enables the cache.

39.3.3.2 XCACHE line commands

XCACHE line commands operate on a single line in the cache at a time. You can perform cache line commands using a physical or cache address that consists of a set address and a way select. The line command acts on the specified cache line.

Cache line commands with physical addresses first search both ways of the cache set specified by the following physical address bits. If they hit, the commands perform their action on the hit way: For cache - [12:4]

You specify cache line commands using the upper bits in Cache Line Control (CLCR). Cache line commands perform their operation on the cache independent of CCR[ENCACHE]. Using a cache address, the command can be specified using Cache Line Control (CLCR). Using a physical address, the command must also use Cache Search Address (CSAR) to specify the physical address.

You can initiate a line cache command by writing 1 to CLCR[LGO] or CSAR[LGO]. This field also acts a busy bit for line commands. This field remains 1 when the command is active and XCACHE writes 0 to it after the command completes.

Table 291. Cache line commands

Cache Line Control (CLCR)[27:24]			Command
CLCR[LACC]	CLCR[LADSEL]	CLCR[LCMD]	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way

Table continues on the next page...

Table 291. Cache line commands (continued)

Cache Line Control (CLCR)[27:24]			Command
CLCR[LACC]	CLCR[LADSEL]	CLCR[LCMD]	
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	Reserved, NOP
1	0	10	Reserved, NOP
1	0	11	Reserved, NOP
1	1	*xx*	Reserved, NOP

39.3.3.2.1 Executing a series of line commands using cache addresses

You can perform a series of line commands with incremental cache addresses by writing to Cache Line Control (CLCR).

- Place the command in the following fields of Cache Line Control (CLCR):
  - LACC
  - LADSEL
  - LCMD
- Write 1 to CLCR[WSEL] and CLCR[TDSEL] as required.
- Place the cache address in CLCR[CACHEADDR].
- Write 1 to CLCR[LGO].

After one line command completes, follow these steps to initiate the next command:

- Increment the cache address (at bit 2 to step through data or at bit 4 to step through lines).
- Write 1 to CLCR[LGO].

39.3.3.2.2 Executing a series of line commands using physical addresses

You can perform a series of line commands with incremental physical addresses using the following steps:

- Write to Cache Line Control (CLCR).
  - Place the command in the following fields of Cache Line Control (CLCR):
    - LACC
    - LADSEL
    - LCMD
  - Write 1 to CLCR[TDSEL]
- Place the physical address in CSAR[PHYADDR] and write 1 to CSAR[LGO].

After one line command completes, follow these steps to initiate the next command:

- Increment the physical address (at bit 2 to step through data or at bit 4 to step through lines).
- Write 1 to CSAR[LGO].

Cache Line Control (CLCR) and Cache Search Address (CSAR) both contains the field called LGO. Therefore, you can complete the above steps in a single write to Cache Search Address (CSAR).

39.3.3.2.3 Line command results

At completion of a line command, Cache Line Control (CLCR) contains information on the initial state of the line targeted by the command. For line commands with cache addresses, read this information before performing a line command action from the targeted cache line. For line commands with physical addresses, read this information on a hit before performing a line command action from the hit cache line or has initial valid bit cleared if the command misses. In general, if CLCR[LCIVB] becomes 0, the targeted line is invalid at the start of the line command and no line operation is performed.

Table 292. Line command results

Cache Line Control (CLCR)[22:20]			For cache address commands	For physical address commands
CLCR[LCWAY]	CLCR[LCIMB]	CLCR[LCIVB]		
0	0	0	Way 0 line is invalid	No hit
0	0	1	Way 0 valid and not modified	Way 0 valid and not modified
0	1	0	Way 0 line is invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line is invalid	No hit
1	0	1	Way 1 valid and not modified	Way 1 valid and not modified
1	1	0	Way 1 line is invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

On completion of a line command other than a write, Cache Read/Write Value (CCVR) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, Cache Read/Write Value (CCVR) holds the write data.

The cache does not have line lock capability.

39.3.3.3 XCACHE ECC enable

There are two ECC control enable inputs - one to enable ECC generation on writes and another to enable ECC checking and correction on reads. These inputs are controlled in an external program model. These signals are:

- ecc_wr_enable - Enable ECC generation on writes.
- ecc_rd_enable - Enable ECC checking and correction on reads.

At reset, the cache is disabled. After reset, to enable the cache with ECC enabled, perform the following:

1. Assert ecc_wr_enable and negate ecc_rd_enabled.
2. Perform the required cache "invalidated all" command. This initializes the TAG ECC.
3. After the invalidate completes, assert both ecc_wr_enable and ecc_rd_enabled.
4. Enable the cache - now the cache is enabled with ECC protection on.

39.3.3.4 XCACHE ECC function

When XCACHE ECC is enabled, for cache tag writes:

- All cache tag write generate the required tag ECC word.
- The cache tag and the associated tag ECC word are written to the tag RAM and tag ECC word RAM simultaneously.

When cache ECC is enabled, for cache data writes:

- All cache data writes of less than 32 bits are converted to a 32-bit read-modify-write sequence.
- All cache data writes generate the required data ECC word.
- The cache data and associated data ECC word are written to the data RAM and data ECC word RAM simultaneously.

When cache ECC is enabled, for cache tag reads:

- The cache tag and its ECC word are read in parallel.
- ECC is checked, any single bit error is corrected on-the-fly, any single, or multi-bit error is flagged.

When cache ECC is enabled, for cache data reads:

- For every data 32-bit word read, the data 32-bit word and its ECC word are read in parallel.
- ECC is checked, any single-bit error is corrected on-the-fly. Any single-, or multi-bit error is flagged.

The cache has single- and multi-bit ECC error indicator outputs.

Because all single-bit ECC errors are corrected on-the-fly, cache operations continue as normal when only single-bit ECC errors occur. Note it is possible to get multiple single- or multi-bit ECC errors on one cache access.

Cache read accesses that get multi-bit ECC errors are handled as follows:

- Any access that gets a tag multi-bit error terminates with a bus fault.
- Any access that gets a data multi-bit error on its hit data terminates with a bus fault.
- Data multi-bit error on miss or invalidate ways are ignored.

NOTE

Cache allocate pushes read the cache data arrays and may get ECC errors. Because the cache access that caused the allocate push may have completed before the ECC error, bus errors do not occur on multi-bit ECC errors. Only single or multi-bit ECC error indicators provide indications for an ECC error.

NOTE

Cache commands, which initiate via the cache's program model, may also access the cache tags and cache data RAMs. If these accesses get a multi-bit ECC error, the peripheral bus access that initiated the cache command does not terminate with a bus error. Only single or multi-bit ECC error indicators provide indications for an ECC error.

39.3.4 Clocks

XCACHE uses the AHB input bus clock.

39.3.5 Interrupts

XCACHE has no interrupts.

39.4 External signals

XCACHE has no external signals.

39.5 Initialization

To configure and enable the cache, you must perform XCACHE commands to clear and initialize the required tag array fields. See the following sequence:

- To enable the cache after reset with the write buffer also enabled, write 8500_0003h to Cache Control (CCR). After you write CCR[GO], it initiates the cache command that the following fields in Cache Control (CCR) specify:
  - PUSHW1
  - INVW1
  - PUSHW0
  - INVW0

  CCR[27:24] indicates a command of clear all entries in both cache ways, CCR[ENWRBUF] enables the write buffer, and CCR[ENCACHE] enables the cache. See XCACHE control for more information.
- To enable the cache after reset with the write buffer disabled, write 8500_0001h to Cache Control (CCR). After you write CCR[GO], it initiates the cache command that the following fields in Cache Control (CCR) specify:
  - PUSHW1
  - INVW1
  - PUSHW0
  - INVW0

  CCR[27:24] indicates a command of clear all entries in both cache ways, and CCR[ENCACHE] enables the cache. See XCACHE control description for more information.

39.6 Application information

XCACHE provides low-latency access to instructions or data. This decouples processor performance from system memory performance, increasing bus availability for other modules, and improving system performance.

39.7 Memory map and registers

The XACHE programming model provides various registers for configuring and controlling the cache, as well as indirect access paths to all cache tag and data storage.

NOTE

The XCACHE registers are accessible in Supervisor mode only.

39.7.1 XCACHE register descriptions

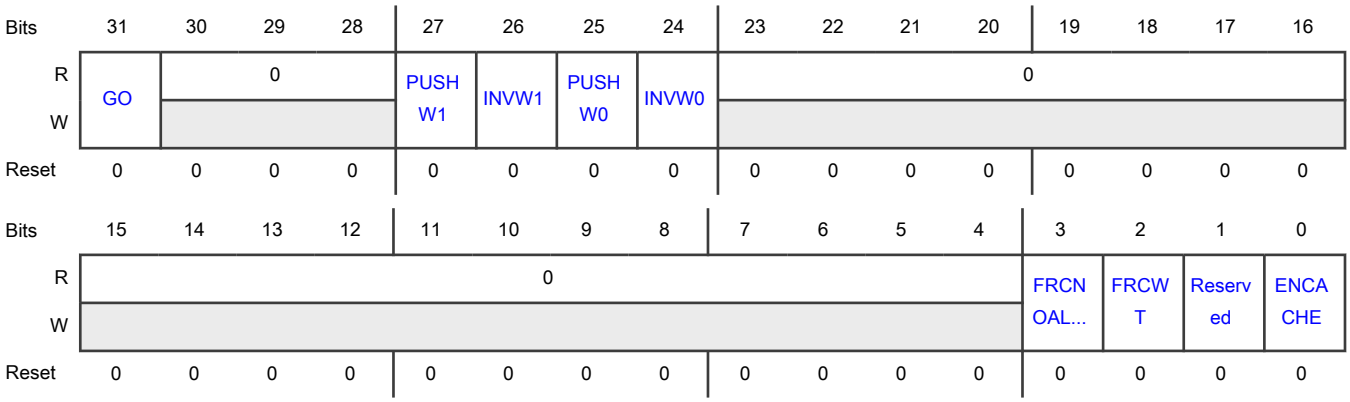
Function

Configures the cache control.

Diagram



Fields

Field	Function
31 GO	Initiate Cache Command Initiates the cache command that CCR[PUSHW1], CCR[INVW1], CCR[PUSHW0], and CCR[INVW0] indicate, if you write 1 to this field. Reading this field indicates whether a command is active. **NOTE** This field remains 1 until the command completes. Writing 0 has no effect. 0b - Write: no effect. Read: no cache command active 1b - Write: initiates command; Read: cache command active
30-28 —	Reserved
27 PUSHW1	Push Way 1 0b - No operation 1b - When you write 1 to GO, push all modified lines in way 1
26 INVW1	Invalidate Way 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If CCR[PUSHW1] and CCR[INVW1] are 1, then after you write 1 to CCR[GO], this field pushes all modified lines in way 1 and invalidates all lines in way 1 (clear way 1). 0b - No operation 1b - When you write 1 to GO, invalidates all lines in way 1
25 PUSHW0	Push Way 0 0b - No operation 1b - When you write 1 to GO, push all modified lines in way 0
24 INVW0	Invalidate Way 0 **NOTE** If CCR[PUSHW0] and CCR[INVW0] are 1, then after you write 1 to CCR[GO], this field pushes all modified lines in way 0 and invalidates all lines in way 0 (clear way 0). 0b - No operation 1b - When you write 1 to GO, invalidates all lines in way 0.
23-4 —	Reserved
3 FRCNOALLC	Forces No Allocation on Cache Misses 0b - Allocation on cache misses 1b - Forces no allocation on cache misses (must also have FRCWT asserted)
2 FRCWT	Force Write Through Mode Specifies whether all cacheable spaces to write through are forced. 0b - Does not force 1b - Force
1 —	Reserved Always write 0 to this field to maintain compatibility.
0 ENCACHE	Cache Enable Enables the cache. 0b - Disable 1b - Enable

39.7.1.3 Cache Line Control (CLCR)

Offset

Register	Offset
CLCR	4h

Function

Defines the specific line-sized cache operations that you perform using a specific cache line address or a physical address.

If you specify the physical address, you can search cache in both the ways, and the command only performs on the way that hits.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

40.2 Overview

CMX_PERFMON contains counters that you can configure to count events used to calculate the performance of a CPU, cache, or memory. You can configure CMX_PERFMON to select the events to be counted for each counter. An additional instruction counter is available to count CPU instruction fetches.

Block diagram provides an overview of CMX_PERFMON, which includes three event counters and an instruction counter.

40.2.1 Block diagram

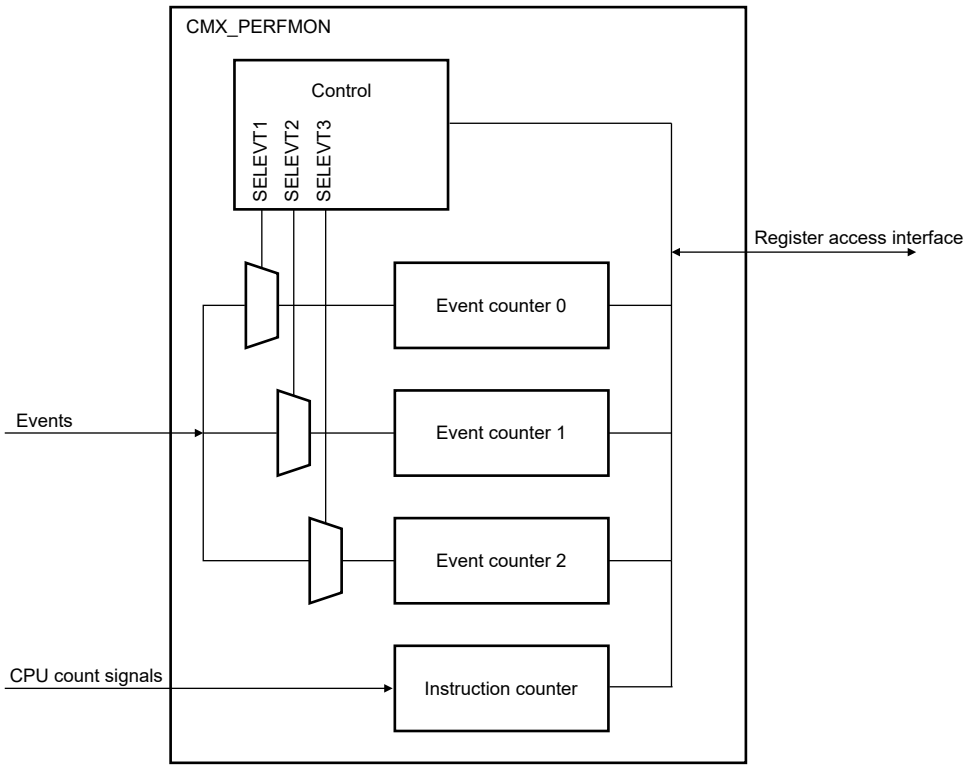

Figure 282. Block diagram

40.2.2 Features

- Three 40-bit event counters
- One 40-bit instruction counter
- Programmable event select
- Countable events that include cache, branch fetches, and stalls
- Memory mapped performance monitor that counts instructions, cache, branch, IPS, and TCM stats
- Count filter based on privilege level

40.3 Functional description

40.3.1 Operations

See the chip-specific CMX_PERFMON information for details about the countable events for the performance counters per CMX_PERFMON instance on this chip.

CMX_PERFMON has 3 programmable counters to count CPU events. The event to be counted is configured using the PMCR*m* register.

Each counter is a 40-bit register that tracks the number of occurrences of the selected event.

The counters can be programmed to take one of the 3 states:

- At idle state, the counters are in idle and do not perform any operation.

- At local start state, the counters are actively listening to CPU and cache and start incrementing when the selected events are observed.
- At local stop state, the counters stop listening to all components. The 3 event counter can be independently cleared by writing to PMCR*m*[RECTR*n*], where *n* denotes the counter instance.

40.3.2 Operating modes

The following table shows:

- The operating modes that you can specify for CMX_PERFMON.
- The PMCR*n*[CMODE] value that you must specify to count events in each mode.

Table 294. Operating modes

Mode	Description	CMODE value (binary)
Privileged	Only events in privilege mode are counted	11
User	Only events in user mode are counted	10
Both Privileged and User	Events in either privilege or user mode can be counted	00

Use PMCR*n*[SSC] to start and stop the counters.

40.3.3 Clocking

This module has no clocking considerations.

40.3.4 Interrupts

This module has no interrupts.

40.4 External signals

CMX_PERFMON has no external signals.

40.5 Initialization

To initialize CMX_PERFMON:

1. Program PMCR*m*[SELEVT*n*] to select the specific CPU event to be counted by this counter, where *n* denotes the counter instance.
2. Set PMCR*n*[CMODE] to filter each counter for the selected event while the CPU is in privilege, user, or either mode.
3. Set PMCR*n*[SSC] to program the counter to be in one of idle, local start, or local stop states.
4. Set PMCR*m*[RECTR*n*] to clear the counters independently where *n* denotes the counter instance.

Fields

Field	Function
31-25 SELEVT3	Select Event 3 Selects the event to be counted in PMECTR3. See the chip-specific CMX_PERFMON information to select which event PMECTR3 counts.
24-18 SELEVT2	Select Event 2 Selects the event to be counted in PMECTR2. See the chip-specific CMX_PERFMON information to select which event PMECTR2 counts.
17-11 SELEVT1	Select Event 1 Selects the event to be counted in PMECTR1. See the chip-specific CMX_PERFMON information to select which event PMECTR1 counts.
10 RECTR3	Reset Event Counter 3 Specifies whether the counter runs normally or the counter value resets at the end of the cycle. Write 1 to this field to clear this counter. This field does not return to 0 automatically, so if you want to restart the counter after clearing it, write 0 to this field. 0b - Run normally 1b - Reset
9 RECTR2	Reset Event Counter 2 Specifies whether the counter runs normally or the counter value resets at the end of the cycle. Write 1 to this field to clear this counter. This field does not return to 0 automatically, so if you want to restart the counter after clearing it, write 0 to this field. 0b - Run normally 1b - Reset
8 RECTR1	Reset Event Counter 1 Specifies whether the counter runs normally or the counter value resets at the end of the cycle. Write 1 to this field to clear this counter. This field does not return to 0 automatically, so if you want to restart the counter after clearing it, write 0 to this field. 0b - Run normally 1b - Reset
7 RICTR	Reset Instruction Counter Determines whether events reset or clear the instruction counter. Write 1 to clear the instruction counter. This field must be 0 to restart the instruction counter. 0b - Do not reset 1b - Clear
6	Disable Counters if Stopped or Halted

Table continues on the next page...

Table continued from the previous page...

Field	Function
DCIFSH	Specifies whether counters continue counting or stop counting when the CPU is halted. 0b - Continue 1b - Stop
5-4 CMODE	Count Mode Determines whether events are counted for Privileged mode, User mode, or both Privileged and User modes. This setting affects the operation of all event counters. 00b - Counted in both User and Privileged modes 01b - Reserved 10b - Counted only in User mode 11b - Counted only in Privileged mode
3-1 SSC	Start and Stop Control Provides a three-phase mechanism to start and stop the counters. It includes a prioritized scheme with the following relative priorities: local start > local stop The start or stop affects all performance monitor event counters concurrently, so that the counters are coherent. 000b - Idle or no-op 001b - Local stop 010b,011b - Local start 100b - Reserved 101b - Reserved 110b,111b - Reserved
0 MENB	Module Is Enabled Indicates whether CMX_PERFMON is enabled. Enabling CMX_PERFMON does not start the counters. To start the counters, write a nonzero value to PMCR*n*[SSC]. 0b - Disabled 1b - Enabled

40.6.1.3 Performance Monitor Instruction Counter (PMICTR_HI)

41.2 Overview

The Memory ECC Controller (MECC64) module supports Single Error Correction and Double Error Detection (SEC-DED) ECC functions to On-Chip RAM (OCRAM) access. It can generate a 8-bit ECC code by Hsiao Hamming algorithm for 64-bit data. Corresponding OCRAM space is available to store ECC code.

41.2.1 Block diagram

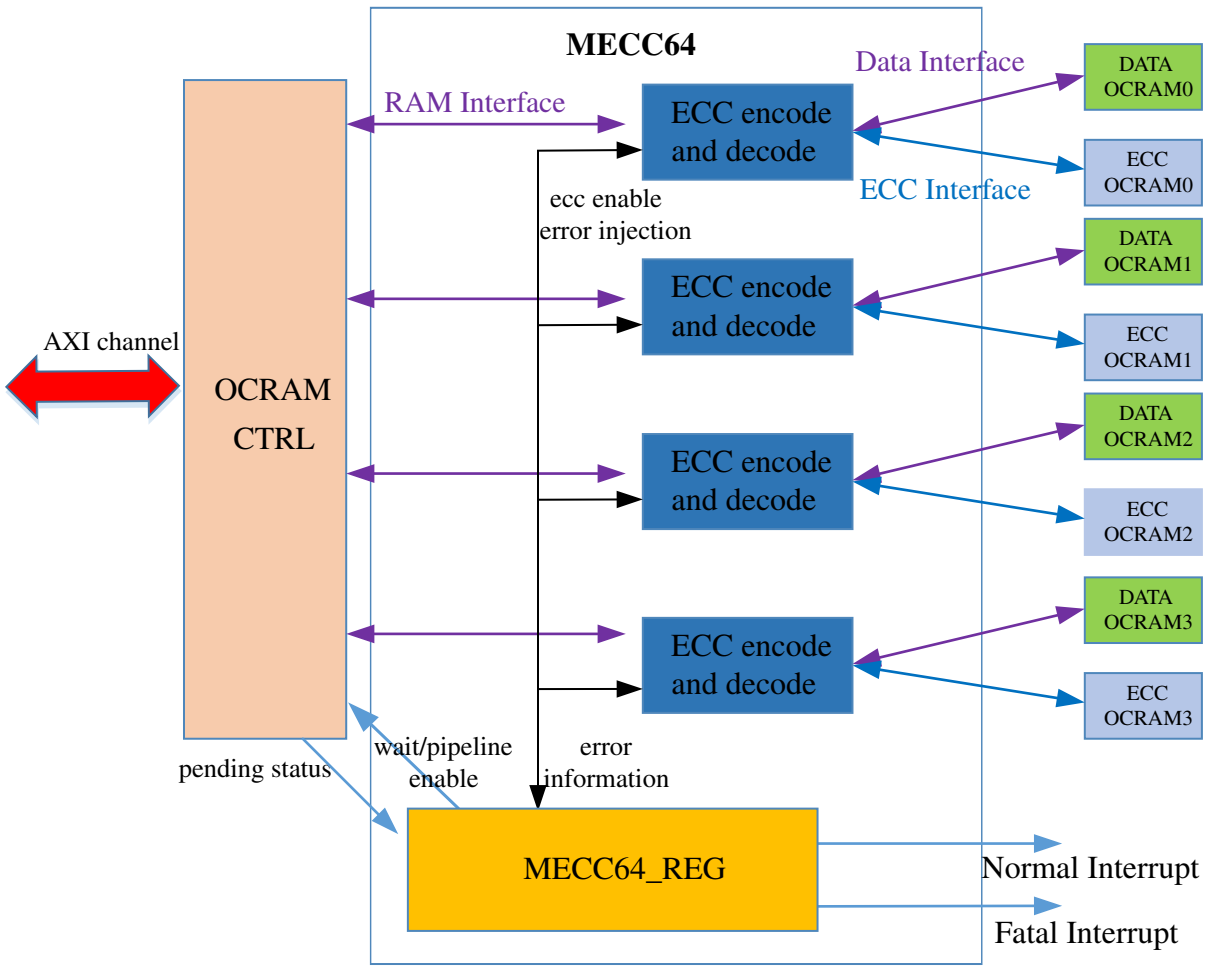

Figure 283. MECC64 block diagram

The following list shows detailed register/bitfield correspondance in the block diagram.

- ecc enable:
  - PIPE_ECC_EN[ECC_EN]
- error injection:
  - ERR_DATA_INJ_LOW/HIGH*n*
  - ERR_ECC_INJ*n*
- error information:
  - SINGLE_ERR_ADDR_ECC*n*
  - SINGLE_ERR_DATA_LOW/HIGH*n*
  - SINGLE_ERR_POS_LOW/HIGH*n*
  - MULTI_ERR_ADDR_ECC*n*
  - MULTI_ERR_DATA_LOW/HIGH*n*
- pending status:
  - PENDING_STAT

- wait/pipeline enable:
  - PIPE_ECC_EN[READ_DATA_WAIT_EN]
  - PIPE_ECC_EN[READ_ADDR_PIPE_EN]
  - PIPE_ECC_EN[WRITE_DATA_PIPE_EN]
  - PIPE_ECC_EN[WRITE_ADDR_PIPE_EN]

41.2.2 Features

The MECC64 includes the following features:

- Generates a 8-bit ECC code for 64-bit write data. Write data and ECC code are written into seperate OCRAM banks.
- Supports SEC-DED function for 64-bit read data and 8-bit ECC code.
- Integrate 4 banks OCRAM controller for converting AXI transaction to RAM interface.
- Error injection on write data and ECC code for debug purpose.
- Two different interrupt types: Normal and Fatal.

41.3 Functional description

The MECC64 converts AXI interface to RAM interface signals, and provides ECC encode/decode function for OCRAM write/read. For each data in OCRAM bank, corresponding space in ECC OCRAM banks is available to store ECC code when ECC function is enabled.

The OCRAM bank address allocation is as below:

- Bank0: ocram_base_address+0x20*i
- Bank1: ocram_base_address+0x20*i+0x8
- Bank2: ocram_base_address+0x20*i+0x10
- Bank3: ocram_base_address+0x20*i+0x18

where i = 0,1,2,3,4,...

41.3.1 Interface Conversion

The MECC64 integrates 4 banks OCRAM controller which converts AXI master interface signals to 4 groups of OCRAM interface signals (see OCRAM chapter for details). The 4 OCRAM banks are organized with lower 2 bits of address interleaved. This allows a read access and a write access to be processed at the same time if they are targeted to different OCRAM banks. OCRAM controller can support to add pipeline or wait-state in read/write access by register configuration.

41.3.2 ECC encode

When ECC is enabled, the 4 groups of OCRAM write access will enter into seperate ECC encode channels. In a ECC encode channel, it will generate 8 bits ECC code for 64 bits OCRAM write data. Then 64 bits OCRAM write access will split into one 64 bits data write and one 8 bits ECC code write. The 64 bits data will be written into one of the DATA OCRAM banks according to address, and 8 bits ECC code will be written simutaneously into the corresponding ECC OCRAM bank.

41.3.3 Error injection

The MECC64 can inject error in write data and ECC code by configuring ERR_DATA_INJ* and ERR_ECC_INJ* registers. The 64 bits write data and 8 bits ECC code can be inverted if corresponding bits in ERR_DATA_INJ* and ERR_ECC_INJ* registers are set. Each OCRAM bank has separate error injection registers. This feature is mainly used for debug.

41.3.4 ECC decode

When ECC is enabled, the 64 bits OCRAM read access will be split into one 64 bits data read and one 8 bits ECC code read. After getting read data from DATA OCRAM and ECC code from the corresponding ECC OCRAM, ECC decode channel can report single bit error or multiple bits error if ECC check is failed. At the same time, the error information will be saved in the module's error registers for debug. When single bit error is detected on read data, the error bit in read data will be corrected. In this case, AXI master will get read data correctly. When multiple bits error is detected on read data, error read data will not be corrected. In this case, master will get read data in error. When single bit error or multiple bits error happens, interrupt will be asserted if the corresponding enable bits are set in ERROR_STAT_EN and ERROR_SIG_EN registers. Each OCRAM bank has separate error and interrupt registers.

NOTE

- If read access is 64-bit, the MECC64 will generate single or multi error interrupt once when meeting ECC error.
- If read access is 32-bit (or 16-bit/8-bit), the MECC64 will generate interrupt twice when meeting ECC error, once each in both the low 32 bits and the high 32 bits, even if it has a bit error in only the low 32 bits or the high 32 bits. This is because the ECC function will do ECC code validation on the full 64 bits for one read access.

41.3.5 Interrupts

The MECC64 can generate two kinds of interrupts:

- Normal interrupt can be generated for the following cases:
  - Single bit error is corrected for read;
  - AXI access address exceeds OCRAM address range;
  - AXI write access to OCRAM bank is not full size (wstrb=0xff).
- Fatal interrupt can be generated when 'multiple bits error' is detected for read.

41.3.6 Clocks

There are two clocks in MECC64:

Clock	Description
clk	Main clock
ips_clk	This is for IPS bus, used for register write/read.

There are no special requirements for these two clocks.

41.4 Signals

There are no external signals for MECC.

41.5 Initialization

The steps for initialization process is as below:

1. Enable MECC function (set PIPE_ECC_EN[ECC_EN] = 1).
2. Enable interrupts (set ERR_STAT_EN = 0xFFFF, ERR_SIG_EN = 0xFFFF).

NOTE

- When the MECC function is enabled, the OCRAM memory region can be initialized with 0x00 or 0xFF (initialization data for the first ECC encode), to generate ECC code within OCRAM ECC code region.
  - Initialization is required because the MECC64 needs a complete OCRAM and OCRAM ECC data. When initialized, it generates ECC code depending on initialization data, store data and its ECC code in OCRAM and OCRAM ECC memory.
  - Do such initialization with 64 bits access, with STRD or STMIA instruction. Do not use memset() API, which is STR instruction, in software coding level.
- OCRAM memory with ECC should be non-cacheable, or cacheable with write through, to assure data in OCRAM memory at the write time. It may have different methods to achieve this goal, such as Memory Protection Unit (MPU) or disable cache.

41.6 Application information

There are no application pseudocode examples for MECC64.

41.7 Memory Map and register definition

This section includes the MECC64 module memory map and detailed descriptions of all registers.

41.7.1 MECC64 register descriptions

41.7.1.1 MECC64 memory map

MECC1 base address: 4292_0000h

MECC2 base address: 4293_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Error Interrupt Status Register (ERR_STATUS)	32	RW	0000_0000h

Fields

Field	Function
31-16 —	Reserved
15 ADDR_ERR3	OCRAM Access Error On Bank3 When OCRAM access unallocated address on bank3, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - OCRAM access error does not happen on OCRAM bank3. 1b - OCRAM access error happens on OCRAM bank3.
14 ADDR_ERR2	OCRAM Access Error On Bank2 When OCRAM access unallocated address on bank2, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - OCRAM access error does not happen on OCRAM bank2. 1b - OCRAM access error happens on OCRAM bank2.
13 ADDR_ERR1	OCRAM Access Error On Bank1 When OCRAM access unallocated address on bank1, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - OCRAM access error does not happen on OCRAM bank1. 1b - OCRAM access error happens on OCRAM bank1.
12 ADDR_ERR0	OCRAM Access Error On Bank0 When OCRAM access unallocated address on bank0, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - OCRAM access error does not happen on OCRAM bank0. 1b - OCRAM access error happens on OCRAM bank0.
11 STRB_ERR3	AXI Strobe Error On OCRAM Bank3 When AXI write access to OCRAM bank3 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - AXI strobe error does not happen on OCRAM bank3. 1b - AXI strobe error happens on OCRAM bank3.
10 STRB_ERR2	AXI Strobe Error On OCRAM Bank2 When AXI write access to OCRAM bank2 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - AXI strobe error does not happen on OCRAM bank2. 1b - AXI strobe error happens on OCRAM bank2.
9	AXI Strobe Error On OCRAM Bank1

Table continues on the next page...

Table continued from the previous page...

Field	Function
STRB_ERR1	When AXI write access to OCRAM bank1 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - AXI strobe error does not happen on OCRAM bank1. 1b - AXI strobe error happens on OCRAM bank1.
8 STRB_ERR0	AXI Strobe Error On OCRAM Bank0 When AXI write access to OCRAM bank0 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - AXI strobe error does not happen on OCRAM bank0. 1b - AXI strobe error happens on OCRAM bank0.
7 MULTI_ERR3	Multiple Bits Error On OCRAM Bank3 When detect multiple bits error on read data from OCRAM bank3, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - Multiple bits error does not happen on OCRAM bank3. 1b - Multiple bits error happens on OCRAM bank3.
6 MULTI_ERR2	Multiple Bits Error On OCRAM Bank2 When detect multiple bits error on read data from OCRAM bank2, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - Multiple bits error does not happen on OCRAM bank2. 1b - Multiple bits error happens on OCRAM bank2.
5 MULTI_ERR1	Multiple Bits Error On OCRAM Bank1 When detect multiple bits error on read data from OCRAM bank1, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - Multiple bits error does not happen on OCRAM bank1. 1b - Multiple bits error happens on OCRAM bank1.
4 MULTI_ERR0	Multiple Bits Error On OCRAM Bank0 When detect multiple bits error on read data from OCRAM bank0, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - Multiple bits error does not happen on OCRAM bank0. 1b - Multiple bits error happens on OCRAM bank0.
3 SINGLE_ERR3	Single Bit Error On OCRAM Bank3 When detect single bit error on read data from OCRAM bank3, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - Single bit error does not happen on OCRAM bank3. 1b - Single bit error happens on OCRAM bank3.

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 SINGLE_ERR2	Single Bit Error On OCRAM Bank2 When detect single bit error on read data from OCRAM bank2, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - Single bit error does not happen on OCRAM bank2. 1b - Single bit error happens on OCRAM bank2.
1 SINGLE_ERR1	Single Bit Error On OCRAM Bank1 When detect single bit error on read data from OCRAM bank1, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - Single bit error does not happen on OCRAM bank1. 1b - Single bit error happens on OCRAM bank1.
0 SINGLE_ERR0	Single Bit Error On OCRAM Bank0 When detect single bit error on read data from OCRAM bank0, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0b - Single bit error does not happen on OCRAM bank0. 1b - Single bit error happens on OCRAM bank0.

41.7.1.3 Error Interrupt Status Enable Register (ERR_STAT_EN)

Offset

Register	Offset
ERR_STAT_EN	4h

Function

Setting the bits in this register to 1 enables the corresponding Error Interrupt Status to be set by the specified event.

41.7.1.4 Error Interrupt Enable Register (ERR_SIG_EN)

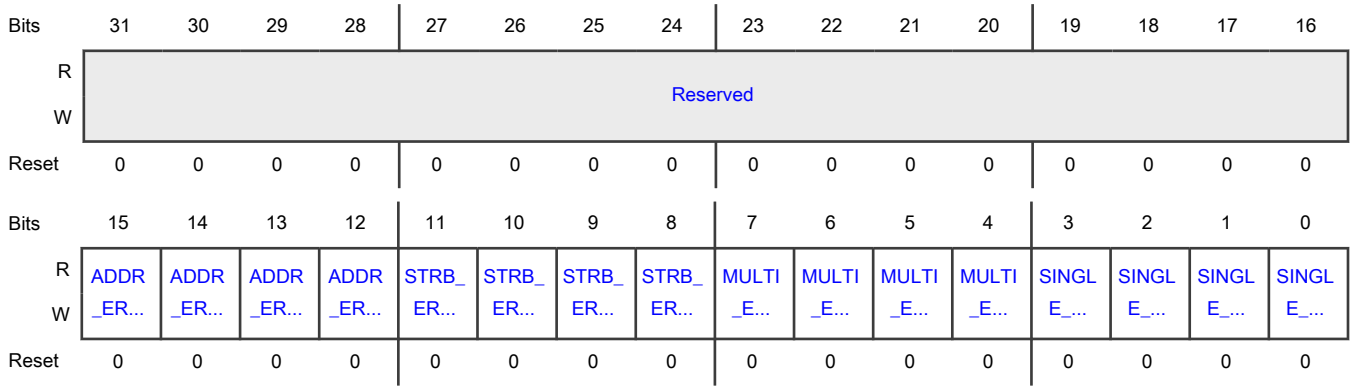
Offset

Register	Offset
ERR_SIG_EN	8h

Function

This register is used to select which interrupt status is indicated to the Host System as the interrupt. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

Diagram



Fields

Field	Function
31-16 —	Reserved

41.7.1.5 Error Injection On LOW 32 bits Of OCRAM Banka Write Data (ERR_DATA_INJ_LOW0 - ERR_DATA_INJ_LOW3)

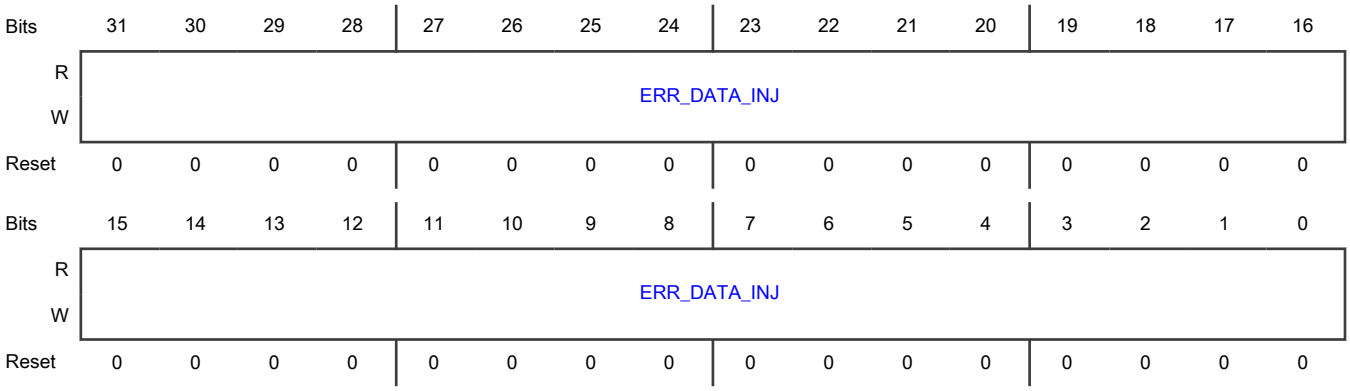
Offset

Register	Offset
ERR_DATA_INJ_LOW0	Ch
ERR_DATA_INJ_LOW1	18h
ERR_DATA_INJ_LOW2	24h
ERR_DATA_INJ_LOW3	30h

Function

LOW 32 bits of OCRAM bank0 write data will be reversed if corresponding bits in this register are set.

Diagram



Fields

Field	Function
31-0 ERR_DATA_INJ	Error Injection On LOW 32 bits Of OCRAM Bank0 Write Data LOW 32 bits of OCRAM bank0 write data will be reversed if corresponding bits in this register are set. For example: • If it is set to 0x00000001, then bit 0 of LOW 32bits of OCRAM bank0 write data will be reversed. • If it is set to 0x00000003, then bit 0 and bit 1 of LOW 32bits of OCRAM bank0 write data will be reversed. • if it is set to 0xFFFFFFFF, all bits of LOW 32bits of OCRAM bank0 write data will be reversed.

41.7.1.6 Error Injection On HIGH 32 bits Of OCRAM Banka Write Data (ERR_DATA_INJ_HIGH0 - ERR_DATA_INJ_HIGH3)

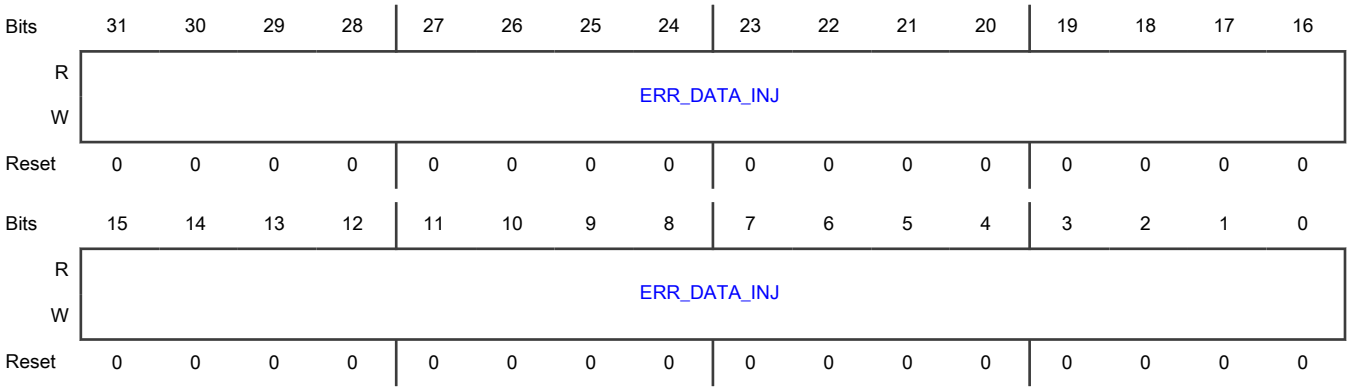
Offset

Register	Offset
ERR_DATA_INJ_HIGH0	10h
ERR_DATA_INJ_HIGH1	1Ch
ERR_DATA_INJ_HIGH2	28h
ERR_DATA_INJ_HIGH3	34h

Function

HIGH 32 bits of OCRAM bank0 write data will be reversed if corresponding bits in this register are set.

Diagram



Fields

Field	Function
31-0 ERR_DATA_INJ	Error Injection On HIGH 32 bits Of OCRAM Bank0 Write Data HIGH 32 bits of OCRAM bank0 write data will be reversed if corresponding bits in this register are set. For example: • If it is set to 0x00000001, then bit 0 of HIGH 32bits of OCRAM bank0 write data will be reversed. • If it is set to 0x00000003, then bit 0 and bit 1 of HIGH 32bits of OCRAM bank0 write data will be reversed. • if it is set to 0xFFFFFFFF, all bits of HIGH 32bits of OCRAM bank0 write data will be reversed.

41.7.1.7 Error Injection On 8 bits ECC code Of OCRAM Banka Write Data (ERR_ECC_INJ0 - ERR_ECC_INJ3)

Offset

Register	Offset
ERR_ECC_INJ0	14h
ERR_ECC_INJ1	20h
ERR_ECC_INJ2	2Ch
ERR_ECC_INJ3	38h

Function

8 bits ECC code of OCRAM bank0 write data will be reversed if corresponding bits in this register are set.

42.2 Overview

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

42.2.1 Block diagram

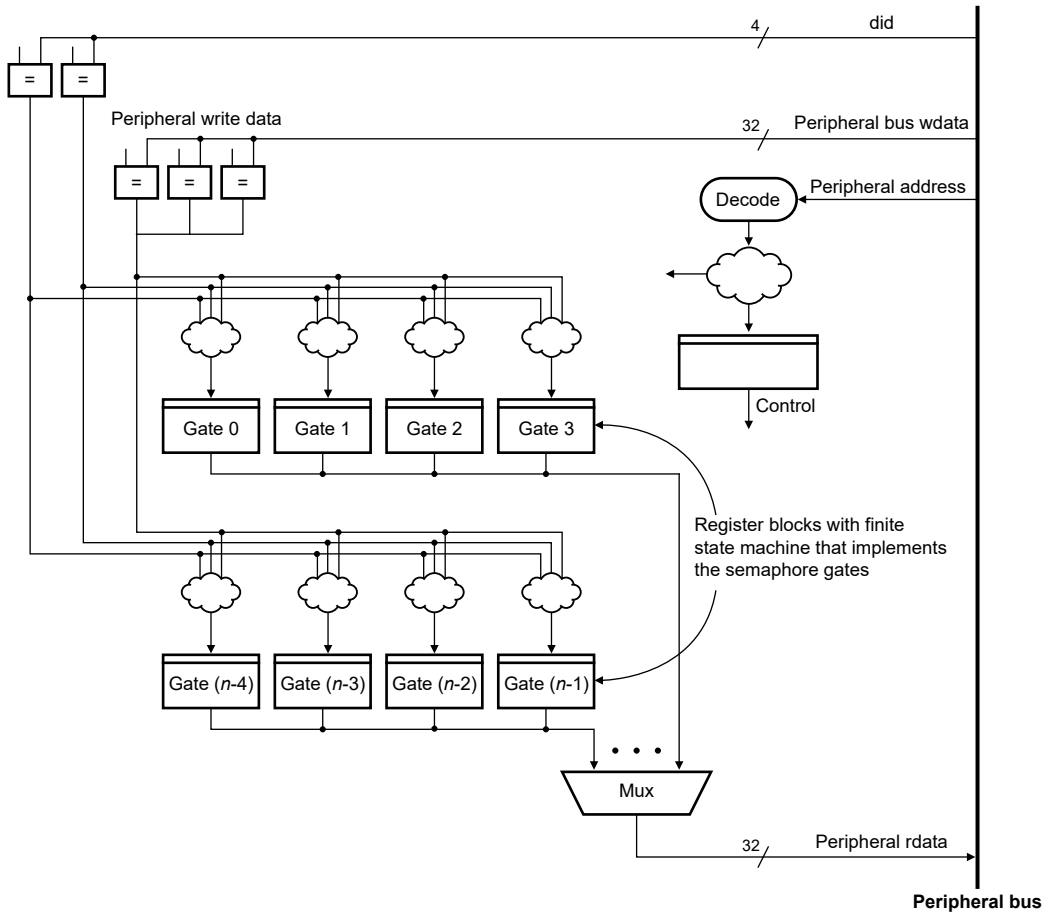

Figure 284. SEMA42 block diagram

42.2.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 64 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains.
- Each hardware gate appears as a 16-state, 4-bit state machine.
- Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability.
- Memory-mapped slave peripheral that offers programming-model accesses.

42.3 Functional description

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 aborts the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit reset state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

42.3.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: domain*X* enters a section of code, where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

42.3.2 64 Hardware-enforced gates

Gates appear as a 64-entry byte-size array with read and write accesses.

Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.

After the gate locks, the locking domain unlocks the gate by writing zeroes.

- 16-state implementation

  If gate = 0h, then state = unlocked

  if gate = 1h, then state = locked by domain (master) 0

  if gate = 2h, then state = locked by domain (master) 1

  …

  if gate = Fh, then state = locked by domain (master) 14

SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.

After a gate locks, the locking domain must unlock the gate by writing zeroes.

42.3.3 State machine of the GATE*n* registers

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

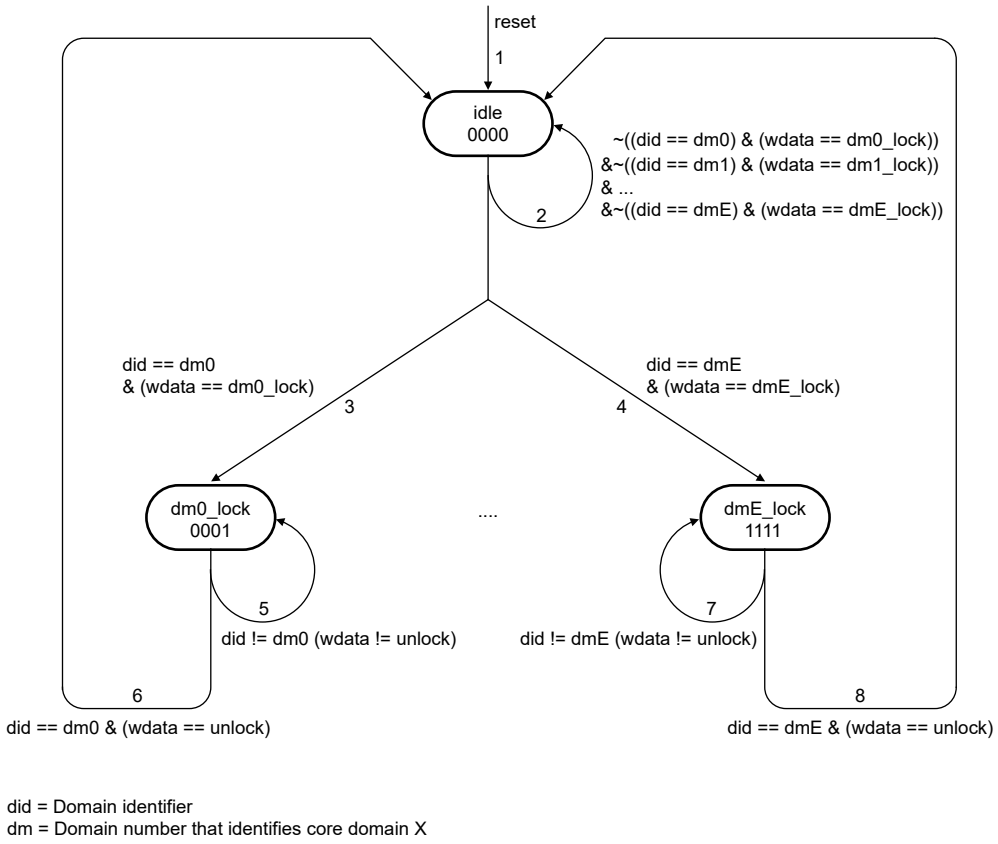

Figure 285. GATE*n* state machine

In the figure above, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 297. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.

Table continues on the next page...

Table 297. GATE*n* state transitions (continued)

Current state	Next state	Transition	Description
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

42.3.4 Clocking

This module has no clocking considerations.

42.3.5 Interrupts

This module has no interrupts.

42.4 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

42.4.1 SEMA42 register descriptions

42.4.1.1 SEMA42 memory map

SEMA1 base address: 4426_0000h

SEMA2 base address: 4245_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h - 3Fh	Gate (GATE0 - GATE63) [1]	8	RW	00h
42h	Reset Gate Read (RSTGT_R)	16	R	0000h
42h	Reset Gate Write (RSTGT_W)	16	W	See section

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

42.4.1.2 Gate (GATE0 - GATE63)

Offset

For n = 0 to 63:

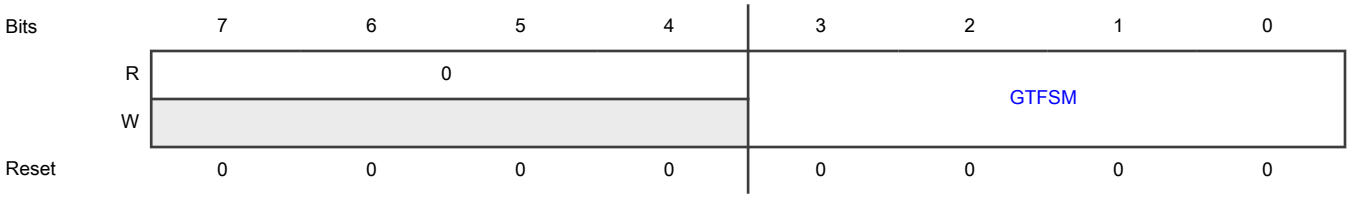
Register	Offset
GATEn	0h + (n + 3 - 2 × (n mod 4))

Function

Implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain masters can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

Diagram



Fields

Field	Function
7-4 —	Reserved
3-0 GTFSM	Gate Finite State Machine Indicates the state of the gate for the last domain that locked the gate. This can be useful during system debug. The hardware gate has a 16-state implementation, defined as: 0000b - The gate is unlocked (free). 0001b - Domain 0 locked the gate. 0010b - Domain 1 locked the gate. 0011b - Domain 2 locked the gate. 0100b - Domain 3 locked the gate. 0101b - Domain 4 locked the gate. 0110b - Domain 5 locked the gate.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0111b - Domain 6 locked the gate. 1000b - Domain 7 locked the gate. 1001b - Domain 8 locked the gate. 1010b - Domain 9 locked the gate. 1011b - Domain 10 locked the gate. 1100b - Domain 11 locked the gate. 1101b - Domain 12 locked the gate. 1110b - Domain 13 locked the gate. 1111b - Domain 14 locked the gate.

42.4.1.3 Reset Gate Read (RSTGT_R)

Offset

Register	Offset
RSTGT_R	42h

Function

Describes the specific hardware gate to be reset and records the logic number of domain. Reset Gate Write (RSTGT_W) also describe the same register showing the fields when you write it.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		RSTGSM		RSTGMS				RSTGTN							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-14 —	Reserved
13-12 RSTGSM	Reset Gate Finite State Machine

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the encoded state machine value when you read the register. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00b - Idle, waiting for the first data pattern write. 01b - Waiting for the second data pattern write 10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11b - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset Gate Domain Records the logical number of the domain performing the gate reset function. To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

42.4.1.4 Reset Gate Write (RSTGT_W)

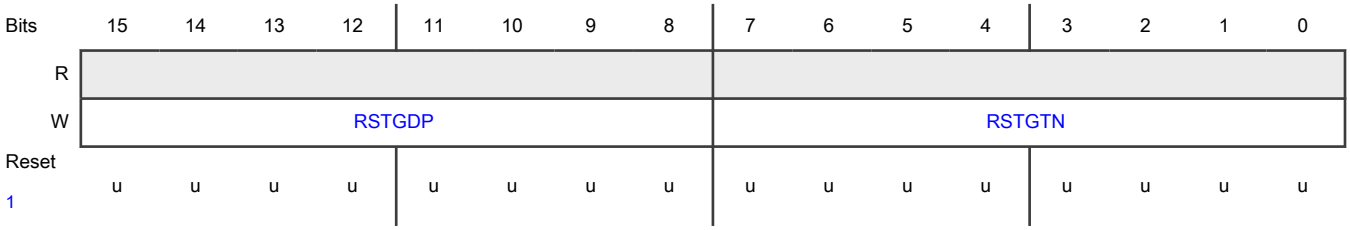
Offset

Register	Offset
RSTGT_W	42h

Function

Specifies the hardware gate to reset when data patterns are specified.

Diagram



1. Reset value is not applicable for writes.

Fields

Field	Function
15-8 RSTGDP	Reset Gate Data Pattern You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

42.5 External signals

This module has no external signals.

42.6 Initialization

This module does not require initialization.

MRC_W5	SEMC	16
MRC_W6	NETC	16

NOTE

DACFG0 register is for non-existent master and should be ignored.

43.2 CM7 PID generation

CM7_MCM's PID register is used to generate the input PID to the TRDC for CM7 accesses. TRDC only uses 6-bits of the PID.

43.3 Overview

TRDC provides an integrated and scalable architectural framework for access control, system memory protection, and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus masters, memory regions, and slave peripherals to processing domains to support enforcement of robust operational environments.

- First, each bus mastering resource is assigned to a domain identifier (domainID, DID). Typically, each processor is assigned to a unique domainID and all remaining non-processor bus masters assigned to a different domainID.

- Next, the access control policies for the individual domains are programmed into any number of registers implemented in the slave memory block and region checkers.
- Finally, all accesses throughout the device are monitored concurrently to determine the validity of each access. If a reference from a given domain has sufficient access rights, it is allowed to continue, else the access is aborted and error information captured.

The access control scheme that TRDC defines supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure, nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism with different access control policies based on read, write, and execute references, where:

SecurePriv > SecureUser > NonsecurePriv > NonsecureUser

Combined with the secure/nonsecure and privileged/user attributes, a domainID is associated with every system bus transaction and forms the hardware basis for the implementation of TRDC's access control mechanisms.

43.3.1 Block diagram

As previously noted, the TRDC implementation is distributed across multiple submodules instantiated throughout the device. The TRDC submodules include:

- TRDC_MGR
  - The Manager (MGR) submodule coordinates all programming model reads and writes.
- TRDC_DAC
  - The Domain Assignment Controller (DAC) submodule handles resource assignments and generation of the domain identifiers.
- TRDC_MBC
  - The Memory Block Checker (MBC) submodule implements access controls for on-chip internal memories and slave peripherals based on a fixed-sized block format.
- TRDC_MRC
  - The Memory Region Checker (MRC) submodule implements the access controls for external off-chip memories and peripherals based on the pre-programmed region descriptor registers.

See Figure 286 for a simplified TRDC block diagram focusing on topology and connections.

NOTE

TRDC typically consists of various submodules like DAC, MGR, MBC, and MRC. However, all the submodules as shown in the block diagram below may not be present for this configuration. For chip-specific implementation details of this module's instances, see the chip-specific information.

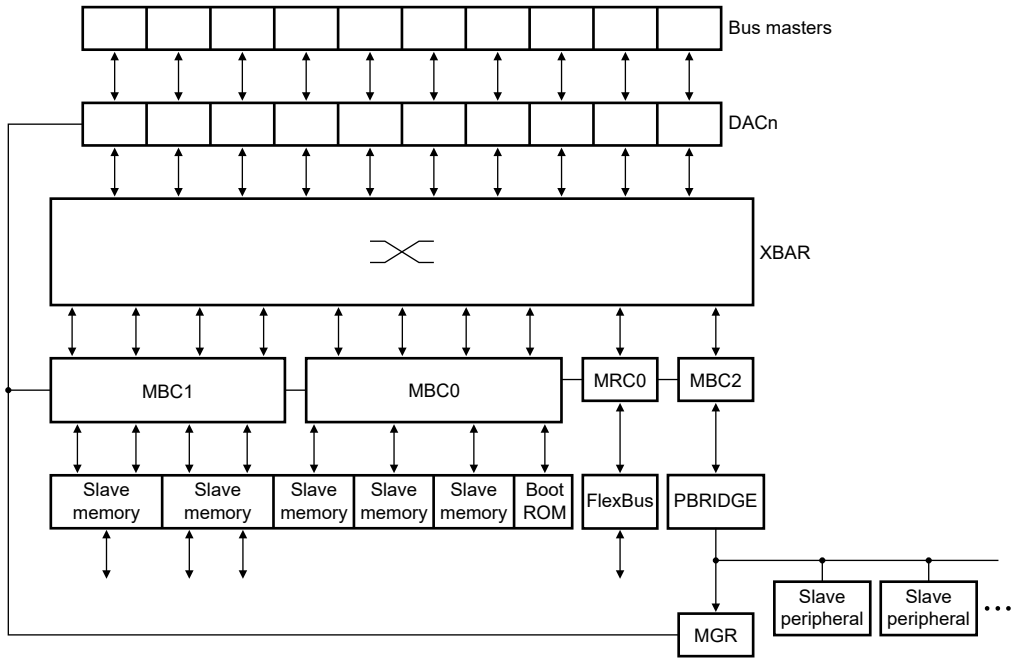

Figure 286. Block diagram

43.3.2 Features

- Ability to assign chip resources to processing "domains":
  - Processor cores, non-core bus masters, slave memories, and slave peripherals
  - Each processing domain is assigned a unique domain identifier (domainID, DID)
  - DomainID is an attribute associated with every system bus transaction
  - Used in conjunction with secure/nonsecure, privileged/user attributes
- Defines access rights to slave targets in MBCs for on-chip memories and peripherals and in MRCs for external memories and peripherals
- Built upon a 4-level hierarchical access control model:
  - SecurePriv > SecureUser > NonsecurePriv > NonsecureUser
  - Defined by multiple sets of user-programmable R/W/X (Read, Write, Execute) flags per access state
- Distributes programming model and hardware implementation across multiple submodules:
  - Supports a broad, highly-configurable architecture definition
  - Supports efficient mechanisms for memory space context switch state changes using nonsecure enables (NSE) for memory blocks and regions

43.4 Functional description

This section provides more details on the operation and implementation of the TRDC submodules.

43.4.1 Modes of operation

TRDC does not support any special modes of operation. As a memory-mapped device located in the core platform's clock domain, it responds strictly on the basis of memory addresses of the connected system buses. TRDC evaluates domain assignment

and access control functions on a reference-by-reference basis using the addresses and attributes connected to the system bus port(s).

43.4.2 Manager (TRDC_MGR)

The MGR submodule is responsible for coordinating TRDC's programming model reads and writes.

The complete programming model is large. Additionally, the programming model is distributed across the various submodule instances (DAC, MBC, MRC).

MGR provides:

- The required hardware management for all programming model accesses.
- Generating and distributing the appropriate address decodes and write data to the DAC, MBC, and MRC submodule instances.
- Collecting and combining all the register read data buses and responses.

MGR implements:

- The Control Register
- All the read-only hardware configuration registers (HWCFG[0-1], DACFGn, MBCm_MEMs_GLBCFG, MRC_GLBCFG)
- The program-visible versions of the domain error capture registers.

To support the domain error reporting functionality, MGR collects the individual captured error indicator output signals from all the submodule instances and remaps them so that they are organized into an instance bitmap by domain that the DERRLOCn register array specifies.

43.4.3 Domain Assignment Controller (TRDC_DAC)

The DAC submodule is responsible for the generation of the domainID on every memory transaction for every bus master in the device. The resulting domainID, and {nonsecure, privileged} signals are generated and then treated as address attributes and associated with each transaction as it moves through the system.

DAC modules that drive the domainIDs (DIDs) for processor cores include an option of processor-identifier (PID) matching to select between DIDs. You can accomplish this by first enabling PID checking by writing TRDC_MDA_Wm_n[PE] = [2,3]. With PID matching enabled, a domain hit is determined by matching TRDC_MDA_Wm_n[PID] with the PID input or PID in the TRDC_PID register. The PIDM field can be used to match specific groups of PIDs.

As a simple example, assume a system with two domainIDs.

- domainID 0 is for critical tasks.
- domainID 1 is for non-critical tasks.
- Two domainIDs require two MDA_Wm_n registers, MDA_W0 and MDA_W1.

Further assume the processor’s task identifier defines whether a task is critical or non-critical as defined by system software.

- PIDs [0-15] are assigned to critical tasks.
- PIDs != [0-15] are assigned to noncritical tasks.

During startup, software initializes the MDA_W[0-1] registers. MDA_W0 defines DID = 1 for PIDs [0-15] and MDA_W1 defines DID = 2 for PIDs != [0-15].

1. MDA_W0 = 0x8000_0F81
    - VLD = 1
    - PID = 0x0
    - PIDM = 0xF
    - PE = 2

- DIDS = 0
- DID = 1

2. MDA_W1 = 0x8000_0FC2
   - VLD = 1
   - PID = 0x0
   - PIDM = 0xF
   - PE = 3
   - DIDS = 0
   - DID = 2

As the processor executes, it loads the appropriate task ID into its PID register as the task is started. The processor's PID register value is input to the corresponding DAC module and used by the MDA_Wr_m comparison logic. The system then dynamically generates two domainIDs and the downstream TRDC access check logic can distinguish and enforce different access control rights based on the different domainIDs.

A special mode is provided for driving the DID of non-processor masters. This is enabled with the DID bypass (DIDB) bit. The DAC has a DID input that can be driven by a master and used directly as the DID output. This allows variability in the DID as dictated by the master and is intended to be used by DMA masters that masquerade as, (that is, drive the DID of) the master that programmed it.

43.4.4 Access evaluation

Fundamental to the TRDC's operation is the actual access violation check performed by the memory block checker (MBC) and memory region (MRC).

Previous descriptions have detailed the domain assignment mechanisms and the tracking of the domain identifier as an address attribute through the system bus switching fabric(s). As transactions reach the slave memory and peripheral controllers, the address is used to select the appropriate memory region descriptor or block configuration register. Once the appropriate register has been selected, the next function is the actual access evaluation.

For this step, the 3-bit M{B,R}ACSEL field of the selected RGD or BLK_CFG register selects the appropriate GLBAC (global access control policy). The GLBAC register defines the access rights for the domain based on the 4-level model combined with the transaction's access attributes (read = 0/write = 1, secure = 0/nonsecure = 1, execute =1/non-execute=0, user = 0/privileged = 1).

The 4-level model is defined by the concatenation of two address attributes: secure/nonsecure and user/privileged attributes. These two attribute signals (nonsecure, privileged) and the resulting access levels are defined as:

```
if {nonsecure, privileged} == 0b00, then level = SecureUser
if {nonsecure, privileged} == 0b01, then level = SecurePriv(ileged)
if {nonsecure, privileged} == 0b10, then level = NonsecureUser
if {nonsecure, privileged} == 0b11, then level = NonsecurePriv(ileged)
```

The resulting hierarchical access control model specifies:

```
SecurePriv , SecureUser , NonsecurePriv , NonsecureUser
```

After the access evaluation is complete and the access error signal generated, the transaction is allowed to continue if it has sufficient access rights, else the access is aborted with the address and attribute information captured in the appropriate error registers.

43.4.5 Memory Block Checker (TRDC_MBC)

The TRDC's Memory Block Checker provides domain-based access control for all system bus references targeted to on-chip internal memories and slave peripherals. Using programmed block configuration registers which define the access rights per domain and block, the MBC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer.

Memory references that have sufficient access rights are allowed to complete, while references that have insufficient rights are terminated with an access error response.

The TRDC architectural framework supports up to 8 MBC instances where each MBC can support up to 4 sub-regions (MEM[s]). Note monitoring of an AXI memory counts as 2 sub-regions since there are independent read and write channels per AXI memory. Conversely, an AHB connection counts as a single subregion.

Each sub-memory is divided up in equal sized consecutive blocks. Sub-memory 0 (MEM0) can support up to 512 blocks while sub-memory 1-3 (MEM1-MEM3) can each support up to 64 blocks. The number of blocks and size of the block is defined in MBCm_MEMs_GLBCFG[NBLKS,SIZE_LOG2] register fields, where m is the MBC instance number, and s is the sub-memory number. For example, Sub-memory 0 (MEM0) may have 16 consecutive blocks, each of size 64 KB, and corresponding MBCm_DOMd_BLK_CFG_W register to a block will control access to that block.

Each MBCm_DOMd_BLK_CFG_W contains eight access control structures. Each structure is comprised of a 1-bit NSE (NonSecure Enable) plus a 3-bit MBACSEL (Memory Block Access Control Select). The NSE controls secure/nonsecure access to the corresponding block, while the MBACSEL field selects a MBCm_MEMN_GLBACr register which controls the read/write/execute access to the corresponding block. There are 8 programmable MBCm_MEMn_GLBACr registers per block checker, each containing contain read-write-execute control flags for each of the four operating modes:

```
SPR, SPW, SPX - Secure    Privileged {Read, Write, Execute}
SUR, SUW, SUX - Secure    User       {Read, Write, Execute}
NPR, NPW, NPX - Nonsecure Privileged {Read, Write, Execute}
NUR, NUW, NUX - Nonsecure User       {Read, Write, Execute}
```

GLBAC1-7 also have a lock bit MBCm_MEMn_GLBACr[LK]. When LK=1, the GLBACr register is read-only until the next reset. Furthermore, if MBCm_DOMd_BLK_CFG_W[MBACSEL] selects a GLBAC that is locked, the 3-bit MBCACSEL field is also locked until the next reset. GLBAC0 cannot be locked.

The MBC also has MBCm_DOMd_MEMs_BLK_NSE_W registers. These registers are a bit map of the block NSE bits. Each word supports up to 32 blocks.

```
MBCm_DOMd_MEM0_BLK_NSE_W[0-15] has a maximum of 16 words to support 512 blocks
MBCm_DOMd_MEM[1-3]_BLK_NSE_W[0-1] has a maximum of 2 words to support 64 blocks.
```

The block NSE bits can be programmed by writing these registers or by writing the MBCm_MEMN_BLK_{INDEX, SET, CLR, CLR_ALL} registers.

The MBCm_MEMn_NSE_BLK_{INDEX, SET, CLR, CLR_ALL} registers provide a mechanism to efficiently and quickly manipulate the NSE bitmap with bitmasks to set or clear individual blocks within the bitmap and a single operation to perform a clear all across multiple DIDs. The BLK_INDEX register provides the control definition for the BLK_SET and BLK_CLR operations.

43.4.5.1 Memory block hit determination

MBCm_MEMs_GLBCFG[NBLK, SIZE_LOG2] is used to determine which bits of the address correspond to block number.

```
block_n_hit = (addr[MSB:LSB] == n)
where LSB=SIZE_LOG2
MSB=f{NBLKS,LSB}
```

Note that the block hit determination is based only on the address comparison of the first byte being accessed; that is, the MBC does not check the size of the access to make sure it entirely fits within the region.

43.4.5.2 Memory block access evaluation

For a block n hit, the MBC logic evaluates the access rights defined by the MBCm_DOMd_BLK_CFG_Ww registers. The domainID attribute and block number hit selects the appropriate MBCm_DOMd_BLK_CFG_Ww register to use in the access evaluation. The {R,W,X}, nonsecure and privilege attributes of the access are compared with the MBC global access control policy defined in MBCm_DOMd_BLK_CFG_W[MBACSEL, NSE] fields.

While TRDC_CR[GVLDB] = 1, and for each sub-memory being monitored, the MBC performs a reduction-AND of all the individual error terms from each access evaluation.

Unlike the MRC access evaluation and termination, the MBC access evaluation terminates the access with a bus error and reports an access error for only one condition - when the access doesn't have sufficient access rights. By nature, the block checker can only hit in ONE block. And by implementation, there are no "miss" accesses. Accesses outside of the range covered by the MBC are not sent to the MBC. There also aren't any individual block valid bits. When TRDC_CR[GVLDB] = 1, checking on all blocks is always enabled.

43.4.6 Memory Region Checker (TRDC_MRC)

The TRDC's Memory Region Controller provides domain-based, hardware access control for all system bus references targeted at non-peripheral memory spaces. Using pre-programmed *region descriptors* which define memory spaces and their associated access rights per domain identifier, the MRC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

The TRDC architectural framework supports up to 16 MRC instances, where each MRC instance can support [1-16] region descriptors, concurrently monitoring up to 8 slave memory ports. Note, monitoring an AXI protocol port counts as two ports since there are independent read address and write address channels. Conversely, an AHB connection counts as a single port.

A partial, simplified one-dimensional block diagram of an instance of the MRC module is shown in Figure 287. In this figure, a single slave bus port is shown. When the remaining slave ports are considered, the MRC hardware's two-dimensional connection matrix, broadcasting each system bus slave port access across the implemented memory region descriptors, is the resulting structure with the basic access evaluation macro shown as the replicated submodule block. In Figure 287, the system bus fabric slave port is shown on the left, the memory region descriptor registers are in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and, based on the domainID associated with the reference, access violations.

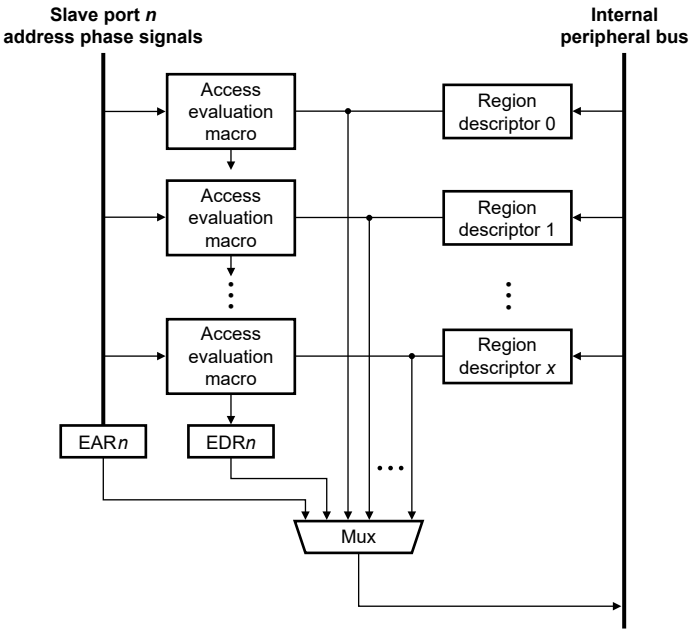

Figure 287. MRC access evaluation macro hardware structure

For each access, the MRC hardware performs a two-step evaluation process. First, the access is compared to all memory region descriptors to determine hit/miss status, and then, using the domainID associated with the reference plus the address attributes {write, nonsecure, privileged}, the access rights are examined using the method detailed in Access evaluation.

43.4.6.1 Memory region descriptor hit determination

To determine if the current reference hits in a given region, two magnitude comparators are used in conjunction with the region's start and end addresses. The boolean equation for this portion of the hit determination is defined as:

```
region_hit_n =
   ((addr >= start_addr) & (addr <= end_addr)) & valid
```

where `addr` is the current system reference address, `start_addr` and `end_addr` are the start and end addresses, and `valid` is the valid bit, all from memory region descriptor n.

Note there are *no hardware checks* to verify that `end_addr ≥ start_addr`, and it is software's responsibility to properly load appropriate values into these fields of the region descriptor.

Also, the region hit determination is based only on an address comparison of the first byte being accessed; that is, the MRC does *not* check the size of the access to make sure it entirely fits within the region.

43.4.6.2 Memory region access evaluation

For each region descriptor hit, the MRC logic evaluates the access rights defined by the MRCm_DOMd_RGDr_Ww registers. Specifically, the domainID attribute selects the appropriate MRCm_DOMd_RGDr_Ww register to use in the access evaluation. The {R,W,X}, nonsecure and privilege attributes of the access are compared with the MRC global access control policy defined in MRCm_DOMd_RGDr_W0[MRACSEL] and MRCm_DOMd_RGDr_W1[NSE] fields. See Access evaluation for additional details on this function.

While CR[GVLDR] = 1, and for each bus slave port being monitored, the MRC performs a **reduction-AND** of all the individual *(no_hit | error)* terms from each access evaluation macro. Recall as specified in Memory region descriptor hit determination, an *invalid* MRC_DOMd_RGDr_Ww (MRCm_DOMd_RGDr_W1[VLD] = 0) forces the region_hit_n evaluation to be negated.

This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. If the access does not hit in *any* region descriptor, an access error is reported.
2. If the access hits in a single region descriptor and that region signals a domain violation, then an access error is reported.
3. If the access hits in multiple (overlapping) regions and one region signals a violation, then an access error is reported.

The third condition reflects that priority is given to access denying over access allowing for overlapping regions.

Unimplemented domain IDs (DIDs) do not have any associated region descriptors and therefore have no access rights.

43.4.7 Interrupts

This module outputs an interrupt signal which can be connected to the system's interrupt controller. Please check chip-specific interrupt assignment for details. Interrupt is asserted on detection of access violation by any checker, and it remains asserted until DERRLOCn registers are cleared. This interrupt is in addition to interrupt generated by master after receiving bus error due to access violation by memory block checker or memory region checker. So, system may receive interrupt through different channels but from the same access violation at checker.

43.5 External signals

The TRDC module does not directly support any external interfaces.

The *internal* interfaces include a standard 32-bit slave bus for all programming model accesses, connections to the address phase signals associated with AHB and/or AXI system buses and connections to the slave peripheral buses as shown in TRDC block diagram.

43.6 Initialization

Out of reset, CR[GVLDR, GVLDB, GVLDM] bits are cleared, TRDC is disabled and in deny by default mode allowing secure privileged startup code to configure the entire programming model. In deny by default mode, only the DIDs that aren't denied by

default are allowed to access memory and peripherals. The allowed DIDs are implementation defined. The initialization process typically is performed in 3 steps:

1. Read the various hardware configuration registers (HWCFG{0,1}, DACFGn, MBCm_MEMs_GLBCFG, MRC_GLBCFG) to obtain the implemented hardware capabilities for the device.
2. Using the information retrieved in Step 1 coupled with the desired domain architecture, program all the register data structures for domain assignment (MDA_Wm_n), memory block configuration (MBCm_DOMd_MEMs_BLK_CFG_Ww) and memory region descriptors (MRCm_DOMd_RGDr_Ww). There are individual valid bits included in these registers which typically would be asserted. Additionally, there are also lock mechanisms available if register settings need to be configured and marked as read-only.
3. Once the TRDC programming model is loaded, the CR is written with GVLD {R, B, M} asserted. Upon the assertion of the 3 GVLD bits, deny by default mode is exited and at that point, the TRDC is fully operational. The TRDC remains enabled until the next reset.

43.7 Application information

As described in Overview, the TRDC architecture is intended to provide a broad, highly-capable framework for access control, system memory protection and peripheral isolation. The resulting microarchitecture implementation is distributed throughout the core platform, highly configurable via hardware design parameters and software programmability.

43.7.1 Master domain assignments

The typical use case related to master domain assignments is to include one (or more) processor core(s) in a single domain, possibly coupled with other bus master devices like DMA, etc. The definition of a domain may be static, based simply on the combination of a processor and other optional bus masters. Alternatively, the processor's operation may be configured to dynamically select between a very small number of domains. In particular, the optional inclusion of PID value(s) to be used to create multiple classes of CPU with different domain values.

For example, "critical" tasks, whether safety-critical, performance-critical, etc. can be grouped together in one domain and all other tasks into a second domain. Non-processor bus masters typically have a single MDA_Wm_n configuration register associated with them. The domainID and {nonsecure, privileged} attributes are usually statically assigned, unless the module can "inherit" attributes from a processor programming it (certain modules like DMAs).

The MDA_Wm_n registers, along with the memory region descriptors and the peripheral domain access control registers all have lock features that allow the register resources to be converted into read-only resources to protect the written configuration.

43.7.2 Memory region descriptor management

There are important concepts to consider in managing the memory region descriptors.

Recall that the association between each MRCn instance and the slave memory regions it monitors is SoC-dependent. The device-specific configuration specifies the number of implemented memory region descriptors in a given instance and the specific port numbers associated with the slave memories being monitored.

43.7.3 Domain error capture management

Recall when a domain access violation is detected by either a memory region checker or a memory block checker, address and attribute information of the offending access is captured. The DERRLOCn read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_n and DERR_W1_n, the DERRLOCn registers provide the instance number details.

These registers are organized as a word array, *indexed by the faulting domain number*, with the contents of each register providing a bitmap signaling the instance number(s) associated with all submodules containing captured error information for that domain.

It is recommended that the exception handler begin by reading the HWCFG1 register to determine its domainID. Next, it uses the just-retrieved domainID to index into the DERRLOCn array. The resulting DERRLOCn value is then examined to determine the instance number of the reporting MBC and/or MRC submodule.

There may be multiple access violations, across multiple instances, pending for a given domain. It is suggested that exception handler use a "find first one" instruction (alternatively known as "count leading zeroes") to quickly and efficiently find the instance number containing access violation details. Once the instance number has been determined, the captured error address (DERR_W0_n) and attribute information (DERR_W1_n) can easily be retrieved from the domain error registers. The 2-bit DERR_W1_n[EST] field provides information signaling whether one or more errors have been detected by the submodule instance. A special write to DERR_W3_n is required to reset (and rearm) the EST error capture state machine.

This process is repeated until all errors associated with a given domainID have been processed.

A graphical representation of this 2-step retrieval of the domain error address and attributes is shown in Figure 288.

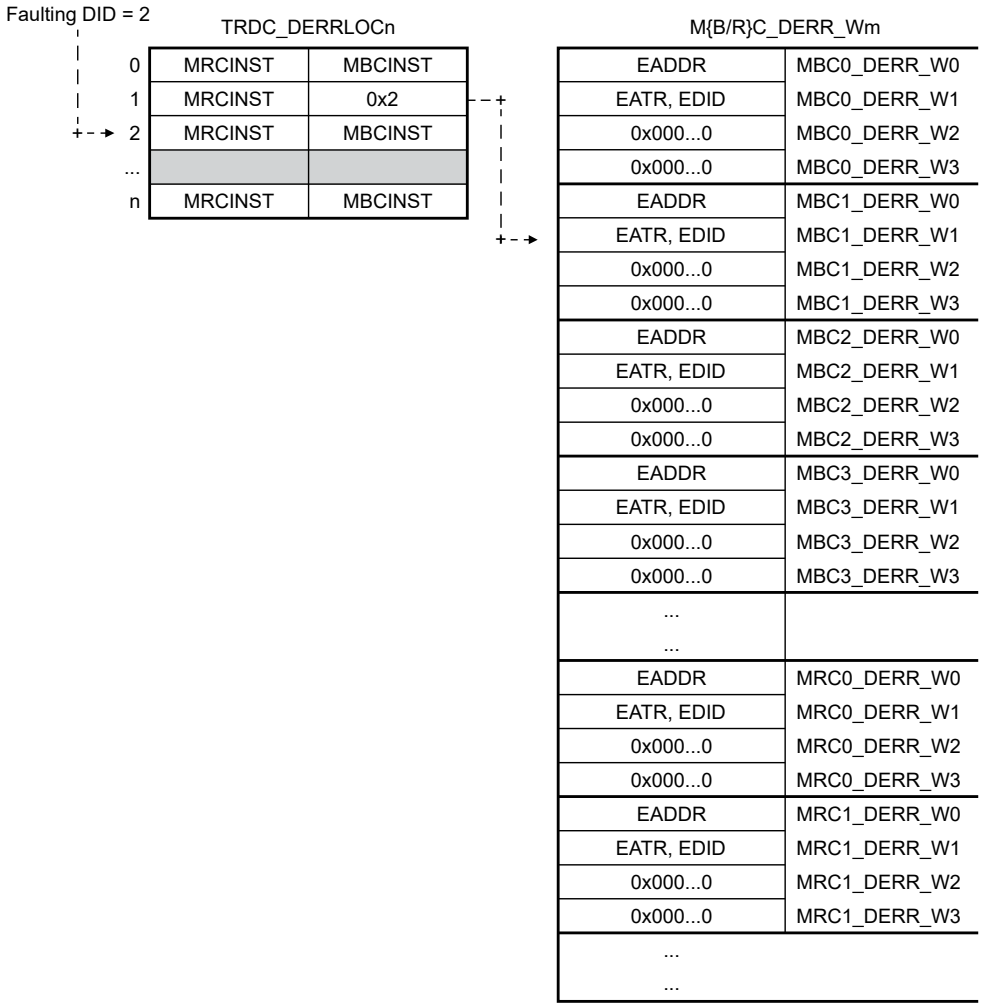

Figure 288. Two-step retrieval of domain error address and attributes

43.8 Register descriptions

The MBCm_NSE_BLK_SET, MBCm_NSE_BLK_CLR and MBCm_NSE_BLK_CLR_ALL registers exist at offset for only domain ID value 0 even when more than 1 domains exist, and address offsets for non-zero domain ID value should be considered reserved space. So, this reserved address space in MBC space does not return transfer error: 0xn14 to 0xn1C where n = (1 to NUM_DID-1) * 2 for each MBC.

If TZ-M is enabled, the TRDC programming model can only be accessed in SecurePrivileged mode. If TZ-M is disabled, it can only be accessed in Privileged mode regardless of Secure or NonSecure; that is it can't be accessed in User mode. Unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted

accesses in a different operating mode, using unsupported write data sizes, writes to read-only resources, or access to reserved spaces are terminated with an error unless noted otherwise. The TRDC programming model is partitioned into these groups of registers:

- Basic hardware control and configuration
- Domain errors: location and details
- Master domain assignments
- Memory block and region checkers

It should be noted that many of the programming model registers in TRDC are organized as 2-, 3- or 4- dimensional data structures. For the 2-dimensional structures, the generic arrays contain "m" words representing the "columns" and "n" instances of the structure representing the "rows". These may be described as `structure[n][m]`. They appear in the address space of the programming model memory map in the standard C language row-major layout, that is, the "m" words representing the "column" appear sequentially with the entire row replicated "n" times. The TRDC register structure uses the naming convention of *TRDC_<regname>_Wm_n*, where the column number "m" appears as a numeric suffix on the W (32-bit word) identifier, and the row identifier "n" appears as the final numerical suffix.

For the 4-dimensional structures, the generic arrays contain "m", "d", "s" or "r", and "w" indices corresponding to MBC/MRC instance, domain index, sub-memory or region index and word index. The naming convention for the MBC block configuration and MRC region descriptor word registers are: *MBCm_DOMd_MEMs_BLK_CFG_Ww* and *MRCm_DOMd_RGDr_Ww*

For the reset values in this section, a "*" indicates an initial value determined by the hardware configuration.

43.8.1.2 TRDC Register (TRDC_CR)

Offset

Register	Offset
TRDC_CR	0h

Function

This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	LK1	0										0			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	GVLDR	GVLDB	0						0				HRL			GVLDM
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Fields

Field	Function
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0b - The CR can be written by any secure privileged write. 1b - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MRCs are disabled. 1b - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MBCs are disabled. 1b - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC’s hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC DACs are disabled. 1b - TRDC DACs are enabled.

43.8.1.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

Offset

Register	Offset
TRDC_HWCFG0	F0h

Function

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus masters along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Field	Function
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

43.8.1.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

Offset

Register	Offset
TRDC_HWCFG1	F4h

Function

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Fields

Field	Function
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus master.

43.8.1.5 TRDC Hardware Configuration Register 2 (TRDC_HWCFG2)

Offset

Register	Offset
TRDC_HWCFG2	F8h

Function

This register contains information on the TRDC's hardware configuration. It provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus master. The HWCFG2 register is associated with bus masters [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Function
31-0 PIDPn	Process identifier present Process identifier present from bus master n, where n = [31-0]. This field provides a bitmap to signal that bus master (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus master n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus master n sources a process identifier register.

43.8.1.6 TRDC Hardware Configuration Register 3 (TRDC_HWCFG3)

Offset

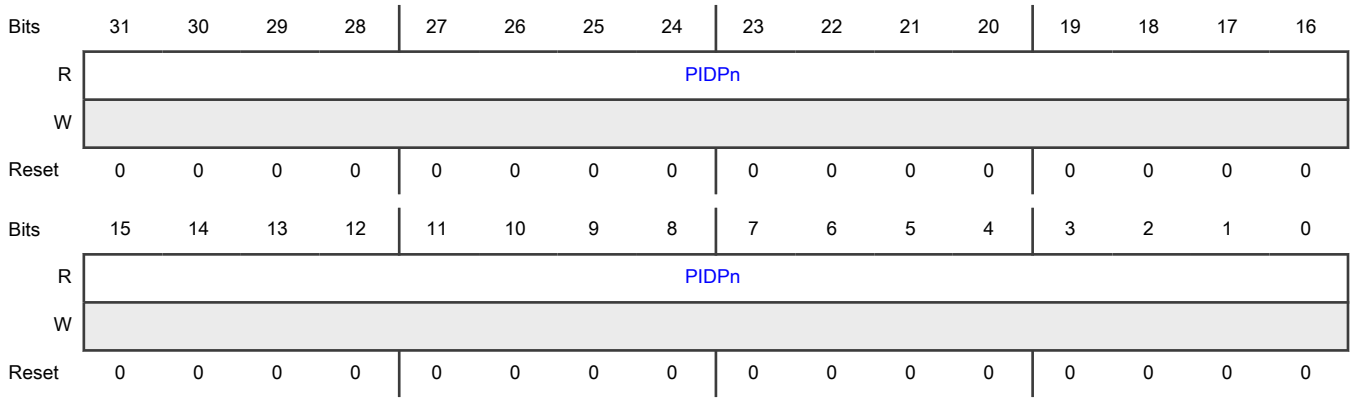
Register	Offset
TRDC_HWCFG3	FCh

Function

This register contains information on the TRDC's hardware configuration. Specifically, it provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus master. The HWCFG3 register is associated with bus masters [63-32], while the HWCFG2 register covers bus masters [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 PIDPn	Process identifier present Process identifier present from bus master n, where n = [63-32]. This field provides a bitmap to signal that bus master n (where n is defined as 32 + bit number) sources a process identifier register to the TRDC_DAC logic. Process identifier present from bus master n, where n = [31-0]. This field provides a bitmap to signal that bus master (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus master n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus master n sources a process identifier register.

43.8.1.7 Domain Assignment Configuration Register (DACFG0 - DACFG3)

Offset

Register	Offset
DACFG0	100h
DACFG1	101h
DACFG2	102h
DACFG3	103h

Function

This register defines the number of implemented domain assignment registers for bus master m, where m+1 can specify from 1 to 64 bus masters. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus master. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a master doesn't exist but it is in the same 32-bit group as DACFG for an existing master. For example, when there are only 2 DACFG0-1 registers for 2 master, and masters for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus masters have one or more domain assignment registers, while non-processor masters have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	See Register reset values.							

Register reset values

Register	Reset value
DACFG0	01h
DACFG1	03h
DACFG2–DACFG3	81h

Fields

Field	Function
7 NCM	Non-CPU Master This read-only field signals that bus master m is a non-CPU master. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus master. 0b - Bus master is a processor. 1b - Bus master is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of master domain assignment registers for bus master m This read-only field specifies the number of registers associated with the master domain assignment register for a given bus master. The value is limited to the range [0-8], where zero indicates a non-existent bus master and non-zero values indicate the number of implemented registers associated with this MDAm.

43.8.1.8 TRDC IDAU Control Register (TRDC_IDAU_CR)

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

Function

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram

2-1 —	Reserved
0 VLD	Valid When VLD =0, all address attribute from IDAU is nonSecure. When VLD=1, values in other fields of this register are valid.

43.8.1.9 TRDC FLW Control (TRDC_FLW_CTL)

Offset

Register	Offset
TRDC_FLW_CTL	1E0h

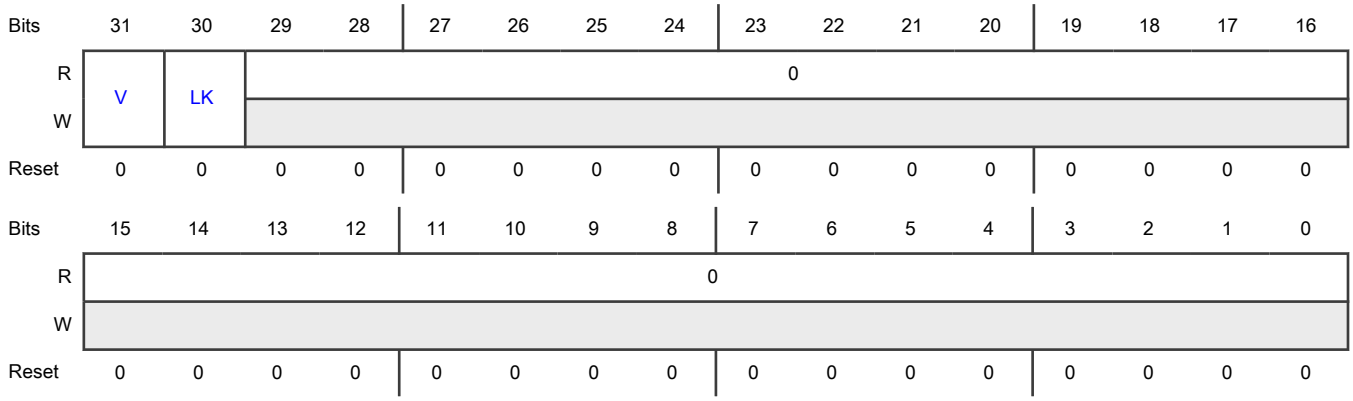
Function

This register provides control of the FLW = Flash Logical Window operation.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31 V	Valid bit 0b - FLW function is disabled. 1b - FLW function is enabled.
30 LK	Lock bit 0b - FLW registers may be modified. 1b - FLW registers are locked until the next reset.
29-0 —	Reserved

43.8.1.10 TRDC FLW Physical Base (TRDC_FLW_PBASE)

Offset

Register	Offset
TRDC_FLW_PBASE	1E4h

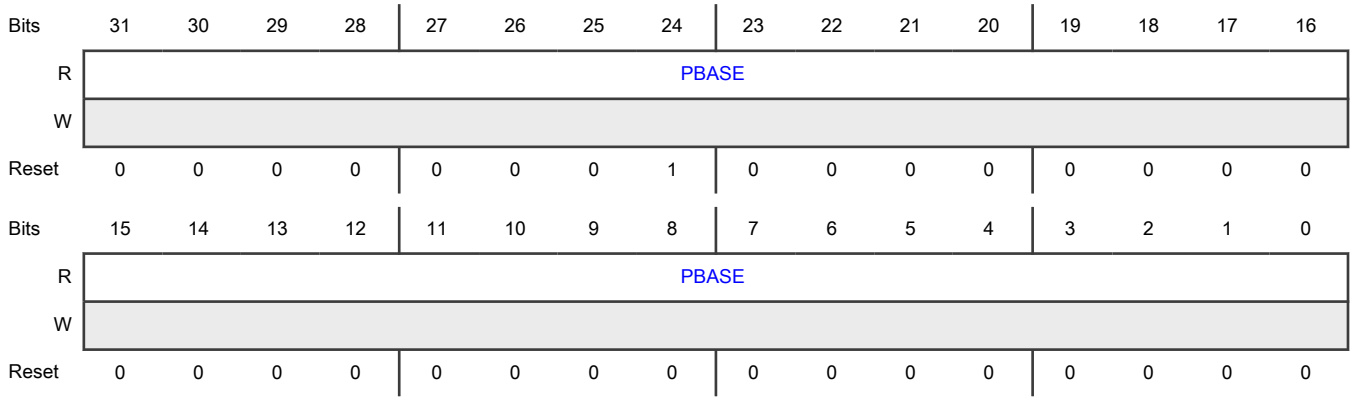
Function

This read-only register gives the physical base address of the Flash Logical Window.

This register exists for this device but has not effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 PBASE	Physical base address Physical address of the base of the FLW (mod 32KBytes).

43.8.1.11 TRDC FLW Array Base (TRDC_FLW_ABASE)

Offset

Register	Offset
TRDC_FLW_ABASE	1E8h

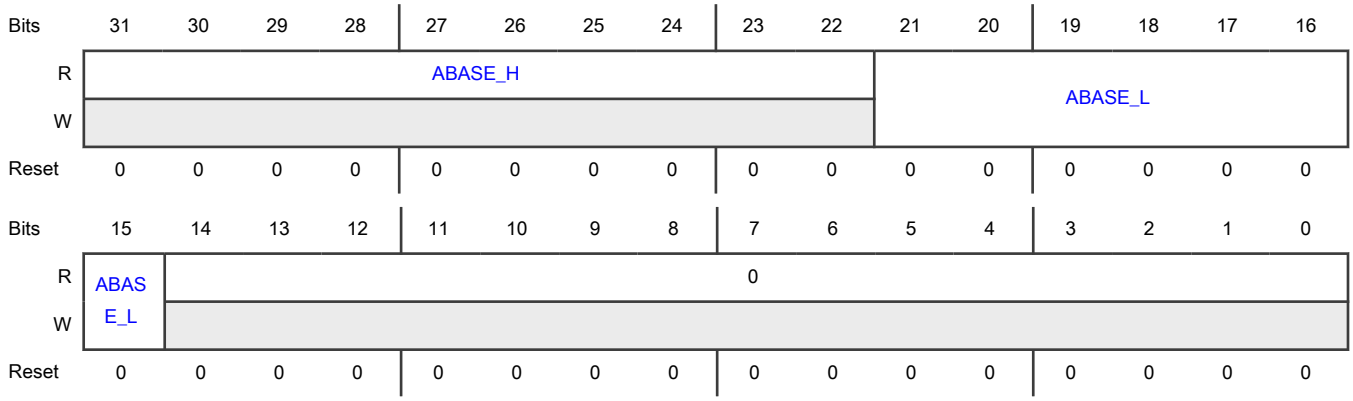
Function

This register gives the flash array base address of the Flash Logical Window.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Diagram



Fields

Field	Function
31-22 ABASE_H	Array base address high Flash array address upper bits of the base of the FLW (mod 32KBytes).
21-15 ABASE_L	Array base address low Flash array address lower bits of the base of the FLW (mod 32KBytes).
14-0 —	Reserved

43.8.1.12 TRDC FLW Block Count (TRDC_FLW_BCNT)

Offset

Register	Offset
TRDC_FLW_BCNT	1ECh

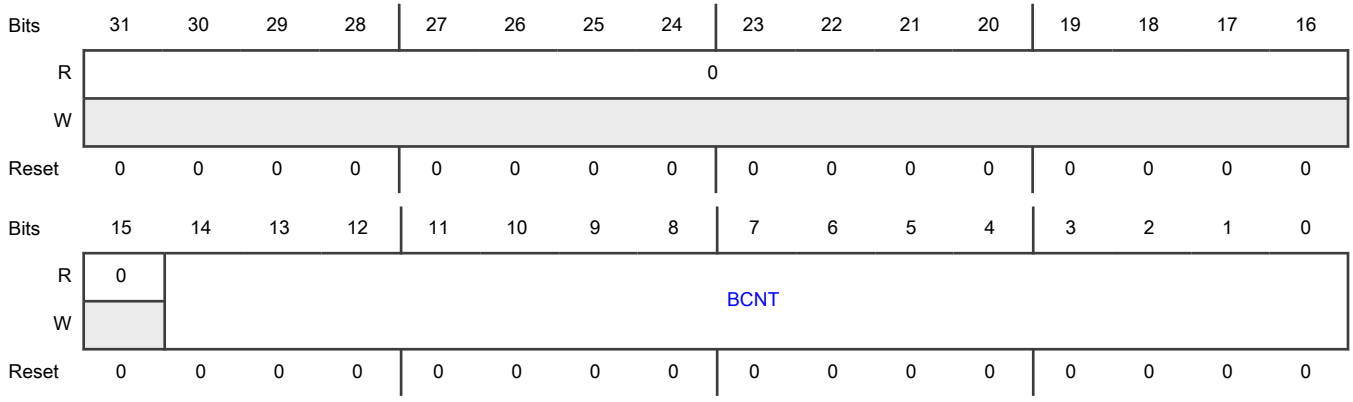
Function

This register gives the size of the Flash Logic Window in 32KByte blocks.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Diagram



Fields

Field	Function
31-15	Reserved

Table continues on the next page...

R	0												FDID			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

43.8.1.14 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Function

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Fields

Field	Function
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

43.8.1.15 MBC Domain Error Word0 Register (MBC0_DERR_W0 - MBC1_DERR_W0)

Offset

Register	Offset
MBC0_DERR_W0	400h
MBC1_DERR_W0	410h

Function

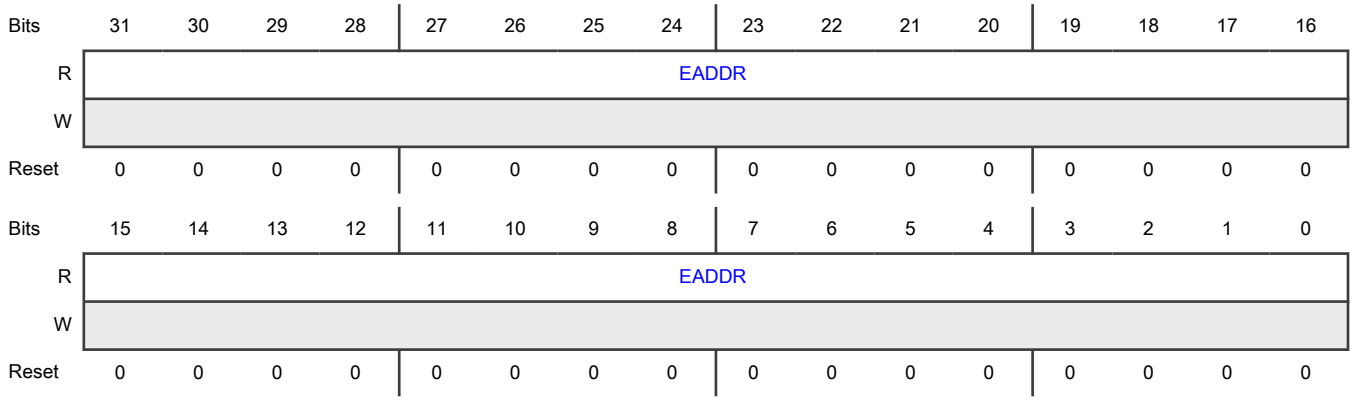
This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 EADDR	Error address This is the unaliased virtual address of the access that generated the access violation.

43.8.1.16 MBC Domain Error Word1 Register (MBC0_DERR_W1 - MBC1_DERR_W1)

Offset

Register	Offset
MBC0_DERR_W1	404h
MBC1_DERR_W1	414h

Function

This read-only register array provides the attributes of an access violation detected by Memory Block Checker (MBC). These registers are organized as a word array, which is indexed by the violating submodule instance number. Refer to register Domain Error Location(DERRLOCd), Domain Error Word0 Register(DERR_W0_i), and Domain error capture management for more information.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Fields

Field	Function
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00b - No access violation has been detected. 01b - No access violation has been detected. 10b - A single access violation has been detected. 11b - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the MBC slave that has the violation. 000b - mbcxslv0 001b - mbcxslv1 010b - mbcxslv2 011b - mbcxslv3
23-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0b - Read access 1b - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000b - Secure user mode, instruction fetch access. 001b - Secure user mode, data access. 010b - Secure privileged mode, instruction fetch access. 011b - Secure privileged mode, data access. 100b - Nonsecure user mode, instruction fetch access. 101b - Nonsecure user mode, data access. 110b - Nonsecure privileged mode, instruction fetch access. 111b - Nonsecure privileged mode, data access.
7-4 —	Reserved
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

43.8.1.17 MBC Domain Error Word3 Register (MBC0_DERR_W3 - MBC1_DERR_W3)

Offset

Register	Offset
MBC0_DERR_W3	40Ch
MBC1_DERR_W3	41Ch

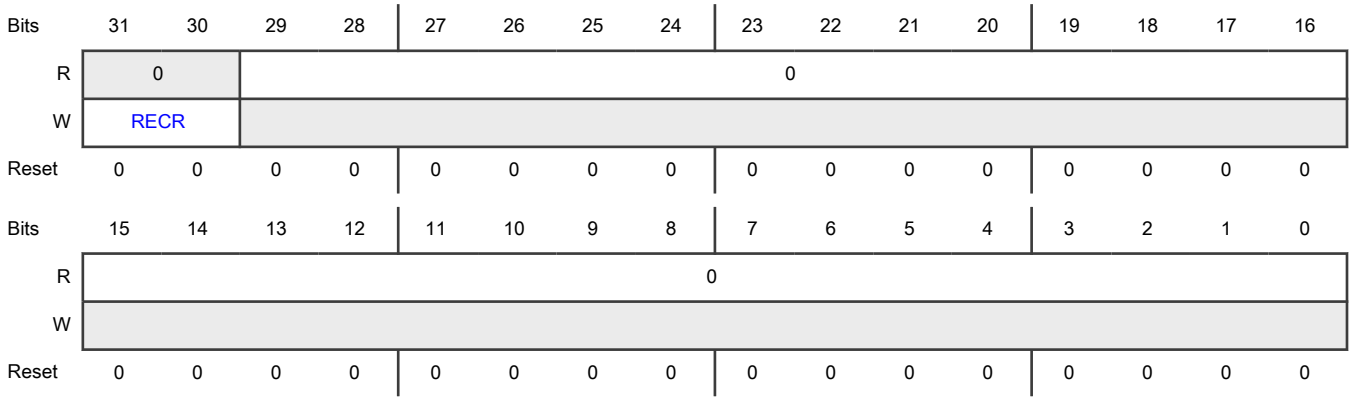
Function

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Diagram



Fields

Field	Function
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

43.8.1.18 MRC Domain Error Word0 Register (MRC0_DERR_W0 - MRC1_DERR_W0)

Offset

Register	Offset
MRC0_DERR_W0	480h
MRC1_DERR_W0	490h

Function

This read-only register array provides the address of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the MRC instance number. That is, the index, i, of this array is the instance number of MRC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MRC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Register	Offset
MRC0_DERR_W3	48Ch
MRC1_DERR_W3	49Ch

Function

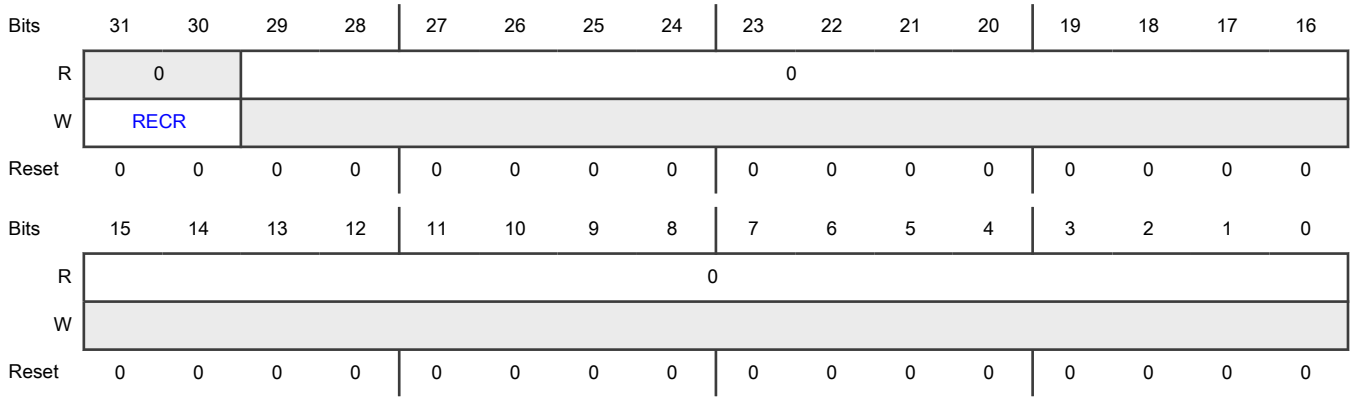
This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a memory region checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

43.8.1.21 Process Identifier (PID0 - PID1)

Offset

Register	Offset
PID0	700h
PID1	704h

Function

In the TRDC's access control definition, each processor has a corresponding process identifier (PID) which performs the important functions: the entire value can be used to group tasks into different domains.

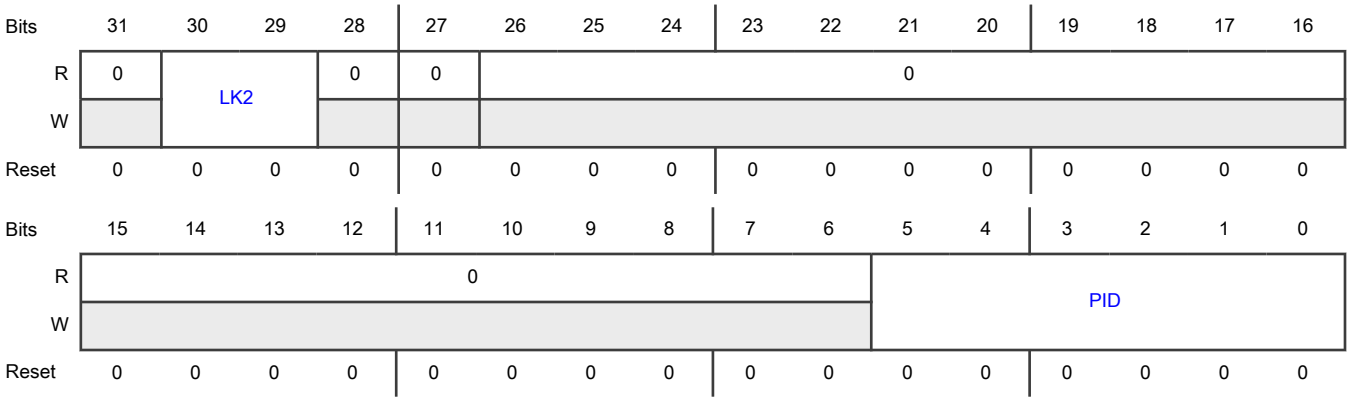
While certain processors include this register in their programming model definitions, others do not. This register is provided for those processors that do *not* include a PID register in their programming models. Secure privileged software saves and restores the PID as part of any context switch.

This data structure defines an array of 32-bit values, one per MDA module, that define the PID. Since this register resource is only applicable to processor cores, the data structure is typically sparsely populated. The HWCFG[2-3] registers provide a bitmap of the implemented PID*n* registers. This data structure is indexed using the corresponding MDA instance number.

Depending on the operating clock domain of each DAC instance, there may be optional information stored in the corresponding PIDm register to properly implement the LK2 = 2 functionality.

Reads of the PID*n* register return the contents of this register, or the PID*n* value directly sourced from a processor. For non-processor bus masters, this register does not exist and any attempted read is error terminated.

Diagram



Fields

Field	Function
31 —	Reserved
30-29 LK2	Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, these bits individually remain asserted until the next reset. If the processor sources its PIDm directly, that is, HWCFG{2-3}[PIDPm = 1], then privileged reads of this memory location return zero for this field. 00b - Register can be written by any secure privileged write. 01b - Register can be written by any secure privileged write. 10b - Register can only be written by a secure privileged write from the bus master that locked the register. 11b - Register is locked (read-only) until the next reset.
28 —	Reserved
27 —	Reserved
26-6 —	Reserved
5-0	Process identifier

Table continues on the next page...

Table continued from the previous page...

Field	Function
PID	This field determines the secure (0) or nonsecure (1) attribute for transactions associated with the corresponding processor. If the processor sources its PID*n* directly, then secure privileged reads of this memory location return the processor register for this field.

43.8.1.22 DAC Master Domain Assignment Register (MDA_W0_0_DFMT0 - MDA_W2_1_DFMT0)

Offset

Register	Offset
MDA_W0_0_DFMT0	800h
MDA_W0_1_DFMT0	820h
MDA_W1_1_DFMT0	824h
MDA_W2_1_DFMT0	828h

Function

The MDA_Wr_m registers provide a 2-dimensional data structure for assigning bus masters to domains. The number of implemented registers is defined by DACFGm[NMDAR]. This per-master domain assignment is then repeated for each bus master (MDAm). Thus, m specifies the master number and r refers to the specific MDA register for a given bus master.

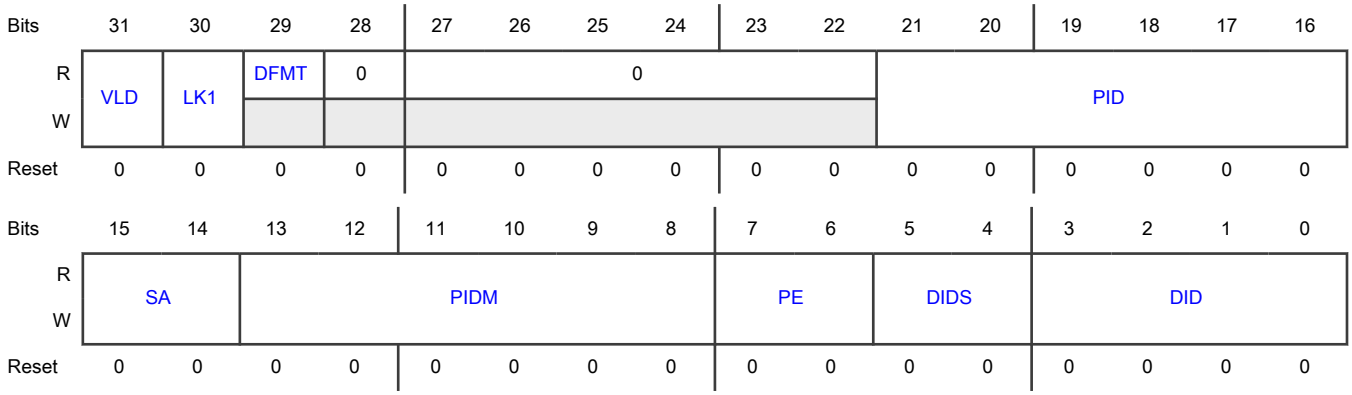
Each Wr within the MDAm structure is a word-sized definition; there are two formats supported, one for processor cores and another for non-processors. Processor masters typically support one or more Wr domain definitions, while non-processor masters support a single Wr. Processor masters Domain Assignment register names use a _DFMT0 suffix. Non-processor masters Domain Assignment register names use a _DFMT1 suffix.

The DAC submodule is responsible for the generation of domain identifiers for every transaction from every bus master. If there is a single Wr for a given master, then the specified domain identifier is used directly. If there are multiple Wr values for a given master, then the DAC evaluates the conditional terms to determine a “hit”. For all Wr hits, their corresponding domain identifiers are simply logically summed together (boolean OR). Use cases are typically expected to *hit in a single Wr* for a processor master. Special care is needed if *none* of the conditional terms hit in any Wr evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

Each MDA_Wr_m register has one of two programming models depending on the state of the domain format field, DFMT. The model described in this section is for DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in Master Domain Assignment (MDA_Wr_m_DFMT1) register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Diagram



Fields

Field	Function
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by CR[GVLDM] = 1. If CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid. 1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROZ 0b - Processor-core domain assignment 1b - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16	Process Identifier

Table continues on the next page...

Table continued from the previous page...

Field	Function
PID	This field specifies that the process identifier is to be combined with the PIDM field and included in the domain hit determination. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.
15-14 SA	Secure attribute This field defines the secure/nonsecure attribute for processor cores. **NOTE** The bus master's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the master attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00b - Force the bus attribute for this master to secure. 01b - Force the bus attribute for this master to nonsecure. 10b - Use the bus master's secure/nonsecure attribute directly. 11b - Use the bus master's secure/nonsecure attribute directly.
13-8 PIDM	Process Identifier Mask This field provides a masking capability so that multiple process identifiers can be included as part of the domain hit determination. If a bit in the PIDM is set, then the corresponding bit of the PID is ignored in the comparison. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.
7-6 PE	Process identifier enable Controls the optional inclusion of the PID, qualified by PIDM, into the domain hit evaluation. It provides the ability to include inclusive or exclusive sets of masked PID values. 00b - No process identifier is included in the domain hit evaluation. 01b - No process identifier is included in the domain hit evaluation. 10b - PE = 2. The process identifier is included in the domain hit evaluation as defined by the expression: `partial_domain_hit = (PE == 2) && ((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))` 11b - PE = 3. The process identifier is included in the domain hit evaluation as defined by the expression: `partial_domain_hit = (PE == 3) && ~((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))`
5-4 DIDS	DID Select This field selects the source of the domain identifier. 00b - Use MDAm[3:0] as the domain identifier.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Use the input DID as the domain identifier. 10b - Use MDAm[3:2] concatenated with the low-order 2 bits of the input DID (DID_in[1:0]) as the domain identifier. 11b - Reserved for future use.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus master connected to the DAC when DIDS=00b. DID[3:2] is used when DIDS=10b

43.8.1.23 DAC Master Domain Assignment Register (MDA_W0_2_DFMT1 - MDA_W0_3_DFMT1)

Offset

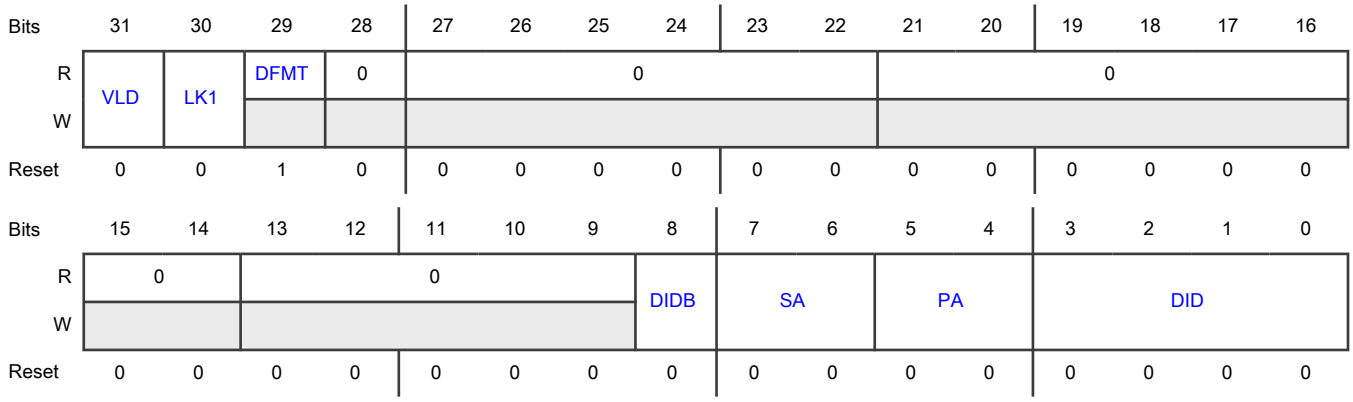
Register	Offset
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h

Function

This register is identical to Master Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus masters.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Diagram



Fields

Field	Function
31	Valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
VLD	This field indicates the domain assignment is valid. It is further qualified by CR[GVLDM] = 1. If CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid. 1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0b - Processor-core domain assignment 1b - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus master. This capability allows non-processor bus masters, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset.

Function

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory slave index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 306. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0
W0	block 7	block 6	block 5	block 4	block 3	block 2	block 1	block 0
W1	block 15	block 14	block 13	block 12	block 11	block 10	block 9	block 8
W2	block 23	block 22	block 21	block 20	block 19	block 18	block 17	block 16
W3	block 31	block 30	block 29	block 28	block 27	block 26	block 25	block 24
W4	block 39	block 38	block 37	block 36	block 35	block 34	block 33	block 32

MBC1_DOM15_MEM1_BLK_NSE_W0	1_3FA0h

Function

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory slave index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 307. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64
. . .			
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

43.8.1.41 MRC Global Access Control (MRC0_GLBAC1 - MRC0_GLBAC7)

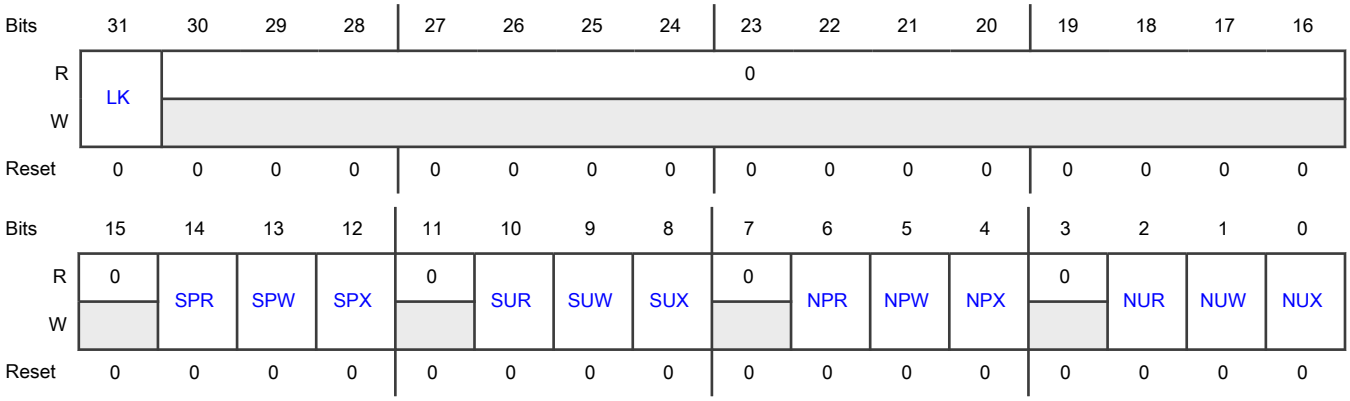
Offset

Register	Offset
MRC0_GLBAC1	1_4024h
MRC0_GLBAC2	1_4028h
MRC0_GLBAC3	1_402Ch
MRC0_GLBAC4	1_4030h
MRC0_GLBAC5	1_4034h
MRC0_GLBAC6	1_4038h
MRC0_GLBAC7	1_403Ch

Function

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, NonsecureUser. The lock bit provides the ability to lock these control access flags, to lock the MRC_BLK_CFG[MRACSEL] field, and to lock the MRC_RGD[STRT_ADDR, END_ADDR, VLD] fields when a locked MRC_GLBAC register is selected.

Diagram



Fields

Field	Function
31 LK	LOCK This 1-bit field provides a mechanism to limit writes to the this register to protect its contents. Once set, this bit remains asserted until the next reset. 0b - This register is not locked and can be altered. 1b - This register is locked (read-only) and cannot be altered.

43.8.1.42 MRC Region Descriptor Word 0 (MRC0_DOM0_RGD0_W0 - MRC1_DOM15_RGD7_W0)

Offset

For m = 0 to 1; d = 0 to 15; r = 0 to 7:

Register	Offset
MRCm_DOMd_RGDr_W0	1_4040h + (m × 1000h) + (d × 100h) + (r × 8h)

Function

MRC[m]_DOM[d]_RGD[r]_W[w], where,

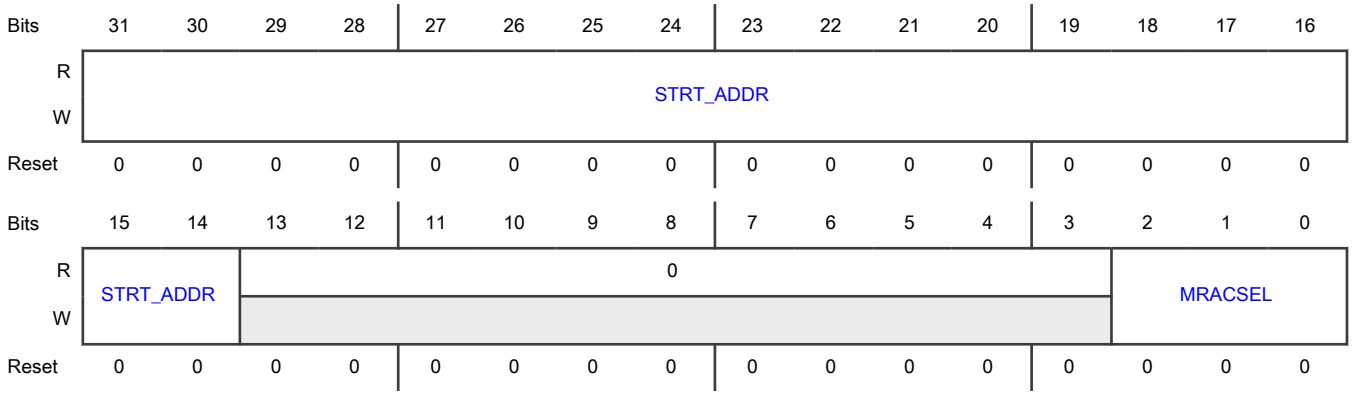
- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_DOM[d]_RGD[r]_W[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 memory region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Diagram



Fields

Field	Function
31-14 STRT_ADDR	Start Address 0-mod-16K physical start address [31:14] of region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.
13-3 —	Reserved
2-0 MRACSEL	Memory Region Access Control Select This field selects the global access control associated with region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1. 000b - Select MRC_GLBAC0 access control policy 001b - Select MRC_GLBAC1 access control policy 010b - Select MRC_GLBAC2 access control policy 011b - Select MRC_GLBAC3 access control policy 100b - Select MRC_GLBAC4 access control policy 101b - Select MRC_GLBAC5 access control policy 110b - Select MRC_GLBAC6 access control policy 111b - Select MRC_GLBAC7 access control policy

43.8.1.43 MRC Region Descriptor Word 1 (MRC0_DOM0_RGD0_W1 - MRC1_DOM15_RGD7_W1)

Offset

For m = 0 to 1; d = 0 to 15; r = 0 to 7:

Register	Offset
MRCm_DOMd_RGDr_W1	1_4044h + (m × 1000h) + (d × 100h) + (r × 8h)

Function

MRC[m]_DOM[d]_RGD[r]_W[w], where,

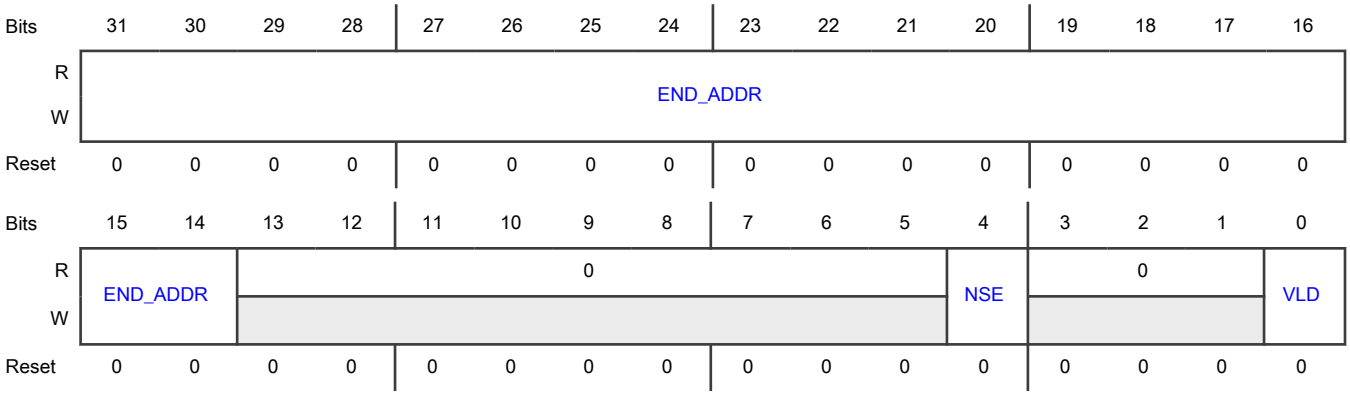
- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_[d]_rgd[r]_w[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Diagram



Fields

Field	Function
31-14 END_ADDR	End Address (16K-1)-mod-16K physical end address [31:14] of region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.
13-5 —	Reserved
4	NonSecure Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
NSE	Alternate view of NSE flag for Region r. 0b - Secure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]), nonsecure accesses to region r are not allowed. 1b - Secure accesses to region r are not allowed, nonsecure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]).
3-1 —	Reserved
0 VLD	Valid If set, this region is valid and accesses are checked for this region. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.

43.8.1.44 MRC Region Descriptor NonSecure Enable (MRC0_DOM0_RGD_NSE - MRC1_DOM15_RGD_NSE)

Offset

For m = 0 to 1; d = 0 to 15:

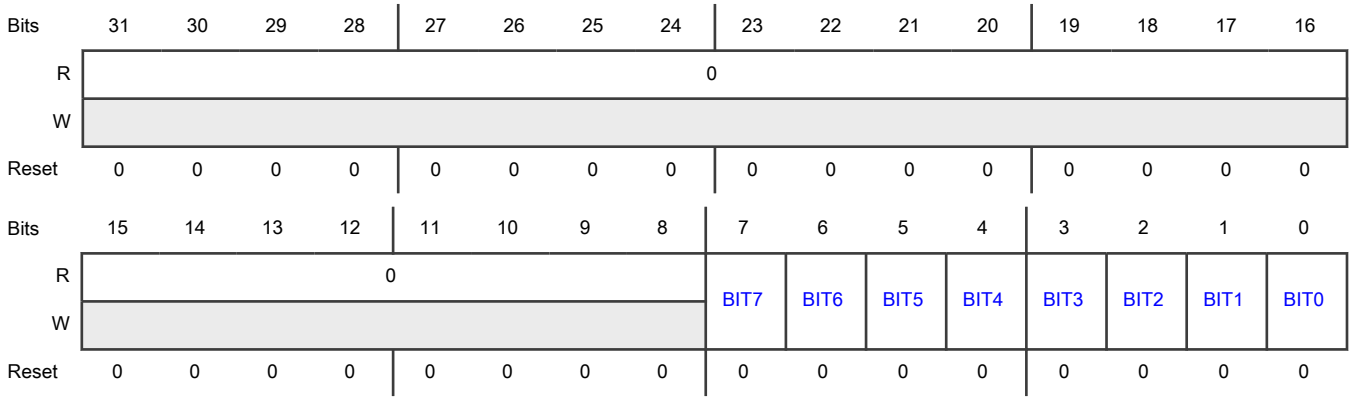
Register	Offset
MRCm_DOMd_RGD_NSE	1_40C0h + (m × 1000h) + (d × 100h)

Function

This register is the bitmap of the individual NSE bits for the region descriptors. Bit n corresponds to region n.

These bits can also be written or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and RGD_W0[NSE] registers.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 BITn	Bit n NonSecure Enable [n = 0 - 15] 0b - Secure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]), nonsecure accesses to region r are not allowed. 1b - Secure accesses to region r are not allowed, nonsecure accesses to region r are based on corresponding MRACSEL field in register (MRCm_DOMd_RGDr_Ww[MRACSEL]).

43.8.1.45 MRC Global Access Control (MRC1_GLBAC0)

Offset

Register	Offset
MRC1_GLBAC0	1_5020h

Function

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, NonsecureUser. The lock bit provides the ability to lock these control access flags, to lock the MRC_BLK_CFG[MRACSEL] field, and to lock the MRC_RGD[STRT_ADDR, END_ADDR, VLD] fields when a locked MRC_GLBAC register is selected.
